Editorial Office: P. Minotti Bernasconi, S. Hoskin, Annals of Oncology, Via Ginevra 4, 6900 Lugano, Switzerland

Annals of Oncology is covered in C.A.B. International, Current Clinical Cancer, Current Contents/Clinical Medicine®, Current Contents/Life Sciences, Elsevier BIOBASE/Current Awareness in Biological Sciences, EMBASE/Excerpta Medica, IBIDS, Index Medicus/MEDLINE, The International Monitor in Oncology, Medical Documentation Service, Science Citation Index® and Science Citation Index Expanded.

Aims and Scope

Annals of Oncology, the journal of the European Society for Medical Oncology and the Japanese Society of Medical Oncology, provides rapid and efficient peer-review publications on innovative cancer treatments or translational work related to oncology and precision medicine.

Main focuses of interest include: systemic anticancer therapy (with specific interest on molecular targeted agents and new immune therapies), randomized trials (including negatives ones), top-level guidelines, and new fields currently emerging as key components of personalized medicine, such as molecular pathology, bioinformatics, modern statistics, and biotechnologies. Radiotherapy, surgery and pediatrics manuscripts can be considered if they display a clear interaction with one of the fields above or are paradigm-shifting.

With a large international editorial board of experts who are leaders in their fields, *Annals of Oncology* aims at delivering the best communication on the fast moving, and continually evolving, global oncology landscape.

For a full and complete Guide for Authors, please go to www.annalsofoncology.org

Author inquiries

Once a manuscript is submitted, you can follow manuscript developments from your online account, at the *Annals of Oncology* online submission website http://mc.manuscriptcentral.com/annonc. You can track your accepted article at http://www.elsevier.com/trackarticle. You are also welcome to contact Customer Support via http://support.elsevier.com.

Publication Information

Publication information: *Annals of Oncology* (ISSN 0923-7534) comprises 12 issues plus supplements in each volume, with volume 34 scheduled for 2023. Subscription prices are available upon request from the Publisher or from the Elsevier Customer Service Department nearest you or from this website (http://www.elsevier.com/locate/annonc). Subscriptions are accepted on a prepaid basis only and are entered on a calendar year basis. Issues are sent by standard mail (surface within Europe, air delivery outside Europe). Priority rates are available upon request.

USA mailing notice

Annals of Oncology, ISSN 0923-7534, is published monthly by Elsevier Ltd, The Boulevard, Langford Lane, Kidlington, Oxford OX5 1GB, UK.

The US annual subscription price is USD 2652. Airfreight and mailing in the USA by agent named World Container Inc., c/o BBT 150-15 183rd St, Jamaica, NY 11413, USA.

Application to Mail at Periodicals Postage Prices is Pending at Brooklyn NY 11256.

US POSTMASTER: Send address changes to Annals of Oncology, World Container Inc., c/o BBT 150-15 183rd St, Jamaica, NY 11413, USA.

Subscription records are maintained at Elsevier Ltd, The Boulevard, Langford Lane, Kidlington, Oxford OX5 1GB, UK.

Orders, claims, and journal inquiries

Please visit our Support Hub page https://service.elsevier.com for assistance.

Advertising

If you are interested in advertising or other commercial opportunities please visit http://www.elsmediakits.com

Advertising orders and inquiries can be sent to: Europe and ROW: Kate Lach, Elsevier Ltd, 125 London Wall, London, EC2Y 5AS, United Kingdom; email: k.lach.1@elsevier.com, +48 500 259 970, USA, Canada and South America: Bill Hipple, Elsevier Inc., 230 Park Avenue, Suite 800, New York, NY 10169-0901, USA; email: b.hipple@elsevier.com, phone: (+1) (212) 646-671-0385.

Reprints

For requests from industry and companies regarding bulk article reprints, translation opportunities for previously published material, and corporate online opportunities, please email one of our sales team http://reprints.elsevier.com/contact or visit http://reprints.elsevier.com/solutions

Journal supplements

For further information about opportunities with regard to Journal supplement issues, please email: Evelina Euren e.euren@elsevier.com or visit https://www.elsevier.com/en-gb/advertisers/editorial-supplements

Language (usage and editing services)

Please write your text in good English (American or British usage is accepted, but not a mixture of these). Authors who feel their English language manuscript may require editing to eliminate possible grammatical or spelling errors and to conform to correct scientific English may wish to use the English Language Editing service available from Elsevier's WebShop http://webshop.elsevier.com/languageediting/ or visit our customer support site http://support.elsevier.com for more information.

This journal and the individual contributions contained in it are protected under copyright, and the following terms and conditions apply to their use in addition to the terms of any Creative Commons or other user license that has been applied by the publisher to an individual article:

Photocopying: Single photocopies of single articles may be made for personal use as allowed by national copyright laws. Permission is not required for photocopying of articles published under the CC BY license nor for photocopying for non-commercial purposes in accordance with any other user license applied by the publisher. Permission of the publisher and payment of a fee is required for all other photocopying, including multiple or systematic copying, copying for advertising or promotional purposes, resale, and all forms of document delivery. Special rates are available for educational institutions that wish to make photocopies for non-profit educational classroom use.

Derivative Works: Users may reproduce tables of contents or prepare lists of articles including abstracts for internal circulation within their institutions or companies. Other than for articles published under the CC BY license, permission of the publisher is required for resale or distribution outside the subscribing institution or company.

For any subscribed articles or articles published under a CC BY-NC-ND license, permission of the publisher is required for all other derivative works, including compilations and translations.

Storage or Usage: Except as outlined above or as set out in the relevant user license, no part of this publication may be reproduced, stored in a retrieval system or transmitted in any form or by any means, electronic, mechanical, photocopying, recording or otherwise, without prior written permission of the publisher.

Permissions: For information on how to seek permission visit www.elsevier.com/permissions.

Author rights: Author(s) may have additional rights in their articles as set out in their agreement with the publisher (more information at http://www.elsevier.com/authorsrights).

Notice

Practitioners and researchers must always rely on their own experience and knowledge in evaluating and using any information, methods, compounds or experiments described herein. Because of rapid advances in the medical sciences, in particular, independent verification of diagnoses and drug dosages should be made. To the fullest extent of the law, no responsibility is assumed by the publisher and European Society for Medical Oncology for any injury and/or damage to persons or property as a matter of products liability, negligence or otherwise, or from any use or operation of any methods, products, instructions or ideas contained in the material herein.

Although all advertising material is expected to conform to ethical (medical) standards, inclusion in this publication does not constitute a guarantee or endorsement of the quality or value of such product or of the claims made of it by its manufacturer.

Funding body agreements and policies

Elsevier has established agreements and developed policies to allow authors whose articles appear in journals published by Elsevier, to comply with potential manuscript archiving requirements as specified as conditions of their grant awards. To learn more about existing agreements and policies please visit http://www.elsevier.com/fundingbodies.

The paper used in this publication meets the requirements of ANSI/NISO Z39.48-1992 (Permanence of Paper).

Printed by Henry Ling Ltd, Dorchester, UK.

Notice:
The content of the abstracts contained in this Abstract Book is subject to an embargo.

Regular abstracts accepted for presentation at ESMO Congress 2023 as Proffered Paper (suffix O), Mini Oral (suffix MO), Poster (suffix P or TiP) EONS Proffered Paper, EONS Rapid Fire and EONS Posters (prefix CN), will be published online via the ESMO website at **00:05 CEST** on **Monday, 16 October 2023**

Late-breaking abstracts accepted for presentation at ESMO Congress 2023 as Proffered Paper or Mini Oral (prefix LBA) will be published online via the ESMO website at **00:05 CEST** on **Thursday, 19 October 2023.**
Also EONS

Abstracts selected for official ESMO communication activities may be subject to a dedicated embargo and details will be made available two weeks prior to the congress.

Disclaimer:
No responsibility is assumed by the organisers for any injury and/or damage to persons or property as a matter of products liability, negligence or otherwise, or from any use or operation of any methods, products, instructions or ideas contained in the material herein. Because of the rapid advances in medical sciences, we recommend that independent verification of diagnoses and drug dosages should be made. Every effort has been made to faithfully reproduce the abstracts as submitted. However, no responsibility is assumed by the organizers for any omissions or misprints.

GOOD SCIENCE
BETTER MEDICINE
BEST PRACTICE

European Society for Medical Oncology (ESMO)

ESMO is the leading professional organisation for medical oncology. With more than 30,000 members representing oncology professionals from 168 countries worldwide, ESMO is the society of reference for oncology education and information. Driven by a shared determination to secure the best possible outcomes for patients, ESMO is committed to standing by those who care about cancer through addressing the diverse needs of #ONEoncologycommunity, offering #educationforLIFE, and advocating for #accessiblecancerCARE.

Drawing on more than 45 years of experience, ESMO serves its members and the oncology community by:

- providing networking and professional growth opportunities: through ESMO, oncologists can engage in projects, committees and working groups aiming to promote science and foster improvements in the oncology practice;
- providing training, resources and tools which enable oncologists to stay up-to-date with the latest scientific advances and continue to deliver the best possible care to cancer patients;
- representing and advocating for the oncology community at the highest political levels, ensuring that the needs of both patients and doctors are properly taken care of.

Cancer care becomes more integrated and more specialised every day; whether their field is research, diagnosis, treatment, care, or advocacy, oncology professionals need to both build their specialist knowledge and connect with the best practitioners in other disciplines worldwide. ESMO membership makes this possible.

www.esmo.org

ESMO Executive Board

President	Andrés Cervantes, Valencia, Spain
President-Elect	Fabrice André, Villejuif, France
Past-President	Solange Peters, Lausanne, Switzerland
Director of Education	Nadia Harbeck, Munich, Germany
Director of Membership	Evandro de Azambuja, Brussels, Belgium
Director of Public Policy	Jean-Yves Blay, Lyon, France

European Oncology Nursing Society (EONS)

The European Oncology Nursing Society (EONS) is a pan-European membership organisation for cancer nurses — the largest group of healthcare workers in the oncology workforce.

EONS provides leadership in all areas of cancer nursing: research, practice, continuing education, communications and advocacy for better recognition of cancer nursing across Europe.

Vision

Our vision is that cancer nursing will be recognised by the cancer community, national and European level policy makers, as a profession with specialised training and qualifications available across the continent. Working conditions for cancer nurses will be optimal, providing a commensurate financial income as well as protecting and promoting individual well-being. We anticipate that this will produce a relatable improvement in the health and clinical outcomes for people affected by cancer. Finally, we envisage that all our members will become confident and empowered cancer nurses operating as leaders in research, practice and education within multi-professional teams.

Strategic goals

All strategic goals are equal and assume no hierarchy. EONS aims to achieve the following:

1. Cancer nursing is recognised across Europe for its positive impact on the lives of people affected by cancer through C.A.R.E. — Communication, Advocacy, Research and Education.
2. All cancer nurses have access to specialised education that is aligned with the EONS Cancer Nursing Education Framework.
3. All cancer nurses gain official recognition, reward and respect as a result of the RECaN and advocacy campaigns.
4. All cancer nurses are connected in order to exchange and share information and support for their work.
5. EONS facilitates, leads and promotes collaborative cancer nursing research across Europe.
6. EONS leads EU-wide advocacy initiatives at EU policy level.
7. EONS provides evidence-based advice to people and organisations affected by cancer on healthy lifestyles and cancer prevention.

EONS has prepared an update strategy for 2024-2028.

Read more about this at https://cancernurse.eu/about-eons/strategy/

EONS Board as of June 2023

President	Virpi Sulosaari, Turku, Finland

ESMO GOOD SCIENCE BETTER MEDICINE BEST PRACTICE

ANNALS OF ONCOLOGY driving innovation in oncology

BASIC SCIENCE

1O CircIGF1R_0001 mediates platinum resistance in ovarian cancer that sensitive to PARP inhibitors via promoting PARP1 binding to DNA damage sites

L. Ruilin[1], Q. Li[2], H. Yao[3]

[1]Department of Gynecologic Oncology, Second Affiliated Hospital/Sun Yat-Sen Memorial Hospital of Sun Yat-Sen University, Guangzhou, China; [2]Medical Oncology, The Second Affiliated Hospital of Sun Yat-Sen University, Guangzhou, China; [3]Guangdong Provincial Key Laboratory of Malignant Tumor Epigenetics and Gene Regu, Second Affiliated Hospital of Sun Yat-Sen University, Guangzhou, China

Background: Clinical research indicated that some platinum-resistant ovarian cancer patients are sensitive to Poly (ADP-ribose) polymerase inhibitors(PARPi) and it is associated with high Poly(ADP-ribosyl)lation (PARylation) activity of PARP1. However, the specific mechanism remains unclear.

Methods: Key functional circRNAs that promote platinum resistance in epithelial ovarian cancer (EOC) were screened and identified through next-generation sequencing, quantitative real-time polymerase chain reaction (qRT-PCR), and comet assay methods. Experiments such as RNA immunoprecipitation (RIP), RNA pull-down, laser micro-irradiation, and fluorescence colonization were used to identify the proteins and domains that interact with target circRNA. The recruitment and trapping of PARP1 at DNA damage sites were detected through Chromatin extract isolation and Biotin-tagged Nicked DNA pulled down.

Results: The circIGF1R_0001 is highly expressed in some platinum-resistant tissues and cell lines, and its overexpression enhances DNA repair and platinum resistance in ovarian cancer cells. The circIGF1R_0001 binds to the DNA binding domain of PARP1 and can be recruited together to DNA damage sites. Silencing circIGF1R_0001 significantly reduces the PARylation of PARP1, weakens the recruitment of PARP1 at DNA damage sites, and inhibits the activation of downstream DNA liag3. Furthermore, EOC patients and cell lines with platinum resistance that overexpressing circIGF1R_0001 are more sensitive to PARP inhibitors; silencing circIGF1R_0001 increases the resistance to PARPi while weakening the DNA trapping effect of PARP1.

Conclusions: 1. Overexpression of circIGF1R_0001 promotes platinum resistance but also promotes sensitivity to PARPi in ovarian cancer. 2. The circIGF1R_ 0001 binds to and regulates the DBD domain of PARP1 to promote its PARylation and enhance its recruitment to DNA damage sites then enhanced the base excision repair pathway. Importantly, circIGF1R_ 0001 also enhances the DNA trapping of PARP1 by PARPi. 3. The circIGF1R_ 0001 acts as a potential biomarker for platinum resistance in ovarian cancer and a marker for screening patients who can benefit from PARPi after platinum resistance.

2O PD-1 defines a distinct, functional, tissue-adapted state in V-delta-1+ T cells with implications for cancer immunotherapy

Y. Wu[1], D. Davies[1], S. Kamdar[1], R. Woolf[2], I. Zlatareva[2], M.L. Iannito[1], C. Morton[3], Y. Haque[2], H. Martin[4], O. O'Neill[5], O. Nussbaumer[2], A. Hayday[2]

[1]Centre for Inflammation Biology and Cancer Immunology, King's College London, London, UK; [2]Peter Gorer Department of Immunobiology, King's College London, London, UK; [3]Department of Oncology, Guy's and St Thomas' NHS Foundation Trust, London, UK; [4]Immunosurveillance Lab, The Francis Crick Institute, London, UK; [5]Advanced Sequencing Facility, The Francis Crick Institute, London, UK

Background: Checkpoint inhibition (CPI), particularly that targeting the inhibitory co-receptor, programmed cell death protein (PD-1), has transformed cancer care. Although CPI can de-repress cancer antigen-specific $\alpha\beta$ T cells that ordinarily show PD-1-dependent exhaustion, it can also be efficacious against cancers evading $\alpha\beta$ T cell recognition through loss of MHC or low mutational burdens. In such settings, tissue-associated Vδ1$^+$ $\gamma\delta$ T cells have been implicated as these cells are not classically peptide-MHC dependent. Despite some evidence for association of Vδ1$^+$ T cells to CPI response, the immunological significance of PD-1 expression by human Vδ1$^+$ T cells remains uncharacterised.

Methods: As Vδ1$^+$ T can operate independent of neoantigen load, we looked for a transcriptomic signature of Vδ1$^+$ T cells in a public dataset of patients with melanoma receiving anti-PD-1 therapy and correlated this signature to response in the context of neoantigen load. Alongside this, we developed a protocol which enabled the extraction of substantial numbers of human skin $\gamma\delta$ T cells to permit transcriptomic and functional studies of these rare cells. Skin-derived PD-1$^+$ and PD-1$^-$ Vδ1$^+$ T cells were sorted and analysed by NanoString using the nCounter Immune Exhaustion Panel. The cells were also activated *in vitro* both in the presence and absence of recombinant PD-L1 +/- atezolizumab and assayed for cytotoxic degranulation and production of effector cytokines.

Results: We found that a transcriptional signature of intratumoral Vδ1$^+$ T cells predicts response to anti-PD-1 in patients with melanoma, particularly in the context of low neoantigen load. Moreover, we found that skin-derived PD-1$^+$ Vδ1$^+$ T cells display a transcriptomic programme of tissue-residence, survival/self-renewal, and functional competence distinct from the canonical exhaustion programme of co-located PD-1$^+$ CD8$^+$ $\alpha\beta$ T cells. Indeed, PD-1$^+$ Vδ1$^+$ T cells retained effector responses to T cell receptor signalling that were inhibitable by PD-1 engagement and partially derepressed by CPI.

Conclusions: Our formal demonstration that Vδ1$^+$ T cells can be suppressed by PD-1 engagement and de-repressed by anti-PD-(L)1 CPI therapy supports their utility as a predictive biomarker for therapy.

3O IGSF8 is an innate immune checkpoint and cancer immunotherapy target

K. Benhadji[1], Y. Li[2], X. Wu[2], H. Liu[2], X. Xiao[2], H. Liu[2], Q. Ding[2], B. Xie[2], C. Sheng[2], R. Zheng[2], Q. Yu[2], X. Hu[3], X.S. Liu[4], T. Xiao[2]

[1]Clinical Department, GV20 Therapeutics, Cambridge, MA, USA; [2]Biology, GV20 Therapeutics, Shanghai, China; [3]Bioinformatics, GV20 Therapeutics, Cambridge, MA, USA; [4]GV20 Therapeutics, Cambridge, MA, USA

Background: Loss of MHC-I antigen presentation is often associated with T cell excluded tumors, and represents a common mechanism of both primary and acquired resistance to immune checkpoint blockade (ICB) treatment. MHC-I normally acts as a marker of "self" and cells that lack MHC-I are recognized and killed by innate immunity. A major puzzle in cancer immunology remains as to how T cell excluded tumors with MHC-I antigen presentation defects evade innate immune killing.

Methods: Integrating functional genomics, big data, and artificial intelligence, we discovered that IGSF8 expressed on cancer cells is a conserved innate immune checkpoint. IGSF8 is normally expressed in neuronal tissues and is not essential *in vitro* or *in vivo*. However, knockout of IGSF8 in B16-F10 melanoma cell line decreased tumor growth *in vivo*. For clinical relevance of IGSF8 in tumor immunity, we analyzed genomics, transcriptomics, and clinical data from The Cancer Genome Atlas (TCGA). We developed an antibody (GV20-0251) against IGSF8 and tested its function to induce immune cell killing of cancer cells *in vitro* and inhibit tumor growth *in vivo*.

Results: IGSF8 has receptors on both natural killer (NK) cells and dendritic cells (DC) to strongly suppress NK cytotoxicity and antigen presentation. In many cancer types across TCGA, IGSF8 is frequently DNA copy number amplified and overexpressed, and IGSF8 expression is associated with low antigen presentation, low immune infiltration, and worse overall survival in patients with low MHC class I expression. We developed a cross-species reactive antibody against IGSF8 (GV20-0251) which blocks IGSF8 interaction with NK and DC. This antibody enhances NK killing of cancer cells *in vitro* and increases antigen presentation, NK-mediated cytotoxicity, and T cell signaling *in vivo*. In multiple syngeneic tumor models (B16-F10, CT26, LLC and EMT6), anti-IGSF8 shows single-agent efficacy and is synergistic with anti-PD1 in controlling tumor growth.

Conclusions: IGSF8 is a novel innate immune checkpoint and cancer immunotherapy target. Given the ability for anti-IGSF8 to activate innate immunity, a phase 1 study has been initiated to explore the IGSF8 inhibitor GV20-0251 in patients with advanced or metastatic solid tumors (NCT05669430).

4P Spatially resolved transcriptome elucidates bidirectional tertiary lymphoid structure interacts with tumor microenvironment of non-small cell lung cancer

X. Zhao[1], B. Zhang[2], S. Qiao[1], S. Cao[1], L. Dian[1], Y. Xu[1], D. Yue[3]

[1]Cancer Research Center, BGI-Shenzhen - Headquarters, Shenzhen, China; [2]Department Of Lung Cancer, Tianjin Medical University Cancer Institute & Hospital, Tianjin, China; [3]Lung Cancer Dept, Tianjin Medical University Cancer Institute & Hospital, Tianjin, China

Background: The presence of tertiary lymphoid structure has a significant correlation with the lung cancer patient's response to immune checkpoint inhibitors. Nonetheless, the developmental characteristics of TLS and their surrounding tumor microenvironmental features in the primary tumor have not been elucidated comprehensively.

Methods: We utilized spatially resolved transcriptome and single-cell RNA sequencing to examine the molecular signatures and the essential cell types of TLS during its maturation process in the tumor microenvironment. Additionally, multiplex immunofluorescence staining and whole transcriptome sequencing were performed for validation.

Results: We categorized 406 potential TLSs into four states: pre-TLS, primary TLS, mature TLS, and aging TLS - based on their spatial molecular characteristics. The high expression of FDCSP in follicular DCs is a novel marker to promote TLS maturation by specifically binding to activated B cells. Three types of receptor-ligand interactions in mature and aging TLS could predict the prognosis in early-stage LUAD. Interestingly, aging TLS with significantly upregulated FOXP3 and TOX2 could limit anti-tumor immunity. Additionally, the molecular characteristics of aging TLS showed a lower expression of a group of CC chemokine ligands compared to mature TLS, which could potentially lead to a weaker anti-tumor response. We also observed an increase in tumor proliferation activity in the periphery of the aging TLS region. One approach to reverse the anti-tumor activity of aging TLS to that of mature TLS could be to increase the concentration of environmental chemokines while simultaneously blocking the upregulation of TIGIT in aging TLS.

Conclusions: Those results demonstrated that the condition of TLS was influenced by the neighboring tumor microenvironment in the early-stage LUAD. And the conventional mature TLS would eventually reach a biologically aged state in the same tumor microenvironment. By regulating chemokine signaling in the aging TLS's surrounding environment, it could potentially serve as an adjuvant therapy to enhance the anti-tumor activity of immune elements in resectable LUAD patients.

5P Tertiary lymphoid structures (TLS) presence and stromal blood vessels heterogeneity differentially influence recurrence, lymphovascular, and perineural invasion in breast cancer molecular subtypes

A.A. Cosma[1], A.C. Barb[1], S.M. Negru[2], M.M. Pasca Fenesan[2], A.M. Cimpean[1]

[1]Department of Microscopic Morphology/Histology, UMFT - University of Medicine and Pharmacy Victor Babes, Timisoara, Romania; [2]Oncology Department, OncoHelp Oncology Center Timisoara, Timisoara, Romania

Background: Tertiary Lymphoid Structures (TLS) mediate local antitumor immunity. Since cancer immunotherapy, TLS interests grown considerably. We examined TLS and tumor stromal blood vessels for BC molecular subtypes associated with recurrence, lymphovascu-lar (LIV), and perineural invasion (PnI).

Methods: CD34/SMA double immunostaining revealed TLS high endothelial venules and BC tumor stromal immature and mature blood vessels. Statistical study linked microscopic data to recurrence, LIV, and PnI.

Results: TLS- subgroups have higher LIV, PnI, and recurrence ($p<0.001$), except for Luminal A type. LIV and PnI rise in HER2+/TLS- subgroups ($p<0.001$). TNBC/TLS- had the highest recurrence and invasion risks. TNBC/TLS- subgroup recurrence is related to tumor grade and LIV/PnI ($p<0.001$), unlike other TLS- subgroups. PnI but not LVI are related with TNBC/TLS+ subgroup recurrence ($p<0.001$).

Conclusions: TLS affect BC molecular subtype recurrence, LVI, and PnI differently. Its antitumor immunity mediator seems closely associated to tumor aggressiveness and stromal blood vessels.

Background: Lymph nodes (LN) act as central hubs for the orchestration of adaptive immune responses. A network of lymph node stromal cells (LNSC), including mesenchymal and endothelial cells, build a 3D network for immune cells to migrate and home to distinct niches in the LN. Within B cell non-Hodgkin lymphomas, indolent follicular lymphomas (FL) are characterized by subtle structural changes while the compartmentalization of the tissue remains present. In contrast, aggressive diffuse large B cell lymphomas (DLBCL) are defined by a complete loss of tissue organization indicating a potential role of LNSCs in tumorigenesis. While the morphological differences are well-known, the underlying molecular and cellular mechanisms remain poorly understood.

Methods: Here, we dissect the mechanisms underlying loss of structure in lymphomagenesis using combined single-cell transcriptome and spatially-resolved mapping approaches of LNSCs and immune cells.

Results: Using ultra-high plex immunofluorescence imaging, we characterized how lymph node cells organize into spatially distinct cellular neighborhoods, the disruption of which was congruent with lymphoma-induced remodeling. Using single-cell transcriptome data, we investigated the molecular programs driving this loss of organization. In DLBCL, chemokines relevant for immune cell organization were downregulated, while chemokines contributing to inflammation were upregulated, suggesting a phenotypic switch from a structural organized to an inflammatory and fibrotic state. *In silico* cell-cell interaction analysis indicated that besides the loss of mesenchyme-derived chemokine gradients, inflammatory immune cells outside of follicles turn into ectopic sources of these chemokines, an effect which likely contributes to the diffuse growth pattern of aggressive lymphomas. High expression of organizing chemokines was associated with better overall survival, this association being significant in FL and a trend in DLBCL.

Conclusions: Collectively, these data suggest that a reprogramming of the LN microenvironment triggers an imbalance in chemokine gradients, which underlies loss of tissue organization in aggressive lymphomas.

7P Engineered salmonella blocks cancer metastasis by activating NK cells in an IFN-γ-dependent manner

J. Huang

School Of Biomedical Sciences, The University of Hong Kong, Hong Kong, China

Background: Metastasis accounts for 90% of cancer related deaths and blocking of metastatic cascade has critical clinical impact. However, the clinical drug development for cancer treatment, including cancer immunotherapies, is evaluated largely depending on their ability to cause tumour shrinkage and ignores the effect on metastasis as it has proven challenging to target. Therefore, there is an urgent need for novel therapeutic strategies and agents targeting metastasis. Using an attenuated *Salmonella typhimurium* strain YB1 engineered by our lab, we have found a potent suppressive effect of attenuated *Salmonella* on cancer metastasis, regardless of cancer types and genetic background, by evoking strong anti-metastatic immune response.

Methods: Mutant mice and antibody-mediated cell depletion were used to identify the host genetic and cellular requirement for the bacterial supression of cancer cell metastasis. CyTOF (mass cytometry or cytometry by time of flight) was used to investigate the the innate immune responses after *Salmonella* treatment.

Results: Our studies showed that suppression of cancer metastasis by attenuated *Salmonella* only requires the innate immune response. Among the many induced cytokines, IFN-γ was identified as an indispensable factor for inhibiting cancer metastasis. CyTOF and antibody-mediated cell depletion analysis of the innate immune responses after *Salmonella* treatment, revealed that NK cells are the major factor involved in *Salmonella*-provoked metastasis suppression.

Conclusions: We found that IFN-γ was mainly produced by NK cells during early *Salmonella* infection, and in turn, IFN-γ promoted the accumulation, activation and cytotoxicity of NK cells. The IFN-γ-dependent NK cells directly eliminated newly accumulated cancer cells in the lung to block the cancer metastasis cascade in response to the *Salmonella* treatment.

8P Modulating tumor microenvironment using a VEGF active immunotherapeutic approach in gastrointestinal tumors: Beyond angiogenesis modulation

M. Bequet-Romero[1], Y. Morera[2], F. Hernández-Bernal[3], C. Canaan-Haden[1], K-H. Selman-Housein[3], I. González-Moya[1], J. Sanchez-Ramirez[1], Y. Martín-Bauta[3], A. de la Torre-Santos[4], M. Ayala[3]

[1]Biomedical Research, Center for Genetic Engineering and Biotechnology, Havana, Cuba; [2]Cancer Immunotherapy, Center for Genetic Engineering and Biotechnology, Havana, Cuba; [3]Clinical Research, Center for Genetic Engineering and Biotechnology, Havana, Cuba; [4]Oncology, General Hospital Celestino Hernández, Havana, Cuba

Background: Targeting of the vascular endothelial growth factor (VEGF) is known for going beyond mere modification of angiogenesis, and extends to the systemic and intratumoral regulation of immune cells activation state. In this study, we aim to explore the effect of a VEGF active immunotherapy based on a recombinant antigen named CIGB-247, in the systemic and tumor compartments in preclinical settings for mice, and in a subset of 22 patients with advanced gastrointestinal cancer (GIC) from phase I clinical trials (RPCEC00000102 and RPCEC00000155).

Methods: BALB/c mice were immunized with CIGB-247, and challenged with CT26 colon carcinoma cells subcutaneously. A week after the last immunization mice were euthanized and the tumor and the systemic compartment, were analyzed by ELISA, flow cytometry, and RT-QPCR assays. GIC patients' serum and leukocyte samples were evaluated for cytokines, specific VEGF antibody titers, and VEGFR2 neutralization using ELISA, while the cellular response was assessed by ELISPOT.

Results: The vaccine significantly boosted the infiltration of activated CD3+ cells and caused a decrease in the number of MDSCs and Tregs in analyzed compartments. The levels of VEGF, PLGF, and CXCL1 were significantly reduced in the tumor lysates, while the concentration of CD8 activation-related molecules like IFN-γ, and GRZ-B were induced. Finally, we analyzed GIC cases within the two phase I clinical trials after stratification between responders and non-responders. The evaluations indicate a significant increase in the VEGF-specific humoral and cellular response parallel to a reduction in VEGF that relates significantly to increased survival. Within this small cohort, reduction or stabilization of other proangiogenic factors was also detected.

Conclusions: CIGB-247 antigen-based vaccine increased tumor-infiltrating lymphocytes and reversed the immunosuppressive effect of the tumor microenvironment in the CT26 mouse model. Such results were corroborated in a GIC patient cohort indicating that the strategy might be a successful treatment option for such patients by modifying systemic and tumor microenvironment beyond angiogenesis modulation.

Clinical trial identification: RPCEC00000102, RPCEC00000155.

9P Identification of a μCT-based radiomic signature of CD8+ tumour infiltrating lymphocytes in an orthotopic murine model

G. Mazzaschi[1], M. Dos Santos[2], P. Bergeron[3], L. Sitterle[3], M. Gérbé de Thoré[3], W. Liu[3], C. Clémenson[3], L. Meziani[3], O. Bawa[4], A. Leroy[3], R. Sun[5], L. Moron Dalla Tor[1], F. Quaini[1], M. Tiseo[1], F. Milliat[2], C. Robert[3], M. Mondini[3], E. Deutsch[5]

[1]Department of Medicine and Surgery, University Hospital of Parma, Parma, Italy; [2]Department of Radiobiology and Regenerative Medicine (SERAMED), Laboratory of Medical Radiobiology (LRMed), Institute for Radiological Protection and Nuclear Safety (IRSN), Paris, France; [3]INSERM U1030, Université Paris-Saclay, Gustave Roussy, Villejuif, France; [4]Plateforme de Pathologie Expérimentale et Translationnelle, UMS AMMICA, 94805, Gustave Roussy, Villejuif, France; [5]Radiation Oncology Dept., Institut Gustave Roussy, Villejuif, France

Background: In the era of immunotherapy (IT), radiomics emerged as a non-invasive tool to decode tumor immune microenvironment (TIME) and predict IT response. Intrinsic patient and tumor variability challenging the explainability of radiomic readouts might be overcome in preclinical settings. Thus, we aimed to develop a μCT radiomic platform in a CD8 T cell functionally manipulated orthotopic murine model, closely mimicking human head and neck cancer, to validate the biological reality of radiomics in assessing tumor infiltrating lymphocytes (TILs).

Methods: Set-up, training and validation experiments (N Tot = 50 C57BL/6 mice) were conducted as follows: submucosal injection of 0.5 x 10^6 TC1-luc cells in the right inner lip and generation of an orthotopic model of head and neck cancer (day [D] -7); tailored treatment consisting of irradiation [D0] ± anti-CD8 antibody [D3] to selectively enrich or deplete CD8+ TILs; in vivo preclinical imaging through Quantum FX μCT technology [D3, D4]; mice euthanasia and tumor sampling [D4], followed by immunohistochemical staining for CD8; μCT image pre-processing (voxel resampling, image discretization and delineation of the volume of interest) and radiomic features (RFs) extraction (pyradiomics).

Results: We developed and optimized an efficient quantitative μCT imaging approach. Overall, 106 μCT RFs (shape, first- and second- order) were extracted and correlated with distinct TIME. Following redundant feature elimination (Spearman correlation, cut-off = 0.99) and Z-score standardization, we identified 12 μCT-RFs differentially regulated in T CD8 enriched *vs* depleted TIME ($P < 0.05$, Mann Whitney). The statistical performance of our CD8 signature, documented in both training and validation sets, was further implemented when pooled data were analysed ($P < 0.01$). Finally, by applying a reconstruction algorithm, we obtained a 3D map of CD8+ TILs, which enabled us to correlate the spatial distribution of immune cells with μCT textural parameters.

Conclusions: Our results document the feasibility and accuracy of radiomics to detect dramatic changes in T cells within the TIME, thus providing effective radio-immune signatures potentially translatable into clinical practice.

10P Cancer cells induce intracellular gap formation in sinusoidal endothelial cells to produce liver metastasis through pro-inflammatory paracrine mechanisms

H.H. Truong[1], M. Sato-Mátubara[2], T. Matsubara[2], H. Yuasa[2], T. Le Thi Thanh[3], J. Gracia-Sancho[4], N. Kawada[5]

[1]Department of Pain Management and Palliative Care, 108 Military Central Hospital, Hanoi, Vietnam; [2]Department of Anatomy and Regenerative Biology, Osaka Metropolitan University, Asahi-machi, Japan; [3]Department of Hepatology, Osaka Metropolitan University, Asahi-machi, Japan; [4]Liver Vascular Biology Research Group, IDIBAPS Biomedical Research Institute, CIBEREHD, Barcelona, Spain; [5]Department of Hepatology, Osaka City University Medical School, Osaka, Japan

Background: Engraftment of cancer cells to liver pre-metastatic niches requires complex interaction with liver sinusoidal endothelial cells (LSECs). Intracellular gap (iGap) formation in LSECs is caused by the destruction of fenestrae and appears under pathological conditions. Here, we aimed to explore the novel role of LSECs-iGap in liver metastasis of cancer cells.

Methods: Mouse models using acetaminophen (APAP) or thioacetamide (TAA) followed by intrasplenic injection of hepatocellular carcinoma (HCC) cell line, Hepa1-6 cells, to assess the LSECs-iGap formation. Functional effects of LSECs-iGap on cancer cells were analyzed using MMPs inducer, monocrotaline and inhibitor, doxycycline and MMP2/9 inhibitor. Morphological and molecular features of LSECs-iGap were examined using *in vivo* mouse models and *in vitro* co-culture system with electron microscopy, 3 dimensions tomographic reconstruction image (3D-TRI), RNA-sequencing, cytokine array and endothelial trans-endothelial migration assay. Biopsy specimens from 98 patients with HCC were statistically evaluated.

Results: APAP-induced liver injury and TAA-induced fibrotic liver resulted in LSECs-iGap formation, which positively correlated with increased numbers of metastatic foci after Hepa1-6 cells injection. In addition, Hepa1-6 cells induced IL-23-dependent TNF-α secretion by LSECs and triggered LSECs-iGap formation, toward which their processes protruded to transmigrate into the liver parenchyma. TNF-α caused depolymerization of F-actin and increased MMP9, ICAM1, and CXCLs expression in LSECs. Moreover, high expression of ICAM1 and MMP9 was significantly associated with intrahepatic metastasis and overall survival of patients with HCC. Blocking MMP9 activity by doxycycline or MMP-2/9 inhibitor eliminated LSECs-iGap formation and attenuated liver metastasis of Hepa1-6 cells.

Conclusions: This study revealed that cancer cells induced LSEC-iGap formation via pro-inflammatory paracrine mechanisms and proposed MMP9 as a novel target for blocking cancer cell metastasis to the liver.

11P Targeting stromal cells to reverse immune suppression in triple-negative breast cancer

J. Chen[1], T. Ruan[1], S. Wu[2], E. Lim[1], A. Swarbrick[1]

[1]Cancer Ecosystem Program, Garvan Institute of Medical Research, Darlinghurst, NSW, Australia; [2]Turley Lab, Immunology Discovery & Oncology Bioinformatics, Genentech, South San Francisco, CA, USA

Background: Although there have been some positive results, the success of immune checkpoint inhibition in triple-negative breast cancer (TNBC) to date remains rather limited. A better understanding of mechanisms of immune evasion other than via PD1/PD-L1 axes and how to overcome these is therefore much needed to improve the efficacy of immunotherapy in this poor prognosis disease. Recent studies of the tumour microenvironment (TME) have elucidated the heterogeneity of stromal cells and suggested that stromal subsets play an important role in regulating anti-tumour immunity. Here we investigate how stromal cells contribute to the immunosuppressive TME and as a potential therapeutic target to overcome this.

Methods: Using co-culture models of patient-derived TNBC cancer-associated fibroblasts (CAFs) and peripheral blood mononuclear cells (PBMCs) from healthy donors, we applied flow cytometry and single-cell RNA sequencing (scRNAseq) to assess stromal-immune interactions *in vitro*. A high throughput drug screen was performed to identify novel stromal-targeting drug candidates which could reverse stromal-induced immunosuppression in our coculture models.

Results: TNBC CAFs suppress the proliferative capability of both CD4 and CD8 T cells *in vitro*. scRNAseq of these co-culture models demonstrate that CAF-cocultured T cells are driven into LAG3+ exhausted state enriched for canonical pathways of immunosuppressive cytokine signalling. Drug screen identified Talabostat as a novel candidate which shifts stromal subtype composition from aSMA-positive to aSMA-negative phenotypes. Talabostat treatment in the co-culture models reverses CAF-induced suppression of T cell proliferation.

Conclusions: Talabostat reverses stromal-mediated T cell suppression and is a potential therapeutic strategy to elicit a more effective immune response.

12P Immuno-suppressive role of tumour-derived GDF-15 on myeloid cells

C. Schuberth-Wagner[1], I. Giese[1], M. Kist[1], N. Vashist[1], S. Genßler[1], B. Haack[2], J. Weigandt[1], M. Auer[3], J. Wischhusen[2], K. Klar[3], E. Leo[4], M. Haake[1]

[1]Research, CatalYm GmbH, Planegg-Martinsried, Germany; [2]Obstetrics and Gynecology, University of Würzburg, Würzburg, Germany; [3]Translational Research, CatalYm GmbH, Planegg-Martinsried, Germany; [4]Clinical Research, CatalYm GmbH, Planegg-Martinsried, Germany

Background: Growth and differentiation factor 15 (GDF-15), a divergent member of the TGF-β superfamily, shows high expression during pregnancy. Beyond that, GDF-15 is induced in stressed and damaged tissues limiting inflammation. GDF-15 also functions as a prognostic marker in numerous cancers and was shown to be a key inhibitor of T-cell infiltration in solid tumors. However, the impact of GDF-15 on other immune cells in the tumor microenvironment (TME) is still poorly understood.

Methods: M1 and M2 macrophages were derived from either the human monocytic THP-1 cell line or monocytes from healthy donors by incubation with IFNγ and LPS (M1) or IL-4 and IL-13 (M2) in combination with or without GDF-15. Analysis was performed by Western Blot, flow cytometry and RT-qPCR. To investigate the role of GDF-15 *in vivo* we inoculated NOG mice subcutaneously with SK-Mel5 *GDF15*$^{-/-}$ cells. On day 35/36 tumors were assessed on myeloid immune cell subpopulations by flow cytometry.

Results: Our initial studies have shown that monocytes are sensitive to GDF-15 mediated inhibition of tumor infiltration. Now we wanted to understand how GDF-15 affects the myeloid compartment beyond infiltration. In primary cells, GDF-15 exposure of monocytes during IFNγ or LPS induced M1 polarization led to a reduction of activation marker expression such as HLA-DR, CD80 and CD86 and an altered cytokine secretion profile. M2 macrophages did not show differences in their activation pattern. This effect was transferable to THP-1 derived M1 macrophages. TGF-ß was not able to exert this biologic effect. Activation was restored by addition of a GDF-15 neutralizing antibody. *In vivo*, GDF-15 had no direct effect on tumor growth, yet we observed that loss of GDF-15 altered the TME and led to an increase of activated myeloid cells such as M1 macrophages and dendritic cells.

Conclusions: GDF-15 secretion helps tumors to generate a TME that is poorly infiltrated by anti-tumoral immune cells. GDF-15 counteracts myeloid activation in the TME, a hallmark of initiation of antitumoral immune responses. By inducing a more pro-inflammatory tumor phenotype, anti-GDF-15 antibodies may synergize with other immunotherapeutic agents. A clinical phase 2 trial combining anti-GDF-15 (CTL-002) with anti-PD-1 (NCT04725474) is ongoing.

13P Disrupting the immunosuppressive tumor microenvironment using genetically engineered macrophages for triple-negative breast cancer therapy

S. Traxel, C. Beerli, F. Schmidt, V. Dinh-Van, R.F. Speck, S. Bredl

Division of Infectious Diseases and Hospital Epidemiology, USZ - University Hospital Zürich, Zurich, Switzerland

Background: Triple-negative breast cancer (TNBC) is an aggressive subtype of breast cancer and accounts for 40% of breast cancer deaths. Currently, surgery and chemotherapy are standard therapy in TNBC, whereas immunotherapies often fail due to a cold tumor microenvironment (TME), which is mainly generated by tumor associated macrophages (TAMs). Importantly, immunosuppressive M2-like TAMs are associated with worse outcome in TNBC patients. Cytokines like IL-10 and TGFβ induce M2-like TAMs, which inhibit the adaptive immune response and promote tumor growth, migration, and vascularization. In contrast, M1-like macrophages induce an anti-tumor immune response and tumor cell death. Thus, we aim to develop an adoptive cell therapy employing macrophages that are polarized towards a M1-like phenotype by the immunosuppressive cytokines, which will generate an inflamed TME.

Methods: To achieve M1 polarization in a M2-inducing TME, we genetically modified macrophages to express a chimeric cytokine receptor (ChCR), which will induce an M1 signaling upon stimulation with M2 inducing cytokines. Here, we evaluated two ChCR variants activated by IL-10 and TGFβ, respectively. We transduced monocytes to express the ChCR using lentiviruses. Upon differentiation to macrophages, we assessed M1 polarization by analyzing surface marker expression and the secretome. Moreover, we assessed their effect on TNBC cell line viability.

Results: We could successfully transduce macrophages at 80% and confirmed ChCR expression and M1 signaling. Furthermore, we could show that stimulation of ChCR macrophages by IL-10 or TGFβ switches them towards an M1-like phenotype, as analyzed by surface marker expression and IP-10 secretion. Moreover, we found that the viability of TNBC cell lines was reduced upon treatment with supernatants of TGFβ or IL-10 stimulated ChCR macrophages.

Conclusions: We could show that we can engineer macrophages to switch towards an M1-like phenotype in an M2-inducing environment. Thus, ChCR macrophages represent a promising strategy to disrupt the immunosuppressive TME. Currently, we are assessing the effect of ChCR macrophages on immune activation in vitro and their phenotype in TNBC co-cultures.

14P Peripheral immune kinetics in survival prediction of small cell lung cancer patients treated with immune checkpoint blockade therapy

M.A. Galindo Campos[1], M. Hardy-Werbin[2], J. Gibert[3], A. Ríos-Hoyo[4], A. Rossell[2], S. Gonzalez[2], P. Rocha[2], R. Del Rey-Vergara[2], A. Rovira[2], E. Arriola[4]

[1]IMIM - Institut Hospital del Mar d'Investigacions Mediques, Barcelona, Spain; [2]Cancer Research Programme, IMIM - Institut Hospital del Mar d'Investigacions Mediques, Barcelona, Spain; [3]Pathology, Hospital del Mar - Parc de Salut Mar, Barcelona, Spain; [4]Medical Oncology Department, Hospital del Mar - Parc de Salut Mar, Barcelona, Spain

Background: Small cell lung cancer (SCLC) is a lethal neoplasia. Chemotherapy (Ct) plus immune checkpoint blockade therapy (ICBt) is now the standard of care although limited survival benefit. Lack of biomarkers of response leads to suboptimal patient selection, distorting results of clinical trials. Deciphering the ICBt-driven peripheral immune events may recognize those patients who benefit the most. Here, we characterize early peripheral immune kinetics in SCLC patients treated with Ct + ICBt with improved survival.

Methods: SCLC patients from 8 centers were prospectively recruited into 3 cohorts. Cohort 1 include patients treated with Ct (n=24). Cohort 2 (n=37) comprise patients treated with Ct + anti-CTLA-4, and cohort 3 (n=20) patients treated with Ct + anti-PD-1/PD-L1. Peripheral blood mononuclear cells were obtained prior to treatment and after the first dose of ICBt. Variation in proliferation, senescence, adhesion, immunosuppression, and checkpoints markers was assessed by FACS. Kaplan−Meier and log-rank test were used for survival analysis. MaxStat was used to calculate cut points. A p-value <0.05 was considered statistically significant.

Results: We found 6 independent cellular subsets which modulation right after the start of ICBt identify patients with improved survival. An increase in CD8+CD103+Ki67+ cells identify survival benefit in cohorts 1 and 3 (p=0.043; 0.0033). An upregulation of Ki67 in total CD4+ (p=0.012; 0.0027) and CD4+PD-1+ T cells (p=0.026; 0.027), predicts long survival in ICBt cohorts 2 and 3, while a downregulation of CD4+ICOS+ T cells (p=0.025; 0.011) identified survival benefit in these ICBt cohorts. Expansion of Ki67+ and ICOS+ (p=0.0024; 0.0074) CD8+ T cells was also observed in CD8+ T cells from long survivors exclusively from cohort 2.

Conclusions: Expansion of CD8+CD103+Ki67+, CD4+Ki67+, and CD4+PD-1+Ki67+, or a reduction in CD4+ICOS+ circulating T cells subsets identify long survival patients treated with anti-CTLA-4 or anti-PD-1/PD-L1, while an increase in CD8+Ki67+ or CD8+ICOS+ cells predicts benefit only in patients treated with anti-CTLA-4. Assessment of the immune kinetics of these peripheral cellular subsets identify patients who benefit the most from ICBt in SCLC.

Background: A significant number of cancer patients do not benefit from PD-L1/PD-1 blockade immunotherapies. PD-1 and LAG-3 co-upregulation in T-cells is one of the major mechanisms of resistance by establishing a highly dysfunctional state in T-cells.

Methods: A high-throughput screening was performed of PD-1/LAG-3 multiomic expression profiles in public databases of human cancer biopsies, to establish relationships between infiltrating tumor-infiltrating PD-1/LAG-3 T cells with biomarkers both in T cells and within the tumour microenvironment. These results were validated in engineered T-cell lines with constitutively active PD-1, LAG-3 pathways, and their combination, analysed by high-throughput quantitative proteomics and validated by conventional molecular techniques on primary T cells from NSCLC patients.

Results: The high-throughput multiomic human cancers screening and the experimental proteomic T cell lines uncovered a strong PD-1/LAG-3 dysfunctionality signature that was found which regulated immune, proteomic, metabolic, genetic, and epigenetic pathways. These mainly relied on differential regulation of E3 ubiquitin ligases CBL-B and C-CBL. Notably, LAG-3 expression has never been associated to CBL ubiquitin ligases before.

Conclusions: PD-1/LAG-3 co-signaling profile uncovers a highly dysfunctional regulated programme. Co-blockade with a bispecific drug but not with a combination of anti-PD-1/anti-LAG-3 antibodies achieved both CBL-B and C-CBL inhibition, reverting T-cell dysfunctionality in lung cancer patients resistant to PD-L1/PD- 1 blockade. These results will help identifying the mechanisms of intrinsic resistance to PD-1 blockade mediated by LAG-3 co-signaling.

16P Terminally exhausted CD8+ T cells and increased immunosuppressive soluble factors in malignant ascites of patients with gastric cancer with peritoneal metastasis

H.S. Han[1], H. Kim[1], M. Kwon[2], S.K. Lee[1], S-M. Son[3], H.K. Kim[1], Y. Yang[1], K.H. Lee[1]

[1]Internal Medicine, Chungbuk National University Hospital, Cheongju, Republic of Korea; [2]Ajou University Hospital School of Medicine, Suwon, Republic of Korea; [3]Pathology, Chungbuk National University Hospital, Cheongju, Republic of Korea

Background: Peritoneal metastasis is a relatively common manifestation of poor prognosis and resistance to immune checkpoint blockades in patients with gastric cancer (GC). In the present study, we aimed to investigate the exhaustion status of $CD8^+$ T cells and immunosuppressive soluble factors in malignant ascites from patients with GC and peritoneal metastasis.

Methods: We obtained pathologically confirmed malignant ascites samples along with peripheral blood from 27 patients with GC peritoneal metastasis and examined the exhaustion status of $CD8^+$ T cells using multicolor flow cytometry. A multiplex enzyme-linked immunosorbent assay for immunosuppressive soluble factors, including matrix metalloproteinase-2 (MMP-2), MMP-7, transforming growth factor beta (TGF-β), hepatocyte growth factor (HGF), vascular endothelial growth factor (VEGF), E-cadherin, and angiopoietin-2, was performed on 45 cell-free fluid samples (15 paired malignant ascites and plasma of patients with GC and 15 benign ascites of liver cirrhosis patients).

Results: $CD8^+$ T cells in the malignant ascites of GC showed significantly increased expression of PD-1, TIGIT, and TIM-3 compared with peripheral blood $CD8^+$ T cells. $CD8^+$ T-cells in malignant ascites had more terminally differentiated phenotypes (T-$bet^{low}Eomes^{high}$) and tumor antigen reactivity ($CD39^+$ $CD103^+$) than peripheral blood $CD8^+$ T cells. The expression levels of immunosuppressive soluble factors, including MMP-2, MMP-7, TGF-β, HGF, VEGF, E-cadherin, and angiopoietin-2, were significantly higher in the malignant ascites than in the plasma of patients with GC or in the benign ascites of liver cirrhosis patients.

Conclusions: We found that $CD8^+$ T cells in the malignant ascites of GC are terminally exhausted and tumor antigen-reactive T cells. Furthermore, immunosuppressive soluble factors were significantly increased in cell-free fluid of malignant ascites of GC. Thus, the present findings suggest that the co-blockade of immune checkpoints and immunosuppressive soluble factors may be a feasible therapeutic option for patients GC with peritoneal metastasis.

17P Continued expansion of long-lived effect CD8+ T cells associates with durable response post-PD-1 blockade

R.A. Watson[1], O. Tong[1], B. Sun[2], C. Taylor[1], E. Jungkurth[1], S. Sijbesma[1], C. Ye[1], F. Matos Santo[1], M.R. Middleton[3], B.P. Fairfax[4]

[1]Department of Oncology, The MRC Weatherall Institute of Molecular Medicine Oxford, Oxford, UK; [2]Nuffield Department of Clinical Neuroscience, John Radcliffe Hospital University of Oxford, Oxford, UK; [3]Oncology Department, Churchill Hospital, Oxford, UK; [4]Oncology Department, University of Oxford, Oxford, UK

Background: Early $CD8^+$ T cell responses to PD-1 blockade are well-characterised. However, an understanding of the long-term clonal and transcriptomic signatures of complete response (CR) to Immune Checkpoint Blockade (ICB) is currently lacking. We aimed to identify and describe $CD8^+$ T cell clonal and transcriptomic changes post complete response to PD-1 blockade in metastatic melanoma (MM).

Methods: We performed single-cell RNA sequencing (scRNAseq) of both the T cell receptor (TCR) and transcriptomes of PBMCs and sorted peripheral $CD8^+$ T cells in patients with MM with a complete response to PD-1 blockade (n=10), patients with progressive disease (PD, n=6) and healthy donors (HD, n=2). Blood was sampled at multiple time points, including a median of 3.2 years following cessation of PD-1 blockade for CR.

Results: Following a CR and cessation of ICB, there is increased abundance of a subtype of $CD8^+$ T cell characterised by high expression of NK-associated genes, termed a killer-like subset. Using the top 25 genes upregulated by this subset to generate a 'Killer Score', we show that patients with CR to anti-PD-1 demonstrate a broad increase in killer gene expression over time absent in those with PD and HDs. By tracking key clones through TCR usage, we identify those which are stable/expanding from pre-treatment to post treatment, occupy >0.5% of the repertoire and are persistent post-cessation of ICB, terming these large expanding persistent clones. These clones have a predominantly cytotoxic, effector, gene expression profile and display surface markers consistent with a recently-described 'Long-lived Effector Cell' subtype.

Conclusions: CR to PD-1 blockade is associated with persistence of highly-cytotoxic effector $CD8^+$ T cells that circulate years after cessation of treatment. Whilst similar subsets have been implicated with chronic viral infection, these observations are novel in the cancer setting and have important implications for mechanisms of durable disease control.

18P Exposure of calreticulin is required for vitamin C immunomediated cancer surveillance

A. Cavaliere[1], M. Macagno[2], F. Maione[1], V. Amodio[3], R. Chilà[3], S. Lamba[2], P.P. Vitiello[1], V. Pessei[2], N. Congiusta[1], A. Lorenzato[1], G. Germano[1], A. Bardelli[1], F. Di Nicolantonio[4]

[1]Dipartimento di Oncologia, University of Turin, Candiolo, Italy; [2]Department of Oncology, Istituto di Candiolo - Fondazione del Piemonte per l'Oncologia - IRCCS, Candiolo, Italy; [3]Genomics of Cancer and Targeted Therapies, IFOM ETS - The AIRC Institute of Molecular Oncology, Milan, Italy; [4]Dipartimento di Oncologia, University of Turin, Candiolo, Italy

Background: Vitamin C (VitC) was shown to synergize with immune checkpoint blockade in tumor bearing immunocompetent mice, which provided the rationale for the ongoing ALFEO trial in colorectal cancer patients (Clinical Trial Registration Number 2022-502101-15-00). In this work, we aimed to elucidate the molecular mechanisms underlying these preclinical observations. We hypothesized that VitC could strain cancer cells, which react by emitting danger signal molecules, which in turn could stimulate an immune mediated anticancer response.

Methods: We assessed expression of the oxidative stress marker hydroxyguanosine (8-OHG) and danger signal molecules (calreticulin and HMGB1) in breast and colon murine tumors treated with VitC. A calreticulin blocking antibody was given in combination with VitC to functionally ascertain the role of this stress signal protein.

Results: Pharmacological doses of VitC were able to strongly induce oxidative stress as indicated by strong 8-OHG staining in tumor sections. VitC-stressed tumor cells mobilized the danger molecules calreticulin and HMGB1. Although the induction of these danger markers was seen in tumors grown both in immunocompromised and immunocompetent VitC treated mice, its anticancer activity was evident only in the presence of an intact immune system. In vivo, a calreticulin blocking antibody effectively prevented its translocation and inhibited HMGB1 release in murine tumors. Notably, preventing calreticulin exposure abrogated the immunomediated anticancer effect of VitC. VitC enhanced the infiltration of natural killers, activated CD8+ T lymphocytes, while it decreased the number of Tregs. Calreticulin blockade impaired the modulation of the immune tumor microenvironment induced by VitC.

Conclusions: We unveil that VitC is able to mobilize calreticulin and HMGB1, which are among the established markers of immunogenic cell death. These results, alongside the observation that VitC exerts its maximal antitumor activity only in immunocompetent mice are clues that VitC could act as immunogenic cell death inducer when given at pharmacological doses. Our findings have implications for cancer patients enrolled in clinical trials based on VitC containing regimens

19P Preclinical and clinical significance of VEGF deprivation in ovarian cancer through a specific active immunotherapy

Y. Morera[1], M. Bequet-Romero[2], F. Hernández-Bernal[3], I. González-Moya[2], K-H. Selman-Housein[3], C. Canaan-Haden[2], J. Sanchez-Ramirez[2], Y. Martín-Bauta[3], A. de la Torre-Santos[4], M. Ayala[3]

[1]Cancer Immunotherapy, Center for Genetic Engineering and Biotechnology, Havana, Cuba; [2]Biomedical Research, Center for Genetic Engineering and Biotechnology, Havana, Cuba; [3]Clinical Research, Center for Genetic Engineering and Biotechnology, Havana, Cuba; [4]Oncology, General Hospital Celestino Hernández, Havana, Cuba

Background: Vascular endothelial Growth factor (VEGF) has an important role in the physiology of normal ovaries and is a major player in the pathogenesis of OvCan. We have designed HEBERSaVax which is an active immunotherapy approach based on the use of a functionally deficient VEGF 121 isoform as antigen combined with an adjuvant. On immunocompetent mice, the ID8 model resembles the advanced stages of human OvCan and intervention results offer data potentially translatable to the clinical setting. Two sequential phase I clinical trials with single HEBERSaVax treatment have been concluded in patients with advanced solid tumors including subjects with advanced OvCan. A phase II clinical trial in this oncologic setting was recently finished. Herein we present data on HEBERSaVax effects on tumor development and reshaping of the microenvironment in OvCan.

Methods: C57BL/6 mouse tumor ID8 model was used to evaluate the vaccine effects in cancer growth control and tumor microenvironment remodeling. Immune response and cytokines concentrations were assessed by ELISA. Ascitic leukocytes were characterized by flow cytometry. Serum and leukocyte samples from selected OvCan patients (n=9) from the phase I clinical trials (RPCEC00000102 and RPCEC00000155) were also analyzed. Human anti-VEGF antibodies and cytokines were determined by ELISA. The cellular response was evaluated by IFN-γ ELISPOT.

Results: HEBERSaVax-based treatment increases the survival of ID8 tumor-bearing mice by reducing the ascites loads. An increase in VEGF-specific antibodies were detected in mice ascitic fluids, in parallel to a reduction of VEGF levels. The numbers of T lymphocytes and the expression of MHCII in macrophages were increased in the ascitic fluid. Data analyses from OvCan patients in clinical trials revealed that decreased or stabilized VEGF serum levels, positive anti-VEGF titers, and cellular responses, were related to an increase in survival. Processing of phase II clinical trial (RPCEC00000246) immune variables evaluations is ongoing (n=38, final data: ESMO).

Conclusions: Our findings indicate that HEBERSavax's impact on preclinical ID8 settings might be translatable to a positive outcome in advanced OvCan patients.

Clinical trial identification: RPCEC00000102, RPCEC00000155 and RPCEC00000246.

20P The essential role of DNA repair in the pharmacological activities of AST-3424

F. Meng[1], T. Qi[1], X. Liu[1], Y. Wang[1], J. Yu[2], Z. Lu[3], X. Cai[2], A. Li[3], J. Duan[3]

[1]Pharmacology, Ascentawits Pharmaceuticals, Shenzhen, China; [2]CMC, Ascentawits Pharmaceuticals, Shenzhen, China; [3]Discovery, Ascentawits Pharmaceuticals, Shenzhen, China

Background: AST-3424 is an AKR1C3-activated prodrug and releases a toxic bis-alkylating moiety after activation by tumor-specific AKR1C3. AST-3424 is currently being investigated in multiple phase I/II clinical trials for the treatment of various cancers. Wild-type p53 cells have checkpoint redundancy via G1/S checkpoint and G2/M checkpoint while p53-mutant tumor cells are solely dependent on G2/M checkpoint to arrest the cell cycle after DNA damage and allow DNA repair before progressing. Here, we have explored the essential role of DNA repair in AST-3424-mediated pharmacological activities *in vitro* and *in vivo*.

Methods: We employed *in vitro* cytotoxicity, DNA damage, apoptosis, cell cycle and cellular signaling assays in both p53-proficient H460 and p53-deficient HT29 cells as well as *in vivo* xenograft models to investigate the essential role of DNA repair in AST-3424-mediated pharmacological activities.

Results: AST-3424 induced cytotoxicity, DNA damage, apoptosis and cell cycle arrest at G2 phase in a dose- and AKR1C3-dependent manner in both p53-proficient H460 and p53-deficient HT29 cells. However, enhancement of AST-3424 cytotoxicity by G2 arrest inhibitors, including adavosertib, AZD7762 and ceralasertib was only observed in HT29 but not in H460 cells. Similarly, AST-3424-induced γH2AX and apoptosis were also enhanced in HT29 upon the addition of G2 arrest inhibitors. The enhanced activity of AST-3424 in HT29 cells by G2 arrest inhibitors was due to the attenuation of cell cycle G2 arrest, as evidenced by decreased phosphorylation of Cdc2-Y15 and increased phosphorylation of histone H3, as well as reduced expression of RAD51, resulting in impaired DNA repair capacity. To further examine the essential role of DNA repair in AST-3424 anti-tumor activity, we utilized two PDX models with BRCA deleterious mutations lacking capacity of double-strand DNA repair. The results showed that AST-3424 exhibited excellent anti-tumor activity in two pancreatic PDX models with BRCA deleterious mutations and high expression of AKR1C3.

Conclusions: DNA repair plays an essential role in AST-3424-mediated *in vitro* biological activities and *in vivo* anti-tumor activity. The preclinical data presented in this study support a new approach for cancer treatment.

21P Implications of KMT2C knockdown for DNA damage repair in breast cancer

P. Bredin[1], S. Toomey[2], E. Tinsley[3], G. Dowling[2], N. Cosgrove[3], S. Furney[3], B. Hennessy[1]

[1]Medical Oncology Department, Beaumont RCSI Cancer Centre, Dublin, Ireland; [2]Department of Molecular Medicine, RCSI Molecular Medicine Laboratories, Dublin, Ireland; [3]Genomic Oncology Research Group, RCSI - Royal College of Surgeons in Ireland, Dublin, Ireland

Background: Pathogenic mutations in the epigenetic modulator histone-lysine N-methyltransferase 2C (KMT2C) occur in up to 1 in every 6 breast cancers and KMT2C likely functions as a tumour suppressor. Despite this high frequency, therapeutic implications of deleterious KMT2C mutations are poorly understood and detailed preclinical work is still needed. DNA damage repair pathways may be affected by KMT2C mutations according to published preclinical data. The aim of this study is to identify the effects of KMT2C knockdown in vitro in breast cancer cells as a basis for identifying potential synthetic lethality drug targets.

Methods: MCF-7 (ER+ breast cancer) cells were cultured and 500,000 cells per well were plated on 6-well plates. KMT2C siRNA was transfected via Lipofectamine as per protocol in three wells, with universal control siRNA in three wells. Total RNA was extracted and sent for sequencing. RNA expression was quantified by RT-qPCR.

Results: RNA-seq confirmed reduction in expression of KMT2C in KMT2C siRNA-treated cells vs controls. RT-qPCR showed a reduction in expression of DNA damage repair genes including BRCA1 (RQ = 0.36), BRCA2 (RQ = 0.37), RAD51 (RQ = 0.36), RAD54L (RQ = 0.28) and POLD3 (RQ = 0.47).

Conclusions: KMT2C loss-of-function in breast cancer may impact DNA damage response pathways including homologous recombination and therefore be implicated in response to established treatments such as PARP-inhibitors. Further study including mapping of co-dependencies by whole genome siRNA screens in KMT2C-mutant breast cancer cells to identify synthetic lethality targets, as well as cell toxicity assays, are being performed in light of these results.

22P Clinical significance of DNA damage response mutations in early stage NSCLC

H. Zhang

Department of Respiratory and Critical Care Medicine, Peking Union Medical College Hospital, Chinese Academy of Medical Sciences, Dongcheng, China

Background: DNA damage response (DDR) pathways are essential to sustain genomic stability and play a critical role in cancer development and progression. Here, we investigated DDR genes mutations profile in early-stage non-small cell lung cancer (NSCLC) and their prognostic values.

Methods: We first examined 74 DDR genes involved in seven DDR pathways and then focused on six specific genes: *ATM, BRCA1/2, CHEK1, BARD1, BRIP1*. A total of 179 stage I and IIIa NSCLC patients who received curative resection in Peking Union Medical College Hospital and their corresponding samples were collected for DNA sequencing, immunohistochemistry and survival analysis.

Results: A total of 167 eligible patients were finally analyzed. Mutation frequencies were 82% and 26.3% for the selected 74 genes and 6 genes, respectively. No association was found between DDR gene status and PD-L1 expression, CD8 positive lymphocyte and tumor-associated macrophage (TAM) infiltration in tumor area. Numbers of gene mutations was significantly increased among patients with DDR alterations. Deleterious mutations in *ATM, BRCA1/2, CHEK1, BARD1* and *BRIP1* were independent prognostic indicators of significantly longer disease-free survival.

Conclusions: Deleterious mutations of these six genes were common in early-stage NSCLC and may serve as prognostic biomarkers.

23P PMC-309: A highly selective anti-VISTA antibody reverses immunosuppressive TME to immune-supportive

C.H. Park, K. Kim, H. Han, W.S. Lee

R&D Center, PharmAbcine, Inc., Daejeon, Republic of Korea

Background: PMC-309 is a novel human monoclonal IgG1 antibody (mAb). It binds with human VISTA, an immune checkpoint protein, with the effect of regulating the immunological activity of myeloid cells such as MDSC or myeloid-derived immune cells, thereby improving the antitumor activities of immune cells. In addition to being a novel drug substance, PMC309 will be the first IgG1 monoclonal antibody to act synergistically with other immunotherapies to improve treatment efficacy.

Methods: In vitro T cell activity: human PBMC was employed for the evaluation of T cell activity, and was stimulated with or w/o PMC-309 in the presence of anti-CD3/28 Antibody. In vivo study: MC38-bearing human VISTA knock-in (KI) mice were employed for the assessment of the anti-tumor activity of PMC-309. The tumor infiltrated immune cells: Immune cells in the TME were evaluated by immunohistochemistry (IHC) or flow cytometry (FACS) analysis.

Results: PMC-309 binding to VISTA-expressing cells is highly selective and the selectivity is maintained even in the low pH conditions that mimic TME. PMC-309 enhances the secretion of IFN-gamma, TNF-alpha, and IL-2 in Mixed Lymphocyte Reaction (MLR) settings. In addition, PMC-309 promoted monocyte differentiation into M1 macrophage which stimulates proinflammatory cytokine secretion of T cells. For the in vivo study, PMC-309 was intravenously administrated in VISTA-KI mice. The tumor growth rate was suppressed accompanied by a synergistic effect with an anti-PD1 antibody. The anti-tumor activity was associated with enhanced T cell activation, increased secretion of pro-inflammatory cytokines, and increased penetration of cytotoxic T cells, but lowing immune-suppressive MDSC cells into TME as demonstrated with IHC analysis.

Conclusions: PMC-309 enhanced both T-cell activation and monocyte activation. PMC-309 increased the number of T cell infiltration while a decrease of MDSCs in the TME. PMC-309 in combination with chemotherapy or other IO drugs could address the high medical unmet needs of patients with drug resistance to currently available IO treatment options.

24P Single cell transcriptomics of the immune cells during chemotherapy in triple-negative breast cancer patients

A. Frolova[1], T.S. Gerashchenko[2], M. Patysheva[1], A.A. Fedorov[2], O. Bragina[3], E. Garbukov[4], N. Cherdyntseva[1], V.Y. Korobeynikov[2]

[1]Laboratory of Molecular Oncology and Immunology, Cancer Research Institute, Tomsk National Research Medical Center of the Russian Academy of Sciences, Tomsk, Russian Federation; [2]Laboratory of Cancer Progression Biology, Cancer Research Institute, Tomsk National Research Medical Center of the Russian Academy of Sciences, Tomsk, Russian Federation; [3]Department of Radionuclide Therapy and Diagnostics, Cancer Research Institute, Tomsk National Research Medical Center of the Russian Academy of Sciences, Tomsk, Russian Federation; [4]Department of General Oncology, Cancer Research Institute, Tomsk National Research Medical Center of the Russian Academy of Sciences, Tomsk, Russian Federation

Background: Chemotherapy is the mainstay of systemic treatment for patients with triple-negative breast cancer (TNBC) due to the lack of targets for targeted therapy (HER2/neu; ER; PR). Components of the immune system are known to be involved in the response to chemotherapeutic treatment. Here we aimed to study the dynamics of changes in immune cell composition during neoadjuvant chemotherapy (NACT).

Methods: The immune cells were purified from peripheral blood and biopsy samples of 5 TNBC patients before NACT and 21st days of first course of NACT (AC regimen). Total cell concentration and viability (Calcein/DRAQ7) were assessed by flow cytometry (Cytoflex, Beckman Coulter). Single cells were sequenced on a Genolab M platform (GeneMind Biosciences) using 10x Genomics technology for fixed multiplexed samples. Data were analyzed using Seurat and SingleR.

Results: Sequencing revealed a variety of immune cell populations including: B cells, DC cells, NK cells, CD4+, CD8+ and T regulatory lymphocytes, classical and non-classical monocytes, granulocytes and others. In the blood, the pool of classical monocytes and NK cells were depleted up to day 21 after the first NACT cycle, while naive CD4+, CD8+ T cells and end effector CD8+ T cells, were increased by day 21. In the populations of monocytes and NK cells overexpression of *RGS2*, *ANXA1*, *FGL2*, *MX1*, *IFI6* genes were observed, involved in induction apoptosis. CD8+T-cells, as well as Th-1 and Th-2 CD4+ T-cells were characterized by increased expression of *NFKBIA*, *JUN*, *FOS*, involved in T cell differentiation. In the tumor microenvironment, depletion of CD4+ T cells, CD8+ T cells and memory B cells and an increase in T-regulatory cells and plasma cells were observed. *DUSP4*, *LCK, CXCR4*, *LTB*, *TNFRSF18*, *IL2RB* and *PTPN7* genes were overexpressed and involved in the regulation of cytokine secretion and inhibition of TCR signaling in CD4+ and CD8+ T cells; chemotaxis-mediated inflammation in memory B cells; T cells differentiation, and induction of invasion/migration of tumor cells in T-regulatory cells and plasma cells.

Conclusions: The first cycle of NACT induced renewal of the immune cells' composition in the blood and tumor microenvironment skewing towards to immune disfunction.

25P Role of AXL activation on adaptive resistance to KRAS-G12C inhibitors in KRAS-G12C-mutated non-small cell lung cancer

T. Yamada[1], K. Morimoto[1], S. Hirai[1], Y. Katayama[1], K. Kunimasa[2], T. Sasaki[3], M. Nishida[4], S. Watanabe[5], S. Shiotsu[6], H. Uehara[7], K. Takayama[1]

Background: KRAS is the most frequent targetable oncogene in non-small cell lung cancer (NSCLC). Recently, novel KRAS inhibitor have been clinically developed for treatment of KRAS G12C-mutated NSCLC patients. However, it is difficult to achieve complete remission of tumor. Therefore, the optimal combined therapeutic intervention with KRAS G12C inhibitors has a potentially crucial role in the clinical outcomes of patients. In this study, we focused on the mechanisms underlying adaptive resistance to KRAS G12C inhibitors and therapeutic strategies required to overcome them.

Methods: We used KRAS G12C-mutated NSCLC cell lines to evaluate the adaptive response to KRAS G12C inhibitors in vitro and in vivo. We also investigated the correlation between AXL expression in pre-treated tumors and clinical outcomes with sotorasib for KRAS G12C-mutated NSCLC patients.

Results: We reveal that AXL signaling was caused to the adaptive resistance to KRAS G12C inhibitors in KRAS-G12C mutated NSCLC, activation of which was induced by GAS6 production via transcriptional coactivator YAP. AXL inhibition reduced the viability of AXL-overexpressing KRAS G12C-mutated lung cancer cells by enhancing KRAS G12C inhibition-induced apoptosis. In xenograft models of AXL-overexpressing KRAS G12C-mutated lung cancer treated with KRAS G12C inhibitors, initial combination therapy with AXL inhibitor markedly regressed tumors and delayed tumor regrowth compared with KRAS G12C inhibitor alone or the combination after acquired resistance to KRAS G12C inhibitor. AXL was highly expressed in clinical specimens of KRAS G12C-mutated lung cancers and its high expression was associated with a low response rate to sotorasib.

Conclusions: These results indicated pivotal roles for AXL activation and its inhibition in the intrinsic resistance to KRAS G12C inhibitor.

26P Pre-clinical modelling and treatment of BRAF mutated colorectal cancer

M. White[1], T. Lannagan[2], L. McGarry[3], L. Carlin[3], M. Mills[1], A.S. Yazgili[1], R. Ridgway[1], R. Jackstadt[4], A.D. Campbell[2], R.H. Wilson[5], O.J. Sansom[1]

[1]Colorectal Cancer and Wnt Signalling Laboratory, CRUK - Cancer Research UK Beatson Institute, Glasgow, UK; [2]Colorectal cancer and Wnt Signalling, CRUK - Cancer Research UK Beatson Institute, Glasgow, UK; [3]BAIR, CRUK - Cancer Research UK Beatson Institute, Glasgow, UK; [4]Cancer Progression and Metastasis, HI-STEM - Heidelberg Institute for Stem Cell Technology and Experimental Medicine, Heidelberg, Germany; [5]Wolfson Wohl Cancer Research Centre - Institute of Cancer Science - University of Glasgow, Glasgow, UK

Background: 10% of colorectal cancers (CRC) have a BRAF mutation (BM). This is a poor prognostic group with distinct clinical characteristics. Robust preclinical models that reflect this CRC subtype are currently lacking. We have developed a novel, aggressive, immune competent, genetically engineered mouse model (GEMM) that aligns well with human BM CRC.

Methods: 4 genes were targeted with the villinCre^{ER}: activating *Braf*$^{V600E/+}$ (B), deletion of *Trp53*$^{fl/fl}$(P), deletion of ALK5$^{fl/fl}$ and NOTCH1 intracellular domain expression *Rosa26*$^{N1icd/+}$ (N). This generated BPNA mice. Mice were induced and aged until clinical endpoint. Clinically relevant treatments were benchmarked, including BRAFi (Dabrafenib) combined with EGFRi (Erlotinib). Mouse tumour organoids were derived and high throughput drug screening was performed.

Results: BPNA mice developed endpoint tumours in the proximal colon in a short time period (37 DPI). Mice had high rates of T4 disease (57%) and, despite short latency, developed peritoneal metastasis in 5/27 mice (19%). Primary tumours had proficient mismatch repair (pMMR). Tumours classified as CMS4, aligned with the BM1 transcriptional subtype and displayed regenerative cancer stem cell markers. Therapeutic interventions based on the BEACON CRC (BRAFi+EGFRi) combinations were tested. Both BRAFi and EGFRi as monotherapies had no significant survival advantage (OS) *in vivo*. However in combination, mice lived twice as long with median OS of the combination group 66 DPI vs 32 DPI in the vehicle control (log-rank $p<0.001$). DUSP6 was only significantly suppressed in the BRAF/EGFRi arm suggesting effective MAPK targeting requires combination therapy. Through organoid drug screening, 28/166 compounds were identified as hits of which 3/5 top hits were proteasome inhibitors.

Conclusions: The BPNA GEMM aligns with human disease in terms of primary tumour characteristics and metastatic pattern. Mice also respond to standard of care therapeutics similarly to humans creating a good benchmark for further investigation. Organoid drug screens have highlighted a potentially novel drug class for BM CRC treatment. Future work will utilize these mice to test therapeutics enabling robust pre-clinical evidence to de-risk future novel early phase trials for BM CRC.

27P Extending a classification system for atypical BRAF mutations to improve targeted therapies in colorectal cancer cells

A.B. Madduri[1], Y. Liu[2], B.G. Nelson[1], K.E. Sanders[1], D. Wang[1], N. Hornstein[3], J.P.Y.C. Shen[3]

[1]GI Medical Oncology, MD Anderson Cancer Center, Houston, TX, USA; [2]TMP, MD Anderson Cancer Center, Houston, TX, USA; [3]GI Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX, USA

Background: Unlike other types of cancer that are sensitive to single-target agents, such as lung cancer and chronic myeloid leukemia, colorectal cancer (CRC) involves a complex network of interactions between activating oncogenes and is thus more likely to respond to multi-target therapy. Approximately 10% of CRC mutations are within the BRAF gene, the most frequent being BRAFV600E. While this mutation can be targeted with relatively high efficacy by single-target therapies, there exists a cohort of atypical BRAF mutations that confer higher resistance to currently available treatments. Furthermore, a large proportion of these atypical BRAF mutations are poorly understood.

Methods: We used principal component analysis and semi-supervised clustering learning methods to classify mutants unassigned by the previous BRAF classification system. By leveraging previously established protein-protein networks, we overlaid them with gene essentiality data to successfully classify 84 new BRAF mutations. We then evaluated the oncogenic potential of the newly classified atypical class-2 or -3 BRAF mutations compared to wild-type and class-1 BRAF mutations to validate that our extended system was consistent with the previously established BRAF classes. We also performed a network analysis to determine which genes were co-mutated for each BRAF class.

Results: Cell viability analysis of the BRAF-mutant Ba/F3 cells yielded no significant differences in the median AUC values between the new and old classification systems. Several key genes (including PIK3CA, EGFR, and MEK) were identified as potential drug targets (IC 50: 0.1 μM) for cell lines with class-2 and -3 atypical BRAF mutations. We found that atypical BRAF mutations have significantly more positive CERES scores than class-1 mutations and thus need to partner with other oncogenes to drive oncogenesis due to their lower oncogenic potential.

Conclusions: In conclusion, we extended the previous Yao classification system to establish a more comprehensive BRAF-mutant classification system, Yao Classification System Plus, that encompasses more atypical BRAF mutations. This allows for greater therapeutic options to target cells carrying these previously uncharacterized mutations.

28P Xanthine oxidase as a prognostic factor in colorectal cancer metastatic disease

A.A. Burlaka[1], A. Burlaka[2], V. Rozhkova[1], S.V. Zemskov[3], I.I. Lisnyy[4]

[1]Department of Minimally Invasive and Endoscopic Surgery, Interventional Radiology, National Cancer Institute of the Ministry of Health of Ukraine, Kiev, Ukraine; [2]Department of Modifiers of Antitumor Therapy, R.E. Kavetsky Institute of Experimental Pathology, Oncology and Radiobiology, NAS, Kiev, Ukraine; [3]University Administration, NMU - National Medical University, Kiev, Ukraine; [4]National Cancer Institute of the Ministry of Health of Ukraine, Kiev, Ukraine

Background: Obesity and related diseases, namely, diabetes and metabolic syndrome, are associated with chronic inflammation and colorectal cancer (CRC). In CRC liver metastases (mCRC) and adjacent liver tissue defects are formed in the mitochondrial electron transport chain that causes mitochondrial dysfunction, activation of redox-molecules (SR, NO) generation sources and MMP-2, -9 activity. Radical oxygen species take a part in the regulation of gelatinases (MMP-2 and -9) and the xanthine/xanthine oxidase reaction is widely used as a source of exogenous ROS in considering of MMPs. The aim of the study was to determine the state of XO, SR and MMPs in liver tissue and CRC liver metastases (MT) and set the clinical significance of obtained results.

Methods: The prospective study on 37 mCRC patients who underwent the liver resection due metastatic disease has been performed. The rate of SR generation of neutrophils and in the tissue samples, the rate of XO and the activity of matrix metalloproteinases in the tissue samples was measured accordingly study design.

Results: The highest level of XO in mCRC patients was detected in metastatic tissue (1.47 ± 0.18 a.u.). The level of XO enzyme in the adjacent tissue (AT) and distant tissue (DT) were 0.38 ± 0.10 a.u. ($p<0.05$) and 0.19 ± 0.008 a.u. ($p<0,05$) respectively. A correlation was found between the BMI and amount of XO in DT of the liver $r^2 = 0,64$. The total activity of gelatinases in subgroup of mCRC patients with BMI $\geq$ 25 was found to be significantly higher than in normal body weight patients withing the DT (1.52; $p<0.001$), as well as in the AT (1.28 times; $p<0.001$). High XO levels (HR (95% CI) = 0,002 (2,63 to 15.05) P = 0,002) and SR generation levels (HR (95% CI) = 0,01 (2,4 to 10,37) P = 0,01) in adjusted liver tissue to metastatic lesions had a negative impact on overall overall survival rates.

Conclusions: Xanthine oxidase and superoxide radicals can be a new metastatic disease prognostic factors for colorectal cancer patients, the latter requiring further randomized trials.

29P The effect of cancer associated fibroblast-derived activin A on colorectal cancer progression

S. Stang[1], L. Armborst[1], S. Hilberath[1], E. Koncina[2], M. Macia-Guardado[1], M. Hengstschläger[1], E. Letellier[2], H. Dolznig[1]

[1]Institute of Medical Genetics, MedUni Wien - Medical University of Vienna, Vienna, Austria; [2]Department of Life Sciences and Medicine, University of Luxembourg, Belvaux, Luxembourg

Background: Colorectal cancer (CRC) is one of the most common cancers worldwide. In particular, the yearly mortality emphasizes the limited spectrum of treatment possibilities. The tumor microenvironment with its relevant influence on malignant tumor initiation, progression and chemoresistance represents a promising target for

cancer therapeutics. Especially cancer-associated fibroblasts (CAFs) are of importance in carcinogenesis as they are involved in tumorigenesis, metastasis, inflammatory responses, and extracellular matrix changes. Based on preliminary data, we found upregulated expression of *INHBA*, a gene encoding for the βA subunit of the TGFβ superfamily members Activin A, Activin AB and Inhibin A, in the stromal compartment of human CRC. Therefore, we wanted to investigate the autocrine and paracrine functional consequences of CAF-secreted Activin A in CRC.

Methods: We knocked down *INHBA* in primary patient-derived CAFs and used *in vitro* 3D collagen gel assays, flow cytometry, immunofluorescence, secretome analysis and Western blotting to check the autocrine effects of Activin A on CAFs. Regarding the paracrine impact on tumor cells and immune cells, we employed 3D co- and triple-culture collagen gel assays to determine the impact of CAF-derived Activin A. Here, we focused on proliferation, apoptosis and invasion levels of tumor cells as well as on monocyte differentiation, myeloid cell plasticity and T-cell activation.

Results: Our data demonstrate that CAFs expressing *INHBA* show a pro-proliferative, pro-motile and pro-contractile phenotype. Furthermore, the secretome and plasticity of CAFs were notably modified by the *INHBA* knockdown. Additionally, CAF-derived Activin A seems to influence various aspects of tumor progression and the plasticity of immune cells.

Conclusions: Together, our results indicate key functions of CAF-derived Activin A in CRC progression suggesting a potential novel therapeutic target.

30P Prostaglandin signaling in tumour stroma interaction in colorectal cancer and its impact on the secretome and functional relevance

M. Macia-Guardado[1], M. Ertl[1], V. Lutz[1], E. Ebner[1], E. Koncina[2], S. Stang[1], M. Hengstschläger[1], E. Letellier[2], J. Schüler[3], H. Dolznig[1]

[1]Institute of Medical Genetics, MedUni Wien - Medical University of Vienna, Vienna, Austria; [2]Life Sciences Research Unit, University of Luxembourg, Belvaux, Luxembourg; [3]Discovery Services, Charles River Discovery Research Services Germany GmbH, Freiburg Im Breisgau, Germany

Background: One of the risk factors to develop colorectal cancer (CRC), which is one of the deadliest types of cancer, is inflammation. Among the factors involved in the inflammatory response, prostaglandins (PGs) seem to play an important role. The tumor microenvironment (TME) influences the development of the tumor and within the TME, cancer associated fibroblasts (CAFs) represent the major compartment. Despite the importance of the TME, there is limited evidence on the secretome-dependent communication of CRC cells with CAFs and myeloid cells with respect to PG signaling. In this project we mainly focus on PGE2 and PGF2α, that we have previously found are secreted by CAFs.

Methods: By using *in vitro* 3D cocultures secreted molecules induced by increased or decreased PGE2 and PGF2α expression were identified. The levels of both PGs were measured by ELISA, whereas the expression of the production enzymes was analyzed by Western Blot. Phenotypic analysis and functional assays were carried out using siRNA or specific inhibitors to analyze the effect on angiogenesis and contractility of CAFs, their proliferation, motility, and apoptosis levels. Finally, preliminary *in vivo* experiments were performed and, additionally, paraffin tissue sections from patient-derived xenografts (PDX) models were stained to prove the stroma expression of the PGs specific synthases.

Results: We demonstrate that a combination of proinflammatory cytokines can increase the expression of COX-2 and mPGES-1 while IL-4 decreases it. Knocking down the specific synthases of PGE2 and PGF2α in the CAFs also leads to a decrease in their proliferation, contractiliy, motility and angiogenesis capacity, but did not induce apoptosis. *In vivo*, knocking down of the PGs specific synthases seems to lead to a worse survival capacity, and some of these enzymes seem to be only expressed in the stromal cells of PDX models.

Conclusions: More information about the link between cancer and its TME would help us to achieve a higher degree of accuracy in the development of potential future therapies. Here we have proved that the action of PGs, especially PGF2α and PGE2, is involved in tumor development in 2D and 3D suggesting a possible therapeutic target.

31P Cell-free tumor microRNA as early biomarkers of high-grade cervical intraepithelial neoplasia using liquid biopsy

S. Calfa[1], A.J.A. de Freitas[2], T.T. Komoto[1], C.R. Nunes[3], J.C.P. Resende[4], R. dos Reis[5], R.M. Reis[2], M.M.C. Marques[2]

[1]Molecular Oncology Research Center, Hospital de Amor (Hospital De Cancer De Barretos) - Fundacao Pio XII, Barretos, Brazil; [2]Molecular Oncology Research Center, Barretos Cancer Hospital, Barretos, Brazil; [3]Centro de Oncologia Molecular, Barretos Cancer Hospital, Barretos, Brazil; [4]Department of Prevention, Hospital de Amor (Hospital De Cancer De Barretos) - Fundacao Pio XII, Barretos, Brazil; [5]Department of Gynecological Oncology, MD Anderson Cancer Center, Houston, TX, USA

Background: Cervical cancer (CC) is the fourth most common type of cancer among women worldwide. Considering that the early diagnosis of cervical intraepithelial neoplasia (CIN) is the main strategy to improve the prognosis of patients, new methodologies based on molecular analyzes performed on liquid biopsy samples, represent promising alternatives for minimally invasive biomarkers. miRNAs have been shown their role as non-invasive biomarkers, providing a wide perspective for personalized treatment and early diagnosis of cervical cancer through liquid-based cytology (LBC). However, more research is under way to identify miRNA signatures that can be implemented in clinical practice specially for early detection. In this study, we aimed to identify molecular signatures of miRNAs in cervical precursor lesions (CIN 2 and CIN 3) from LBC and their interaction with molecular pathways related to CC in a prospective study.

Methods: We analyzed 96 LBC cervical samples, that were divided into two groups: the case group was composed of women diagnosed with CIN 2 and CIN3 ($n = 48$); the control group corresponded to women without cervical precursor lesions ($n = 48$). We performed miRNA expression profiling using the nCounter® miRNA Expression Assay (NanoString Technology), which evaluated 800 targets. A functional analysis in silico was performed by mirDIP and enrichment were performed using Cytoscape with the Reactome plugin.

Results: We identified 54 miRNAs that were differentially expressed between case and control groups ($p \leq 0.05$). Using logistic regression analysis, we identified a signature composed of five miRNAs, with a fold change ≥ 1.5 and FDR-corrected p-value of ≤ 0.05, of which two were up-regulated and three were down-regulated. The signature had a predictive value with an AUC of 0.90. Furthermore, we found 26 miRNA target genes for four of the five identified miRNAs, mainly related to pathways in cancer, RNA Polymerase II Transcription, RhoA signaling pathway, and PI3K-Akt signaling pathway.

Conclusions: This study demonstrated that those miRNAs could be used as non-invasive biomarkers in LBC samples, once they were able to distinguish CIN 2 and CIN3 patients from healthy women and regulate important molecular pathways of onset carcinogenesis.

32P Epigenetic reprogramming induced prostaglandin E2 accumulation via overactivated arachidonic acid metabolism during trastuzumab resistance formation of HER2-positive breast cancer

Y. Yin, N. Duan, Y. Hua

Oncology Department, Jiangsu Province Hospital/The First Affiliated Hospital of Nanjing Medical University, Nanjing, China

Background: Secondary trastuzumab resistance seriously affects HER2-positive breast cancer treatment. However, we still lack knowledge about changes in tumor cells and their interaction with tumor microenvironment (TME) components during resistance formation. This study aimed to uncover metabolism pathway changes during trastuzumab resistance formation and potential epigenetic variations that are relevant to these processes.

Methods: Induced secondary trastuzumab-resistant SKBR3_HR cell line together with the original trastuzumab-sensitive SKBR3 cell line were applied in this study. Total RNA was collected for transcriptome analysis. Anti-H3K4me3, K27me3 and K27ac antibodies were chosen for CUT&Tag sequencing library preparation. Total genome DNA was prepared for Micro-C sequencing library preparation. Activity score of metabolism pathway was calculated as relative gene expression value averaged over all genes in this pathway in certain cell types. Extracellular prostaglandin E2 (PGE2) was measured by ELISA.

Results: SKBR3_HR cells showed higher trastuzumab tolerance than SKBR3 cells. Upregulation of arachidonic acid metabolism, which was characterized by two over-expressed genes, PTGS1 and PTGES, was observed in SKBR3_HR cells, resulting in PGE2 accumulation in culture medium. Variations of 1519 H3K27me3 peaks and 256 H3K4me3 peaks at promoters were observed during resistance formation. Little H3K27me3 but considerable raised H3K4me3 levels at PTGS1 and PTGES gene promoters may stimulate their transcription.692 altered active enhancers were measured

during resistance formation. Meanwhile, 2741 and 7007 DNA loops were lost and gained. New DNA loops formation between PTGS1 gene promoter and enhancers nearby, indicating a positive synergy regulatory on PTGS1 gene expression together with promoter modifications.

Conclusions: During trastuzumab resistance formation, promoter H3K4me3, active enhancers and DNA loops together regulate PTGS1 and PTGES expression, activate arachidonic acid metabolism, and eventually stimulate PGE2 accumulation.

33P Visualizing trastuzumab-deruxtecan action in HER2+ breast cancer cells at nanoscale

K. Cortese[1], O. Garrone[2], M.C. Gagliani[1], G. Bellese[1], P. Arnaldi[1], A. Abbona[3], M. Paccagnella[4], F. Ruatta[5], M.C. Merlano[6], P. Castagnola[7]

[1]Dipartimento di Medicina Sperimentale, Università degli Studi di Genova, Genoa, Italy; [2]Medical Oncology, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy; [3]Fondazione ARCO - Cuneo, Fondazione ARCO - Cuneo, Cuneo, Italy; [4]Azienda Ospedaliera St. Croce e Carle, Azienda Ospedaliera St. Croce e Carle, Cuneo, Italy; [5]Astellas Pharma S.p.A., Assago, Italy; [6]Clinical Oncology Dept., Candiolo Cancer Institute, Candiolo, Italy; [7]Bioterapie, IRCCS Policlinico San Martino, Genoa, Italy

Background: Breast cancers that test positive for the human epidermal growth factor receptor 2 (HER2+) are known to be highly aggressive and hold poor survival rates. However, advances in therapies targeting HER2 have led to anti-HER2 antibodies like Trastuzumab and tyrosine kinase inhibitors. Trastuzumab-deruxtecan (Tz-Dxd) is an antibody-drug conjugate that has shown remarkable results in both HER2+ and HER2-low BCa. By promoting its internalization and trafficking to lysosomes through HER2 binding, Tz-Dxd has great potential to revolutionize cancer treatment.

Methods: This study aimed to investigate the effects of Tz-Dxd on HER2+ breast cancer cell lines at the nanoscale level using high-resolution light and electron microscopy techniques, biochemistry and flow cytometry analysis.

Results: We found that after 2 hours, Tz-Dxd induced ERBB2 phosphorylation and downstream signaling activation without significant internalization of the receptor. However, the receptor was internalized towards lysosomes at later stages (72 hours), but only in a limited fraction of cells. Nonetheless, Tz-Dxd induced apoptosis in more than 50% of cells after 72 hours of treatment, even in cells where ERBB2/Tz-Dxd was not internalized. This suggests that deruxtecan was efficiently released from Tz in lysosomes reaching by diffusion surrounding cells. In addition to apoptotic cells, we observed a consistent fraction of cells displaying suggestive hallmarks of senescence. In particular, we detected dramatic cell flattening, increased nuclear size, chromatin reorganization, nuclear envelope ruptures and expansion of the lysosomal compartment. Cells also displayed alterations of the mitochondrial network dynamics and induction of autophagy; indicative of an elevated energy demand to sustain autophagy and senescence.

Conclusions: These results suggest that Tz-Dxd has potent anti-tumor activity in vitro but might also induce cellular senescence, which would merit further investigation due to its uncertain role in cancer progression in the long run.

35P SAT-122: A potential first-in-class, potent, small-molecule disruptor of RAD51-BRCA2, attenuates RAD51 foci formation and tumor progression in preclinical models

S. Patra[1], M. Pothuganti[1], V. Sankeshi[1], G. K[1], H. Pathange[1], R. S[1], K. Soumyajit[2], S. Viswanadha[1]

[1]Biology, Satya Pharma Innovations, Hyderabad, India; [2]Biochemistry, SDU - University of Southern Denmark - Medical Biotechnology Center, Odense, Denmark

Background: The DNA damage repair pathway plays a crucial role in signalling for effective DNA repair and cell cycle progression. DNA double-strand breaks (DSBs) are primarily repaired by homologous recombination. Acting downstream of ATR, ATM and PARP, RAD51 is a central recombinase in HR-mediated DDR pathway that participates in DSB repair *via* interaction with BRCA2, followed by its nuclear translocation. RAD51:BRCA2 interaction disruptors represent a first-in-class anticancer target with therapeutic potential in refractory solid tumors.

Methods: Binding of SAT-122 to RAD51 and its interaction with BRC4 was determined using Surface Plasmon Resonance (SPR) and pull-down of the RAD51:BRC4 complex, respectively. Downstream modulation of RAD51 and gamma H2AX foci, along with effect on cell cycle was studied. Antiproliferative effects of SAT-122 was evaluated in a panel of multiple solid tumor cell lines. Selectivity was evaluated in a kinase panel. Nanostring based evaluation of pathway-related genes following incubation of cells with SAT-122 was conducted. *In Vivo* efficacy was evaluated in NCI-H358 and MDA-MB-231 xenograft models.

Results: SAT-122 binds to RAD51 and disrupts RAD51:BRCA2 interaction with an IC_{50} of 20 nM. Fluorescent microscopy studies indicated a dose dependent reduction of RAD51 foci, and an increase in g-H2AX foci at 500 nM. FACS analysis demonstrated arrest at late S and G2 phase with subsequent apoptosis. SAT-122 inhibited proliferation of over 30 different cancer cell lines at IC_{50}ranging from 150-800 nM. Biochemical selectivity was established against a 345-kinase panel. RNA seq studies suggested modulation of multiple genes in the homologous recombination repair (HRR) pathway in line with the mechanism. *In vivo* translation was confirmed in NCI-H358 and MDA-MB-231 xenograft models with TGI of $>$70% and 50%, respectively. Pharmacokinetic studies and tolerability studies in rodents, revealed sufficient exposures, along with a wide therapeutic window.

Conclusions: SAT-122 is a novel and potent disruptor of RAD51:BRCA2 with potential to be used in the DDR context, in solid tumors. IND-enabling studies are ongoing with clinical trials planned in H1 2024.

36P Molecular assessment of clinical antitumour therapeutics utilising established pancreatic ductal adenocarcinoma patient-derived models

Y-A. Suh

CMI, Seoul National University Hospital, Seoul, Republic of Korea

Background: Our proteogenomic analysis using pancreatic ductal adenocarcinoma (PDAC) tissues provides significantly mutated genes/biomarkers, cell signaling pathways and cell types as potential therapeutic targets to improve stratification of PDAC patients (Nat. Can., 2023). The current study aimed to evaluate clinical chemotherapeutics to validate targeting molecules and signaling pathways based on previous results, using patient-derived primary cells and tumor organoids.

Methods: The sensitivity on drugs was also evaluated on established primary PDAC cells and tumor organoids. To explore the mechanistic molecular changes for the development of drug resistance, we established resistant-cells on gemcitabine combined with radiation through long term treatment of the combination and selection procedure. Signaling pathways, EMT and cancer were explored at protein as well as RNA levels, and metabolomics were performed

Results: PDAC cells and organoids showed growth inhibition when treated with inhibitors against RhoA phosphorylation, HIF1A, or gemcitabine combined with radiation, respectively. Each chemotherapeutics showed reduced tumor growth through cell cycle arrest, apoptosis or autophagy. Biochemical analyses showed that drug-treated cells showed reduced expressions of phosphorylated ERK, phosphorylated Akt, or phosphorylated RhoA. HIF1A together with HK2 genes was overexpressed in resistant cells. Metabolomics showed differential glycolysis patterns among parental and resistant primary PDAC cells.

Conclusions: The results suggest that the targeting molecules associated with squamous PDAC malignancy discovered in our previous study would provide significant therapeutic advantage. Additionally, hypoxic tumor microenvironment (TME) plays a critical role for chemotherapeutics sensitivity, according to the metabolomics analysis. Importantly, the study implicates the critical role of patient-derived models, especially tumor organoids, for precise evaluation of drug sensitivity, and to validate functional mechanism of drug resistance on individual PDAC patients.

37P Nischarin can be a target for stromal normalisation in pancreatic ductal adenocarcinoma

J. Grahovac[1], K. Živić[1], D. Galun[2]

[1]Experimental Oncology, Institute for Oncology and Radiology of Serbia, Belgrade, Serbia; [2]HBP Unit, Clinical Center of Serbia, Belgrade, Serbia

Background: Nischarin (NISCH) is a scaffolding protein involved in the control of cytoskeletal dynamics. Its tumor suppressive role has been demonstrated in breast cancer; and high expression in tumor tissue was reported as a positive prognostic marker in breast and ovarian cancers. Of interest, there are several approved nischarin agonists used in treatment of hypertension. We have previously found that NISCH is expressed in both tumor cells and cancer-associated fibroblasts (CAFs) in pancreatic ductal adenocarcinoma (PDAC) and that nischarin agonist rilmenidine can limit cancer cell invasion. As the dense tumor stroma makes up to 80% of the bulk tumor tissue in PDAC, and is one of the causes of current treatment failure, the aim of this study was to examine the effects of nischarin agonists on the phenotype of cancer-associated stroma in PDAC.

Methods: NISCH expression and co-localization with CAF markers were examined by immunohistochemistry in PDAC tissue microarray. CAFs were isolated from fresh tumor tissue by the outgrowth method. MTT test was used to evaluate cytotoxicity of nischarin agonist rilmenidine on patient-derived CAFs. Immunoblotting, immunocytochemistry, ELISA and qRT-PCR were used to examine the effects of rilmenidine treatment on the extracellular matrix deposition and cytokine and growth factor production in CAFs and *ex vivo* cultures of PDAC tumor tissue.

Results: Nischarin was expressed in both aSMA$^+$ and FAP$^+$ cells in the tumor tissue. Patient-derived CAFs were a heterogeneous population, positive for aSMA$^+$ FAP$^+$, collagen I and fibronectin. Rilmenidine treatment of patient-derived CAFs *in vitro* was not cytotoxic at concentrations achievable in the human plasma. Nevertheless, rilmenidine treatment decreased fractions of both aSMA$^+$ and FAP$^+$ cells *in vitro* and decreased the production of pro-inflammatory cytokines IL-6, IL-8 and CCL-2. Treatment of *ex vivo* PDAC tumor cultures for 72h remodeled the extracellular matrix.

Conclusions: Our results imply that rilmenidine treatment *in vitro* and *ex vivo* shows a potential for normalizing PDAC tumor-derived CAFs and may be a good candidate for drug repurposing.

38P Effects of antiemetics on zolbetuximab-induced gastric injury and emesis frequency in ferrets

J. Weng[1], F. Kinugasa[2], S. Kajikawa[3], Y. Yamanaka[4], T. Ugawa[5], H. Fushiki[6], S. Akuzawa[7]

[1]Astellas Pharma Inc., Tsukuba, Japan; [2]Drug Discovery Research, Astellas Pharma Inc., Tsukuba, Japan; [3]Veterinary, The University of Tokyo, Meguro-ku, Japan; [4]Applied Drug Metabolism & Pharmacokinetics-Non-Clinical Regulatory Science, Astellas Pharma Inc., Tsukuba, Japan; [5]Nonclinical Regulatory Science, Astellas Pharma Inc., Tsukuba, Japan; [6]Research Program Management, Astellas Pharma Inc., Tsukuba, Japan; [7]Applied Pharmacology, Astellas Pharma Inc., Tsukuba, Japan

Background: Claudin 18.2 (CLDN18.2) is expressed in normal gastric tissue and gastric cancers. Zolbetuximab is a chimeric IgG1 monoclonal antibody that selectively targets CLDN18.2, inducing antibody- and complement-dependent cytotoxicity and cancer cell lysis. In phase 3 studies of zolbetuximab for HER2-negative, advanced gastric/gastroesophageal junction adenocarcinomas (SPOTLIGHT, GLOW), the most frequent adverse events were nausea and vomiting (N/V). We investigated the mechanism of zolbetuximab-induced N/V and effects of antiemetic agents on gastric injury and emesis frequency in ferrets.

Methods: Ferrets were administered zolbetuximab with/without single or combination antiemetic treatment (Table). Retching/vomiting were monitored for 6 hours, after which gastric tissues were sampled for histopathologic assessment. The study was conducted twice.

Results: Zolbetuximab induced emesis within 30 minutes of administration. Singly, dexamethasone (DEX), ondansetron (OND), and fosaprepitant (FOS) significantly reduced emesis vs control (no antiemetic) in Study 1; olanzapine (OLA) did not. In Study 2, FOS alone (but not DEX, OND, or OLA) almost completely suppressed emesis. Further, both combination regimens containing FOS reduced emesis. Histopathologic analysis indicated that zolbetuximab induced gastric injury, evidenced by submucosal inflammation in the corpus and pylorus. DEX alone and the DEX-based combination regimen showed a tendency to alleviate submucosal inflammation in the corpus and pylorus, although the other antiemetics did not show any clear suppression of gastric mucosal damage. The combination of OND+FOS also tended to alleviate gastric mucosal abnormalities.

Table: 38P Study groups

Group (n=4, each study)	Emesis Agent	Antiemetic Agent(s) Study 1	Antiemetic Agent(s) Study 2
1 — Normal	Saline IV	—	
2 — Control	Zolbetuximab 1 mg/kg IV	—	
3 — DEX		DEX 20 mg/kg IV	
4 — OND		OND 3 mg/kg IV	
5 — FOS		FOS 3 mg/kg IV	
6 — OLA		OLA 0.03 mg/kg IM	
7 — Combination		DEX+OND+FOS+OLA	OND+FOS

DEX, dexamethasone; FOS, fosaprepitant; IM, intramuscular; IV, intravenous; OLA, olanzapine; OND, ondansetron.

Conclusions: These findings in ferrets demonstrate that zolbetuximab-induced emesis may be associated with gastric mucosal damage. Further, antiemetics may have the potential to mitigate N/V in patients treated with zolbetuximab.

39P Casein kinase 2 modulates epithelial—mesenchymal transition through helicobacter pylori CagA-dependent pathway in gastric cancer cells

S. Lee

Internal Medicine, Yonsei University College of Medicine, Seoul, Republic of Korea

Background: *Helicobacter pylori* is the most important carcinogen in human gastric cancer. However, the pathogenic molecular mechanism which underlies the carcinogenesis in gastric cancer by *H. pylori* remains largely unknown. In this study, we understand that molecular biological mechanism related to gastric carcinogenesis by investigating the role of CK2 in EMT. Casein kinase 2 is a serine/threonine protein kinase and consists of two catalytic subunits (α or α') and regulatory subunits (β). CK2 regulates many substrates and its involved in cell growth, proliferation, invasion. EMT is involved in many signaling pathways, but the key regulatory kinases in this process have not been clearly identified. Although the role of CK2 catalytic subunits has remained largely uncharacterized, several studies have recently focused on regulator subunits in EMT.

Methods: AGS and MKN74 cells as human gastric epithelial cells and *H. pylori* strains, *H. pylori* 60190 (CagA+) and *H. pylori* ΔCagA (CagA-) were used. Protein and mRNA levels of CK2 were tested by Western blot and RT-PCR in AGS cells infected with *H. pylori* 60190. We also examined *in vivo* assay through tumor weight and size by xenograft mouse model. Expression levels of CK2 were analyzed in 54 gastric tissues from patients with gastric carcinoma by immunohistochemistry.

Results: Although CK2α protein expression remained unchanged during *H. pylori* infection, we found that CK2α kinase activity was increased in gastric epithelial cells. We also found that the CK2β protein level decreased in *H. pylori*-infected gastric cancer cells in CagA-dependent manner and demonstrated that CagA induced CK2β degradation via HDM2. We observed that CagA induced HDM2 protein phosphorylation and that p53 levels were decreased in *H. pylori*-infected gastric cancer cells. We also found that the downregulation of CK2β triggered the upregulation of Snail levels in gastric cancer cells. Furthermore, our *in vivo* experiments and functional assays of migration suggest that CK2β downregulation is a major factor responsible for the EMT in gastric cancer.

Conclusions: In summary, we have shown that the downregulation of CK2β in *H. pylori*-infected gastric cancer cells promotes the EMT in CagA-dependent manner.

Background: Identification of tumor associated antigens (TAAs) expressed on the cell membrane of tumoral cells is a main goal in cancer research. T cell engagers (TCE) are bi-specific antibodies that engage a TAA with an effector T cell receptor mainly CD3. Kallikrein-2 (KLK2) is a surface protein for which TCE are currently in clinical development. In our study we explore genomic correlates and the transcriptomic and immunologic profile of tumors with high expression of KLK2.

Methods: Primary prostate cancer data was downloaded from TCGA to study transcripts up or down regulated when high expression of KLK2 was present. Tumor Estimation Resource (TIMER) platform was employed to investigate the association between high expression of KLK2 and immune cell populations. Correlations between transcripts were performed using Spearman's correlation test.

Results: KLK2 was specifically upregulated in prostate cancer compared with other solid tumors and normal tissue (tumor 5956.5 TPM versus normal 4175.26 TPM). KLK2 expression did not associate with the presence of any immune cell population either innate or adaptive cells including CD8+ (Rho = 0.339, p = 1.03E-12), CD4+ (Rho = -0.244, p = 4.56E-07), B cells (Rho = 0.047, p = 0.332), neutrophils (Rho = -0.139, p =0.004), dendritic cells (Rho =-0.152, p = 0.001), or macrophages (Rho= 0.074, p =0.128). No clear association was observed for any biomarker of T cell activation including CD8A, CD8B, GZMA, GZMb or PRF1, or an additional battery including more than 40 additional genes linked with T cell cytotoxic. A mild correlation was observed between high expression of KLK2 and TMPRSS2 (Rho = 0.481, p = 1,68E-11). Protein protein interaction analysis showed interactions with AR, KLK3, IGF1, IGFBP3 (PPI enrichment p-value: 4.51e-07), among others. Co- upregulated surface proteins include TMEFF2, OR51E2, CD320 and FAM17AB; and nonsurface proteins: RDH11, FX4D3, SSR4 and NDUFA13. None of them were specifically expressed in tumoral cells or associated with biochemical (PSA) relapse.

Conclusions: KLK2 is highly and exclusively expressed in prostate cancer mainly in inmune desert tumors. Future studies should be performed in other clinical scenarios like in androgen resistant prostate tumors.

41P Evaluation of ARX517: A next-generation anti-PSMA antibody drug conjugate for prostate cancer treatment, in preclinical enzalutamide-resistant and enzalutamide-sensitive pharmacology models and in toxicology models

S. Zhang, D. Mills, J.Y. Kim, N. Knudsen, J. Nelson, Y. Buechler, L. Skidmore

Preclinical, Ambrx, Inc., La Jolla, CA, USA

Background: Prostate cancer is the second leading cause of cancer death among men in the United States. Metastatic castration-resistant prostate cancer (mCRPC) is an advanced disease stage in which patients ultimately fail androgen-deprivation therapies and exhibit a poor survival rate. Recently, prostate-specific membrane antigen (PSMA) has been validated as a mCRPC tumor antigen with its over-expression in tumors and low expression in healthy tissues. Using an expanded genetic code to create Engineered Precision Biologics, Ambrx has developed ARX517, a PSMA-targeted antibody drug conjugate (ADC), which is composed of a humanized anti-PSMA antibody site-specifically conjugated to a tubulin inhibitor drug-linker at a drug-to-antibody ratio of 2. After binding to PSMA, ARX517 is internalized and catabolized, leading to cytotoxic payload delivery and cellular apoptosis. To minimize premature payload release and maximize delivery to tumor microenvironments, ARX517 employs a non-cleavable PEG linker and stable oxime conjugation chemistry, enhancing systemic stability.

Methods: ARX517 was evaluated in multiple pre-clinical pharmacology and toxicology models using standard methodology.

Results: In vitro studies demonstrate that ARX517 selectively induces cytotoxicity of PSMA-expressing tumor lines. ARX517 exhibited a long terminal half-life and high serum exposure in mice, and dose-dependent anti-tumor activity in both enzalutamide-sensitive and -resistant CDX and PDX prostate cancer models. Repeat dose toxicokinetic studies in non-human primates demonstrated ARX517 was tolerated at exposures well above therapeutic exposures in mouse pharmacology studies, indicating a wide therapeutic index.

Conclusions: In summary, ARX517 inhibited tumor growth in diverse mCRPC models, demonstrated a tolerable safety profile in monkeys, and had a wide therapeutic index based on preclinical exposure data. Based on strong preclinical data and recent clinical validation of PSMA targeting, ARX517 is being evaluated in a phase 1/2 clinical trial (NCT04662580).

42P Developing a photodynamic therapy strategy targeted to endometrial cancer stem cells

B. Serambeque[1], S. Ferreira[1], M. Piñeiro[2], S. Lopes[2], B. Costa[2], N.A. Pereira[2], C.M. Marto[3], M.F. Botelho[3], M.J. Carvalho[4], T. Pinho e Melo[2], M. Laranjo[1]

[1]Coimbra Institute for Clinical and Biomedical Research (iCBR) area of Environment Genetics and Oncobiology (CIMAGO), Institute of Biophysics, Faculty of Medicine; CIBB; CACC, Univ Coimbra, Coimbra, Portugal; [2]Coimbra Chemistry Centre-Institute of Molecular Sciences and Department of Chemistry, Univ Coimbra, Coimbra, Portugal; [3]Coimbra Institute for Clinical and Biomedical Research (iCBR), Area of Environment, Genetics and Oncobiology Research (CIMAGO), Institute of Biophysics, Faculty of Medicine; Institute of Experimental Pathology; CIBB; CACC, Univ Coimbra, Coimbra, Portugal; [4]Gynecology Service, CHUC - Centro Hospitalar e Universitário de Coimbra, EPE, Coimbra, Portugal

Background: Cancer stem cells (CSC) motivate the investigation of novel anticancer-targeted therapies. In endometrial cancer (EC), overexpression of aldehyde dehydrogenase (ALDH) was associated with endometrial CSC, highlighting its therapeutic target potential. Photodynamic therapy (PDT), a minimally invasive anticancer approach, emerges as a promising targeted therapy for endometrial CSC, through a structural modulation of optimized photosensitisers with aldehyde moieties. Thus, the aim is to investigate PDT based on the 4,5,6,7-tetrahydropyrazolo[1,5-*a*]pyridine-fused chlorins (PX), modulated to target endometrial CSC by incorporation of aldehyde substituents.

Methods: A solution of a mono-esther/mono-alcohol derivative chlorin was added to Dess-Martin periodinane in dichloromethane solution and stirred to synthesise a mono-aldehyde derivative of 4,5,6,7-tetrahydropyrazolo[1,5-*a*]pyridine-fused chlorin (A-PX). The presence of the aldehyde group was confirmed by proton nuclear magnetic resonance (^{1}H-NMR). The ALDH1A1-promoted oxidation of A-PX was followed through reverse-phase high-performance liquid chromatography (HPLC). This was done by reacting 50nM ALDH1A1 with 1mM A-PX in a 2% DMSO, Tris pH 7.5, KCl, DTT and β-NAD solution at 37 °C. The reaction was stopped every 30' with acetonitrile. To evaluate A-PX-based PDT (7.5mW/cm2, 10J) the resazurin assay was performed on endometrial CSC.

Results: The A-PX ^{1}H-NMR revealed a peak at 10.28ppm corresponding to the aldehyde. The kinetics of the enzymatic reaction, followed by HPLC, showed the decreasing relative area of the aldehyde peak (retention = 2'13'') in parallel with the increase of the carboxylic acid (retention = 3'04'') formed by ALDH1A1-promoted oxidation, reaching complete conversion at 120'. Preliminary results of the A-PX-PDT cytotoxicity on the endometrial CSC pointed to decreased proliferation, while A-PX *per se* did not show toxicity.

Conclusions: It was possible to develop chlorins able to interact with ALDH1A1, allowing the *in situ* modification of the hydrophilicity of the photosensitizer. A-PX seem to be effective PDT agents against endometrial CSC. The promising results encourage further studies to confirm this rationale for endometrial CSC-targeted PDT.

43P Looking for therapeutic targets on the proteome profile of endometrial cancer stem cells

M. Laranjo[1], C. Mestre[1], B. Serambeque[1], A.S. Carvalho[2], H.C. Beck[3], M.F. Botelho[4], M.J. Carvalho[5], R. Matthiesen[2]

[1]Coimbra Institute for Clinical and Biomedical Research (iCBR), Area of Environment, Genetics and Oncobiology Research (CIMAGO), Institute of Biophysics, Faculty of Medicine; CIBB; CACC, Univ Coimbra, Coimbra, Portugal; [2]INOVA4Health, NOVA Medical School (NMS), Faculdade de Ciências Médicas (FCM), Universidade Nova de Lisboa, Lisboa, Portugal; [3]Clinical Biochemistry, Odense Universitetshospital, Odense, Denmark; [4]Coimbra Institute for Clinical and Biomedical Research (iCBR), area of Environment, Genetics and Oncobiology Research (CIMAGO), Institute of Biophysics, Faculty of Medicine; Institute of Experimental Pathology; CIBB; CACC, Univ Coimbra, Coimbra, Portugal; [5]Gynecology Service, CHUC - Centro Hospitalar e Universitário de Coimbra, EPE, Coimbra, Portugal

Background: Endometrial cancer (EC) is one of the most frequent gynaecological malignant diseases whose incidence presents an increasing trend. Cancer stem cells (CSC), a subpopulation of undifferentiated tumour cells identified in EC, are the main actors in the resistance mechanisms to conventional therapies. Thus, the main aim of this study is to identify novel molecular targets in endometrial CSC for the future development of innovative targeted therapies for EC.

Methods: Two EC cell lines, ECC-1 and RL95-2, were cultured, and endometrial CSC were obtained through an optimized 5-day sphere formation assay. A proteomic profile of cell lines and endometrial CSC was determined through mass spectrometry-based proteomics. The analysis was performed through the comparison of CSC *vs.* cell line proteins significantly up-regulated by a 40-fold change and their cellular localization. R package was used for statistical analysis.

Results: The proteomic analysis of ECC-1 samples allowed the identification of 477 up-regulated ECC-1-CSC-specific proteins, 108 ECC-1-specific proteins, and 2306 common proteins. Regarding RL95-2 samples, the analysis identified 76 up-regulated RL95-2-CSC-specific, 994 cell line-specific, and 1420 common proteins. The cellular localization of up-regulated proteins identified from CSC populations was mainly the cytoplasm (25-31%), nucleus (19-23%), and membrane (21-22%). Regarding the functional analysis, the more regulated subcategories were the intracellular ferritin complex, poly(A) RNA binding, (acetyl-CoA carboxylase) kinase activity, (hydroxymethylglutaryl-CoA reductase (NADPH)) kinase activity, and ubiquitinyl hydrolase activity for ECC-1-CSC *vs.* ECC-1; the proteasome, cytosol, extracellular vesicular exosome, poly(A) RNA binding, glutamate dehydrogenase (NAD+) activity, and glutamate dehydrogenase (NADP+) activity for RL95-2-CSC *vs.* RL95-2; and poly(A) RNA binding, (acetyl-CoA carboxylase) kinase activity, NADPH kinase activity, and ubiquitinyl hydrolase activity for both.

Conclusions: CSC population-specific proteins were identified, as well as their cellular localization and functional enrichment. This information allows for the future development of endometrial CSC targeted therapies.

44P PAUF as a target for treatment of high PAUF-expressing ovarian cancer

J. Cho[1], Y.J. Kim[1], F. Jiang[1], J. Park[2], H.H. Jeong[3], J.E. Baek[3], S-M. Hong[4], S-Y. Jeong[5], S.S. Koh[3]

[1]R&D, Prestige Biopharma IDC, Busan, Republic of Korea; [2]Asan Institute for Life Sciences, Asan Medical Center - University of Ulsan, Seoul, Republic of Korea; [3]Biomedical Sciences, Dong-A University, Busan, Republic of Korea; [4]Department of Pathology, Asan Medical Center - University of Ulsan, Seoul, Republic of Korea; [5]Convergence Medicine, Asan Medical Center - Asan Institute for Life Science, Seoul, Republic of Korea

Background: Pancreatic adenocarcinoma up-regulated factor (PAUF) plays an important role in tumor growth, metastasis, and immune evasion in the pancreatic tumor microenvironment, and recent studies suggest an association between PAUF expression and poor prognosis in ovarian cancer patients. However, the role of PAUF in ovarian cancer development has not been clearly understood at the molecular level, and whether PAUF can be used as a therapeutic target of ovarian cancer awaits more scientific evidence.

Methods: The current study characterized the functions of PAUF in ovarian cancer using cell-based assays and mouse xenograft experiments, and further evaluated whether an anti-PAUF antibody can become a potential ovarian cancer treatment in human ovarian cancer models.

Results: Recombinant PAUF significantly increased tumor metastatic capacity (migration, invasion, and adhesion) in all the ovarian cancer cell lines tested, except for the OVCAR-5 cell line which expresses PAUF at a much higher level than the other cells. PAUF-knockout in the OVCAR-5 cell line led to apparently delayed tumor growth *in vitro* and *in vivo*. Furthermore, the administration of an anti-PAUF antibody exhibited notable sensitizing and synchronizing effects on docetaxel in mice bearing the OVCAR-5 xenograft tumors, the docetaxel + anti-PAUF antibody combination group showed the most potent anti-tumor efficacy demonstrated as a nearly 5-fold improved survival in this group (HR: 0.22, 95% CI: 0.09 to 0.54), compared to the control group (Table).

Table: 44P Survival data in OVCAR-5 xenograft human ovarian cancer mouse model. Treatments (started from day 0): Human IgG (control), Anti-PAUF antibody (10 mg/kg, twice/week, ×4 weeks), Docetaxel (10 mg/kg, once, on day 0), or Anti-PAUF antibody + Docetaxel (via the same regimens of the two drugs)

Time elapsed (Day)	Human IgG (n = 15)	Anti-PAUF (n = 15)	Docetaxel (n = 15)	Anti-PAUF + Docetaxel (n = 15)
0	15	15	15	15
20	15	15	15	15
23	13	15	15	15
26	10	15	15	15
31	3	11	13	15
34	2	5	10	14
37	0	4	7	9
40	0	2	2	6
HR (95% CI)	**1**	**0.42 (0.19-0.93)**	**0.32 (0.14-0.74)**	**0.22 (0.09-0.54)**

Conclusions: Taken together, this study shows that the expression level of PAUF is an independent factor determining malignant behaviors of ovarian cancer and, for the first time, it suggests that PAUF may be a promising therapeutic target for high PAUF-expressing ovarian cancer. The anti-PAUF antibody used in this study, PBP1510, has gained orphan drug designation from the EMA, FDA, and MFDS (Korea), and entered phase I clinical trials.

Background: Glutaminyl-peptide cyclotransferase-like protein (QPCTL), mediates the trafficking of monocytes as well as the CD47/SIRPa interaction which blocks macrophage phagocytosis. Genetic deletion of QPCTL in tumor or host immune cells promotes anti-tumor activity. We evaluated ISM8207, a novel QPCTL inhibitor, in preclinical triple-negative breast cancer (TNBC) and B-cell Non-Hodgkin Lymphoma (B-NHL) models.

Methods: Gene expression datasets, METABRIC (TNBC), and GSE4475 and GSE10846 (diffuse large B cell lymphoma [DLBCL]), were analyzed for association between QPCTL expression and overall survival (OS). *In vitro* SIRPα binding to the human cell lines (MDA-MB-231, TNBC; and Raji, B-NHL) was evaluated after pre-treatment with ISM8207. *In vivo* antitumor efficacy was assessed in the murine 4T1 TNBC model and in human B-NHL OCI-Ly10 or Raji xenografts in CB17 SCID mice treated with ISM8207.

Results: Patient tumor dataset analyses revealed QPCTL was overexpressed in TNBC and DLBCL, and that a higher expression correlated with a shorter OS. ISM8207 treatment (IC50 $<$ 0.5 nM in enzymatic assay) phenocopied the genetic deletion of QPCTL and reduced the binding of SIRPα to CD47 in TNBC cells, without affecting cell viability. In the murine 4T1 TNBC model, ISM8207 (30 mg/kg BID) demonstrated modest but significant anti-tumor activity. Circulating monocytes and the binding affinity of SIRPα to peripheral white blood cells were reduced. ISM8207 combined with an anti-PD-1 antibody potently and synergistically inhibited tumor growth, with Tumor Growth Inhibition (TGI) of $\sim$50%. The bulk RNA-seq profiling for combined ISM8207 and anti-PD-1-treated tumors showed a higher infiltrating potential of $CD8^+$ T-cells in the tumor microenvironment vs anti-PD-1 alone. ISM8207 (10 mg/kg BID) combined with rituximab resulted in synergistic effects in the B-NHL xenografts. In the Raji model, TGI with the combination was 86% vs 41% with rituximab alone. In the OCI-Ly10 model, 7/8 mice achieved complete remission with the combination vs 1/8 with rituximab alone. ISM8207 was well-tolerated with favorable ADME and PK properties.

Conclusions: These data strongly support the clinical evaluation of ISM8207 as a novel cancer immunotherapy in TNBC and B-NHL.

46P Effect of coadministration of antioxidant chlorophyllin with docetaxel on invasion and metastasis in triple-negative breast cancer in vivo/in vitro

A. Burus[1], M. Ozcan[2], H. Canpinar[3], O. Bozdemir[4], N.D. Zeybek[5], Y. Bayazit[6]

[1]Medical Biochemistry Department, Hacettepe University Faculty of Medicine, Ankara, Turkey; [2]Medical Biochemistry, Zonguldak Bulent Ecevit University, Zonguldak, Turkey; [3]Basic Oncology, Hacettepe University, Ankara, Turkey; [4]Stem Cell Sciences, Hacettepe University, Ankara, Turkey; [5]Histology and Embryology, Hacettepe University - Faculty of Medicine, Ankara, Turkey; [6]Medical Biochemistry, Hacettepe University - Faculty of Medicine, Ankara, Turkey

Background: The drug resistance against chemotherapy and high metastasis rate in triple-negative breast cancer reduce the success of breast cancer treatment. Glutathione S-transferase P1 enzyme (GSTP1) expression increases in cancer cell lines and leads to the development of drug resistance against chemotherapy. The antioxidant chlorophyllin is shown to have an inhibitory effect on GSTP1. The purpose of this study is to investigate the effects of GSTP1 inhibitor chlorophyllin and/or its coadministration with anticancer drug docetaxel on metastatic processes in vitro/in vivo in the 4T1 triple-negative breast cancer cell line and animal model.

Methods: Cell viability, cell cycle, and cell migration were investigated by MTT test, flow cytometry, and wound closure assay, respectively. Matrix metalloproteinase 9 (MMP-9) expression, causing invasion, was determined by Western Blot in the 4T1 cell line and tissue samples. Further, total gelatinase enzyme activity was also detected by gelatin degradation assay. Total GST enzyme activity and glutathione levels of tissue were investigated by colorimetric methods. Micrometastatic foci in liver tissue sections were evaluated by histochemistry.

Results: As a result, coadministration of chlorophyllin and docetaxel significantly inhibited cell migration in vitro. Chlorophyllin significantly reduced the expression of MMP-9 in the tissue samples, and this effect was higher when it is coadministered with docetaxel. In coadministration, a significant decrease was observed in the total gelatinase activity in vivo. It was also determined that chlorophyllin increased in vivo total glutathione levels and decreased GST enzyme activity. Finally, the micrometastases in the liver were reduced by coadministration.

Conclusions: Our results suggest that the coadministration of chlorophyllin and docetaxel may have a potential role in the control of metastatic processes by suppressing cell migration and invasion which is mainly characterized by gelatinase enzyme expression & activity.

47P An ozone delivery system by cisplatin prodrug self-assembling micelles combining microwave to sensitizing immune checkpoint inhibitor in triple-negative breast cancer

D. Zheng[1], T. Luo[2], H. Shi[3]

[1]Breast Disease Center, West China Medical Center of Sichuan University, Chengdu, China; [2]Head and Neck Oncology Department, West China School of Medicine/West China Hospital of Sichuan University, Chengdu, China; [3]Laboratory of Integrative Medicine, Clinical Research Center for Breast, West China School of Medicine/West China Hospital of Sichuan University, Chengdu, China

Background: Immunotherapy based on T cells has gained great success and is now in its infancy. Despite a high mutation load, triple-negative breast cancer (TNBC) remains a poor response to the immune checkpoint blockades (ICBs) due to an infertile tumor microenvironment (TME). Chemotherapy shows an outstanding synergizing effect with ICB in TNBC due to its cell lysis effect. However, limited bioavailability, significant systematic toxicity, and immunosuppressive metastatic niche induced by chemotherapy restrict its systematic application.

Methods: We constructed self-assembled micelles consisting of fluorocarbon chain-modified cisplatin prodrugs, which loaded ozone-saturated perfluorodecalin (PFD) emulsion as a cargo. Cisplatin is controllably released from the prodrug by ROS triggered by the microwave excitation of ozone. The appearance of the ozone carried prodrug was visualized by Transmission electron microscope and the hydrodynamic sizes and stability were measured with nanoparticle tracking analysis. Cell function experiments were performed to assess the biological effect of the ozone-delivery prodrug in vitro. The biodistribution and biological effect of the ozone-loaded prodrug were also verified in 4T1 tumor-bearing mice model.

Results: The hydrodynamic sizes were about 130.5 nm of PtF and 174.7 nm of PFD@PtF, and both of the two showed good stability in weak acidic (pH $=$ 6.0), neutral (pH $=$ 7.0), and weak alkaline (pH $=$ 8.0) environment at 4°C, room temperature, and 37°C. Ozone was well stabilized by the PFD@PtF as the ROS donor which in turn boosts the intracellular GSH concentration, and decomposed rapidly upon the excitation of microwave. Once endocytosed by TNBC cells, Pt(IV) can be reduced and released from the prodrug upon the triggering of reducing substance (e.g. GSH). The released cisplatin crosses cell membranes to form cross-links with DNA, resulting in cell cycle arrest, apoptosis, and immunogenic cell death. A significant inhibiting effect of tumor proliferation and TME reediting effect were observed in mice model.

Conclusions: We successfully constructed an ozone-delivery cisplatin prodrug with enhanced anti-tumor activity and attenuated toxicity.

48P Non-steroid anti-inflammatory treatment enhances the efficacy of modulated electro hyperthermia on triple-negative breast cancer and melanoma cancer models in vivo

N. Giunashvili

Institute of Basic and Translational Medicine, Semmelweis University, Budapest, Hungary

Background: Modulated electro-hyperthermia (mEHT) is an advanced option in the hyperthermia field, applying a 13.56 MHz radiofrequency electromagnetic current to induce tumor-specific damage. This study investigates the mEHT-induced molecular effect and the potential of combination non-steroid anti-inflammatory drugs (NSAIDs) to enhance its anti-tumor effects in 4T1 triple-negative breast cancer (TNBC) and B16F10 melanoma mouse models.

Methods: 4T1 TNBC and B16F10 melanoma cell lines were injected into Balb/C and C57BL/6 mice, respectively. They have been treated according to the protocol with only mEHT or mEHT combined with non-selective COX-inhibitors (Aspirin) or selective COX2 inhibitors (SC236). Tumor volume was monitored by ultrasound and a digital caliper. At the end of the experiments, mice were euthanized and tumors excised for molecular studies.

Results: Here we report that mEHT monotherapy stimulates local IL1-beta and IL6, and consequently cyclooxygenase 2 (COX 2) production. These effects could be considered as part of a self-defensive, wound-healing reaction of the tumor to protect itself from the mEHT-induced stress. In the present study, we combined mEHT with non-steroid anti-inflmmatory drugs (NSAIDs), the non-selective (Aspirin), or the selective COX2 inhibitor (SC236) in vivo. Here we demonstrate that NSAID treatment synergistically increased the effect of mEHT in 4T1 TNBC. Tumor weight and tumor volume (measured by ultrasound and a digital caliper) were lowest, and the tumor destruction ratio (TDR) was the highest in the combination treated (NSAID + mEHT) groups. Tumor damage was accompanied by a significant increase in cleaved caspase-3 (cC3), suggesting an important role for apoptosis. Similarly, in the B16F10 melanoma model, lung nodules were significantly less in mice treated with mEHT + Aspirin.

Conclusions: NSAIDs effectively enhance the mEHT anti-tumor effect in TNBC and melanoma cancer models; they increase tumor destruction, where apoptosis may play a role. Disecting the exact molecular mechanisms further is under our current investigation.

49P Circulating miRNA signatures to predict recurrence in patients with pathological complete response of triple-negative breast cancer

A.J.A. de Freitas[1], C.R. Nunes[2], R.L. Causin[2], S. Calfa[1], M.A. de Oliveira[3], C. de Pádua Souza[4], M.M.C. Marques[1]

[1]Molecular Oncology Research Center, Barretos Cancer Hospital, Barretos, Brazil; [2]Centro de Oncologia Molecular, Barretos Cancer Hospital, Barretos, Brazil; [3]Nucleus of Epidemiology and Biostatistics, Barretos Cancer Hospital, São Paulo, Brazil; [4]Oncology Department, Hospital de Amor (Hospital De Cancer De Barretos) - Fundacao Pio XII, Barretos, São Paulo, Brazil

Background: Triple-negative breast cancer (TNBC) is characterized by aggressive clinicopathological features and is associated with a poor prognosis. Identifying patients who respond to chemotherapy and yet relapse early remains the subject of many studies and a critical goal for effective personalized therapies. In the present study, we investigated the role of miRNAs in TNBC that responded to neoadjuvant chemotherapy (NAC). Circulating miRNAs were isolated from TNBC patients who underwent NAC and who had a pathologic complete response (pCR).

Methods: The miRNA expression analysis was conducted by nCounter® Human v3 miRNA assay (NanoString Technologies, Seattle, USA) on plasma samples. Sample collected from patients participating in a phase II prospective clinical trial. About 800 human miRNAs were screened, and the resulting data were normalized using the normalization method based on the low coefficient of variation (low CV). Further analysis was carried out using parameters such as fold change and area under the curve (AUC).

Results: A total of 33 differentially expressed miRNAs were identified between relapsed and non-relapsed patients who achieved pCR. Of the 33 miRNAs, only one was downregulated. Of these, we identified 7 miRNAs (hsa-miR-654-5p, hsa-miR-433-5p, hsa-miR-520c-3p, hsa-miR-376a-2-5p, has-miR-4741, has-miR- 513c-3p, hsa-miR-506-5p) which showed better accuracy to discriminate patients with pCR with a higher probability of relapse, with the area under the curve value ranging from 0.80 to 0.93. In network analysis, "TGF-beta signaling pathway", "cancer transcriptional dysregulation" and "JAK-STAT signaling pathway" were identified as the crucial pathways in breast cancer patients who also developed recurrence.

Conclusions: In conclusion, our study hypothesizes that circulating miRNAs may be useful non-invasive biomarkers to identify patients who are more likely to develop recurrence even after achieving pCR in TNBC patients.

Clinical trial identification: NACATRINE trial (NCT02978495).

50P Application and mechanism of tarloxotinib in HER2-positive breast cancer

X. Shao[1], D. Yang[2], H. Zhou[3], Q. Yu[3], Y. Ding[4], J. Tang[3]

[1]The First Clinical College, Nanjing University of Traditional Chinese Medicine, Nanjing, China; [2]Department of Pharmacy, The Second Hospital of Nanjing, Nanjing, China; [3]General Surgery, The First Affiliated Hospital of Nanjing Medical University, Nanjing, China; [4]Department of General Surgery, Jurong Branch Hospital of Jiangsu Province Hospital, Zhenjiang, China

Background: HER2 (Human epidermal growth factor receptor-2)-positive breast cancer occupies about 15%—20% of all breast cancer, the current treatment of which is still based on surgery and adjuvant targeted therapy with monoclonal antibody. Problems of drug resistance and cardiotoxicity hinder the use of monoclonal antibodies. And, TKIs (Tyrosine Kinase Inhibitors) have the advantages of multi-target, reduced drug resistance and lower cardiotoxicity. Tarloxotinib is a prodrug that harnesses tumor hypoxia to generate high levels of a potent, covalent pan-HER TKI, Tarloxotinib-effector (Tarloxotinib-E), within tumor microenvironment. This tumor-selective delivery mechanism was designed to minimize the dose-limiting toxicities.

Methods: HER2-positive breast cancer BT-474, SK-BR-3, HCC-1954 and JIMT-1 cells were treated with different concentrations of Tarloxotinib-E, Lapatinib and Tucatinib. The IC50 values were determined by CCK-8 assay. Then, we used Western Blot to detect the changes in the phosphorylation of EGFR, HER2, HER3, HER4, AKT and ERK and the protein expression of Cleaved Caspase-3, Caspase-7 and Parp1. Flow cytometry was used to determine the apoptosis rates and mitochondrial membrane potentials, and the mitochondrial superoxide was detected by the Immunofluorescence. Importantly, we used HPLC-TQ-MS to determine the ratio of Tarloxotinib-E released by Tarloxotinib. Finally, the subcutaneous xenograft mice were used to evaluate the antitumor effect and toxicity of Tarloxotinib in vivo.

Results: Tarloxotinib could be transformed into Tarloxotinib-E by breast cancer cells under hypoxia. Meanwhile, Tarloxotinib-E could effectively inhibit the level of HER family phosphorylation and downstream signaling in HER2-positive breast cancer cells, and superior to Lapatinib and Tucatinib. Mechanistically, Tarloxotinib-E induced apoptosis in HER2-positive breast cancer cells through a ROS-dependent manner, with significant decrease in the potential of mitochondrial membrane and increase in mitochondrial superoxide. During the in vivo experiment, Tarloxotinib significantly inhibited tumor growth in nude mice compared with Lapatinib.

Conclusions: Tarloxotinib released Tarloxotinib-E under hypoxic microenvironment of breast tumors, and inhibited the phosphorylation of HER2 dimers and downstream pathways to induce apoptosis in HER2-positive cells through a ROS-dependent manner. This lays a foundation for the further development of Tarloxotinib in HER2-positive breast cancer.

51P Nanoengineered sonosensitive platelets for synergistically augmented sonodynamic breast tumour therapy by glutamine deprivation and cascading thrombosis

L. Zhou

Faculty of Health Sciences, University of Macau, Macau, China

Background: Ultrasound (US)-activated sonodynamic therapy (SDT) stands for a distinct antitumor modality because of its attractive characteristics including intriguing noninvasiveness, desirable safety, and high tissue penetration depth, which, unfortunately, suffers from compromised therapeutic efficacy due to cancer cell-inherent adaptive mechanisms, such as glutathione (GSH) neutralization response to reactive oxygen species (ROS), and glutamine addictive properties of tumors.

Methods: In this work, we developed a biological sonosensitive platelet (PLT) pharmacytes for favoring US/GSH-responsive combinational therapeutic of glutamine deprivation and augmented SDT. The amino acid transporter SLC6A14 blockade agent α-methyl-DL-tryptophan (α-MT)-loaded and MnO2-coated por- phyrinic metal-organic framework (MOF) nanoparticles were encapsulated in the PLTs through the physical adsorption of electrostatic attraction and the intrinsic endocytosis of PLTs.

Results: When the sonosensitive PLT phar- macytes reached tumor sites through their natural tendencies to TME, US stimulated the PLTs-loaded porphyrinic MOF to generate ROS, resulting in morphological changes of the PLTs and the release of nanoparticles. Subse- quently, intracellular high concentration of GSH and extracellular spatio-temporal controlled US irradiation programmatically triggered the release of α-MT, which enabled the synergistically amplified SDT by inducing amino acid starvation, inhibiting mTOR, and mediating ferroptosis. In addition, US stimulation achieved the targeted activation of PLTs at tumor vascular site, which evolved from circulating PLTs to dendritic PLTs, effectively blocking the blood supply of tumors through thrombus formation, and revealing the encouraging potential to facilitate tumor therapeutics.

Conclusions: It offers a bioinspired design strategy to improve SDT efficiency, and rends an innovative paradigm for cooperatively ablating refractory tumor.

53P Treatment of cancer cells based on circulating tumor cell's expression profile using off-label drugs

P. Apostolou[1], G. Beis[1], A. Iliopoulos[1], I. Papasotiriou[2]

[1]R&D, Research Genetic Cancer Centre S.A., Florina, Greece; [2]Oncology Department, Research Genetic Cancer Centre International GmbH, Zug, Switzerland

Background: Circulating tumor cells (CTCs) constitute a cell subpopulation with great prognostic value in oncology. They detach from the primary tumor, and through the blood stream can initiate metastatic spread to other organs. Their gene and protein expression profile, provides useful information about their resistance to specific therapeutic agents, including chemotherapeutic drugs, targeted therapies (monoclonal antibodies (MoAbs) or small molecular weight molecules (SMW)), or their sensitivity to other treatment options, such as hyperthermia or radiation. The present study aimed to identify whether the expression profile could contribute to success treatment using off-label drugs.

Methods: Blood samples were collected from more than 500 patients, suffering from different types of cancer. CTCs detected and isolated with Fluorescence Activated Cell Sorting (FACS), evaluated with specific biomarkers for each cancer type, and then used for gene and protein expression assays, with qPCR and Flow Cytometry respectively. In parallel, literature research was performed for these proteins, and the approved drugs against them. Based on the expression profile, off-label drugs for the specific targets used and viability/chemosensitivity assays followed on patients' isolated CTCs.

Results: Expression profile of CTCs revealed overexpression in a wide variety of biomarkers, for whom there are already approved drugs, but only in specific types of cancer. The highest percentages observed for ALOX5, DHFR, DPYD, KIT, PDGFA, RET and others. The use of approved drugs against these targets, such us Zileuton, Pemetrexed, Capecitabine, Dasatinib, Imatinib and Cabozantinib respectively, led to decrease in CTCs' viability independent the type of cancer up in approximately 25% of the cases. Among them, there were included also refractory cases (5%).

Conclusions: In this study, we demonstrated that CTCs' expression profile, could be an indicator of treatment response, using off-label drugs. It is noteworthy that efficient data observed also in refractory cases, representing different types of cancer. Drug repositioning might be beneficial for cancer patients, and it should be taken into consideration, mainly in cases where no other options are available.

54P Enhanced oxidative phosphorylation of metastasis-initiating cells facilitates esophageal tumor cell seeding in lymph nodes

S. Li[1], B. Zhang[1], C. Huang[2], X. Guan[1]

[1]Clinical Oncology Center, The University of Hong Kong - Shenzhen Hospital, Shenzhen, China; [2]Clinical Oncology Center, Li Ka Shing Faculty of Medicine, The University of Hong Kong (HKUMed), Hong Kong, China

Background: Lymph nodes (LN) are the most frequent metastasis sites in oesophageal squamous cell carcinoma (ESCC), but the associated mechanisms are poorly understood. Tumor cells seed and survive at LN during the early adaptation step, which is the bottleneck for successful metastasis. However, the phenotypic and molecular characteristics of heterogeneous metastatic cells that contribute to such a challenging process remain elusive.

Methods: We established a human xenograft spontaneous LN metastasis model to capture tumor cell dissemination behaviors. We conducted single-cell RNA sequencing on tumor cells collected from primary tumors and metastatic LN to profile the dynamic cellular and molecular changes in tumor cells associated with LN metastasis. We further identified and characterized the early metastasis tumor cells in LN through *in vitro* and *in vivo* functional assays.

Results: We revealed that LN metastasis is initiated by rare ESCC subpopulations with stemness and mesenchymal regulatory gene expression signatures. These tumor cell subpopulations are critical to driving metastasis in distant organs through the blood circulation in mice, supporting the metastasis-initiating cells (MICs) properties. Importantly, these key driver cells were observed to convert the metabolic strategy to mitochondrial oxidative phosphorylation (OXPHOS) during cell seeding in the LN. Enhanced OXPHOS in LN metastatic cells is induced by fatty acids and regulated by NRF2 signaling. Pharmacological inhibition of OXPHOS with IACS-010759 markedly attenuated metastasis in mice.

Conclusions: Our results demonstrate the important role of mitochondrial OXPHOS in promoting ESCC metastasis and suggest the clinical therapeutic potential of OXPHOS inhibitors for preventing metastatic spread in ESCC patients.

55P Transcriptional profiles of engineered T cells stimulated with different receptor structures and co-stimulatory domains

U. Shin[1], S-H. Kim[2], C. Han[1]

[1]Immuno-Oncology Branch, NCC - National Cancer Center, Goyang, Republic of Korea; [2]Biomedical Laboratory Science, Catholic Kwandong University, Gangneung, Republic of Korea

Background: T cells engineered with chimeric antigen receptor (CAR-T) have shown success in treating hematological malignancies. However, the limited efficacy and potential side effects hinder the use of CAR-T in solid tumors. Research on this heterogeneous cell therapeutics at single-cell level can advance the current understanding and strategy of CAR-T therapy.

Methods: We used single-cell transcriptome analysis to characterize the transcriptional profile of stimulated CAR-T. T cells engineered with second-generation CAR constructs (with 4-1BB or CD28 co-stimulation domains) were stimulated with anti-CD3/CD28-coated beads and Nalm6 and subjected to microwell-based single-cell transcriptome analysis.

Results: A broad spectrum of transcripts was differentially expressed in T cells under various conditions. The sequence derived from the 3'-untranslated region of the CAR transcript distinguished CAR-T from non-transduced T cells within the analyzed cell population. CAR-T stimulation, mediated by either CD3/CD28 or CAR, significantly changed the gene-expression landscape compared to unstimulated CAR-Ts. Notably, CAR stimulation triggered higher expression of immune-related genes compared to CD3/CD28 stimulation. Additionally, comparing 4-1BB and CD28 co-stimulatory domains showed distinct transcriptional profiles contingent upon each co-stimulation signal.

Conclusions: This study revealed characteristic features of CAR-T signals affected by receptor structure (CD3/CD28 vs. CAR) and co-stimulation domain (4-1BB vs. CD28).

These findings provide insights into a deeper understanding of CAR-T therapy, ultimately leading to the development of more effective CAR-T therapy.

56P SLC34A2-ROS1 L2026M+G2032R confers resistance to ROS1 tyrosine kinase inhibitors in Ba/F3 cells through a reduced ATP binding pocket volume

C. Dijkhuizen[1], P. Korthuis[1], J. Vilacha[2], M. Smelt[1], A.J. Van Der Wekken[3], A. van den Berg[4], L. Drayer[1]

[1]Institute for Life Science and Technology, Hanze University of Applied Sciences, Groningen, Netherlands; [2]Faculty of Science and Engineering, Molecular Dynamics — Groningen Biomolecular Sciences and Biotechnology, University of Groningen, Groningen, Netherlands; [3]Pulmonary Oncology, University of Groningen - UMCG - University Medical Center Groningen, Groningen, Netherlands; [4]Faculty of Medical Sciences, University of Groningen - UMCG - University Medical Center Groningen, Groningen, Netherlands

Background: The ROS1 G2032R mutation is the most common on-target resistance mutation in crizotinib treated ROS1-positive lung cancer patients. The aim of our study was to investigate resistance mechanisms in SCL34A2-ROS1^{G2032R} positive Ba/F3 cells against second line treatment with lorlatinib.

Methods: Ba/F3 SLC34A2-ROS1^{G2032R} cells were subjected to N-ethyl-N-nitrosourea (ENU) mutagenesis and clones were selected upon treatment with 1000 nM lorlatinib for 4 weeks. Resistant clones were analyzed for presence of on-target resistant mutations using Sanger sequencing. In addition, we generated subclones expressing SLC34A2-ROS1$^{L2026M+G2032R}$ and SLC34A2-ROS1^{L2026M} in Ba/F3 cells. Sensitivity to ROS1 TKIs was determined by measuring cell viability and ROS1 phosphorylation. Molecular Dynamic simulations of the ATP binding pocket were performed for all ROS1 variants.

Results: The ENU-screen of 41 lorlatinib resistant clones revealed one with a mutation in the kinase domain: L2026M. Cell viability assays of the ENU-induced resistant cell line and the Ba/F3 cells transfected with the mutant SCL34A2-ROS1 fusion gene constructs revealed a decreased sensitivity of SLC34A2-ROS1$^{L2026M+G2032R}$ cells for lorlatinib, crizotinib, entrectinib and repotrectinib compared to the single mutants. Consistent with these findings, we observed phosphorylation of ROS1 fusion protein in the double mutant cells which was not inhibited upon treatment with ROS1 TKIs. The single mutant cells showed as expected a clear reduction in phosphorylated ROS1 fusion protein . Molecular modeling to unravel the effect of the mutations demonstrated that the volume of the ATP-binding pocket was reduced in single and double mutants compared to wild type. The double L2026M+G2032R mutant displayed the smallest pocket.

Conclusions: We identified a novel on-target mutation after inducing lorlatinib resistance in SLC34A2-ROS1^{G2032R} Ba/F3 cells. This SLC34A2-ROS1$^{L2026M+G2032R}$ cell line was also resistant to crizotinib, entrectinib and repotrectinib. The resistance can be explained by a smaller ATP binding pocket in the mutated ROS1 fusion protein preventing effective binding of the investigated TKIs.

57P Metastasis organotropism: Unveiling associated proteins using network biology

M. Carrolo[1], J.A.I. Miranda[2], A.F.R. Coelho[2], A. Quintela[1], F.R. Pinto[2]

[1]Medical Oncology Department, Hospital CUF Descobertas, Lisbon, Portugal; [2]RNA Systems Biology, BioISI - Biosystems and Integrative Sciences Institute, Lisbon, Portugal

Background: The formation of distant metastases is the deadliest phase of cancer progression. Nevertheless, it is a very inefficient process. Chances of a tumor cell surviving the metastatic process depend on its ability to communicate with the surrounding environment. We hypothesize that metastasis organotropism can be partially explained by the intercellular communication established between cancer cells and other cells in the organ microenvironment.

Methods: Network biology tools are well suited for studying complex diseases such as cancer. Using this computational approach we looked at the complex interplay between proteins and pathways affected in metastasis and identified new metastasis-associated proteins. We built networks of tissue-specific intercellular protein-protein interactions between pairs of primary tumor location and metastasis tissues. Using these networks we identified interactions significantly more frequent in organotropism tissue pairs (primary tumor and metastasis organ) that potentially influence the success of metastasis in specific organs.

Results: Overall, we identified 607 proteins involved in 1095 metastasis-associated interactions. Of these, 881 interactions were positively associated with metastasis, meaning that these interactions occur more frequently in organotropism tissue-pairs than in other tissue pairs. Of the 607 proteins found, 222 are already targeted by known drugs and 53 are targeted by drugs that are not used in cancer treatment.

Conclusions: Cell-cell communication is of paramount importance for the development of metastasis. Experimental studies of the non-oncological drugs targeting the 53 identified proteins are needed to select the most promising candidates to test in drug repurposing clinical trials.

59P Correlation of tumor microenvironment signature in advanced stage non-small cell lung cancer with EGFR mutation who received EGFR-TKIs

C. Ngamchokwathana[1], S. Santisukwongchote[2], N. Zungsontiporn[1], P. Sitthideatphaiboon[1], P. Chantranuwat[2], C. Vinayanuwattikun[1]

[1]Division of Medical Oncology, Department of Medicine, King Chulalongkorn Memorial Hospital - Thai Red Cross Society, Bangkok, Thailand; [2]Pathology, King Chulalongkorn Memorial Hospital - Thai Red Cross Society, Bangkok, Thailand

Background: The impact of tumor microenvironment in advanced non-small cell lung cancer (NSCLC) who had epidermal growth factor receptor (EGFR) mutation remained debated. We investigated the correlation of tumor microenvironment (PD-L1, CD8 and FOXP3) and the association of EGFR TKI treatment outcome.

Methods: A prospective study was conducted to recruit 100 participants who were diagnosed advanced NSCLC with EGFR mutation. All patients were received treatment with EGFR-tyrosine kinase inhibitors (TKIs). Tumor microenvironment composed of programmed cell death ligand-1 (PD-L1) expression, CD8+ tumor infiltrating lymphocyte (TILs) and forkhead box P3 (FOXP3+) TILs density were evaluated by immunohistochemistry. The primary endpoint was the correlation between PD-L1, CD8+, and FOXP3+ TILs density. The Correlations among TILs and clinicopathological characteristics/outcome of treatment were analyzed.

Results: Eighty-five patients with adequate tumor material were evaluated. Twelve (14%) patients expressed high PD-L1 ($\geq$15%) or intratumoral CD8+ TILs ($>$10%). The correlation of PD-L1 and intratumoral CD8+ TILs was significantly ($r = 0.3034$, $p=0.005$). Multivariate analysis revealed that Inflamed tumor was correlated with shorten PFS with the HR of 2.110, 95%CI: 0.968-4.599, p-value 0.06.

Conclusions: Among advanced stage NSCLC with EGFR mutation, tumor microenvironment PD-L1 and intratumoral CD8+ TILs expression was correlated with outcome of treatment.

60P Establishment and characterization of a novel lung adenocarcinoma cell line HX-JCJ harboring MET ex14 skipping mutation

X. Ou[1], M. Feng[2], Y. Wang[3]

[1]Cancer Center, SCU - Sichuan University - Huaxi Campus, Chengdu, China; [2]Cancer Center, West China Hospital of Sichuan University, Chengdu, China; [3]Cancer Center, West China School of Medicine/West China Hospital of Sichuan University, Chengdu, China

Background: MET exon14 skipping mutations are considered an important driver of oncogenesis and are observed in approximately 3-4% of patients diagnosed with non-small cell lung cancer (NSCLC). Various MET tyrosine kinase inhibitors (TKIs) are currently being developed for clinical use in the treatment of NSCLC patients with

MET exon14 skipping mutation. However, preclinical research in this area has been restricted due to the rarity of MET exon14 mutant cases. Almost all the studies conducted have been on patients or patent-derived xenografts (PDX). To address this issue, there is a need for a NSCLC cell line with MET exon14 skipping mutation. In this study, we have established a novel lung adenocarcinoma cell line that harbors MET exon14 skipping mutation. This new cell line represents a valuable tool for the research of MET targeted therapy.

Methods: The cell line was established using the primary tumor tissue from a 67-year-old male patient with NSCLC, and named as HX-JCJ. The cell line has been growing well for more than 10 months and has been passaged over 50 times. Phenotypes of the cell line, such as proliferation, invasion, protein expression, and xenografting were characterized in vitro and in vivo. MET ex14 skipping mutation of this cell line was validated by RT-PCR and Sanger sequencing.

Results: Drug screen showed that this cell line was extremely sensitive to KC1036 (IC50=4.8nm), which is a home-made small molecule inhibitor with strong anti-MET and anti-angiogensis activity.

Conclusions: In conclusion, we successfully established a novel NSCLC cell line (HX-JCJ) harboring MET ex14 skipping mutation from the primary tumor tissue, which may provide a promising cell model for further MET relevant research.

61P Next generation sequencing and its clinical utility in advanced cancer: Single institute experience from low-middle income country

A. Badola[1], P. Bansal[1], P. Mehta[2], M. Malhotra[1], S.C. Cheemala[1], S. Sood[1], S. Anand[1], V. Sekar[1], P. Singh[1], J. Verma[1], A. Zaidi[1]

[1]*Medical Oncology Department, Asian Institute of Medical Sciences, Faridabad, India;* [2]*Medical Oncology Department, Amrita Institute of Medical Sciences, Faridabad, India*

Background: Advances in DNA sequencing over the past decade have made it possible to systematically study the genetic changes responsible for cancer development, and we now have a better understanding of the commonly involved processes and signaling pathways. As more genetic alterations become targetable by specific drugs, DNA sequencing is becoming part of routine clinical care but its clinical utility is not well known in low and middle income country.

Methods: This was a single center, retrospective cohort study, which include adult advanced metastatic solid tumor patient who underwent next generation sequencing (NGS) either on tissue block or liquid biopsy (Illumina NGS 560 genes 1000X coverage). Primary end point was to assess the clinical utility of NGS in advanced stage. Secondary end point was to assess the progression free survival (PFS) in patients who received treatment based on NGS.

Results: Over the period of 18 months (from 1st January 2021 to 30th 2022), a total of 93 patients were enrolled in the study, and their baseline characteristics are presented in the table. Patients received a median of 2 lines (range:0-4) of prior systemic therapy and genomic alteration were identified in 45% (n=42) of them. Of the patients with genomic alterations, 33% (n=31) had a targeted therapy option available either in the form of an approved drug or a clinical trial. However, only 19% (n=18) of the patients received treatment based on the results of NGS testing. Among these patients, 9%(n=8) had a progression-free survival of 6 months or more following NGS-guided treatment

Table: 61P Baseline characteristics of study population(n=93)

	Percentage (number of patients)
Gender	
Male	**60%(n=56)**
Female	**40%(n=37)**
Type of Biopsy	
Tissue	**71%(n=66)**
Liquid	**29%(n=27)**
Genetic alteration present	**45%(n=42)**
Targetable approved treatment or clinical trial available	**33% (n=31)**
Patient received treatment as per Molecular alteration	**19%(n=18)**
PFS ≥ 6 months in molecular alteration guided	**9% (n=8)**

Conclusions: Advances in DNA sequencing over the past decade have made it possible to discover new genetic changes, and more genetic alterations are now targetable by specific drugs . However, in routine practice, the results are not very promising, especially in low- and middle-income countries where cost is a major constraint.

62P Prebiotics modulate gut microbiota-mediated T cell immunity to enhance sintilimab inhibition of lung cancer

Q. Yan

Oncology, Chengdu Fifth People's Hospital - West District, Chengdu, China

Background: Sintilimab (Sin) helps the body to restore the anti-tumor response of T lymphocytes. However, in clinical use, the treatment process is more complicated due to adverse effects and different dosing regimens. It is not clear whether prebiotics (PREB) have a potentiating effect on Sin for lung adenocarcinoma, and this study intends to investigate the inhibitory effect, safety and possible mechanism of Sin combined with PREB on lung adenocarcinoma from animal experiments.

Methods: Lewis lung adenocarcinoma cells were inoculated into the right axilla of mice subcutaneously to prepare the Lewis lung cancer mouse model and treated in groups. The volume of transplanted tumors was measured, the histopathology of the liver and kidney of mice was observed by H&E staining, the levels of ALT, AST, UREA, CREA, WBC, RBC, and HGB in blood were analyzed biochemically; the ratio of T-cell subpopulations in blood, spleen, and bone marrow was detected by flow cytometry, the expression of PD-L1 in tumor tissue was detected by immunofluorescence staining, and 16S rRNA to analyze the diversity of fecal flora.

Results: Sin inhibited tumor growth and regulated immune cell homeostasis in lung adenocarcinoma mice, but liver and kidney histopathology showed different degrees of damage after Sin treatment, while the addition of PREB reduced liver and kidney damage in lung adenocarcinoma mice and promoted Sin's regulation of immune cells. In addition, the beneficial effects of Sin were associated with changes in intestinal flora diversity.

Conclusions: The mechanism by which Sintilimab combined with prebiotics inhibits tumor volume and regulates immune cell subpopulation balance in lung adenocarcinoma mice may be related to gut microbes.

63P Addition of human chorionic gonadotropin to the current standard mobilization approach with granulocyte-colony stimulating factor increases overall survival in a murine model of peripheral blood stem cell transplantation: Are we far enough for therapy?

A.C. Cismaru[1], C. Tomuleasa[2], S. Chira[1], E. Isacescu[1], G. Cismaru[3], L-M. Gherman[4], D.T. Gulei[2], R. Muntean[2], I. Berindan-Neagoe[1]

[1]*Research Center for Functional Genomics, Biomedicine and Translational Medicine, UMF - University of Medicine and Pharmacy Iuliu Hatieganu, Cluj-Napoca, Romania;* [2]*Medfuture - The Research Center for Advanced Medicine, UMF - University of Medicine and Pharmacy Iuliu Hatieganu, Cluj-Napoca, Romania;* [3]*5th Department of Internal Medicine, Cardiology-Rehabilitation, UMF - University of Medicine and Pharmacy Iuliu Hatieganu, Cluj-Napoca, Romania;* [4]*Laboratory Animal Facility - Centre for Experimental Medicine, UMF - University of Medicine and Pharmacy Iuliu Hatieganu, Cluj-Napoca, Romania*

Background: One important limitation of the current standard approach of mobilizing hematopoietic stem cells (HSCs) in the peripheral blood (PB) using granulocyte-colony stimulating factor (G-CSF) for the prophylaxis of chemotherapy induced febrile neutropenia or in donors for PB stem cell transplantation (PBSCT) is insufficient mobilization. Based on our preliminary results on the effect of human chorionic gonadotropin (HCG) on stimulating the peripheral mobilization of HSCs *in vivo,* the aim of the current study was to assess the effect of the addition of HCG to mobilization with G-CSF on the overall survival (OS) as the primary endpoint in a mouse model of PBSCT.

Methods: Male donor mice (n=20) were pretreated with a single dose of either peg-G-CSF alone (group A, n=10) or HCG + peg-G-CSF (group B, n=10), 5 days prior to PBMC harvest. PBMCs were immediately transplanted to the equivalent number of Busulfan mieloablated female mice by intravenous tail injection and OS was assessed in both recipient groups.

Results: The median OS in the group of recipients transplanted with peg-G-CSF mobilized PBMCs (group A`) was 81 days. In the recipients transplanted with HCG+ peg-G-CSF mobilized PBMCs (group B`} the median OS is not reached at 154 days with 90% of the recipients still being alive.

Conclusions: Addition of HCG to the current standard mobilization approach with G-CSF in donors has almost doubled the survival rate in the recipients of a murine model of PBSCT with the median OS not yet reached after 154 days. This prompts for the translation of the preclinical study`s approach in a human proof-of-principle/feasibility clinical trial.

64P Developing novel therapeutics for bladder cancer leveraging drosophila models

T. Moriguchi[1], M. Sonoshita[2], N. Shinohara[3]

[1]Department of Renal and Genitourinary Surgery, Hokkaido University Hospital, Sapporo, Japan; [2]Institute for Genetic Medicine, Hokkaido University, Division of Biomedical Oncology, Sapporo, Japan; [3]Department of Renal and Genitourinary Surgery, Hokkaido University Hospital, Sapporo, Hokkaido, Japan

Background: The prevalence of bladder cancer (BC) has been increasing worldwide. Particularly, patients carrying the Basal/Squamous BC (BSBC) have poor prognosis. Mammalian models such as cultured human BSBC cells and their xenografts have provided critical insights into its mechanisms, but effective therapeutics for BSBC is still lacking. Recently, the fruit fly *Drosophila* has made significant contributions to cancer research. Here, we employed *Drosophila* to generate the first fly model reproducing the BSBC genotypes and to discover novel therapeutic candidates for BSBC treatment.

Methods: BSBC often harbors mutations in genes '*A*', '*B*' and/or '*C*'. To model various alteration patterns in *Drosophila*, we employed the binary GAL4/UAS system, which targets expression of exogenous transgenes to a desired fly tissue. We prepared GAL4 driver strains expressing a transcription factor GAL4 specifically in the eye cells and wing cells (*GMR-GAL4* and *nub-GAL4*, respectively, for validating transgene functions), or the Malpighian tubule which corresponds to human bladder (for modeling BSBC genotypes). We also generated UAS transgenic strains which carry mutated cDNA and/or shRNA sequences as transgenes downstream of the GAL4 target UAS sequence.

Results: Previous studies have reported that induction of wild-type *A* in fly eyes causes 'rough eye' phenotype by promoting apoptosis, which we confirmed using the eye-specific *GMR-GAL4* driver. We found that additional expression of missense-mutated *A* or knockdown of *A* by shRNA rescued the phenotype as expected. Furthermore, we confirmed that overexpression of *B* using the same driver increased the fly eye size as previously reported. Using the wing-specific *nub-GAL4* driver, we validated that knockdown of *C* by shRNA reduced the fly wing area, verifying its reported function to control tissue growth.

Conclusions: The eye and wing phenotypes induced by transgenes were consistent with their reported functions and our expectation, proving our strategy effective in validating functions of the transgenes and in modeling the BSBC genotypes in flies. We will next perform whole-body assays such as comprehensive genetic and drug screenings using these flies to demonstrate the mechanisms of BSBC pathogenesis and to develop novel BSBC treatments.

65P Ionizing radiation induces vascular smooth muscle cell senescence through activating NF-κB-CTCF-p16 pathway

X. Zheng, Z. Liu, Y. Bin, J. Wang, X. Rao, G. Wu, X. Dong, F. Tong

Thoracic Oncology Department, Cancer Center, Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, China

Background: Radiation injury of blood vessels (RIBV) is a serious long-term complication of radiotherapy, and the main pathophysiological change of which is atherosclerosis. Senescence of vascular smooth muscle cells (VSMCs) is implicated in the pathogenesis of radiation-induced atherosclerosis. The mechanisms underlying VSMCs senescence, however, remain poorly understood.

Methods: Using cultured human aortic smooth cells (HASMC) and SD male explored whether IR could induce transformation of senescent phenotype of VSMCs. ChIP assay explored whether SICC bind to p16 gene in irradiated cells. SA-β-gal staining indicate radiation-induced senescence.

Results: Using cultured human aortic smooth cells (HASMC) and SD male rats showed that IR could induce transformation of senescent phenotype of VSMCs with significant positive dose and time dependence in vitro and in vivo. IR activated DDR/NF-κB pathway and induced the nuclear loss of HMGB2 and thus spatial aggregation of CTCF, known as senescence-induced CTCF clusters (SICC), but had no significant effect on the expression level of CTCF. And ChIP assay showed that SICC exhibited stronger binding ability to p16 gene in irradiated cells. Overexpressing HMGB2 and silencing CTCF abrogated radiation-stimulated p16 upregulation with less SICC formation. Suppression of the activation of NF-κB by PDTC (a common inhibitor of NF-κB) attenuated radiation-induced senescence, indicated by less SA-β-gal staining, downregulation of p16. We also found that PDTC reduced radiation-induced nuclear loss of HMGB2 and formation of SICC.

Conclusions: In summary, we demonstrated here, for the first time, that IR induced transformation of senescent phenotype of VSMCs in vivo and in vitro, and activated NF-κB pathway to initiate HMGB2 nuclear loss and thus promote the formation of SICC, which further strengthen the binding ability of CTCF and p16 gene, and resulted in the occurrence of radiation-induced senescence in VSMCs. These findings may have a significant impact on the research of radiation-induced atherosclerosis and open a new prospective in the prevention and therapeutic intervention in RIBV.

66P Exploring the radiobiology and dosimetry of targeted alpha therapy as a tool to optimize its clinical application: A preclinical study

M.F. Botelho[1], I.A. Marques[1], D. Cancelinha[1], A. Belchior[2], G. Costa[3], A.S. Pires[1], A.M. Abrantes[1]

[1]Coimbra Institute for Clinical and Biomedical Research (iCBR), Area of Environment, Genetics and Oncobiology Research (CIMAGO), Institute of Biophysics, Faculty of Medicine; CIBB; CACC, Univ Coimbra, Coimbra, Portugal; [2]Centro de Ciências e Tecnologias Nucleares, Instituto Superior Técnico, Universidade de Lisboa, Lisbon, Portugal; [3]Department of Nuclear Medicine, CHUC - Centro Hospitalar e Universitário de Coimbra, EPE, Coimbra, Portugal

Background: The use of molecular radionuclide therapy (MRT), such as targeted alpha therapy, is an emerging option for cancer treatment. The first alpha-emitter approved for therapeutic use was radium-223 (Ra-223), indicated for metastatic castration-resistant prostate cancer (mCRPC), with exclusive bone metastasis. However, treatment outcomes are below expectations. There are some limitations, such as precise dosimetry, that could be addressed to improve clinical outcomes. In fact, there is no inclusion of radiobiology and molecular dosimetry data obtained in preclinical studies into MRT planning as occur for radiotherapy. Moreover, there is a lack of these data for MRT. Thus, the aim of this study was to develop preclinical studies to access radiobiology and dosimetry for MRT, namely for Ra-223.

Methods: Preclinical studies were conducted using metastatic PCa cells or spheroids, to better mimic tumor architecture, as cellular models of mCRPC. Radiobiological endpoints, such as viability, survival and death, were measured 7days post-irradiation of cellular models with increasing activities of Ra-223 (0-7040 Bq/mL) for 24h. The size, geometry and cell distribution of each cellular model were analyzed by confocal microscopy and values were used in combination with radiobiological and kinetics endpoints to perform cell dosimetry using MIRDcell V3.

Results: The exposure to increasing activities of Ra-223 induces a decrease in viability, survival with increasing of cell death for both cellular models, with biological effects depending on the cell model characteristics. These effects are less evident when evaluated in spheroids, when exposed to the same activities of Ra-223. These biological data were validated with dosimetric calculations that confirm differences in absorbed doses depending not only on initial activity but also on cellular model characteristics.

Conclusions: The radiobiological and dosimetric studies showed that radiation effects for Ra-223 are dependent on molecular and structural characteristics of the cellular model, being the spheroids more representative of tumor architecture and better to conduct translational preclinical studies for MRT, as well as to obtain precise dosimetry.

67P The effect of non-viral gene-immune therapy via OX40L or 4-1BBL on murine subcutaneous CT26 colon cancer model

O. Rakitina, A. Kuzmich, D. Didych, S. Kondrateva, O. Bezborodova, I. Alekseenko

Group of Gene Immuno Oncotherapy, Shemyakin-Ovchinnikov Institute of Bioorganic Chemistry, Moscow, Russian Federation

Background: One way to significantly reduce the incidence of systemic side effects of antitumoral immunotherapeutics is intratumoral gene-immune therapy. The use of non-viral systems is attractive for gene therapy due to low immunogenicity of the carrier, low production costs, and relatively high capacity. Thus, non-viral intratumoral gene-immune therapy is a promising area for development of antitumor drugs. OX40 and 4-1BB T cell co-stimulators are popular targets in immunotherapeutic drug development, but currently there are no approved drugs targeting these receptors. We suppose that the natural ligands of these receptors, OX40L and 4-1BBL, would be effective in non-viral gene-immune therapeutics.

Methods: The antitumor effect of stable OX40L or 4-1BBL expression by inoculated cancer cells on CT26 tumor growth was studied. CT26 cell lines stably expressing OX40L or 4-1BBL were obtained, tumor graftability and growth in BALB/c mice were evaluated. Next, antitumor effect of non-viral gene-immune therapy with OX40L or 4-1BBL was studied, complexes of polymeric carrier with plasmid DNA encoding OX40L or 4-1BBL were prepared and injected three times into CT26wt subcutaneous tumors in BALB/c mice, starting when tumors reached 50±15 mm^3 .

Results: Stable expression of OX40L and 4-1BBL significantly suppressed CT26 tumor growth, delayed tumor resorption was observed in the experimental groups. The use of OX40L and 4-1BBL in the context of gene-immune therapy had a significant effect on CT26 tumor growth — median animal survival compared to the control group was increased by 26.5% (OX40L) and 41.2% (4-1BBL), life expectancy was increased by 24% (OX40L) and 24.5% (4-1BBL), tumor growth inhibition 10 days after treatment was 70% (OX40L) and 71.3% (4-1BBL). No visible immune-related adverse events (irAEs) were observed.

Conclusions: OX40L and 4-1BBL have a comparable potent antitumoral effect on CT26 tumor growth in the context of non-viral gene-immune therapy, and such therapeutic approach does not yield visible systemic irAEs.

68P Dendritic polylysine with paclitaxel and triptolide codelivery for enhanced NSCLC ferroptosis through the accumulation of ROS

H. Xu[1], Y. Wen[2], M. Ni[1], H. Jiang[1], T. Wu[1], X. Li[3]

[1]School of Pharmacy, Nanjing Medical University, Nanjing, China; [2]Pharmacy, Jiangsu Cancer Hospital, Nanjing, China; [3]Department of Geriatric Gastroenterology, Jiangsu Province Hospital/The First Affiliated Hospital of Nanjing Medical University, Nanjing, China

Background: The clinical application of Paclitaxel (PTX), a first-line chemotherapeutic for NSCLC, is severely limited because of its developed resistance and insolubility. It is reported by our previous studies that the resistance to PTX is closely related to intracellular redox balance in cancer cells. Moreover, our preliminary data demonstrated that Triptolide (TPL) could improve the cytotoxicity of PTX through inducing ROS production. Most importantly, the synergistic anticancer effect between PTX and TPL is mainly through the induction of ferroptosis in NSCLC cell lines. To improve the delivery efficiency of both drugs, we constructed a novel nano-drug delivery system NDDS chemosynthesis by PEGylated generation 3 (G3) dendritic polylysine co-loaded with PTX and TPL (PTX-TPL-PEG-PLL, PTPP), which was endowed with the ability of tumor targeting and favorable solubility. this is the first report on the dendritic polylysine loaded with PTX and TPL for NSCLC treatment. In addition, the enhanced ferroptosis-inducing effect of PTPP was mediated through ROS level, which illustrated the possible mechanism underlying the synergistic effect of PTX and TPL.

Methods: First, the PTPP was characterized by 1H NMR analysis, mass spectra, and HPLC. the in vitro synergetic effect and mechanism of PTX and TPL were explored by MTT assay and western blot. In vivo evaluation was performed in a xenograft mice model of NSCLC cell lines.

Results: The PTPP was synthesized successfully through covalent bonding and the MTT assay indicated the synergetic effect of PTX and TPL. Besides, regarding the mechanism, the TPL could promote the generation of ROS by inhibiting the NF-κB signaling pathway, which synergistically increased ROS level with PTX, inducing NSCLC cells ferroptosis. In the end, in vivo experiments suggested the outstanding tumor-inhibiting ability of PTPP.

Conclusions: Overall, the current study suggested that PTPP exerted an excellent antitumor effect than PTX, TPL, or PTX combined with TPL through ferroptosis induction. PTPP may be a potential treatment system for NSCLC treatment.

69P Novel monoclonal antibodies can distinguish Cripto-1 from Cripto-3 proteins: Clinical implications and potential new biomarkers

J. Garcia-Sanmartin[1], F. Cuttitta[2], Y. Feng[3], M.E. Sunday[4], Y.S. Kim[5], A. Martínez[1]

[1]Oncology, Center for Biomedical Research of La Rioja (CIBIR), Logroño, Spain; [2]Tumor Angiogenesis Unit, National Cancer Institute - Technology Transfer Center, Frederick, MD, USA; [3]Tumor Angiogenesis Unit, National Cancer Institute, Bethesda, MD, USA; [4]Clinical Science Department, Duke University Medical Center, Durham, NC, USA; [5]Cancer Prevention Science Branch, Division of Cancer Prevention, National Cancer Institute - Shady Grove Campus, Rockville, MD, USA

Background: Cripto-1 (CR1) is an oncofetal protein required for implantation and expressed in the adult during wound repair, inflammation, and tumorigenesis. A second gene codes for a very homologous protein, Cripto-3 (CR3). Both proteins contain 188 amino acids and differ only in 6 residues. Heretofore, all available antibodies cannot discriminate between these two proteins, preventing any investigation on their differential contributions to cancer biology. Here, we present the generation, characterization, and clinical implications of highly specific monoclonal antibodies (MoAbs) for these two proteins.

Methods: Different peptide fragments of either protein were used as antigens to generate mouse MoAbs (233 clones for CR1, 319 clones for CR3) that were selected by their target protein specificity through SPR and ELISA assays. Selected MoAbs were used for immunohistochemistry on tissue arrays including normal tissues as well as cancers of the lung, breast, colon, ovary, and prostate. MoAbs were also used for Western blotting and ELISA characterization of human serum (breast cancer vs healthy controls).

Results: MoAbs NCI 5G1-1 and NCI 5G11-2 were highly specific for CR1 and CR3, respectively. No crossreactivity was observed with the other protein. Immunohistochemical analysis of cancer specimens showed differential staining patterns, where some tumor cells expressed both proteins, others expressed only CR3, and still others show vascular endothelial cells stained for CR1 while tumor cells express CR3. In prostate, colon, and breast cancer, CR1 and/or CR3 protein expression correlates with clinical parameters, such as TMN_N, TMN_M, tumor stage, tumor grade, or PR expression. Lastly, both CR1 and CR3 interact with established binding proteins Nodal, GRP78 and Alk4 and competitively interfere with one another for targeted binding.

Conclusions: We describe for the first time the development of MoAbs that discriminate human CR1 from CR3, confirming that CR3 is translated into a protein in human cells, thus removing its pseudogene status. We also confirm CR1, and propose CR3, as cancer prognosis and severity markers.

70P The human intratumor mycobiome is significantly influenced by an individual's race

D. Coster[1], T. Margalit[1], B. Boursi[2], R. Shamir[1]

[1]Computer Science, Tel Aviv University (TAU), Tel-Aviv, Israel; [2]Oncology, Chaim Sheba Medical Center, Ramat Gan, Israel

Background: Recently, the intratumor mycobiome has been characterized in 17,401 cancer patients, covering 35 cancer types from The Cancer Genome Atlas (Narunsky-Haziza et al., 2022), revealing a previously overlooked aspect of cancer research. Moreover, Recent study showed that race is a key determinant of the human intratumor microbiome. We aimed to better understand the effects of patients' demographic factors (age, sex, and race) on the intratumor mycobiome composition.

Methods: We analyzed the Narunsky-Haziza et al. de-contaminated and normalized intratumor fungal abundance data for 11 cancer types and 224 fungal species. We performed a systematic characterization of the tumor mycobiome across different cancer types using a propensity score algorithm, adjusting for the potential confounding factors of histological type and tumor stage.

Results: Fungus species abundances differed significantly between races in all cancer types. For example, in breast cancer, we identified 42 significantly differentially

abundant fungal species in European vs. Asian, 45 species in European vs. African, and 56 in Asian vs. African. Notably, 19 fungal species *Talaromyces marneffei, Scheffersomyces stipites, Debaryomyces fabryi, Lachancea lanzarotensis, Ogataea polymorpha, Tetrapisispora blattae, Fusarium proliferatum, Kazachstania Africana, Torulaspora delbrueckii, Naumovozyma castellii, Wickerhamomyces anomalus, Yamadazyma tenuis, Naumovozyma dairenensis, Sugiyamaella lignohabitans, Clavispora lusitaniae, Candida tropicalis, Vanderwaltozyma polyspora, Meyerozyma guilliermondii, Lachancea thermotolerans* — had significantly different abundances in all three race comparisons. Moreover, regarding age (>65) and sex, only 5 fungal species abundance in stomach adenocarcinoma varied significantly for age and *Malassezia sympodialis* differed significantly with respect to sex. In thyroid carcinoma, 3 species varied by age and *Cordyceps militaris* for sex.

Conclusions: Our research reveals that the composition of the fungal community within tumors varies significantly across races, underscoring the importance of accounting for this demographic factor when conducting fungal-related analysis and clinical trials involving microbiota modulation.

71P Preclinical characterization of ARX305: A next-generation anti-CD70 antibody drug conjugate for the treatment of CD70-expressing cancers

L. Skidmore, D. Mills, J.Y. Kim, K. Tatsukawa, N. Knudsen, J. Nelson, J. Wang, S. Zhang

Preclinical, Ambrx, Inc., La Jolla, CA, USA

Background: CD70 is an attractive tumor target due to its over-expression in numerous solid and hematological cancers and limited expression in healthy cells. In the last decade, multiple anti-CD70 antibody drug conjugates (ADCs) have been developed, but most have been discontinued due to unacceptable toxicity or a narrow therapeutic index. Using an expanded genetic code to create Engineered Precision Biologics, Ambrx has developed ARX305, a CD70-targeted next-generation ADC to potentially overcome the challenges associated with earlier ADCs. ARX305 is comprised of a proprietary, high-affinity, humanized anti-CD70 antibody stably and site-specifically conjugated to AS269, a potent microtubule inhibitor. After binding to CD70 expressed on tumor cells, ARX305 is internalized and catabolized, releasing the cytotoxic payload pAF-AS269 which inhibits cellular proliferation. ARX305 utilizes stable oxime conjugation chemistry, a non-cleavable PEG linker, and a membrane-impermeable payload to minimize premature payload release in circulation and associated off-target toxicity.

Methods: ARX305 was evaluated in multiple pre-clinical pharmacology and toxicology models using standard methodology.

Results: In vitro studies demonstrate that ARX305 selectively induces cytotoxicity of CD70-expressing tumor lines. In multiple *in vivo* xenograft or disseminated models, ARX305 induced significant tumor growth inhibition or regression whereas unconjugated antibody exhibited poor activity. The stable conjugation and cell-impermeable payload of ARX305 led to high serum stability, a long terminal half-life, and a similar exposure profile as unconjugated antibody in rodent pharmacokinetic studies. Repeat dose studies in cynomolgus monkeys demonstrated ARX305 was tolerated at exposures well above therapeutic exposures in mouse pharmacology studies, indicating a wide therapeutic index.

Conclusions: In summary, the highly selective and potent anti-tumor activity in multiple tumor types and wide pre-clinical therapeutic index of ARX305 support clinical evaluation of this next generation anti-CD70 ADC. ARX305 is currently in a phase 1 dose-escalation study in China.

72P Impact of extended panel of genes for germline cancer testing

S. Dawood[1], M. Wasfy[2], R. Khoury[2]

[1]Oncology Department, Mediclinic City Hospital, Dubai, United Arab Emirates; [2]Medical Department, IPS Genomix, Beirut, Lebanon

Background: Traditional genetic screening was based previously on the analysis of classical high penetrance genes such as BRCA1 and BRCA2. In the context of our clinical practice in Dubai, individuals fulfilling the criteria are tested for germline mutations to subsequently establish the clinical management. Our current standard diagnostic approach focuses on sequencing 110 genes through NGS leading to increase the chance of finding the causal mutation and to the widespread clinical use of genes for germline cancer testing.

Methods: A total of 111 cases were tested in UAE with a traditional panel (BRCA1, BRCA2 and CHEK2) from October 2013 till September 2016. Then we have integrated extended panels (36 then 110 genes) from October 2016 till March 2023 and tested 509 cases. Median age was 47 years. Cases were referred for genetic testing mainly due to personal history of breast and ovarian cancer.

Results: Mutations in traditionally screened cases represent 8.1% for BRCA1, BRCA2 and 1% for CHEK2 for all types of panels. However extended panel analysis had a higher detection rate of pathogenic mutations compared to traditional analysis with an average increase of 7% in several genes mainly MUTYH, TP53, MLH1, RAD51D, PALB2 (respectively 2.6%, 0.8%, 0.8%, 0.6%, 0.6%). The heterogeneity of the newly detected mutations identified reinforces the value of using an extended hereditary panel. Further analysis will correlate the characteristics of germline mutations and their correlation with the tumor type and with the age group.

Conclusions: To our knowledge this is the first abstract from the MEA focusing on the impact of the analysis of extended panel of genes to patients with suspicion of hereditary cancer. Our findings reinforce the utility of extended panels involved in hereditary cancer predisposition in the diagnostic routine which may impact their clinical management. The use of this approach facilitates the detection of pathogenic mutations in non-BRCA1/2 genes and aided management. This will allow opportunities for enhanced surveillance and intervention in a range of tumors.

73P Preclinical and clinical presentation of the nerve-driven tumor spread

D.S. Sigorski[1], M. Michalak[1], S. Galli[2], S. Hyeok Hong[3], E. Iżycka-Świeszewska[4], J. Kitlińska[3]

[1]Department of Oncology, University of Warmia and Mazury in Olsztyn, Olsztyn, Poland; [2]Department of Pathology, Georgetown University Medical Center, Washington, DC, USA; [3]Department of Biochemistry and Molecular & Cellular Biology, Georgetown University Medical Center, Washington, DC, USA; [4]Department of Pathology and Neuropathology, Medical University of Gdansk, Gdansk, Poland

Background: Tumor infiltration by nerves and axial bone metastases often occur in prostate cancer (PCa) patients, however the mechanisms and the link between these processes are not well understood. Here, we report a PCa mouse model, which recapitulates this cancer route of spreading and correlates with radiological images from PCa patients.

Methods: The human androgen-independent PC3-ML cell line with reported bone metastasis potential was orthotopically injected into the prostate of SCID/Bg mice to observe the natural history of cancer spread instead of commonly used intratibial or intracardiac injections. The process of primary and secondary tumor development was monitored by magnetic resonance imaging (MRI). The tissues were collected and immunostained for neuronal markers, neurofilament (NF), and tyrosine hydroxylase (TH), as well as prostate cancer cell marker, pan-cytokeratin, and a vascular marker, CD31. Additionally, clinical cases of patients with representative MRI images of bone metastases and PNI were selected.

Results: The mice MRI revealed the presence of primary prostate tumor with secondary tumors located mostly along the lumbar spinal cord and pelvis, which led to secondary bone infiltration. The histopathological analysis confirmed the presence of PCa cells along the spine with its infiltration. The PCa cells created clusters, which spread along the small, NF-positive nerve fibers that were directed into the bone area. We ruled out the retrograde vessel infiltration by CD31 immunostaining. The clinical relevance of our model was confirmed by the radiological presentation of human PCa cases: 1) a patient with castration-sensitive PCa, with oligometastatic disease (one sacrum metastasis) and infiltration of neurovascular bundle; 2) a patient with castration-resistant PCa with PNI and a relapse in the ilium, who subsequently developed perispinal metastases along the lumbar plexus and spine.

Conclusions: Altogether, the results of our study suggest that PNI may be responsible for the initial PCa dissemination to bone. MRI imaging has adequate sensitivity to detect the nerve infiltration, however it is not commonly used in disseminated PCa patients. Consequently, the number of cases with spine infiltration and bone metastases may be underreported.

74P Characterization of ERBB2 variation and their association with immune response in solid tumours

D. Wang[1], S. Yuan[2], W. Zhizheng[2], H. Chen[2], F. Pang[2]

[1]Respiratory Medicine, Jinling Hospital Affiliated to Nanjing University School of Medicine, Nanjing, China; [2]Medical Department, Shanghai OrigiMed Co., Ltd., Shanghai, China

Background: *ERBB2*, a receptor tyrosine kinase, is commonly affected by mutations, amplifications, and overexpression in various types of cancers. Drugs targeting ERBB2 are gradually being promoted to various types of cancer. However, the variation of ERBB2 in Chinese population and the relationship between *ERBB2* high expression abnormalities and the tumor immune microenvironment remains unclear.

Methods: We utilized genomic data from over 10,000 pan-cancer Chinese populations in CbioPortal to detect somatic mutations and copy number variations. We also performed RNA sequencing date in TCGA (pan-cancer Atlas studies) to determine *ERBB2* expression in diverse cancer types and evaluate the immune gene characteristics and content of tumor-infiltrating immune cell populations.

Results: A total of 309 *ERBB2* amplifications, 169 *ERBB2* substitution or insertion deletions, and 28 *ERBB2* fusions or rearrangements were detected in 10,194 patients. The *ERBB2* amplification rate of breast cancer (23.84%), gallbladder cancer (13.75%) and urothelium cancer (8.33%) ranked the top three among all cancer types. Among the co-mutated genes with *ERBB2* mutations, TP53 (68.8%), CDK12 (34.7%), and RARA (18.7%) have the highest proportion of mutations. Furthermore, among 10,967 RNA datasets in TCGA, breast cancer, esophageal squamous cell carcinoma, and gastric adenocarcinoma displayed the highest average expression levels of *ERBB2*. Patients with high *ERBB2* expression exhibited similar TMB values to those with low *ERBB2* expression. However, in breast cancer, colon cancer, lung adenocarcinoma and lung squamous carcinoma, *ERBB2* high expression was significantly associated with a higher proportion of activated mast cells, monocytes, and regulatory T cells, while the percentage of resting mast cells and M1 macrophages was notably lower.

Conclusions: Our study identified *ERBB2* variation patterns among a cohort of Chinese solid tumor patients and demonstrated that *ERBB2* abnormality high expression is associated with an activated immune system and a stronger inflammatory response. Our findings offer insights into the potential benefits of using immune checkpoint inhibitors for this type of patient.

75P Double-stranded RNA transfection induced anti-tumour effect mediated by dual RIG-I and TLR-3 immune pathways

J.A. Tai[1], C.Y. Chang[2], T. Nishikawa[1], K. Yamashita[1], Y.D. Kuan[1]

[1]Device Application for Molecular Therapeutics, Graduate School of Medicine/Faculty of Medicine, Osaka University, Suita, Japan; [2]Gene & Stem Cell Regenerative Therapy, Graduate School of Medicine/Faculty of Medicine, Osaka University, Suita, Japan

Background: Cancer immunotherapy is dependent on immunostimulation to reorganise the tumour microenvironment (TME) and to increase anti-tumour effects of immune cells. There are currently many immunostimulants applicable to cancer therapy, such as antibodies, molecular drugs and PAMP activators. Choice of immunostimulant may be key, but method of delivery of treatment is equally as important as different routes may stimulate different immune pathways. Despite of the rapid development of nucleic acid drugs in recent years, the effect of nucleic acid on tumor immunity needs to be further investigated. Polyinosinic:polycytidylic acid (poly I:C) is a synthetic double-stranded RNA analog that shows promise as an adjuvant in cancer vaccines or immunotherapies. Poly I:C is known to interact with Toll-like receptor 3 (TLR3) when taken up by endocytosis, but when directly transfected into cells, poly I:C stimulates retinoic acid-inducible gene I (RIG-I) instead.

Methods: Poly I:C was used to mimic anti-tumour response after nucleic acid administration. Murine 4T1 mammary tumour-bearing BALB/c mice were treated with poly I:C by electroporation (EP) or syringe injection (SI) and monitored for tumour growth. To determine whether poly I:C-activated immune pathways differed between delivery modes, RIG-I and TLR3 pathway inhibitors were used to inhibit poly I:C-induced anti-tumour effect in 4T1 tumour model.

Results: Our results showed that poly I:C EP treatment induced stronger tumour suppression effect and tumour-specific adaptive immune response than via SI. And that this EP-treated anti-tumour effect could be suppressed by both RIG-I and TLR3 pathway inhibitors, but not in SI, suggesting that treatment of poly I:C via different delivery modes do activate different immune pathways.

Conclusions: We have demonstrated that poly I:C could induce different anti-tumour effects dependent on treatment delivery method. Our results suggest that the effects of nucleic acid drugs may vary depending on how they are administered.

76P Improvement of whole-cell cancer vaccine anti-tumor effect by different injection methods

C.Y. Chang[1], J.A. Tai[2], Y.D. Kuan[3], T. Nishikawa[4], K. Yamashita[2], M. Shimamura[1]

[1]Gene & Stem Cell Regenerative Therapy, Graduate School of Medicine/Faculty of Medicine, Osaka University, Suita, Japan; [2]Device Application for Molecular Therapeutics, Graduate School of Medicine/Faculty of Medicine, Osaka University, Suita, Japan; [3]Graduate School of Medicine, Osaka University, Suita, Japan

Background: It is common for cancer to recur even after successful treatment of the primary tumor. Recurrent or metastatic cancers are less responsive to existing therapies and often have high mortality rate. Whole-cell cancer vaccine, which utilizes patient-derived primary tumor tissue may be a promising approach in preventing recurrence. A major advantage is the provision of a plethora of patient-specific tumor antigens, but overall whole-cell vaccine efficacy is still limited and insufficient. To improve on the efficacy of whole-cell cancer vaccine, we explored the use of different injection methods. It has been previously shown that injection method and location of injection may vary vaccine efficacy and effects. Therefore, we investigated different injection methods to improve the effectiveness of the whole-cell cancer vaccine.

Methods: We compared the efficacy of needle-syringe injection and needle-free (pyro-drive jet injector) injection to evaluate the differences in effectiveness of whole-cell cancer vaccines using murine MC38 colon adenocarcinoma or 4T1 mammary tumor cell lines, by analyzing tumor challenge and the inhibition of cancer metastasis using the C57BL/6 and BALB/c mouse models. We also analyzed the *in vitro* activation of APCs and innate immune cells using the expelled whole-cell vaccine following each injection method by flow cytometry, cytokine array and quantitative real-time PCR.

Results: Our results showed that whole-cell vaccine administered via needle-free injection induced higher tumor suppression effect and stronger tumor-specific immunity than traditional needle-syringe injection in both MC38 and 4T1 tumor models. *In vitro*, the whole-cell cancer vaccine preparation discharged through the needle-free injection device induced a stronger immune stimulation on immune cells than from the syringe method.

Conclusions: In contrast to needle injection, needle-free injection of whole-cell cancer vaccine resulted in more pulverized cancer cell fragments, which potentiates APC phagocytosis and adaptive immune activation, thereby improving anti-tumor effect of the vaccine. Therefore, needle-free injection or pre-pulverized formulations should be considered to improve anti-tumor effects of whole-cell cancer vaccines.

77P Normative data on the sexual health questionnaires - QLQ-SHQ22, and the sexual domains of the QLQ-BR23/BR45 - for Norwegian general population with and without cancer

R.E. Åsberg[1], G. Giskeødegård[2], M.J. Hjermstad[3], K.V. Reinertsen[4], J. Karlsen[5], M. Nilsen[6], R.J. Reidunsdatter[7]

[1]Department of Circulation and Medical Imaging, NTNU - Norwegian University of Science and Technology - Faculty of Medicine and Health Sciences, Trondheim, Norway; [2]Department of Public Health and Nursing,K.G. Jebsen Center for Genetic Epidemiology, NTNU - Norwegian University of Science and Technology, Trondheim, Norway; [3]Department of Oncology, Regional Advisory Unit for Palliative Care, Oslo University Hospital - Ulleval Hospital, Oslo, Norway; [4]National Advisory Unit for Late Effects After Cancer Treatment, Departement of Oncology, Oslo University Hospital - The Norwegian Radium Hospital, Oslo, Norway; [5]Department of Oncology, St. Olavs Hospital, Trondheim, Norway; [6]Department of Social Work, NTNU - Norwegian University of Science and Technology, Trondheim, Norway; [7]Department Of Circulation And Medical Imaging, NTNU - Norwegian University of Science and Technology, Trondheim, Norway

Background: Sexual dysfunction is of the most common late effects after cancer. Normative general population data on sexual health is essential for supporting the interpretation of patient-reported outcomes (PROMs) in cancer studies and clinical practice and can contribute to improve survivorship care. This study aims to provides age-, sex- and morbidity specific Norwegian normative values for the European Organisation for Research and Treatment of Cancer Quality of Life Questionnaires; the Sexual Health Questionnaire QLQ-SHQ22, and the sexual domains of the breast modules QLQ-BR23/QLQ-BR45 inindividuals with and without history of cancer.

Methods: A nationwide general population sample stratified by sex and age (18—29, 30—39, 40—49, 50—59, 60—69, 70-79 years) was drawn from the Norwegian Population Register. Participants were notified through National online health services and postal mail. The survey included sociodemographic background, morbidity assessed bythe Self-Administered Comorbidity Questionnaire and sexual health assessed by the sexual health EORTC questionnaires.

Results: Of the 15,627 eligible individuals, 5,135 (33%) responded. Among these, 453 persons reported being diagnosed one or several times with cancer, and 4669 persons had no former history of cancer (breast, prostate, gynecological and others). Individuals with cancer scored significantly lower ($p<0.01$) on several functional scales: *libido* (scores 54 vs. 70), *sexual functioning* (45 vs 58), *sexual enjoyment* (67 vs 76), and for women *femininity (*65 vs. 84). The most prominent differences in symptoms were *fatigue* (32 vs 20) and *worry of incontinence* (27 vs. 9). Women and individuals with comorbidities had in general poorer sexual health, and differences were most pronounced in the youngest age groups.

Conclusions: The present study is the first to use normative EORTC data to compare sexual health in individuals with- and without cancer. Sexual health was in general significantly poorer in individuals with history of cancer compared to individuals without cancer.

78P Peroxiredoxin-1 knockout negatively affects the viability of ph+ B-cell acute lymphoblastic leukemia cells and sensitizes them to tyrosine kinase inhibitors

J. Hunia[1], Ł Komorowski[1,2], K. Szczygieł[3], M. Firczuk[1,4]

[1]Department of Immunology, Medical University of Warsaw, Warsaw, Poland; [2]Hospital for Sick Kids, Toronto, ON, Canada; [3]Polpharma Biologics SA, Gdańsk, Poland; [4]Laboratory of Immunology, Mossakowski Medical Research Institute, Polish Academy of Sciences, Warsaw, Poland

Background: Breakpoint cluster region-Abelson (*BCR:ABL1*) gene fusion is an essential oncogene in both chronic myeloid leukemia (CML) and Philadelphia-positive (Ph^+) B-cell acute lymphoblastic leukemia (B-ALL). While tyrosine kinase inhibitors (TKIs) are effective in up to 95% of CML patients, 50% of Ph^+ B-ALL cases do not respond to treatment or relapse. This calls for new therapeutic approaches for Ph^+ B-ALL. Dysregulation of redox homeostasis and reliance on the thioredoxin (TXN) antioxidant system has been previously shown in B-ALL. Herein, we investigated the role of peroxiredoxin-1 (PRDX1), an enzyme responsible for the scavenging of hydrogen peroxide, in Ph^+ myeloid and lymphoid leukemia.

Methods: PRDX1 knockout and apoptotic proteins were assessed by immunoblotting. The numbers of viable BV173 (lymphoid) and K562 (myeloid) cells were evaluated by light microscope counting after discriminating dead cells with Trypan Blue staining. Cell cycle and proliferation were assessed with MUSE and Click-iT EdU tests, respectively. The viability of K562 and BV173 knockouts treated with TKIs was assessed with propidium iodide staining and flow cytometry.

Results: PRDX1 knockout reduced the numbers of viable BV173 cells grown in vitro, but did not affect the numbers of K562 cells. The addition of hydrogen peroxide scavenges to the culture medium restored the viability of BV173 cells. We observed no significant differences in cell proliferation or in cell cycle fractions in BV173sgPRDX1 cells. Notably, in contrast to the myeloid K562 cell line, lymphoid B-ALL cells lacking PRDX1 were much more sensitive to three tested TKIs: imatinib, dasatinib, and ponatinib.

Conclusions: The results reveal that the important role of PRDX1 for Ph^+ leukemic cell viability and sensitivity to TKIs is restricted to lymphoid leukemias. The observed reduced numbers of PRDX1 knockout cells were not the effect of an altered cell cycle or proliferation but most likely due to increased apoptosis. These findings are part of a larger ongoing in vitro and in vivo study examining the sensitization of Ph^+ lymphoid leukemia to TKIs through inhibition of the thioredoxin system and PRDX1.

79P Co-delivered crizotinib and gefitinib based on nanoparticle for synergically overcoming resistance lung adenocarcinoma treatment

H. Zhou[1], J. Deng[1], B. Xu[1], F. Zeng[2]

[1]Department of Thoracic Surgery, Guangdong Province People's Hospital, Guangzhou, China; [2]Institute of Geriatrics, Guangdong Province People's Hospital, Guangzhou, China

Background: Gefitinib has been employed as a first-line treatment for patients with NSCLC with EGFR mutation, but rapid drug resistance in tumors induces disease progression. Overactivation of PI3K/AKT is associated with gefitinib resistance (GR) in lung adenocarcinoma. Clinically, crizotinib inhibits AKT and extracellular regulated protein kinases (ERK) signal activation in various tumor cells.

Methods: Gefitinib and crizotinib were loaded into a hydrophobic core, which was formed by the amphiphilic block poly (ethylene glycol)—poly (hexyl ethylene phosphate) (GC@NP) through nano self-assembly method. And the anti-tumor effect and mechanism of GC@NP were verified in vivo and in vitro.

Results: According to particle characterization results, GC@NP had a homogeneous and stable nanoscale, which was 40.1±1.1 nm. Especially, GC@NP had a good drug loading efficiency, the values are 6.52 ± 0.21% and 7.09 ± 0.39% for gefitinib and crizotinib respectively. At the cellular level, GC@NP can be effectively ingested by PC9GR cells within 2 hours. When the concentration of gefitinib was set to 2 μM, the cell viability of the free gefitinib group was 90%, while GC@NP group was only about 50%. At the same time, GC@NP exhibited higher proliferative inhibition and apoptotic induction effects compared to free gefitinib group, the apoptosis rates were 25% and 5% respectively. At the animal level, GC@NP significantly inhibited the growth and metastasis of PC9GR tumors, and also inhibited the brain metastasis associated with GR. Meanwhile, we validated GC@NP has good biosafety in the transgenic zebrafish model. In the nude mouse tumor model, our results indicate that GC@NP can significantly inhibit the growth of PC9GR tumors, while the combination of free gefitinib and crizotinib didn't show significant therapeutic effects. Mechanistically and importantly, GC@NP synergism promoted the dephosphorylation of the overactivated AKT signal and inhibited the feedback activation of ERK signal, which inducing apoptosis in PC9GR cells.

Conclusions: The co-delivery nanoparticle GC@NP we have constructed provides a potential therapeutic approach for advanced lung adenocarcinoma patients with targeting-drug resistance and brain metastasis.

80P Steroidal oximes: A new potential therapeutic approach for cancer treatment

M. Laranjo[1], A.R. Gomes[2], S. Costa[3], A.M. Abrantes[1], A.C. Gonçalves[4], R. Alves[4], M.F. Botelho[1], E. Tavares-da-Silva[5], S. Pires[1], F. Roleira[5]

[1]Coimbra Institute for Clinical and Biomedical Research (iCBR) area of Environment Genetics and Oncobiology (CIMAGO), Biophysics Institute of Faculty of Medicine; CIBB; CACC, Univ Coimbra, Coimbra, Portugal; [2]Coimbra Institute for Clinical and Biomedical Research (iCBR), CIMAGO, Biophysics Institute of Faculty of Medicine; CIEPQPF, Faculty of Pharmacy, Laboratory of Pharmaceutical Chemistry, Univ Coimbra, Coimbra, Portugal; [3]Faculty of Pharmacy, Laboratory of Pharmaceutical Chemistry, Univ Coimbra, Coimbra, Portugal; [4]Coimbra Institute for Clinical and Biomedical Research (iCBR) area of Environment Genetics and Oncobiology (CIMAGO), Laboratory of Oncobiology and Hematology and University Clinics of Hematology and Oncology, Faculty of Medicine; CIBB; CACC, Univ CoimbraA, Univ Coimbra, Coimbra, Portugal; [5]CIEPQPF, Faculty of Pharmacy, Laboratory of Pharmaceutical Chemistry, Univ Coimbra, Coimbra, Portugal

Background: Cancer still remains one of the life-threatening diseases worldwide despite the large number of therapeutic approaches currently available. Steroidal compounds possess numerous biological activities being antitumor one of them. Oximes have also been associated with antitumor activity. Moreover, previous studies by our group demonstrated that steroidal oximes were also very potent against several types of cancer. Thus, we embarked in the design and synthesis of new steroidal oximes and evaluated their potential antitumor activity against lung, prostate, and triple-negative breast cancer cells, with the aim of finding alternative cytotoxic compounds for cancer treatment.

Methods: Compounds **OX1**, **OX2, ExeOx and Formox** and their parent compounds **P1**, **OL2**, **Exe** and **Form** were synthesized, and their cytotoxicity evaluated in H1299, PC3 and HCC1806 cell lines through SRB assay after the treatment of the cells with the compounds (1-75 μM). Cell viability, cell death profile, alterations on cell cycle and mitochondrial membrane potential were assessed by flow cytometry.

Results: All compounds decreased H1299, PC3 and HCC1806 cancer cell proliferation in a dose-dependent manner, with the exception of **OX2**. Overall, the parent compounds decreased cancer cell proliferation in a less pronounced way, proving that the introduction of an oxime group was beneficial for the cytotoxicity displayed. Moreover, the best compound was **OX1** in all cell lines with IC_{50} values of 18.69, 22.90 and 29.95 μM in H1299, HCC1806 and PC3, respectively. Flow cytometry studies with **OX1** showed that this compound was able to decrease cell viability in all cell lines by causing cell death mainly by apoptosis, which was accompanied by a blockage at phases G2/M and S, depending on the cell line. Considering the mitochondrial membrane potential, **OX1** induced mitochondrial dysfunction, which might also be related to apoptosis.

Conclusions: Our results show that **OX1** possesses a beneficial antitumor effect from the introduction of the oxime group, which is mediated by apoptosis. This effect encourages further studies on its mechanism of action and selectivity in order to discover new molecules for cancer treatment.

81P miR-23b and -133a role on TRAIL-induced apoptosis pathway components expression and TRAIL sensitization in lung adenocarcinoma cells

D. Leite, E. Maquigussa, M.A. Boim

Medicine Department, UNIFESP, São Paulo, Brazil

Background: TRAIL-induced apoptosis pathway is a potential therapeutic target, but the majority of tumors are TRAIL-resistant. TRAIL receptors translocation is associated to TRAIL resistance. Besides TRAIL receptors, DR4 and DR5, other potentially TRAIL-induced apoptosis pathway regulatory proteins are: Apaf-1, CUL3, CLTA (clathrin chain A , involved in TRAIL receptors nuclear translocation) and KPNA-1 (involved in TRAIL receptors internalization). Overcome TRAIL resistance is essential to therapeutic strategies development.

Methods: A549 cell line was used. Expression of miR-23b, miR-133a, DR4, DR5, Apaf-1, CUL3, CLTA/CLTC and KPNA-1 were estimated by RT-qPCR. Transfection effects of miR-23b inhibitor and Mimic-133a on TRAIL apoptosis pathway components expression. Western Blotting to TRAIL receptors compartmentalization after Mimic-133a and TRAIL stimulus. MTT cell viability assay to evaluate TRAIL-induced cytotoxicity of miR-23b inhibition and Mimic-133a transfection.

Results: A549 was TRAIL resistant. miR-23b was superexpressed and miR-23b inhibition upregulated Apaf-1 and CUL3 expression. miR-133a was undetectable. Mimic-133a transfection downregulated CLTA and DR5 expression. miR-23b inhibition and Mimic-133a transfection promoted TRAIL sensitization.TRAIL receptors were predominantly located in nuclear compartment. Mimic-133a downregulated CLTA expression but did not alter receptors compartmentalization. Mimic-133a and TRAIL associated stimulus leaded to predominant nuclear TRAIL receptors localization in comparison to control cells.

Conclusions: Both miR-23b and -133a are involved in TRAIL cells resistance. Apaf-1 and CUL3 expression downregulation by miR-23b can contribute to resistance. miR-133a role on TRAIL sensitization mechanisms must be further investigated. Mimic-133a downregulated CLTA expression but did not alter TRAIL receptors compartmentalization, suggesting that receptors translocation is clathrin independent.CLTA expression control by miR-133a, however, can contribute to drug-resistance research. Although more research is needed to fully clarify miRs roles on TRAIL-induced apoptosis, our findings deepen TRAIL resistance understanding.

83P Impact of VHL-associated tumor treatment on mental health: An international patient survey

O. Iliopoulos[1], C. Atkinson[2], C. Cooper[2], G. Taylor-Stokes[2], J. Mann[3], M. Sundaram[4]

[1]Centre for Cancer Research, Massachusetts General Hospital Cancer Center, Boston, MA, USA; [2]Observational Research, Adelphi Real World - Adelphi Group, Bollington, UK; [3]VHL Alliance, VHL Alliance, Boston, USA; [4]Center for Observational and Real-World Evidence, Merck, Rahway, NJ, USA

Background: Treatment (tx) options for patients (pts) with Von Hippel-Lindau syndrome (VHL) were previously limited to surgeries between regular scans, observation and txs that preserve organ function. Little data exists on the burden of VHL-associated tumor tx on the mental health of pts.

Methods: International, cross-sectional survey comprising pts in the United States, Canada, UK, France, and Germany. Pts recruited via the VHL Alliance. Pts must have renal cell carcinoma (RCC), pancreatic neuroendocrine tumors (pNET), and/or central nervous system hemangioblastoma (CNS Hb). Data collected included demographics, impact of most recent surgery on aspects of their condition (1-7 scale 1: greatly worsened and 7: greatly improved), feelings before/after their most recent surgery (1-5 scale, 1: completely disagree, 5: completely agree with presented statements), and treatment preference questions.

Results: Data collected from 220 pts (68% female, median age 40 years, median disease duration 16 years) in US (n=108), CA (n=37), UK (n=21), FR (n=3), and DE (n=51). 146 pts reported RCC (66%), 122 pNET (56%), and 190 CNS-Hb (86%). 205 (93%) pts had experienced surgery; 171 (78%) had experienced multiple surgeries (median = 4). Top three concomitant self-reported conditions were anxiety (36%), depression (29%) and high blood pressure (28%). 24% of pts consulted a mental health specialist. 51% of pts indicated that their most recent surgery worsened their mental health (rated 1-3), 84% of pts agreed they felt anxious before their most recent surgery (rated 4-5). After their most recent surgery 50% of pts agreed they felt anxious. 33% of pts indicated improving quality of life was in their top 3 treatment goals; 17% indicated improving mental wellbeing was in their top 3 treatment goals. 73% of patients indicated they would prefer to take a pill which would possibly delay time until surgery, rather than watch and wait to see if the tumor would grow.

Conclusions: Pts with VHL-associated disease report anxiety and depression as the most common mental health conditions, and agree that upcoming surgery worsens their anxiety. Over half of pts reported that their most recent surgery worsened their mental health. Despite this, less than a quarter of pts consulted a mental health specialist.

84P Microenvironment immune differences between sexes in multiple myeloma

M.D.L.A. Clavo[1], K. Paez[2], U. Infante[3], L. Rodrigo[3], Z.D. Morante Cruz[4], J. Pinto[5]

[1]Facultad de Medicina Humana, San Luis Gonzaga University, Ica, Peru; [2]Escuela Profesional de Medicina Humana-Filial Ica, Universidad Privada San Juan Bautista, Lima, Peru; [3]Facultad de Ciencias Biológicas, San Luis Gonzaga University, Ica, Peru; [4]Medical Oncology Dept., INEN - Instituto Nacional de Enfermedades Neoplasicas, Lima, Peru; [5]Unit of Basic and Translational Research, Auna Ideas, Lima, Peru

Background: Several studies showed that sex is a biological variable that influence immune response in several types of solid tumors; however, there is scarce information in hematological malignancies. In this work, we evaluate differences in immune cells compositions and immune response of multiple myeloma between sexes.

Methods: We conducted a computational biology study using transcriptomic data obtained from bone marrow aspiration collected from untreated multiple myeloma patients under the MMRF-COMMPASS protocol (study accession phs000748). Data was pre-processed and the expression levels were normalized to TPM (transcript per million). To evaluate differences in immune cells compositions, we quantified the immune cell in the tumor microenvironment with the analytic platform CIBERSORT. Differences in activated immune pathways was evaluated with the gene set enrichment analysis (GSEA). Pre-processed counts were normalized to TMM (trimmed mean of M-values) and GSEA was performed using the GSEA java desktop application (v4.3.2). In both analysis, patterns of immune gene sets and the immune cell composition were compared between tumors from female vs. male patients. A $p<0.05$ and a FDR<25% were considered statistically significant for GSEA analysis, while a $p<0.05$ and a FDR<0.05 6.1x10-5 was considered statistically significant for CIBERSORT analysis.

Results: Overall, 451 males and 313 female patients were included. We detected in samples from female patients an enrichment of dendritic cells activated (p=0.0023, FDR=0,0257) and NK cells activated (p=0.0059, FDR=0,0326). In contrast, we observed in male patients an enrichment of monocytes (p=6.10x 10^{-5}, FDR=0,0013) and macrophages M1(p=0,0050, FDR=0,0326). The GSEA analysis revealed an overregulation of natural killer cell degranulation (p=0.007, FDR=0.21624), positive regulation of type I interferon mediated signaling pathway (p<0.0001, FDR=0.23946), and regulation of natural killer cell proliferation (p=0.01, FDR=0.2495).

Conclusions: The computational analysis showed some differences in the immune microenvironment, between sexes in multiple myeloma. Studies about the influence of these differences in the clinical outcomes of patients should be evaluated.

85P In silico evaluation of the transcriptomic and immunologic profile of lung adenocarcinomas with deletions or disruptive mutations of SMARCA4

E. Garcia Lorenzo[1], C. Nieto-Jimenez[2], C. Diaz-Tejeiro[2], B. Doger de Spéville[1], I. Moreno[3], M. Pedregal[1], L. Paniagua Herranz[2], A. Sanvicente[2], B. Gyorffy[4], V. Moreno Garcia[1], E. Calvo[3], A. Ocana Fernandez[2]

[1]Dept. Early Clinical Drug Development, START Madrid-FJD, Hospital Universitario Fundación Jiménez Díaz, Madrid, Spain; [2]Experimental Therapeutics Unit, Medical Oncology Department, Hospital Clinico Universitario San Carlos, Madrid, Spain; [3]Dept. Early Clinical Drug Development, START Madrid-CIOCC, Centro Integral Oncológico Clara Campal, Madrid, Spain; [4]Institute of Enzymology, Research Centre for Natural Sciences, Budapest, Hungary

Background: Characterization of the immune microenvironment is key. In tumors with wide presence of genomic alterations like non-small cell lung cancer (NSCLC) the evaluation of the immune profile can help to better select treatment options. In this study we explored the transcriptomic landscape of lung adenocarcinoma tumors (LUAD) with genomic alterations at SMARCA4.

Methods: Data from TCGA was downloaded to evaluate the expression of transcripts up or down regulated when deletions or disruptive mutations of SMARCA4 were present in LUAD. Median values were used and genes with fold change (FC) > than 2.5 were selected. Gene set enrichment analysis was performed with Enricher. TIMER platform was employed to investigate the association with immune cell populations.

Results: Of the 507 evaluated patients, disruptive mutations were present in 43 and gene deletions in 5. Molecular/biological functions enriched within the upregulated genes in tumors with SMACA4 deletions included: ncRNA 3'-end processing (GO:0043628) or ketosteroid monooxygenase activity (GO:0047086), among others; involving representative genes like CT45A10; SAGE1; CT45A3; CT45A5; CT45A1, AKR1C1; AKR1C2, CBR1 or CBR3. In tumors with no deletion the most represented molecular/biological functions included the antigen processing and presentation of lipid antigen via MHC class Ib (GO:0048003) with relevant genes as: CD1E; CD1C; CD1B; CD1A; CX3CR1; P2RY12, among others. Presence of CD1A, CD1B, CD1C, CD1E in tumors with no SMARCA4 genomic alterations strongly associated with the presence of dendritic cells (DC) (Corr Rho 0.41, 0.48, 0.44 and 0.45, respectively) and dendritic resting cells (DRC) (Corr Rho 0.75, 0.70, 0.71 and 0.72, respectively). A direct comparison between SMARC4 deletions and DC and DRC, showed a clear negative correlation (Corr Rho -0.5, -4,3, respectively). Similar findings were observed with SMARC4 mutations (DC Corr -0.69, DRC Corr -0.91).

Conclusions: SMARCA4 deletions in LUAD tumors associated with loss of antigen presenting genes including CD1E; CD1C; CD1B; CD1A that are present in myeloid dendritic cells. We hypothesized that loss of antigen presentation functions can be present in LUAD with genomic alterations of SMARCA4.

86P Effect of chemotherapy-induced autophagic secretome on natural killer cell activity

A. Karlitepe[1], E. Celik[2], T. Sütlü[2], T. Süzek[3], M.K. Kilic Eren[1]

[1]Medical Biology, Aydin Adnan Menderes University Faculty of Medicine, Aydin, Turkey; [2]Molecular Biology and Genetics, Bogazici University, Istanbul, Turkey; [3]Computer Engineering, Mugla Sitki Kocman University Faculty of Engineering, Mugla, Turkey

Background: Autophagy achieves a tumor-suppressing function in the initial stages of cancer by eliminating protein aggregates and damaged organelles that might promote genomic instability and lead to tumor formation. Autophagy induced by hypoxia or metabolic stress also plays an important role in the regulation of inflammatory pathways. In cancer cells, this may lead to secretion of pro- and/ or anti-inflammatory cytokines and chemokines which may help the immune escape of the tumor. However, the underlying mechanism of autophagy-mediated modulation of anti-tumor immune response is not yet fully understood. Our aim is to investigate whether chemotherapy-induced autophagy-associated secretome has the potential to modulate the NK cell-mediated anti-tumor immune responses.

Methods: Initially, western blot and immunostaining analyses were performed for autophagy markers (LC3I/II and p62) to demonstrate that Etoposide (Eto) induces autophagy in MCF-7 cells. LC/MS-MS analysis was performed to determine the content of chemotherapy-induced autophagic secretome in supernatants of autophagy-induced MCF-7 cell cultures. Finally, how the chemotherapy-induced autophagic secretome effects the capacity of DNAM1-NK-92 cells to target MCF-7 cells was determined by degranulation assays.

Results: We demonstrated Etoposide (Eto) induces autophagy in MCF-7 cells as confirmed by detection of autophagy markers including LC3I/II and p62 by WB and by immunostaining analysis. LC/MS-MS results revealed that, metabolic enzymes, tumor antigens, chaperones and metastasis-related proteins were secreted during etoposide induced autophagy which could be reduced by use of Chloroquin. When wildtype or DNAM1 overexpressing NK-92 cells were treated with autophagic secretomes, it was observed that there were differences in the capacity of targeting MCF-7 cells.

Conclusions: This study provides new insights in the field of chemo-immunotherapy by characterizing the chemotherapy-induced autophagic secretome and determining its possible effect on NK cells.

87P WIP1 phosphatase promotes etoposide induced autophagy in medulloblastoma and neuroblastoma

H. Pilevneli[1], A. Karlitepe[1], N. Kaygusuz[1], C. Ak[1], M. Kilic Eren[2]

[1]Medical Biology, Aydin Adnan Menderes University Faculty of Medicine, Aydin, Turkey; [2]Medical Faculty, Adnan Menderes University Training and Research Hospital, Aydin, Turkey

Background: Wip1/PPM1D is a serin/threonine phosphatase which is involved in timely termination of DNA damage response. Overexpression of Wip1 is commonly seen in human solid cancers including neuroblastoma and medulloblastoma that displays oncogenic features. Oncogenic Wip1 negatively regulates tumor suppressor responses such as apoptosis or senescence. Autophagy plays a tumor suppressor role by removing damaged organelles/proteins and limiting cell growth and genomic instability in cancer cells. The molecular mechanisms underlying autophagy's tumor-promoting activities are largely unknown Here, we investigated the role of oncogenic

Wip1 phospahates in regulation of autophagy in neuroblastoma and medulloblastoma.

Methods: D283-med and IMR32 cells are grown according to ATTC protocol. Autophagy was stimulated with etoposide and inhibited with chloroquine. GSK2830371 is used to target Wip1. Autophagy markers are tested with WB analysis and with confocal microscopy analysis of LC3 I/II puncta formation. Vacuolazion was measured by quinacrine staining. Wip1-Ulk1 interaction was investigated via co-IP and co-localization analysis. BrDU/PI and Annexin V/7AAD assays were used to examine the cell cycle and apoptosis, respectively.

Results: In neuroblastoma and medulloblastoma cells, oncogenic Wip1 promotes etoposid induced autophagy and improves cancer cell survival. Wip1 phosphatase interacts with and dephosphorylates Ulk1 during etoposide induced autophagy which is associated with elevated p53 levels. Suppression of Wip1 and/or autophagy prevents degredation of pro-apoptotic proteins thus results in promotion of apoptosis. Furthermore, inhibition of Wip1 and autophagy reduce cancer cells ability to colonize in vitro.

Conclusions: Oncogenic Wip1 play a key role in enhancing etoposide induced autophagy by dephosphorylating ULK1 and contributes to cancer cell survival. Wip1 mediated autophagy may be a promising therapeutic target for improvment of chemotherapy response.

88P PPM1D/WIP1 phosphatase mediates basal and genotoxic stress-induced autophagy via ULK-1 de-phosphorylation

C. Ak[1], A. Karlitepe[2], H. Pilevneli[2], N. Kaygusuz[1], M.K. Kilic Eren[3]

[1]Department of Medical Biology, Adnan Menderes University, Faculty of Medicine, Aydin, Turkey; [2]Department of Medical Biology, Adnan Menderes University, Medical School, Aydin, Turkey; [3]Medical School, Department of Medical Biology, Adnan Menderes University, Faculty of Medicine, Aydin, Turkey

Background: PPM1D/WIP1 is a Ser/Thr phosphatase activated upon genotoxic stress in a p53 dependent manner and involved in regulation of DNA damage response (DDR) . Wip1 is amplified and over expressed in common human cancers and thus exerts oncogenic functions. Oncogenic Wip1 negatively regulates cellular responses to chemotherpy such as apoptosis and senescence. Here, we aimed to investigate the role of oncogenic Wip1 in induction of basal autophagy and chemotherpy mediated autophagy in breast cancer cells.

Methods: Etoposide was used to induce autophagy and Chloroquin (CQ) for inhibition. GSK2830371 was used to inhibit Wip1. LC3I/II conversion P62 degradation, total and phosphorylated (Ulk1 p-Ser757) levels were by analysed WB. Wip1-Ulk1 interaction was demonstrated by co-IP analysis. LC3 puncta formation was analysed by and immunofluorescence staining. Apoptosis, cell cycle, and senescence were measured by AnnexinV/7AAD, BrdU/PI analysis and SAβ-gal staining, respectively Colony formation assay was used to assess cells ability to colonize.

Results: Utilizing Wip1 over expressing MCF-7 cells, here we showed that oncogenic Wip1 increased basal autophagy and mediated etoposide-induced autophagy as confirmed by accumulation of LC3-II, degradation of p62, and formation of LC3II puncta. Inhibition of Wip1 increased phosphorylation of Ulk1 from Ser757 both in basal and etoposide induced autophagy. Further, endogenous Wip1 co-precipitated with Wip1 during basal and etoposide induced autophagy. Inhibition of autophagy or Wip1 enhanced apoptosis in response to etoposide but not senescence.

Conclusions: In conclusion our data suggest that oncogenic Wip1 may increase basal autophagy to support the survival of cancer cells. In addition Wip1 dependent autophagy in response to chemotherpy agents may cause resistance to chemotherapy. Thus targeting of Wip1-Ulk1 may lead enhancement of the chemotherapy response as a promising therapetic strategy.

89P Cold atmospheric plasma-activated fluids as a potential new intravesical agent for the treatment of bladder cancer

M.F. Botelho[1], E. Tavares-da-Silva[2], E. Pereira[1], J. Craveiro[3], L. Fernandes[3], F. Caramelo[1], A.M. Abrantes[1], A.S. Pires[1], A. Figueiredo[4]

[1]Coimbra Institute for Clinical and Biomedical Research (iCBR), Area of Environment, Genetics and Oncobiology Research (CIMAGO), Institute of Biophysics, Faculty of Medicine; CIBB; CACC, Univ Coimbra, Coimbra, Portugal; [2]Dept. of Urology and Renal Transplantation, CHUC - Centro Hospitalar e Universitario de Coimbra - Hospital Geral, Coimbra, Portugal; [3]Coimbra Institute for Clinical and Biomedical Research (iCBR), Area of Environment, Genetics and Oncobiology Research (CIMAGO), Institute of Biophysics, Faculty of Medicine, Univ Coimbra, Coimbra, Portugal; [4]CHUC - Centro Hospitalar e Universitario de Coimbra - Hospital Geral, Coimbra, Portugal

Background: Cold atmospheric plasma (CAP) has been studied for cancer treatment. One of its forms, CAP activated liquids (CAPAL), may be an alternative to intravesical agents to treat bladder cancer (BC). The surgical bipolar resectoscope, when in use, is a source of thermal plasma (TP), which exerts effects on the surrounding sodium chloride solution for irrigation (NaCl 0.9%), transforming it into a TP activated liquid (TPAL), which is produced in very close contact with the bladder wall. To accelerate a possible introduction of plasma-activated liquid in the treatment of BC, we decided to compare the properties and biological effects of CAPAL and TPAL.

Methods: An electronic device was designed by our group to create CAP. TP was produced by a resectoscope. NaCl 0.9% was exposed to CAP or TP during short periods of time (30, 60, 120, 180 seconds) creating CAPAL or TPAL. The reactive oxygen and nitrogen species (RONS) activity was evaluated using the OxiSelect™ RONS Assay Kit in each activated liquid. BC cell lines, TCCSUP (grade IV) and HT-1376 (grade III), were incubated with CAPAL or TPAL. Metabolic activity was evaluated by MTT assay and protein content by SRB assay, 24h post-incubation.

Results: In comparison to non irradiated NaCl 0.9%, both CAPAL and TPAL, in all exposure times resulted in a significant rise in the activity of RONS. Regarding the biological activity of the activated liquids in the BC cell lines, both CAPAL and TPAL induced a decrease in cell metabolic activity and protein content in an exposure-time dependent manner. CAPAL induced a higher antitumor effect on the high-grade cell line (TCCSUP), while TPAL had a similar effect on both cell lines. Comparing the two activated liquids, CAPAL required longer exposure times to achieve the same effects observed with TPAL at lower exposure times.

Conclusions: This study shows that PAL can be a therapeutic agent for BC. Both TPAL and CAPAL showed similar biologics in BC cells. Currently, in clinical practice, TPAL is already in close contact with the bladder wall during surgery, however only briefly and diluted by irrigation. This work intends to get one step closer to demonstrate that CAPAL can be a safe and effective BC treatment.

90P Discovery of CMPD1 as a tumor-specific cytotoxic microtubule inhibitor

M. Takada[1], Y-C. Chen[2], J. Wang[1], H. Yamada[1], M. Yu[1], J. Sakakibara[1], H. Fujimoto[1], T. Nagashima[1], M. Ohtsuka[1], M. Takaku[3], A. Suzuki[2]

[1]General Surgery Department, Chiba University, School of Medicine, Chiba, Japan; [2]Oncology, University of Wisconsin Carbone Cancer Center, Madison, WI, USA; [3]Biological Sciences, University of North Dakota - School of Medicine and Health Sciences, Grand Forks, ND, USA

Background: Microtubule-targeting agents (MTAs) have been widely used as first- and second-line agents in various cancers for several decades. Furthermore, the value of MTAs is currently increasing due to their usefulness as combination drugs with immune checkpoint inhibitors. However, many development resources have been devoted to molecular-targeted agents, and the development of new MTAs has not progressed, leaving many patients struggling with the toxicity of existing MTAs. In other words, there is an urgent need to develop new microtubule inhibitors with high cancer-specificity.

Methods: Time-lapse images were taken every 2-3 minutes for 24-72 hours. Microtubules nucleated from GMPCPP-stabilized seeds were prepared and imaged using total internal reflection fluorescence (TIRF) microscopy (Ecklund KH et al. Nature Comm 2017). Tubulin polymerization activity, Trans-well migration assay were measured using the HTS-Tubulin Polymerization Assay Biochem Kit (Denver, CO, USA), CytoSelect 24-well cell invasion assay kits (Cell Biolabs). Orthotopic breast cancer model (MDA MB 231) and treatment - CMPD1 (i.p., 15 µg/mouse/inj, 10 times for 3 wks), Taxol (i.p., 5 mg/kg/inj, 10 times for 3 wks) were performed. Vascular invasion was identified by tumor cells within vessels in HE staining. RNAs Sequencing libraries

were prepared with the TruSeq stranded mRNA kit and sequenced on NovaSeq6000 at Macrogen Japan.

Results: CMPD1, a known inhibitor of MAP kinase-activated protein kinase 2(MK2), rapidly induces microtubule depolymerization in several cancer cell-lines, resulting in robust prometaphase arrest. CMPD1 levels alter the fate of cancer cells, either inducing mitotic slippage or resulting in mitotic defects. CMPD1 inhibits microtubule polymerization and specifically induces microtubule depolymerization at the plus end in in vitro assays; resulting in significant inhibition of tumor growth, cancer cell migration, and invasion in both in vitro and in vivo. Furthermore, clinically relevant low doses of CMPD1 induced severe and prolonged mitotic failure specifically in cancer cells, but not in non-transformed cells, with only modest effects on microtubules in vitro.

Conclusions: CMPD1 has the potential to serve as a cancer cell-selective MTA chemotherapeutic agent.

91P Erythroid precursor-differentiated myeloid cells promote pulmonary metastasis in hepatocellular carcinoma

W-H. Zhu

Third Affiliated Hospital, Sun Yat-Sen University, Guangzhou, China

Background: Pulmonary metastasis is the most frequently occurring distant metastases of hepatocellular carcinoma (HCC). However, the indicated mechanism of pulmonary metastasis in HCC remains unclarified. Erythroid progenitor-differentiated myeloid cells (EDMCs) were reported to mediate immunosuppression and curtail anti-PD-1/PD-L1 treatment efficacy. The role of EDMCs in the metastasis of HCC and the development of pulmonary metastasis was investigated here.

Methods: The existence of EDMCs in the circulation and spleen of HCC mouse model were validated through Flow Cytometry. EDMCs were sorted using fluorescence-activated cell sorting. CFSE stained EDMCs transfer experiment were conducted to evaluated the Pulmonary metastasis promoting role in HCC mouse model. The transwell migration and invasion experiment of hepa1-6 cells (HCC cell line) cocultured with EDMCs were performed.

Results: Mouse with Pulmonary metastasis of HCC showed higher level of EDMCs in the circulation and spleen than those without Pulmonary metastasis. CFSE EDMCs stained with 5 , 6- carboxyfluorescein diacetate, succinimidyl ester (CFSE) were detected in the lung of HCC mouse after infusion though caudal vein and those infused mice developed more frequency of pulmonary metastasis than those without EDMCs infusion. IN the coculture experiment EDMCs promoted the migration and invasion of hepa1-6 cells.

Conclusions: EDMCs existed in the circulation of HCC mouse model. EDMCs could migrated from the circulation to the lung of HCC mice. EDMCs could facilitate migration and invasion of hepa1-6 cells migrate and invade. Thus, EDMCs can promote Pulmonary metastasis in Hepatocellular Carcinoma.

92P Discovery of novel AXL and MER inhibitors as potential anticancer and immune modulator drugs

H-P. Hsieh[1], M-C. Li[1], W-C. Yen[1], J.T-A. Hsu[1], T-K. Yeh[1], W-S. Li[2], H-C. Wu[3]

[1]Institute of Biotechnology and Pharmaceutical Research, National Health Research Institutes, Miaoli, Taiwan; [2]Institute of Chemistry/Biomedical Translation Research Center, Academia Sinica, Taipei, Taiwan; [3]Institute of Cellular and Organismic Biology/ Biomedical Translation Research Center, Academia Sinica, Taipei, Taiwan

Background: In cancer progression, abnormal expression of AXL could lead to tumor growth and metastasis and resistance to chemotherapy, while MER could identify apoptotic cancer cells and induce immune suppression in the tumor microenvironment. Combination of AXL and MER inhibitors could generate a synergistic effect, enhancing antitumor responses, and further suppressing resistance formed by monotherapy with AXL selective or MER selective inhibitors. According to the explicit function of AXL and MER, the development of dual AXL and MER inhibitors may provide tremendous advantages to cancer patients.

Methods: Based on our experience in the discovery of an anti-EGFR and anti-HER2 clinical candidate, we introduced several AXL-active and MER-active pharmacophores into DBPR112. We also modified the scaffold and the solubilizing groups to improve the drug-like properties. We have constructed a comprehensive SAR study to discover promising AXL and MER inhibitors.

Results: Upon synthesizing about 200 compounds, we identified several potent dual AXL and MER inhibitors. These compounds were evaluated for their anti-AXL and anti-MER activities, as well as their anti-tumor abilities. Our candidate 5K230 exhibited satisfied oral bioavailability (F% = 55%) and promising in vivo antitumor effects in several mouse xenograft models, including MDA-MB-231, 4T1, MC-38 tumors. Our compound also overcome erlotinib-acquired resistance via the combination with erlotinib in the PC9 xenograft model.

Conclusions: We have described the discovery of potential AXL and MER inhibitors, in which we identified potential candidate 5K230 which showed potent anti-AXL and anti-MER activities. Moreover, 5K230 displayed anti-tumor efficacy in several mouse xenograft models. Further preclinical evaluation of 5K230 is underway to develop it as a promising anticancer and immune modulator drug.

93P Transcriptome changes of immune cells across chemotherapy of triple-negative breast cancer

T.S. Gerashchenko[1], A. Frolova[2], A.A. Fedorov[1], M. Patysheva[1], M. Vashisth[3], P. Iamshchikov[1], O. Bragina[4], N. Cherdyntseva[2]

[1]Laboratory of Cancer Progression Biology, Cancer Research Institute, Tomsk National Research Medical Center of the Russian Academy of Sciences, Tomsk, Russian Federation; [2]Laboratory of Molecular Oncology and Immunology, Cancer Research Institute, Tomsk National Research Medical Center of the Russian Academy of Sciences, Tomsk, Russian Federation; [3]Psychology, National Research Tomsk State University, Tomsk, Russian Federation; [4]Department of Radionuclide Therapy and Diagnostics, Cancer Research Institute, Tomsk National Research Medical Center of the Russian Academy of Sciences, Tomsk, Russian Federation

Background: Immune system plays an important role in the development, treatment response, and progression of triple-negative breast cancer. Here, we aimed to assess the dynamics of cell populations and their transcriptome changes during neoadjuvant chemotherapy (NACT) in triple-negative breast cancer patients.

Methods: Mononuclear cells were purified from peripheral venous blood before NACT, after 3rd and 21st days of NACT using a ficoll density gradient. Total cell concentration and viability (Calcein/DRAQ7) were assessed by flow cytometry (Cytoflex, Beckman Coulter). Single cells were sequenced on a NextSeq 2000 (Illumina) using targeted panel Immune Response from Rhapsody Express (Becton Dickinson). Data were analyzed using Seurat and SingleR.

Results: According to single cell sequencing data we revealed 10 main populations of mononuclear leukocytes: B cells (*CD79+*), NK cells (*KIR2DL+*), classical (*CD14+*) and non-classical (*CD16+*) monocytes, T-cytotoxic cells (*CD8+*), T-helpers (*CD4+*), T-regs (*FOXP3+*), CD4 memory cells (*CD4+*, *IL32+*, *KLRB+*, *RGS1+*), CD8 naïve (*CD8+*, *LEF1+*, *CCR7+*, *PIK3IP1+*), CD4 naïve (*CD4+*, *LEF1+*, *CCR7+*, *PIK3IP1+*). 3 days after NACT overexpression of *BAX*, *FOSb*, *JUN*, *CXCR4*, *CD69* genes were observed, that mediating apoptosis of CD4 memory/naïve and CD8 naïve lymphocytes, T regs and monocytes; chemotaxis and proliferation of NK and T-cytotoxic lymphocytes. The population of blood monocytes was selectively depleted (up to 3%). 21 days after NACT overexpression of *CCR2*, *S100A9*, *ITGAM*, *CXCL8*, *CCL4*, *CCL5* genes were observed, mediating migration of monocytes to tissue, chemotaxis of immune cells and inflammation. The population of monocytes increased by up to 20%.

Conclusions: Chemotherapy affects the quantitative and qualitative composition of mononuclear leukocytes and changes their transcriptomic profile towards proinflammatory activation. This study was funded by the Russian Science Foundation (grant #22-75-10128).

ESMO GOOD SCIENCE BETTER MEDICINE BEST PRACTICE

ANNALS OF ONCOLOGY driving innovation in oncology

BILIARY TRACT CANCER, INCL. CHOLANGIOCARCINOMA

94MO Advanced extrahepatic cholangiocarcinoma: Post-hoc analysis of the ABC-01, -02 and -03 clinical trials

A. Lamarca[1], P.J. Ross[2], H.S. Wasan[3], R. Hubner[4], M.G. McNamara[4], A. Lopes[5], D. Palmer[6], J.W. Valle[5], J.A. Bridgewater[7]

[1]Medical Oncology Department, Hospital Universitario Fundacion Jimenez Diaz, Madrid, Spain; [2]Medical Oncology Department, Guy's Hospital, London, UK; [3]Oncology Department, Hammersmith Hospital - Imperial College Healthcare NHS Trust, London, UK; [4]Medical Oncology Department, The Christie NHS Foundation Trust, Manchester, UK; [5]Medical Oncology, CRUK & UCL Cancer Trials Centre, London, UK; [6]Liverpool Clinical Trials Centre, University of Liverpool - Imaging Centre at Liverpool, ICaL (formerly NiCaL), Liverpool, UK; [7]Medical Oncology, UCL Cancer Institute - Paul O'Gorman Building, London, UK

Background: Prior data suggest that patients with iCCA have a better prognosis compared to other biliary tract tumours (BTC) (Lamarca et al, JNCI 2019). However, the outcome for eCCA is not well described and some of the current studies focused on this patient population may be challenging to contextualise.

Methods: The aim of this post-hoc analysis is to provide reference survival data for patients with advanced eCCA treated with first-line cisplatin-gemcitabine (CisGem) chemotherapy within the prospective, randomised Advanced Biliary tract Cancer (ABC)-01, -02 and -03 studies. Individual level data from patients with eCCA recruited to these studies were retrieved.Survival analysis was performed using univariate and multivariable Cox Regression. All statistical tests were two-sided.

Results: Of 534 patients recruited into the ABC-01, -02 and -03 studies,179 (33.5%) had eCCA (107 distal (dCCA), 72 hilar (hCCA)). Of these, 117 were treated with CisGem and eligible for analysis. Most patients (n=82; 70.1%) had metastatic disease at the time of recruitment. Objective radiological response was achieved in 28 (23.9%) of eCCA: 19 dCCA (27.9%) and 9 (18.4%) hCCA. The median progression-free survival (PFS) for eCCA, dCCA and hCCA were 8.4 (95% CI 7.36-9.33), 8.3 (95% CI 6.3-9.4) and 8.4 months (6.5-10.6), respectively; median overall survival (OS): 12.8 months (95%CI 10.4-16.1), 14.3 (95% CI 8.8-17.4) and 12.2 (95% CI 8.3-16.1), respectively. eCCA with locally advanced disease had longer median PFS (13.1 (95% CI 8.8-16.6) and OS (17.4 (95% CI 14.3-21.1) . Multivariable survival analysis for OS confirmed worse OS for eCCA with performance status of 2 (vs 0; HR 45.877 (95% CI 9.55-219.45)) and high baseline CA125 (HR 1.0007 (95% CI 1.0001-1.001; p-value 0.017) when adjusted for other prognostic factors identified in the univariate analysis (stage, Ca 19.9). These remained significant when adjusted for site of eCCA (data not shown).

Conclusions: Patient outcomes were similar regardless of location of eCCA but worse than those reported historically for iCCA (specifically OS). Performance status and baseline tumour markers (CA125) were strongly associated with survival in eCCA. Outcomes with first-line CisGem + immunotherapy should also be explored.

Clinical trial identification: NCT00262769; NCT00939848.

Legal entity responsible for the study: University College London (UCL).

Funding: This post-hoc analysis did not receive any external funding.The ABC-1, -02 and -03 clinical trials received funding from Cancer Research United Kingdom (CRUK) and unrestricted educational grants from Lilly Oncology and AstraZeneca Pharmaceuticals.

Background: FGFR inhibitors (FGFRi) have a proven role for the management of FGFR-altered cholangiocarcinoma (CCA) after chemotherapy. However, disease progression occurs in 6-8 months. Secondary polyclonal mutations in the FGFR2 kinase domain represent a prominent acquired resistance mechanism. Tinengotinib was identified as a novel FGFRi with high potency to a variety of FGFR2 kinase domain mutations and has shown promising clinical results in CCA pts who have progressed on prior FGFRi. Here, we present pooled data from three trials.

Methods: Pts received tinengotinib orally once daily for 28 days per cycle. Pooled analyses of treatment-related adverse events (TRAEs), overall response rate (ORR), disease control rate (DCR), and median progression-free survival (mPFS) in the stratified CCA population were performed.

Results: A total of 73 advanced CCA pts were enrolled between Dec 2019 - Mar 2023. Median age was 60 years (24-81), 60% were female, 100% pts had $\geq$ 1 prior therapy including 47% pts with prior FGFRi, 97% had stage IV disease at screening. TRAEs were reported in 63 (86.3%) pts. 28 (38.4%) were Grade (G) 1-2, 32 (43.8%) were G3, 3 (4.1%) were G4, no G5 was observed. The most common TRAEs ($\geq$20%) were hypertension (43.8%, G3 19.2%), stomatitis (32.9%, G3 4.1%), diarrhea (30.1%, G3 4.1%) and palmar-plantar erythrodysesthesia (24.7%, G3 2.7%). Among 58 evaluable pts, the ORR and DCR were 20.7% and 75.9%, respectively. In 29 pts with FGFR2 alteration who received prior FGFRi, the ORR and DCR were 34% and 89.7%, respectively. 21 pts who acquired resistance to prior FGFRi had ORR of 38.1%, DCR of 95.2% and mPFS of 6.90 months (95%CI, 4.90-9.20). 10 pts who developed FGFR2 kinase domain mutations (N549D/H/K/T, V564F/I/L, E565A/G/K) detected by liquid biopsy at baseline had ORR of 50%, DCR of 90% and mPFS of 7.03 months (95%CI, 0.95-11.86).

Conclusions: These pooled results suggest that tinengotinib has a manageable toxicity profile in CCA pts. Notable clinical benefit was noted with tinengotinib in FGFR-altered CCA pts with acquired resistance to prior FGFRi. A global phase III clinical trial is planned to further evaluate the efficacy and safety of tinengotinib for CCA with FGFRi resistance.

96P Comparing the outcome of doublet therapy (gemcitabine and cisplatin) with triplet therapy (gemcitabine and cisplatin, nab paclitaxel) in locally advanced or metastatic gall bladder cancer patients an open label randomised control trial

C. Khatri[1], R. Rattan[2], A. Narwariya[2], P.K. Das[2], J. Patowary[2]

[1]Medical Oncology Department, Charak Hospital and Research Centre Lucknow, Uttar Pradesh, India; [2]Medical Oncology Department, Indraprastha Apollo Hospital, New Delhi, India

Background: To compare the doublet gemcitabine and cisplatin which is a standard of care in locally advanced or metastatic gall bladder cancer to a triplet gemcitabine, cisplatin and nab paclitaxel regime which has shown promising results in a single arm phase II study.

Methods: A total of 60 patients with locally advanced or metastatic gall bladder cancer were randomized 30 in each arm after imaging [contrast enhanced CT scan of chest, abdomen, and pelvis / MRI abdomen and pelvis with CECT chest /whole-body PET CT scan] and biopsy. Arm A received two drugs gemcitabine 1000mg/m2 i.v and cisplatin 25mg/m2 i.v on Day1 and Day8 of 21-day cycle and arm B received three drugs gemcitabine, 1000 mg/m2 , cisplatin, 25 mg/m2 , and nab-paclitaxel, 125 mg/m2 , on days 1 and 8 of 21-day cycle. Evaluation was done post 3 and 6 cycles of chemotherapy. Then patients were followed up every 6 months for 2 years period for assessment of primary and secondary endpoints of the study.

Results: The combination of gemcitabine and cisplatin (arm A) showed an overall radiological response rate (complete response and partial response) of 13.3% while it was 61.9 % in patients who received gemcitabine, cisplatin, and nab-paclitaxel. This difference was statistically significant with a p-value of 0.004. The median progression-free survival for the patients who received gemcitabine and cisplatin was 4.5 months (95% CI, 4.0-4.9) vs 7.6 months (95% CI, 3.9-11.2) for the patients who were treated with gemcitabine, cisplatin, and nab-paclitaxel. This difference was statistically significant with a p-value of ≤ 0.05. The median overall survival for the doublet was 9.2 months (95% CI 2.6-15.7) vs not reached for the patients who were treated with gemcitabine, cisplatin, and nab-paclitaxel. There was no increase in grade 3 adverse events with the addition of nab-paclitaxel.

Conclusions: To conclude, our study showed that the triplet chemotherapy with gemcitabine and cisplatin and nab-paclitaxel was significantly better in terms of overall response rate, and median progression-free survival with a longer follow up needed to comment on median overall survival.

97P Neoadjuvant durvalumab plus gemcitabine and cisplatin (D+GemCis) versus gemcis alone for localized biliary tract cancer (BTC): Results of a randomized, multicenter, open-label, phase II trial (DEBATE)

C. Yoo[1], J.O. Park[2], K-P. Kim[1], J. Hyung[1], B-Y. Ryoo[1], J.Y. Hong[3], S.H. Shin[4], T.J. Song[5], D. Oh[5], W. Iee[6], B.J. Kwak[6], J.H. Lee[6], D.W. Hwang[6]

[1]Oncology, Asan Medical Center - University of Ulsan College of Medicine, Seoul, Republic of Korea; [2]Hematology/Oncology, Samsung Medical Center (SMC) - Sungkyunkwan University School of Medicine, Seoul, Republic of Korea; [3]Hematology/Oncology, Samsung Medical Center (SMC), Seoul, Republic of Korea; [4]Surgery, Samsung Medical Center (SMC), Seoul, Republic of Korea; [5]Gastroenterology, Asan Medical Center - University of Ulsan, Seoul, Republic of Korea; [6]Surgery, Asan Medical Center - University of Ulsan, Seoul, Republic of Korea

Background: D+GemCis demonstrated significantly improved efficacy in patients (pts) with advanced/metastatic BTC compared to GemCis alone. However, the efficacy of D+GemCis in the neoadjuvant setting has not been studied.

Methods: This was a multicenter, open-label, non-comparative, randomized phase 2 trial including treatment-naïve pts with histologically or cytologically confirmed localized BTC. Pts were randomly assigned (2:1) to receive either 4 cycles of neoadjuvant D+GemCis or GemCis alone. Postoperative 6 cycles of D were given if pts underwent surgery regardless of assigned neoadjuvant therapy. The primary endpoint was R0 resection rate. ctDNA analysis was performed using GuardantOmni platform.

Results: A total of 45 pts were enrolled (n=31 in the D+GemCis arm and 14 in the GemCis arm). Intrahepatic cholangiocarcinoma (n=18, 40%) was the most common primary tumor site and 69% (n=31) had clinical stage III. Response rates were 36% (n=11) in the D+GemCis arm and 7% (n=1) in the GemCis alone arm. In the D+GemCis and GemCis arms, surgical exploration was performed in 68% (n=21) vs 36% (n=5), curative-intent resection (R0+R1) in 61% (n=19) vs 36% (n=5), and R0 resection in 48% (n=15) vs 36% (n=5), respectively. Median PFS were 15.1 mo (95% CI, 4.5-25.8) in the D+GemCis arm and 3.6 mo (0-13.0) in the GemCis alone arm. Pts able to receive curative-intent surgery after study treatment had significantly better overall survival ($p<0.001$). No new safety signal for D+GemCis were identified. ctDNA analysis revealed that 5 pts (11%) had actionable genetic alterations including 4 with IDH1 R132C and 1 with ERBB2 amplification, and 2 pts (4%) were MSI-H.

Conclusions: Neoadjuvant D+GemCis resulted in a higher surgical resection rate in pts with localized BTC, and surgical resection was associated with better survival. ctDNA analysis was shown to be a feasible method for assessing actionable target gene alterations in early BTC.

Clinical trial identification: NCT04308174.

Background: At the TOPAZ-1 (NCT03875235) primary analysis, first-line treatment with durvalumab (D) + gemcitabine and cisplatin (GC) significantly improved overall survival (OS) and progression-free survival (PFS) v placebo (P) + GC; the regimen has been approved by multiple health authorities globally for advanced biliary tract

cancer (BTC).[1] Here, we present prespecified exploratory analyses in an extended cohort of TOPAZ-1 enrolled in China.

Methods: Participants (pts) with BTC were randomised 1:1 to D (1500 mg) or P every 3 weeks (Q3W) + GC (G 1000 mg/m^2 and C 25 mg/m^2 on Days 1 and 8 Q3W) for $\leq$8 cycles, followed by D (1500 mg) or P Q4W until disease progression, unacceptable toxicity or other discontinuation criteria. The primary endpoint was OS. Secondary endpoints included PFS, objective response rate (ORR) and safety. Results from the China cohort (data cut-off [DCO] 14 Oct 2022, 72.3% OS maturity) are compared with the global cohort (primary analysis; DCO 11 Aug 2021, 61.9% OS maturity)[1] and a pooled global + China cohort (China and pooled cohort analyses are exploratory).

Results: In the China cohort, 130 pts were randomised (65 to D + GC, 65 to P + GC; 5/130 were recruited to the global cohort and 125/130 to the extension). OS and PFS benefit with D + GC v P + GC in the China cohort (hazard ratio [HR], 0.78 and 0.79) were consistent with the global[1] and pooled cohorts (Table). OS rates at 12 and 18 months and ORR in the China cohort were numerically higher for D + GC v P + GC. D + GC was tolerable across cohorts.

Table: 98P

	China		Global[1]		Pooled, global + China	
	D + GC n=65	P + GC n=65	D + GC n=341	P + GC n=344	D + GC n=405	P + GC n=405
Median OS; 95% CI, months	9.1; 6.3 −13.7	9.2; 7.1 −10.2	12.8; 11.1 −14.0	11.5; 10.1 −12.5	12.6; 11.0 −13.6	10.9; 9.7 −11.9
OS HR; 95% CI	0.78; 0.51−1.18		0.80; 0.66−0.97		0.79; 0.67−0.94	
Median PFS; 95% CI, months	4.7; 3.1 −6.4	4.4; 3.1 −5.4	7.2; 6.7 −7.4	5.7; 5.6 −6.7	7.2; 6.4 −7.4	5.7; 5.4 −5.9
PFS HR; 95% CI	0.79; 0.52−1.19		0.75; 0.63−0.89		0.76; 0.65−0.89	
12-month OS, %	40.3	27.4	54.1	48.0	52.0	44.6
18-month OS, %	30.5	12.5	35.1	25.6	34.3	23.9
ORR, %	12.3	9.2	26.7	18.7[†]	24.4	17.1[‡]
Grade 3/4 TRAEs, %*	67.7	63.1	62.7	64.9	63.4	64.3
TRAEs leading to discontinuation, %*	16.9	7.7	8.9	11.4	10.2	10.7

*In safety analysis set. [†]Total n=343. [‡]Total n=404. AE, adverse event; TRAE, treatment-related AE

Conclusions: Consistent with the global cohort, D + GC demonstrated a clinically meaningful OS and PFS benefit compared with PBO + GC in pts enrolled in China. D + GC was tolerable and represents a potential new first-line standard of care regimen in China. References 1. Oh et al. *NEJM Evid* 2022.

Background: Patients with chemotherapy-responsive advanced biliary tract cancer (BTC) are usually observed post 6 months of gemcitabine-based therapy, though most progress within a short time-span and there is limited prospective evidence for maintenance strategies.

Methods: The study is an integrated phase II — III randomised clinical trial (Clinical Trial Registry of India number: CTRI/2017/10/010112) conducted at 2 centres in India. Eligible patients with advanced BTC who had responsive or stable disease status post 6 months of gemcitabine — based chemotherapy were randomly assigned (1:1) to either observation arm (O) or intervention arm (BEER), which was a combination of Bevacizumab 5 mg/m2 IV every 21 days plus erlotinib 100 mg once daily, . Both arms were continued till disease progression, significant toxicity or patients choice. The primary endpoint of the phase II component was progression free survival, measured from randomization into the trial.

Results: Between May 2021 and November 2022, 98 patients (O: 48; BEER: 50) comprising 78 patients with gallbladder cancer (GBC) and 20 patients with cholangiocarcinoma (CC) were randomised with all 98 patients included in the final analysis. With a median follow up of 11.2 months, patients in the BEER cohort showed an improved PFS compared to the observation cohort [5.2 months (95% CI: 3.4-6.9) vs. 3 months (95% CI: 2.5 - 3.5); p=0.004]. The CC cohort tended to derive greater benefit from BEER (6.7 months vs. 2.2 months) than the GBC cohort (4.3 months vs. 3 months). There were no grade 3 or grade 4 adverse events noted, though temporary cessation of erlotinib was required due to grade 2 skin rash in 7 patients (14%), and grade 2 oral stomatitis in 1 patient (2%).

Conclusions: The combination of bevacizumab and erlotinib improves progression free survival in patients with chemotherapy responsive advanced BTC in this phase 2 clinical trial. The ongoing phase III component of the study will evaluate whether the significant benefit in PFS translates to improvement in overall survival.

Inc., Rahway, NJ, USA; [18]Global Clinical Development, Merck & Co, Rahway, NJ, USA; [19]GI Cancer Center, Cancer Center of People's Liberation Army, Nanjing, China

Background: Pembro + gem/cis significantly improved OS versus placebo (pbo) + gem/cis as 1L therapy for unresectable or metastatic BTC in KEYNOTE-966 (NCT04003636). Pembro monotherapy had limited impact on underlying HBV infection in advanced HCC. The effect of chemoimmunotherapy on underlying HBV in pts with cancer is unknown. We characterized HBV-related outcomes in pts with HBV enrolled in KEYNOTE-966.

Methods: Pts were randomized 1:1 to pembro 200 mg or pbo Q3W for $\leq$35 cycles plus gem/cis. Pts with clinically resolved HBV infection (ie, HBsAg negative, anti-HBc positive, and HBV DNA $<$20 IU/mL) were eligible. Pts with chronic HBV infection (ie, HBsAg positive or HBV DNA $\geq$20 IU/mL) were eligible if antiviral therapy was started $\geq$4 wk before study therapy if HBV DNA was $>$100 IU/mL. HBV DNA and HBsAg were assessed every 6 wk in pts with undetectable HBV DNA at baseline (BL) not taking HBV therapy and every 12 wk in pts taking HBV therapy. Pts with HBV DNA $>$100 IU/mL were to start HBV treatment. Pts on HBV therapy at BL were to stay on same therapy throughout the study. HBV reactivation and HBV-associated hepatitis were defined per AASLD criteria.

Results: 164 (30.8%) of 533 pts in the pembro arm and 165 (30.8%) of 536 in the pbo arm had BL HBV infection, including 150 (28.1%) and 149 (27.8%) with clinically resolved and 14 (2.6%) and 16 (3.0%) with chronic HBV. In the pembro and pbo arms, 6.0% and 5.4% with clinically resolved and 100% and 93.8% with chronic HBV received antiviral drugs during the study. Among evaluable pts with clinically resolved HBV, 4 (3.1%) of 127 in the pembro arm and 1 (0.8%) of 128 in the pbo arm had HBV reactivation. Among evaluable pts with chronic HBV, 1 (11.1%) of 9 in the pembro arm and 2 (15.4%) of 13 in the pbo arm had HBV reactivation. All reactivation was detected by HBV DNA increase. No pts developed HBV-associated hepatitis.

Conclusions: The low incidence of HBV reactivation and lack of HBV-associated hepatitis in pts with clinically resolved or controlled chronic HBV on antiviral therapy suggest that with careful monitoring, pembro plus gem/cis is unlikely to affect underlying HBV in advanced BTC.

Clinical trial identification: NCT04003636, first posted July 1, 2019.

Background: In the pivotal HERIZON-BTC-01 study, the HER2 bispecific antibody zani demonstrated rapid, durable responses (confirmed objective response rate, 41% by independent central review; median duration of response, 12.9 mo; data cut-off: Oct 2022) and manageable safety in pts with HER2+ BTC. Here we report QoL outcomes for those pts with HER2+ BTC.

Methods: HERIZON-BTC-01 (NCT04466891), an ongoing open-label, global phase 2b study, evaluated zani (20 mg/kg IV every 2 wks) in pts with HER2+ (gene amplification with immunohistochemistry of 2+ or 3+), locally advanced, unresectable or metastatic BTC (gallbladder cancer, intra-/extra-hepatic cholangiocarcinoma) who received prior gemcitabine-containing treatment (tx). QoL, an exploratory endpoint, was assessed using the EQ-5D-5L descriptive system and visual analogue scale (VAS) at baseline (BL) and every 8 wks; best on-treatment score (BONT) was the lowest descriptive or highest VAS value observed post-BL.

Results: A total of 80 pts with HER2+ BTC were evaluated for primary efficacy analyses (median age, 64 years; 56% female). Of these, 1 (1%) had complete response (CR), 32 (40%) had partial response (PR), 22 (28%) had stable disease (SD) and 24 (30%) had progressive disease (PD); 1 pt was not evaluable. Pts with CR or PR reported the greatest improvement in QoL followed by those with SD, while pts with PD generally reported worsening QoL (Table). Median VAS scores improved by ≥10 points from BL to time of BONT for pts with CR and PR, by 5 points for pts with SD and worsened by 10 points for pts with PD. In each dimension, the proportion of pts reporting 'no problem' increased more from BL to BONT for pts with PR than for pts with SD or PD.

Table: 101P EQ-5D-5L QoL outcomes in pts with HER2+ BTC by tumour response

	Confirmed Best Overall Tumour Response							
	CR		PR		SD		PD	
	BL n=1	BONT n=1	BL n=31	BONT n=32	BL n=21	BONT n=22	BL n=24	BONT n=19
Median VAS score	40	80	80	95	80	88	80	70
Median VAS change from BL[a]		40		10		5		-10
Least severe response level (no problem), n (%)								
Mobility	0	0	23 (74)	30 (94)	16 (76)	19 (86)	15 (63)	12 (63)
Self-care	0	0	28 (90)	31 (97)	18 (86)	19 (86)	23 (96)	16 (84)
Usual activities	0	0	23 (74)	29 (91)	11 (52)	15 (68)	16 (67)	10 (53)
Pain/discomfort	0	1 (100)	15 (48)	28 (88)	10 (48)	13 (59)	10 (42)	7 (37)
Anxitey/ depression	0	0	18 (58)	28 (88)	12 (57)	14 (64)	13 (54)	14 (74)

[a]Out of pts with a BL and ≥1 post-BL score

Conclusions: In HERIZON-BTC-01, pts with HER2+ BTC who responded to zani reported improved QoL compared with BL, while those with PD reported worsening QoL compared with BL. These results support the continuing development of zani as a HER2+ BTC tx option.

Clinical trial identification: NCT04466891, first posted July 10, 2020.

Background: In TOPAZ-1 (NCT03875235), durvalumab (D) + gemcitabine and cisplatin (GC) improved overall survival (OS) vs placebo (PBO) + GC in participants with advanced biliary tract cancer (aBTC; primary analysis: hazard ratio [HR] 0.80, 95% confidence interval [CI] 0.66–0.97, p=0.021 [significance threshold p=0.03]) and after a further 6.5 months of follow-up (HR 0.76, 95% CI 0.64–0.91). This exploratory analysis assessed baseline clinical factors for potential prognostic (associated with OS) or predictive (of OS benefit with D + GC) value in TOPAZ-1.

Methods: Potentially prognostic factors were evaluated using Cox proportional hazards models with treatment and each factor. An exploratory adjusted HR for D + GC vs PBO + GC was estimated with a model adjusting for prognostic factors identified by stepwise selection. Unstratified Cox proportional hazards models and interaction tests were performed to assess potential predictive factors. Data cut-off was 25 February 2022.

Results: Potentially prognostic clinical factors are shown (Table). The HR for D + GC vs PBO + GC, adjusted for disease status, primary tumour location, sex, PD-L1, neutrophil to lymphocyte ratio (NLR), cancer antigen 19-9 (CA19-9), carcinoembryonic antigen (CEA), liver metastasis, liver involvement (locally advanced or metastatic site in liver/gallbladder), body weight, LDH, albumin and total bilirubin, was 0.70 (95% CI 0.59–0.84). OS HRs for D + GC vs PBO + GC were <1 across assessed clinical (Table) and laboratory factors; no predictive factors for D + GC were found.

Table: 102P

		Predictive		Prognostic	
Factor	**Subgroup**	**HR (95% CI), D + GC v PBO + GC**	**Interaction p**	**HR (95% CI), top v bottom subgroup**	**p**
Disease status	IU	.79 (.65–.95)	.93	2.14 (1.69–2.76)	<.01
	R	.76 (.49–1.20)			
ECOG PS	0	.87 (.68–1.12)	.14	1.29 (1.09–1.53)	<.01
	1	.70 (.55–.89)			
Disease classification	LA	.54 (.32–.88)	.13	1.35 (1.05–1.76)	.02
	M	.80 (.67–.97)			
NLR	<3	.75 (.56–1.01)	.83	2.14 (1.79–2.58)	<.01
	≥3	.76 (.61–.94)			
CA19-9	<500 U/mL	.72 (.57–.92)	.53	2.08 (1.73–2.50)	<.01
	≥500 U/mL	.82 (.62–1.08)			
CEA	<5 ng/mL	.75 (.58–.97)	.75	1.78 (1.49–2.14)	<.01
	≥5 ng/mL	.81 (.63–1.05)			
Liver metastasis	Y	.83 (.66–1.06)	.32	1.37 (1.56–1.63)	<.01
	N	.69 (.54–.88)			
Liver involvement	Y	.76 (.63–.91)	.76	1.67 (1.32–2.14)	<.01
	N	.77 (.49–1.20)			

IU, initially unresectable; LA, locally advanced; M, metastatic; R, recurrent

Conclusions: Benefit with D + GC was consistent across assessed factors and stable after adjusting for potentially prognostic factors, supporting D + GC as first-line treatment for aBTC.

Clinical trial identification: NCT03875235.

103P Individual patient data (IPD) meta-analysis of randomised trials to compare efficacy of second-line fluoropyrimidine-based chemotherapy in advanced biliary tract cancer (BTC)

J. Hyung[1], M. Kang[2], I. Kim[3], K-P. Kim[1], B-Y. Ryoo[1], J. Cheon[4], H. Ryu[5], J.S. Lee[6], G.K. Abou-Alfa[7], J-W. Kim[2], I. Choi[8], J.H. Park[8], J.W. Kim[2], C. Yoo[1]

[1]Oncology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Republic of Korea; [2]Internal Medicine, Seoul National University Bundang Hospital, Seongnam, Republic of Korea; [3]Internal Medicine, Inje University Haeundae Paik Hospital, Busan, Republic of Korea; [4]Internal Medicine, Ulsan University Hospital, University of Ulsan College of Medicine, Ulsan, Republic of Korea; [5]Internal Medicine, Chungnam National University Hospital, Daejeon, Republic of Korea; [6]Clinical Epidemiology and Biostatistics, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Republic of Korea; [7]Medicine, Memorial Sloan Kettering Cancer Center, New York, NY, USA; [8]Internal Medicine, Seoul Metropolitan Government Seoul National University Boramae Medical Center, Seoul, Republic of Korea

Background: For patients (pts) with advanced BTC with progression on gemcitabine plus cisplatin (GemCis), fluoropyrimidine-based chemotherapy, including liposomal irinotecan (nal-IRI) plus fluorouracil and leucovorin (5-FU/LV) and 5-FU/LV plus oxaliplatin (FOLFOX) showed clinical benefit in prior randomized trials (NIFTY and ABC-06). However, there is no trial for head-to-head comparison among these agents.

Methods: We performed IPD meta-analysis of two multicenter, randomized trials performed in South Korea, which compared efficacy of second-line chemotherapy for advanced BTC after progression on GemCis, including the phase 2b NIFTY trial (nal-IRI plus 5-FU/LV vs. 5-FU/LV, NCT03524508) and the phase 2 FIReFOX trial (modified FOLFOX [mFOLFOX] vs. modified 5-FU/LV plus irinotecan [mFOLFIRI], NCT03464968). ITT population of the two trials were included and survival outcomes were compared between the 4 treatment groups by pairwise log-rank test. Hazards ratio (HR) adjusted by potential prognostic variables was estimated by Cox proportional hazards modeling with shared frailty to account for the trials effect.

Results: A total of 278 pts were included in this analysis (178 pts from the NIFTY trial and 99 pts from the FIReFOX trial). The nal-IRI plus 5-FU/LV group (n=88) showed

significantly better overall survival compared to the mFOLFOX group (n=49, p = 0.02), mFOLFIRI group (n=50, p = 0.03), and 5-FU/LV group (n=90, p = 0.008). Multivariable analysis showed consistent trends with adjusted HR of 1.44 (95% CI 0.93-2.07, p = 0.11), 1.36 (95% CI 0.92-2.03, p = 0.13), and 1.52 (95% CI 1.37-1.09-2.10, p = 0.01), respectively. Also, nal-IRI plus 5-FU/LV group showed trends toward better progression-free survival compared to the other 3 groups with adjusted HR of 1.44 (95% CI 0.98-2.11, p = 0.06), 1.29 (95% CI 0.87-1.89, p = 0.20), and 1.88 (1.38-2.55, p < 0.001), respectively.

Conclusions: Nal-IRI plus 5-FU/LV showed better survival outcomes when compared to mFOLFOX, mFOLFIRI, or 5-FU/LV alone. Nal-IRI plus 5-FU/LV may be a preferable second-line regimen for advanced BTC pts without targetable genetic alterations.

[1]Department of Oncology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Republic of Korea; [2]Department of Surgery, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Republic of Korea; [3]Internal Medicine Department, The Catholic University of Korea - Seoul St. Mary's Hospital - Catholic Medical Center, Seoul, Republic of Korea; [4]Medical Oncology, Bundang Cha Medical Center, Seongnam, Republic of Korea; [5]Department of Radiation Oncology, Asan Medical Center - University of Ulsan, Seoul, Republic of Korea; [6]Department of Clinical Research Center, Asan Medical Center - University of Ulsan, Seoul, Republic of Korea

Background: The primary analysis of the STAMP trial demonstrated that adjuvant GemCis did not improve disease-free survival (DFS) compared to CAP in patients (pts) with resected, lymph node (LN)-positive extrahepatic CCA. As overall survival (OS) data were not matured at primary analysis, we report the updated analysis with an additional 19 months (mo) of follow-up.

Methods: Pts with adenocarcinoma of perihilar/distal bile duct with regional LN metastasis who underwent curative-intent surgery was randomized to receive GemCis (Gem 1000 mg/m2, Cis 25 mg/m2 on days 1, 8) or CAP (1250 mg/m2 twice daily on days 1—14) every 3 weeks for 8 cycles. Primary endpoint was DFS. Secondary endpoints were OS and safety. All P values were one-sided and considered significant if < 0.1.

Results: A total of 101 pts (50 in the GemCis and 51 in the CAP group) were included in the intention-to-treat population. The median follow-up duration was 52.8 mo (one-sided 90% CI, 50.1-58.2). In the GemCis and CAP groups, the median DFS was 14.6 mo (10.7-16.5) and 11.1 mo (8.4-12.7), respectively, and the 4-year DFS rates were 15.9% (9.4-24.0) and 19.4% (12.4-27.5) respectively (HR = 1.02 [0.76-1.37], P = 0.47). Median OS was 35.0 mo (29.5-42.7) and 32.3 mo (28.3-45.6), respectively, and the 4-year OS rates were 35.7% (26.5-45.1) and 38.4% (29.2-47.5), respectively (HR = 1.04 [0.75-1.44], P = 0.43). Subgroup analyses showed consistent results without significant interactions in the DFS and OS between groups, except that pts with R1 resection favored CAP in DFS and OS, and females favored GemCis in OS.

Table: 104P

	GemCis	CAP	HR (CI) and P-value
DFS events/pts	40/50	41/51	
Median DFS (months) (CI)	14.6 (10.7-16.5)	11.1 (8.4-12.7)	1.02 (0.76-1.37) P = 0.47
4Y DFS rates (%) (CI)	15.9 (9.4-24.0)	19.4 (12.4-27.5)	
Deaths/pts	33/50	33/51	
Median OS (months) (CI)	35.0 (29.5-42.7)	32.3 (28.3-45.6)	1.04 (0.75-1.44) P = 0.43
4Y OS rates (%) (CI)	35.7 (26.5-45.1)	38.4 (29.2-47.5)	

Conclusions: In this final analysis of the STAMP trial, adjuvant GemCis did not improve OS compared with CAP in LN-positive extrahepatic CCA. Biomarker analyses, including ctDNA-guided minimal residual disease (MRD), are currently underway.

Clinical trial identification: NCT03079427.

105P A phase II study of SHR-1316 plus IBI310 in patients with advanced intrahepatic cholangiocarcinoma after failure of first-line therapy

J. Fan[1], J. Zhou[1], G. SHI[1], X. Huang[1], X. Guo[1], J. Lu[1], F. Liang[2], Y. Chen[3], D. Wu[4], Y. Ji[5], Y. Hou[6], X. Meng[1], Z. Tang[1], X. Huang[1], Q. Ye[1], S. Qiu[1], Q. Gao[1], Y. Shi[1], H. Sun[1], H. Li[7]

[1]Department of Liver Surgery and Transplantation, Zhongshan Hospital, Fudan University, Shanghai, China; [2]Clinical Research Unit, Institute of Clinical Science, Zhongshan Hospital, Fudan University, Shanghai, China; [3]Liver Cancer Institute, Zhongshan Hospital, Fudan University, Shanghai, China; [4]Department of Radiology, Zhongshan Hospital, Fudan University, Shanghai, China; [5]Department of Pathology, Zhongshan Hospital, Fudan University, Shanghai, China; [6]Department of Pathology, Zhongshan Hospital, Fudan University, Shanghai, Changning, China; [7]Clinical Research & Development, Jiangsu Hengrui Pharmaceuticals Co., Ltd., Shanghai, China

Background: Advanced intrahepatic cholangiocarcinoma (iCCA) is highly invasive and holds high mortality due to limited therapeutic strategies after failure of first-line therapy. This study aimed to evaluate the efficacy and safety of anti-PD-L1 antibody SHR-1316 in combination with anti-CTLA-4 antibody IBI310 for patients (pts) with previously treated advanced iCCA.

Methods: The study was an ongoing open-label, single-arm, phase 2 trial. Unresectable, locally advanced or metastatic iCCA pts who had failed first or subsequent-line therapy were enrolled. A combination of SHR-1316 (IV 20mg/kg q3w) and IBI310 (IV 3mg/kg q3w) were administered for 4 cycles, followed by SHR-1316 monotherapy until disease progression, unacceptable toxicity, or a maximum of 2 years after enrollment. The primary endpoint was objective response rate (ORR). Secondary objectives included safety, overall survival (OS), progression-free survival (PFS), and disease control rate (DCR). Response was evaluated according to RECIST1.1. Adverse effects (AEs) were assessed according to CTCAE V5.0.

Results: Up to May 1, 2023, 39 pathologically confirmed advanced iCCA pts were enrolled. Median age was 59 years (range 28 to 74). Previous treatments included systemic chemotherapy (39 pts), anti-PD-1 antibody (21 pts), and tyrosine kinase inhibitors (26 pts). At date cut-off, the median follow-up was 6.1 months (95%CI, 0.2-18.7), 28 pts were alive, 18 pts remained on treatment. Of 25 evaluable pts, 2 pts achieved complete response and 3 had partial response. The confirmed ORR and DCR were 20.0% and 60.0%, respectively. Notably, the ORR for pts previously treated with anti-PD-1 antibody was 16.7% (2/13). Median PFS and OS was not reached yet. Grade 3 or higher AEs occurred in 16 pts (41.0%), most commonly jaundice (15.4%), rash (10.3%), ALT elevation (7.7%), anaphylaxis (7.7%), AST elevation (5.1%), diarrhea (5.1%) and dyspnea (5.1%).

Conclusions: The treatment of SHR-1316 combined with IBI310 was tolerable and showed promising antitumor activity in iCCA refractory to standard therapy. Further studies are required to identify predictive/prognostic biomarkers to improve selection of pts most likely to benefit from this treatment strategy.

Clinical trial identification: NCT04634058.

106P The impact of alterations in cancer driver genes and other potentially targetable mutations on progression and overall survival in patients with biliary tract cancer treated on the randomised phase III multicentre BILCAP clinical trial

V.E. Crolley[1], R. Guest[2], A.D. Beggs[3], E. Jaynes[4], S. Thorn[5], J. Herrero[1], I. Tomlinson[6], J.W. Valle[7], J.N. Primrose[8], J.A. Bridgewater[9]

[1]Cancer Institute, University College London, London, UK; [2]Clinical Surgery, University of Edinburgh, Edinburgh, UK; [3]Institute of Cancer & Genomic Science, The University of Birmingham - Medical School, Birmingham, UK; [4]Pathology, University Hospital Southampton NHS Foundation Trust, Southampton, UK; [5]Edinburgh Cancer Research Centre, University of Edinburgh, Edinburgh, UK; [6]Nuffield Department of Medicine, University of Oxford, Oxford, UK; [7]Medical Oncology Department, The Christie NHS Foundation Trust, Manchester, UK; [8]Hepaticopancreatobiliary Surgery, Southampton General Hospital, Southampton, UK; [9]UCL Cancer Institute, UCL Cancer Institute - Paul O'Gorman Building, London, UK

Background: The BILCAP clinical trial established adjuvant capecitabine as the current standard of care treatment after biliary tract cancer resection.

Methods: Translational work from this clinical trial involved collecting archived fixed formalin tissue from consented BILCAP patients and carrying out low-pass whole genome (lp-WGS), targeted gene (TGS) and RNA sequencing (RNAseq) for copy number (CN), mutation and gene-fusion analysis. In total, 98 patients underwent RNAseq, 95 of 98 underwent lp-WGS and 39 of 98 underwent TGS.

Results: 47 patients had intrahepatic cholangiocarcinoma, 47 patients had gallbladder cancer, 2 patients had perihilar cholangiocarcinoma, and 2 patients had distal cholangiocarcinoma. 62 (63.3%) patients were female, and 48 (49.0%) received adjuvant capecitabine. FGFR2 gene fusions were present in 24 patients (24.5%), as were fusions in NTRK1 (n=4, 4.1%), FGFR1 (n=4, 4.1%), FGFR3 (n=2, 2.0%) and FGFR4 (n=2, 2.0%). Known pathogenic mutations were seen in IDH1(n=4, 10.3%, total number of mutations=8, 20.5%), IDH2 (n=1, 2.6%, total n=6, 15.4%), and FGFR2 (n=1, 2.6%, total n=7, 17.9%). Commonly amplified (CN $\geq$ 4) genes included NTRK1 (n=28, 29.5%), ERBB2 (n=27, 28.4%) and MDM2 (n=20, 21.1%) with MYC (n=19, 20.0%), EGFR (n=16, 16.8%) and MET (n=15, 15.8%) also amplified. Nearly all the alterations investigated did not significantly affect recurrence risk (PFS) or overall survival (OS), including FGFR2 fusions (OS hazard ratio (HR) 1.11 p=0.762, PFS HR 1.10 p=0.763). However, the presence of amplified EGFR (CN $\geq$ 4) significantly decreased both OS (HR 5.40 p=0.01) and PFS (HR 3.44 p=0.04).

Conclusions: The BILCAP cohort shows a wide variety of driver and potentially targetable mutations in unselected biliary tract cancer patients, comparable to similar datasets. Of note, patients with EGFR amplification had significantly reduced OS and PFS. This indicates that EGFR amplification may be an important indicator in determining prognosis and could provide an attractive target for future targeted anti-cancer therapy in biliary tract cancer.

107P Comprehensive genomic profiling of "The German-registry of incidental gallbladder carcinoma" cases

N.B. Agaoglu, L. Kochen, D.W. Müller, D. Vortmeyer, T. Habibzada, S-E. Al-Batran, T.O. Goetze

Oncology Department, IKF - Institut für Klinische Krebsforschung GmbH, Frankfurt am Main, Germany

Background: Gallbladder cancer (GBC) is a biliary tract cancer with an aggressive progression and poor prognosis. Although high throughput sequencing revealed some driver variations in genes like *EGFR, TP53, SMAD4, ARID1A, PIK3CA, and CDKN2A/B,* there is no specific biomarker for GBC. Due to the low incidence rate, the studies are limited and generally covered under all biliary tract cancer (BTC) types. Here we present the clinical, histopathological, and molecular spectrum of a large series of patients from the German Registry of Incidental GBC.

Methods: A total of 1040 (793 female and 247 male) completely documented cases with a median age of diagnosis 70.79 (min:30-max:98) were enrolled in the study. The majority of tumors were diagnosed at pathological stage pT2 (60.6%), and distant metastasis was detected in 15.2% of cases. The patients presented a tumor grade of G2 or G3 with a ratio of 53% and 36%, respectively. Among the cohort, 116 cases were already analyzed by a targeted panel (FMI Heme Panel) which combines more than 400 DNA and 250 RNA-sequenced genes.

Results: In 91 of the cases, at least one pathogenic gene variation was detected. The median TMB was 4.67 (0—52.95) mutations/Mb, and in 6.5% of the cases, the total TMB was $\geq$ 10 mutations/Mb ("TMB-intermediate/high"). The tumor with the highest TMB (52.95 mutations/Mb) presented 12 pathogenic variants. *TP53* was the most commonly altered gene (59.34%), followed by *CDKN2A* (20.6%) amplifications. In 11.2% of the cases, likely functional fusions/rearrangements were also detected.

Conclusions: This study presents one of the largest isolated GBC cohorts, analyzed by a comprehensive targeted NGS panel with a precision oncology approach. These findings will provide insights into a rare but severe type of upper GI cancer. The analysis is currently ongoing, and a further 84 patients will be molecularly characterized till the meeting to be able to present complete molecular data of 200 patients.

108P FGFR2 fusions and their impact on efficacy of standard chemotherapy in patients with biliary tract cancer

B. Zheng-Lin[1], D. Walden[1], J. Larson[2], S. McDonnell[2], J. Frank[2], P. Raman[3], C. Eslinger[3], B. Ueberroth[3], F-S. Ou[2], N. Larson[2], M.B. Sonbol[1], C. Wu[3], N. Tran[4], H. Babiker[5], M. Borad[1], L. Roberts[6], D. Ahn[1], T. Bekaii-Saab[1]

[1]Department of Hematology and Oncology, Mayo Clinic, Phoenix, AZ, USA; [2]Department of Quantitative Health Sciences, Mayo Clinic, Rochester, NY, USA; [3]Department of Internal Medicine, Mayo Clinic, Phoenix, AZ, USA; [4]Department of Hematology and Oncology, Mayo Clinic, Rochester, NY, USA; [5]Department of Hematology and Oncology, Mayo Clinic, Jacksonville, FL, USA; [6]Department of Gastroenterology and Hepatology, Mayo Clinic - Rochester, NY, USA

Background: The incidence of biliary tract cancer (BTC) is increasing globally, while its survival remains dismal. *FGFR2* fusions offer a potential therapeutic option with oral inhibitors, although the optimal treatment sequence for these patients remains unclear.

Methods: We included patients from all three Mayo Clinic sites diagnosed with *FGFR2* fusion-positive (F2P) BTC and used patients with *FGFR2* fusion-negative (F2FN) BTC as historical controls. We estimated overall survival (OS) and progression-free survival (PFS) using Kaplan-Meier techniques.

Results: We identified 43 F2P and 155 F2FN patients with BTC. The most common gene fusion partner was *BICC1* (28%). *FGFR2* fusion was associated with age $\leq$65 years (74% vs 44%), female gender (72% vs 45%), intrahepatic BTC (95% vs 71%), and advanced stage at diagnosis (60% vs 11%). In advanced disease, 25 patients in the F2P group received first-line (1L) chemo of which 14 (56%) received gemcitabine/cisplatin (GC). In the F2FN group, 37 had 1L chemo, 16 (43%) with GC. The F2P group had significantly lower PFS compared to F2FN patients, respective median PFS were 5.4 (95% CI 3.8-9) vs 7.6 months (95% CI 4.6-13.3) (p=0.038). In the F2P group who received second-line (2L) therapy, PFS was longer with an FGFR inhibitor (8.2 months, 95% CI 7.2-NE) vs. chemo (5.5 months, 95% CI 4.8-19.3) (Table). The median OS was significantly higher in the F2P patient who never received an FGFR inhibitor (14.8 months, 95% CI 13.2-NE) vs F2FN group (9.6 months, 95% CI 5.52-22.9) (p=0.04).

Table: 108P Median PFS in F2FN and F2P groups based on 1L and 2L therapies

	FGFR2 Fusion Negative		*FGFR2* Fusion Positive	
	N	PFS, months (95% CI)	N	PFS, months (95% CI)
1L chemo	37	7.6 (4.6-13.3)	21	5.4 (3.8-9)
1L FGFR inhibitor	0	na	4	7.7 (2.1-NE)
1L Overall	37	7.6 (4.6-13.3)	25	5.9 (3.8-8.5)
2L chemo	20	10 (4.6-13.8)	9	5.5 (4.8-19.3)
2L FGFR inhibitor	0	na	16	8.2 (7.2-NE)
2L Overall	20	10 (4.6-13.8)	25	8.4 (7.2-13.8)

Conclusions: Our study highlights the distinct features of *FGFR2* fusion-positive BTC, which is associated with a significantly longer OS despite a shorter PFS on standard 1L chemo. These findings underscore the need for trials to evaluate the efficacy of 1L FGFR inhibitors in these patients.

109P DNA damage repair pathways in biliary tract cancer: A new target for precision medicine?

I. Mavroeidi[1], T. Reissig[1], S. Kalbourtzis[2], S-T. Liffers[3], T. Herold[4], S. Kasper-Virchow[1], H-U. Schildhaus[5], M.H.H. Schuler[6], J. Siveke[3]

[1]Department of Medical Oncology, West German Cancer Center, University Hospital Essen, University Duisburg-Essen, Essen, Germany; [2]Institute of Pathology, West German Cancer Center, University Hospital Essen, Essen, Germany; [3]Bridge Institute of Experimental Tumor Therapy, Universitätsklinikum Essen, Essen, Germany; [4]Institute of Pathology, Universitätsklinikum Essen, Essen, Germany; [5]Institute of Pathology, University Hospital of Essen, Essen, Germany; [6]Department of Medical Oncology, West German Cancer Center, University Hospital Essen, University Duisburg-Essen, Essen, Germany

Background: Biliary tract cancers (BTC) show a high mortality quote and heterogeneity in terms of clinical and molecular profile. Aim of this work is the molecular characterisation of a BTC cohort focusing on genomic alterations of DNA damage repair (DDR) genes.

Methods: A retrospective analysis of the clinical course and mutation status of patients with locally advanced or metastatic BTC treated at the West German Tumour Centre of the University.113 (96%) patients received the MAPK-TRON DNA-based NGS panel (47 included genes), 81 (72%) patients the AmoyDx HRD Focus panel (32 genes), which focuses on DDR genes. DNA mismatch repair (MMR) status was determined in 59 patients by immunohistochemistry and DNA sequencing. 33 patients received an RNA fusion assay (FusionPlex CTL panel [Archer]) too. The primary endpoints of the study were the time in first palliative regime till disease progression (Time on Treatment=TTE) and the overall survival (OS). To form a clear defined DDR cohort, the annotation of DDR gene alterations was not only performed by the local Institute of Pathology but also by quering the databases ClinVar and COSMIC.

Results: The cohort of the present study was divided in 7 molecular subgroups: TP53 (34/118, 29%), KRAS (25/118, 21%), IDH1/2 (18/118, 15.2%), PIK3CA (8/118, 7%) and BRAF (6/118, 5%) and FGFR2 (5/33, 15%, with different fusion partners). BRAF- und PIK3CA-mutated BTC showed a slight benefit in primary endpoints, whereas KRAS- and TP53- mutated showed worse prognosis. 13 DDR-mutated BTC were identified (13.5%). The patients with DDR mutations showed a weak but coherent benefit in all primary endpoints (OS, TTE, TTE under platinum-based therapy). Comparison of our data with BTC data of The Cancer Genome Atlas (TCGA) in cbioportal showed a similar trend in OS (19,1 months in TCGA data vs 22,7 months in the studied cohort).

Conclusions: Pathogenic alterations in DDR pathway genes were seen in 13.5% of the cases studied. DDR-deficient BTC patients showed a trend for better OS and TTE representing a potential subgroup that could benefit from targeted treatment strategies, like PARP-inhibitors. Moreover the slight benefit of DDR-mutated BTC under platinum-based therapy supports the hypothesis of better response of DDR-mutated tumours to platinum.

110P Detection of HER2 overexpression in biliary tract cancers: Comparison of AmoyDx® HER-2 (29D8) assay with ventana PATHWAY anti-HER-2/neu (4B5) assay

H. Dong[1], W. Su[2], H. Lu[3], Z. Liu[3], Z. Tang[3], Z. Huang[2], L. Ruan[3], C. Zhu[2]

[1]Department of Pathology, Shanghai Eastern Hepatobiliary Surgery Hospital, Shanghai, China; [2]Department of Translational Medicine, Amoy Diagnostics Co., Ltd., Xiamen, China; [3]Department of Research and Development, Amoy Diagnostics Co., Ltd., Xiamen, China

Background: The human epidermal growth factor receptor 2 (HER2/neu), a member of epidermal growth factor receptor protein family, play a role as predictive and prognostic biomarkers in various tumor types, particularly biliary tract cancers (BTCs), a heterogeneous group of poor-prognosis solid tumors with limited treatment options. Accurate evaluating of HER2 overexpression is essential for selection and determination of eligible patients for HER2-directed therapy. Herein, we report the results of an immunohistochemistry (IHC) concordance study comparing the AmoyDx® HER-2(29D8) assay and the well-established Ventana PATHWAY anti-HER-2/neu (4B5) assay using a BTC cohort of 432 samples.

Methods: Performance of the AmoyDx® HER-2 (29D8) assay was compared against the Ventana PATHWAY anti-HER-2/neu (4B5) assay using 432 pre-selected BTC samples. Further ISH testing was successfully performed in 134 of the samples to identify HER2-positive and HER2-negative samples according to standard criteria.

Results: There was a high concordance between results from the AmoyDx 29D8 and PATHWAY 4B5 assays for HER2-negative (IHC 0, 1 +) and HER2-positive (IHC 2 + , 3 +) BTCs (98.38%, 425/432). When combined with the ISH results, the aggrement was even increased to 99.29% (422/425) (Table). In addition, the low concordance (34.63%, 9/26) between the two assays for IHC 1+ samples, indicating that the detecton criteria for HER2 IHC 0 and 1+ still need further clarification, which reminds researchers to carefully select appropriate assays if they focus on BTC with HER2-low expression types.

Table: 110P Comparison of HER2 scorings derived from the indicated assays

		Ventana PATHWAY anti-HER-2/neu (4B5)		
		+	-	Total
AmoyDx® HER-2 (29D8)	**+**	19	2	21
	-	1	403	404
	Total	20	405	**425**
Positive percent agreement		95.00% (95%CI: 75.13%, 99.87%)		
Negative percent agreement		99.51% (95%CI: 98.23%, 99.94%)		
Overall percent agreement		99.29% (95%CI: 97.95%, 99.85%)		

Conclusions: Our data demonstrate that AmoyDx 29D8 exhibited high concordance with PATHWAY 4B5, and could provide critical information for the selection of HER2-targeted therapy for BTC patients.

111P The concordance between circulating tumor DNA and tissue genomic profiling in patients with advanced biliary tract cancer

S. Woo[1], S. Hwang[2], G. Kim[2], H. Kang[2], D.S. Kyung[3], W. Lee[3], H-P. Kim[3], B. Kang[4], C. Kim[3], H.J. Chon[4]

[1]Department of Biomedical Science, CHA University, Seongnam, Republic of Korea; [2]Department of Pathology, Cha Bundang Medical Center, Seongnam, Republic of Korea; [3]Clinical Support Team, IMB Dx, Inc., Seoul, Republic of Korea; [4]Department of Medical Oncology, CHA Bundang Medical Center, Seongnam, Republic of Korea

Background: Recent advances in molecular profiling have revealed potential therapeutic targets for biliary tract cancer (BTC). However, difficulties in obtaining an adequate sample could hamper molecular evaluations in patients with BTC. Circulating tumor DNA (ctDNA) can thus help address any challenges associated with the

limited use of tissue-based analysis in BTC. In this study, we aimed to evaluate the concordance between ctDNA and tissue genomic profiling in patients with advanced BTC and evaluate the feasibility of liquid biopsy in the treatment of patients with BTC.

Methods: Patients who underwent tissue-based next-generation sequencing (NGS) before systemic chemotherapy for advanced BTC at CHA Bundang Medical Center from January 2019 to December 2022 and for whom sufficient plasma samples were available for ctDNA analysis (AlphaLiquid®100 from IMB Dx) were included. Clinically important (tier 1 or 2) variants detected in tissues with a variant allele frequency (VAF) of >0.05 were considered as true positive for concordance.

Results: Of one hundred two patients, 49.0%, 26.5%, and 24.5% had intrahepatic cholangiocarcinoma, extrahepatic cholangiocarcinoma, and gall bladder cancer, respectively. The concordance between intra-patient ctDNA and tumor tissue for mutations indicated 84.8% sensitivity and 79.4% positive predictive value. In ctDNA, targetable alterations were detected in 34.3% of patients, such as *IDH1* mutation (7.8%), *FGFR2* fusion (2.0%), microsatellite instability (MSI)-high (2.0%), *ERBB2* amplification (4.9%), *PIK3CA* hotspot mutations (6.9%), *BRCA1/2* mutations (9.8%), and *MET* amplification (2.9%). Among the two *FGFR2* fusions, one FGFR2-TNS1 fusion was novel, because it was not targeted in tissue NGS panel. Lastly, patients with high ctDNA VAF showed poor prognosis in gemcitabine-cisplatin based chemotherapy in both overall survival and progression-free survival ($p = 6.9 \times 10^{-6}$ and $p = 9.8 \times 10^{-10}$), respectively.

Conclusions: ctDNA-based genotyping demonstrated acceptable concordance with tissue genomic profiling in patients with advanced BTC. Thus, liquid biopsy using ctDNA could complement the limitation of tissue-based genomic analysis in BTC.

Background: Biliary tract cancers (BTC), including cholangiocarcinomas (CCA) are rare but aggressive cancers primarily affecting patients (pts) >70 years (median age at diagnosis : 72-78 years). However, there has been a rise in the incidence of CCA among younger individuals (<50 years). This study aimed to investigate clinical, genomic and transcriptomic characteristics and outcomes of young-onset BTC/CCA (YOC) pts.

Methods: We identified all consecutive patients with histologically confirmed CCA treated at Gustave Roussy (France) between 2015 and 2021 as part of the ACABI-PRONOBIL multicenter cohort study. Clinical data were extracted from medical records. Genomic data were obtained through in-house or Foundation Medicine® panels. Transcriptomic analyses were performed for 58 pts (13 YOC) at metastatic diagnosis.

Results: Of the 546 pts with CCA, 92 (16.8%) had YOC (median age, 42 years; range, 27-50). Median overall survival (mOS) from 1st line therapy was 22.7 months (mo) (95%CI: 18.3-27.6) for YOC patients vs 19.2 mo (95%CI: 18.0-22.0) for non-YOC patients (p=0.14). Molecular profiling was more often performed for YOC pts (68% vs 55%, p<0.05). Rates of actionable molecular alterations (*IDH1/2*, *BRAF*, *FGFR2*, *NTRK*, *HER2*, MSI) and targeted therapies administration did not differ between YOC and non-YOC pts. *CDKN2A* alterations were less frequent in YOC than in non-YOC pts (12.6% vs 25.2%, p<0.05). Differentially expressed genes between YOC and non-YOC pts with *Gene Set Enrichment Analysis* were mostly genes involved in immunity and WNT signaling pathways.

Table:112P

Genomic characteristics		Age <=50 n=92		age>50 n=454 [BA1]	
		n	%	n	%
Molecular profile available	No	29	32%	204	45%
	Yes	63	68%	250	55%
Actionable alteration	No	41	65%	141	56%
	Yes	22	35%	109	44%
Main actionable alterations	No alteration	11	17%	43	17%
	Mutation IDH1/2	8	13%	40	16%
	Fusion FGFR 1-4	8	13%	21	8%
	Amplification HER2	3	5%	15	6%
	Mutation BRAF V600E	0	0%	10	4%
	EGFR	2	3%	7	3%
	Fusion NTRK	6	10%	11	4%
	Mutation KRAS G12C	1	2%	3	1%
Other relevant alterations	KRAS	16	25%	40	16%
	TP53	25	40%	91	36%
	CDKN2A/B	8	13%	63	25%
MMR status (n=199)	dMMR/MSI	0	0%	11	7%
	pMMR/MSS	47	100%	141	93%
Targeted therapies administration	No	41	65%	141	56%
	Yes	22	35%	109	44%

Conclusions: Although tending to have a more advanced disease at diagnosis, YOC patients had OS similar to that of non-YOC pts, and no more actionable molecular alterations. Our findings suggest that the biological mechanisms driving CCA in YOC patients may be different from those in older patients and warrant further investigation.

113P Molecular profiling of biliary tract cancers in patients of African and European ancestries

Z.I. Hu[1], A. Danner De Armas[1], D.C. Pavlick[2], J.S. Ross[3], S. Lee[4], M. Eluri[1], M. Javle[1]

[1]Gastrointestinal Medical Oncology, MD Anderson Cancer Center, Houston, TX, USA; [2]Cancer Genomics Research, Foundation Medicine, Inc, Cambridge, MA, USA; [3]Pathology Department, Foundation Medicine, Inc, Cambridge, NY, USA; [4]Gastrointestinal Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX, USA

Background: Molecular differences between genetic ancestries in patients (pts) with bilary tract cancers (BTCs) and how they affect prognosis and treatment response are largely unknown. Compounding this problem is clinical trial enrollment for racial minorities with BTCs have been historically low, making it difficult to assess differences in treatment response between genetic ancestries. Our prior data indicated significant variation in somatic cancer genes between Caucasian and Asian pts. However, variations in African ancestry (AA) pts have not been described.

Methods: 12,932 cases of BTCs of AA and European ancestries (EA) were reviewed from 3 databases (Foundation Medicine (n=10,849), MD Anderson Cancer Center (n=167) and AACR Genie (n=1,916). BTCs were divided into intrahepatic (ICC) and extrahepatic (ECC) cholangiocarcinomas and gallbladder cancers (GBC). Prevalence of alterations in 30 genes between genetic ancestries were compared using Fischer's exact test on the Foundation Medicine database. P-values were corrected for false discovery rate using the Benjamini/Hochberg adjustment.

Results: We identified key clinical and genomic differences between AA and EA BTC cases in all 3 databases. The mean age of AA pts at diagnosis was earlier (62.3 years) compared to EA pts (65.1 years) (p<0.05). There was a higher percent of female AA BTC cases (63.2%) compared to female EA BTC cases (52.4%) (p<0.05). AA BTC cases had a statistically significant higher prevalence of *TP53* (55.1% vs 39.7%) and *TERT* (10.0% vs 5.4%) alterations (p<0.001) compared to EA BTC cases. AA BTC cases also had a statistically significant higher prevalence of *STK11, CCNE, ERBB2,* and *ARID2* alterations (p<0.05), and lower prevalence of *IDH1*, *ARID1A*, *BAP1*, *BRAF*, and *PBRM1* alterations (p<0.05) compared to EA BTC cases. AA ICC cases had a statistically significant higher prevalence of *FGFR2* (16.8% vs 11.7%) alterations (p<0.001) compared to EA ICC cases.

Conclusions: Our results highlight significant differences in genomic profiles among BTC cases of different genetic ancestries and support further research in how these differences contribute to prognosis and treatment response to targeted therapies.

114P Prospective longitudinal tumor-informed ctDNA in resectable biliary tract cancers

G. King[1], S.A. Cohen[1], E.G. Chiorean[1], W.P. Harris[1], R. Yeung[2], J. Park[2], D.B. Zhen[3], A.L. Coveler[1], A. Diehl[1], R. Safyan[1], A. Jurdi[4], C. Brdiges[4]

[1]Medical Oncology, University of Washington, Fred Hutchinson Cancer Center, Seattle, WA, USA; [2]Surgery, University of Washington Medical Center, Seattle, WA, USA; [3]Division of Medical Oncology, Department of Internal Medicine, University of Washington, Seattle; Fred Hutchinson Cancer Center, Seattle, WA, USA; [4]Oncology, Natera, Inc., San Carlos, CA, USA

Background: Circulating tumor DNA (ctDNA) is an emerging strategy to define minimal residual disease (MRD) in resected cancers. Data in biliary tract cancers (BTC) is limited. We describe a prospective evaluation of ctDNA as part of a feasibility study of multi-platform profiling of resected BTC (NCT04561453).

Methods: We conducted a prospective multi-platform profiling study for resectable BTC from 2020 to 2023, which included tumor-informed ctDNA testing (Signatera™, Natera USA) obtained pre-operatively, within 6 weeks post-operatively prior to adjuvant therapy (MRD detection) and longitudinally every 3 months thereafter until death or last follow-up.

Results: 12 patients were included, median age 70 years (range 61-83), 6 female. BTC subtypes: intrahepatic (9) and perihilar (1) cholangiocarcinoma, and gallbladder carcinoma (2). Median follow up was 20.5 months (range 6-33 months). Median tumor size was 5.2cm (range 2.1-8.3 cm), stage II-III disease 67%, R1 resection 33%. All patients received post-operative therapy: adjuvant capecitabine (9), chemoradiation (2), gemcitabine and cisplatin (1). Two patients received neoadjuvant gemcitabine and cisplatin. Pre-operatively, all 12 patients (100%) had detectable ctDNA, while only 4 pts (33%) had elevated CA 19-9. For post-operative MRD detection, 2/12 patients had a detectable ctDNA level, while none had an abnormal CA 19-9. Among 10 patients with undetectable ctDNA MRD postoperatively, 5 patients have remained ctDNA negative without evidence of recurrence, 4 of which are ctDNA negative for $\geq$18 months (range 20-33 months). During adjuvant therapy, 2 patients converted from ctDNA positive to negative, neither have recurred. During longitudinal follow up, 4/12 patients have confirmed recurrence: 1 patient was ctDNA MRD positive while the others converted from negative to positive during adjuvant therapy or surveillance. Rise in ctDNA preceded radiographic recurrence in all patients with recurrence.

Conclusions: Baseline ctDNA had higher detection rate compared to CA 19-9 prior to resection. Longitudinally negative ctDNA was associated with improved recurrence free survival. Assessing ctDNA levels may have potential utility in evaluating response in the absence of radiographically visible disease.

Clinical trial identification: NCT04561453.

115P Inhibition of KLF5 reduces tumor growth and sensitizes to chemotherapy-induced cell death in experimental models of cholangiocarcinoma

A. Landa Magdalena[1], P.M. Rodrigues[1], O. Erice[1], N.A. Paiva[1], M.G. Fernandez-Barrena[2], P. Olaizola[1], A. Lapitz[1], C.J. O'Rourke[3], J.B. Andersen[3], D.F. Calvisi[4], M. Azkargorta[5], F. Elortza[5], I. Goicoechea[6], C.H. Lawrie[6], L. Bujanda[1], M.J. Perugorria[1], J.M. Bañales[1]

[1]Liver Diseases Group, Biodonostia Health Research Institute, San Sebastian, Spain; [2]Division of Hepatology, CIMA-University of Navarra, Pamplona, Spain; [3]BRIC, Department of Health & Medical Sciences, University of Copenhagen, Copenhagen, Denmark; [4]Institute of Pathology, University of Regensburg, Regensburg, Germany; [5]Proteomics Platform, CIC bioGUNE - Centro de Inv. Cooperativa en Biociencias, Derio, Spain; [6]Molecular Oncology Group, Biodonostia Health Research Institute, San Sebastian, Spain

Background: Cholangiocarcinoma (CCA) comprises a heterogeneous group of cancers with bad prognosis. Krüppel-like factors (KLF) are a family of transcription factors involved in organogenesis, differentiation and cellular homeostasis. Here, we studied the role of KLF5 in CCA development and evaluated the therapeutic potential of its inhibition.

Methods: *KLF5* expression was measured in human CCA tissues [Copenhagen (n=210), TCGA (n=36), Job (n=78), TIGER-LC (n=90) and San Sebastian cohorts (n=12)] and cell lines. *KLF5*$^{-/-}$ CCA cells were created by CRISPR/Cas9. The functional effects of KLF5 genetic silencing with CRISPR technology, or chemical inhibition with ML264, were evaluated *in vitro* and *in vivo*.

Results: *KLF5* expression was upregulated in human CCA tissues from 5 different patient cohorts compared to surrounding normal liver tissue. High *KLF5* levels correlated with lymph node invasion and worse overall survival. *In vitro*, KLF5 protein and mRNA levels were overexpressed in human CCA cells compared to normal human cholangiocytes. Functionally, *KLF5*$^{-/-}$ CCA cells displayed decreased cell proliferation, migration, invasion and colony formation while promoting cell cycle arrest at G1/S and apoptosis *in vitro*, when compared to control cells. In agreement, *KLF5*$^{-/-}$ CCA cells did not develop any tumor after subcutaneous or orthotopic injection in a xenograft animal model of CCA. Likewise, chemical inhibition of KLF5 with ML264 hampered CCA cells proliferation and migration *in vitro* and blocked tumor growth *in vivo*. Lastly, both genetic and chemical inhibition of KLF5 sensitized CCA cells to chemotherapy-induced apoptosis *in vitro*, and the combination of gemcitabine + cisplatin and ML264 completely halted CCA tumor growth in mice. Accordingly, *KLF5*$^{-/-}$ CCA display altered levels of several proteins related to chemoresistance when compared to control cells, that were shown to significantly correlate with *KLF5* expression in human CCA tissues.

Conclusions: Increased KLF5 is a general event in CCA, contributing to cancer progression and chemoresistance. KLF5 inhibition with ML264 may represent a potential therapeutic strategy for CCA.

116P Circulating tumour DNA- based minimal residual disease detection for biliary tract cancer

Z. Li[1], P. Yan[1], Q. Hao[2], L. Guo[2], F. Pang[2], X. Jiang[1], Y. Yu[1]

[1]Department of Biliary Surgery, Third Affiliated Hospital of Naval Military Medical University, Shanghai, China; [2]Medical Department, Shanghai OrigiMed Co., Ltd, Shanghai, China

Background: Although circulating tumor DNA-based minimal residual disease (MRD) is useful for prediction of prognosis, but clinical value of MRD for BTCs are remain clear.

Methods: The OriMIRACLE S™ MRD assay (OrigiMed, Shanghai, China) uses whole exome sequencing (WES) for detecting patient-specific somatic alterations from tumor tissues and for blood a personalized panel designed to target up to 45 variants.

Results: A total of 26 biliary tract cancer (BTC) patients including 13 gallbladder carcinoma and 13 extrahepatic cholangiocarcinoma patients were enrolled. Among the patients, 53.85% (14/26) were male and 46.15% (12/26) were female, and the median age was 61 years, ranging from 49 to 73 years old. Fifteen patients underwent radical surgery, 4 patients underwent local tumor resection and 7 patients could not undergo radical surgery. Based on WES, we found that 58.33% (4005/6866) of the mutated genes were unique to each patient and100% (26/26) of patients successfully constructed MRD panels, suggesting that tumor-informed MRD is superior to panel-based MRD in BTC. For each patient, we selected up to 45 clonal somatic mutations for a personalized ctDNA assay design. MRD detection was performed on 26 cases and revealed a positive rate of 42.31% (11/26). Among the 11 patients with positive MRD at postoperative or, 71% (5/7) of patients who could not undergo radical surgery, 100% (4/4) of the patients underwent local tumor resection and 13.3% (2/15) of patients underwent radical surgery. MRD detection was performed 4 times on one female GBC patient with stage IV throughout the treatment course. we found that

MRD at baseline was positively detected by tumor-informed assay with a higher variant allele fraction (VAF), and decreased after neoadjuvant therapy. CT image also showed local control of the tumor, but CA199 and CEA levels were elevated in patients with obstruction, suggesting the limits of tumor markers in BTC patients with obstruction.

Conclusions: Up to 58% of mutated genes of BTC are unique individually, and 100% of patients successfully constructed MRD panels, which may be more suitable for monitoring with tumor-informed MRD panel. The VAF of ctDNA could be used to predict the efficacy of neoadjuvant therapy and tumor progression in BTC patients.

117P Genomic landscape of biliary tract cancers from India show distinct geographic variation

N. Rohatgi[1], A. Agarwal[2], V. Maniar[3], S. Patil[4], A. Bahl[5], S. Advani[6], P.K. Julka[7], S. Limaye[8], A. Kakroo[9], A. Kumar[10], M. Javle[11]

[1]Medical Oncology, Fortis Memorial Research Institute, Gurugram, India; [2]Medical Oncology, Fortis Hospital, Shalimar Bagh, New Delhi, India; [3]Medical Oncology, Mumbai Oncocare Centre (MOC Ghatkopar), Mumbai, India; [4]Radiation Oncology, HCG HealthCare Global Enterprises Ltd, Bangalore, Karnataka, India; [5]Medical Oncology, Fortis Memorial Research Institute, Gurugram, Delhi, India; [6]Medical Oncology, Sushrut Hospital and Research Centre, Mumbai, India; [7]Department Of Medical Oncology, Max Oncology Day Care Centers, New Delhi, India; [8]Medical Oncology, Sir H N Reliance Foundation Hospital, Mumbai, India; [9]Medical Oncology Department, Hemato-Oncology Clinic Vedanta - Navrangpura, Ahmedabad, India; [10]Medical Affairs, Roche Product India Pvt Ltd, Mumbai, India; [11]Gastrointestinal Medical Oncology, MD Anderson Cancer Center, Houston, TX, USA

Background: Biliary tract cancers (BTC) are a group of heterogeneous tumors that include intrahepatic, perihilar, and distal cholangiocarcinoma and gall bladder cancers (1). India has a high burden of biliary tract tumors, particularly gallbladder cancers. It contributes to 10% of global burden of gall bladder cancers. Within India, the Indo-Gangetic doab has a higher incidence of BTCs of 21/100,000 individuals affected (2). Cholangiocarcinoma and gall bladder cancers have distinct genomic diversity (3). Genomic profiling of BTCs from India are scarce. Understanding of genomic diversity of BTCs in India shall help in strategizing therapy and prevention. **Aim** The main objectives of the study are: 1. Retrospective analysis of genomic profile of biliary tract cancers from India 2. Pathway analysis of BTCs based on genomic profiling.

Methods: 46 BTC cases from India were recruited for the study spanning 10 centers across India. All the cases were tested using comprehensive genomic profiling under Foundation One CDx or Foundation One Liquid CDx assay. Only the genomic results were used for retrospective analysis.

Results: 33 cases of cholangiocarcinoma and 13 cases of gallbladder cancers were analyzed. The most commonly altered genes in cholangiocarcinoma were TP53 (45%), CDKN2A/B (33%), ARID1A (21%), KRAS (21%). The most commonly altered genes in gallbladder were TP53 (77%), CDKN2A/B (31%), RB1 (23%) and SMAD4 (23%). Pathway analysis showed a distinct difference between cholangiocarcinoma and gallbladder tumors. Transcriptional factors and Immune-modifier pathways were enriched in gallbladder tumors compared to cholangiocarcinoma, while the cell cycle pathway was more commonly altered in cholangiocarcinoma. When the cholangiocarcinoma cases were stratified by demographic origin within India, we found cell cycle pathway genes to be significantly less among North Indian samples, while RAS-RAF pathway was significantly more among North Indian samples.

Conclusions: The genomic landscape of BTCs in India showed distinct variation compared to the rest of the world. A trend of variation in the genomic landscape of BTCs between North & South India was observed. Further study with higher sample size is warranted.

118P Artificial intelligence (AI)-powered spatial analysis of tumor-infiltrating lymphocytes (TILs) as a predictive biomarker for anti-PD-1 in advanced biliary tract cancer (BTC)

Y. Bang[1], C-K. Lee[2], K. Bang[3], H-D. Kim[1], K-P. Kim[1], J.H. Jeong[1], B-Y. Ryoo[4], C. Oum[5], S. Kim[5], Y. Lim[5], G. Park[5], C-Y. Ock[5], J.H. Shin[6], C. Yoo[4]

[1]Department of Oncology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Republic of Korea; [2]Division Of Medical Oncology, Yonsei Cancer Center, Yonsei University, Seoul, Republic of Korea; [3]Department of Oncology, Chung-Ang University, Gwangmyeong Hospital, Gyeonggi-do, Republic of Korea; [4]Department of Oncology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Republic of Korea; [5]Oncology Group, Medical Affairs, Lunit Inc., Seoul, Republic of Korea; [6]Department of Pathology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Republic of Korea

Background: Recently, anti-PD-1/L1 plus gemcitabine and cisplatin (GemCis) has demonstrated significant survival benefits in randomized phase 3 trials for advanced BTC. However, no biomarker has been established for anti-PD-1 in BTC. Here, we assessed TILs using artificial intelligence (AI)-powered spatial analysis in advanced BTC treated with anti-PD-1.

Methods: An AI-powered whole-slide image (WSI) analyzer (Lunit SCOPE IO, Lunit, Seoul, Korea) was used to segment tumor epithelium and stroma, and identification of intratumor TIL (iTIL) and stromal TIL (sTIL). H&E-stained WSI from pre-treatment samples was acquired from Asan Medical Center and Yonsei Cancer Center (n = 354), and a total of 337 samples (95.2%) after quality control were used for the final analysis. Immune phenotypes (IP) were defined as follows: inamed as high iTIL and sTIL; immune-excluded as low iTIL and high sTIL; immune-desert as low TIL overall. Among them, 29 patients (pts) were available for multi-color flow cytometry analysis (FACS) using peripheral blood mononuclear cells (PBMC), collected at baseline and C1D8.

Results: All patients were treated with anti-PD-1 monotherapy, and 188 pts (55.8%) were treated as 2nd line. In overall pts, anti-PD-1 showed median overall survival (OS) of 5.7 months (mo), median progression-free survival (PFS) of 2.0 mo, and objective response rates (ORR) of 10.1%. IP were classified as inflamed in 40 pts (11.9%), immune-excluded in 167 (49.6%), and immune-desert in 130 (38.6%). The inflamed group showed better OS (12.5 vs. 5.1 mo, $P<0.001$), PFS (5.0 vs. 2.0 mo, $P=0.001$), and ORR (27.5% vs. 7.7%, $P<0.001$) than non-inflamed groups. In the FACS, the inflamed group showed significantly higher proportion of baseline CD8+Tem and lower baseline CD8+Tnaive than non-inflamed groups. At C1D8 of anti-PD-1, CD69+CD8+T, GZMB+CD8+T, and PRF1+CD8+T cells were increased, while PD1+CD8+T cells was decreased in PBMC of the inflamed group.

Conclusions: Immune phenotype classified by AI-powered spatial TIL analysis was effective to predict the efficacy outcomes of advanced BTC pts treated with anti-PD-1 therapy. Further evaluation is required in the setting of anti-PD-1/L1 plus GemCis.

Background: Biliary tract cancers (BTC) including cholangiocarcinomas (CCA) and gallbladder cancer (GBC) are uncommon tumors with poor prognosis, often diagnosed after age of 70, where comorbidities and altered performance status (PS) are more

frequent. We aimed to compare clinical characteristics, molecular profile, and outcomes of patients (pts) with BTC < and ≥ 70 years old.

Methods: A retrospective chart review was performed in treated BTC pts in 16 French centers from 2003 to 2021. Data on demographics, therapeutic management, molecular profile, progression-free survival (PFS) and overall survival (OS) were collected.

Results: Overall, 1256 pts with BTC were included (male, 52%; median age, 64.5 years), including 384 pts (31%) over 70. Older pts had poorer PS (PS ≥2, 17% vs 8%; p<0.0001) and more comorbidities (≥1 comorbidity, 89% vs. 78%; p<0.0001). They were diagnosed more frequently with extrahepatic CCA and GBC (respectively, 18% vs.12% and 16% vs. 13%, p=0.0073) and less advanced disease stage at diagnosis (bilobar liver involvement, 29% vs 37%; p=0.008). They were offered less frequently first-line systemic therapy (87% vs 97%, p<0.0001)(gemcitabine 3% vs 0.3%; gemcis 31% vs 35%; gemox 54% in 2 groups; p=0.007) and molecular profiling (43% vs 65%, p<0.0001) than pts <70. Proportions of actionable alterations were significantly different, with more HER2 amplifications and less IDH1 mutations and FGFR2 fusions in older patients (p=0.0419). MSI status were similar between groups. OS after resection was similar in older and younger pts (median OS, 47.0 months (mo) [95%CI: 37.8-71.9] vs 48.8 mo [95%CI 41.4-57.3]), but shorter in older pts at advanced stage (14.6 [95%CI 12.7-16.5] vs. 17.4 mo [95%CI 16.1-18.9), p<0.0001). First-line PFS did not differ (median, 6.6 mo [95%CI 5.5-7.2] vs 5.8 mo [95%CI, 5.3-6.2), p=0.61).

Conclusions: Older BTC pts presented more frequently eCCA and GBC and a less advanced disease at diagnosis. At advanced stages, older pts had poorer OS and received less often first-line chemotherapy. If treated, PFS of older pts was similar to younger pts. Molecular profiling was less often performed in older pts.

Background: Biliary tract cancers (BTC) including cholangiocarcinoma (CC) and gallbladder cancer (GBC) are rare cancers with poor prognosis. Few data are available on early-onset BTC (EOBTC) defined as patients (pts) under age of 50.

Methods: A retrospective chart review was performed in pts treated for BTC in 14 French centers between 2003 and 2021. Data on demographic characteristics, therapeutic management, and molecular profile were collected. Progression-free survival (PFS) and overall survival (OS) were estimated by the Kaplan Meier method. Prognostic factors were assessed by univariate and multivariate analyses by Cox regression.

Results: Overall, 1256 pts with BTC were included. Patients with EOBTC (n=188, 15%) had less comorbidities according to Charlson score (63.5% vs 84.4%, p<0.0001), higher tumor stage (cT3-4: 49.9% vs 32.17%, p=0.0126), bilobar liver involvement (47.7% vs 32.1%, p=0.0002) and metastatic disease (67.5% vs 57.49%, p=0.0097) compared to older pts, but did not differ regarding primary tumor location (intrahepatic vs extrahepatic CC vs GBC), WHO performance status (PS 0-1: 94.4% vs 85.5%, p=0.15), and sex-ratio (50.8% vs 53.4% of males). First-line systemic therapy for advanced BTC (n=818, 65.2%) was mostly a doublet by GEMCIS (45.5% vs 32.1%, p=0.0091) or GEMOX (43.3% vs 56.5%, p=0.0091) in EOBTC vs non-EOBTC respectively. EOBTC pts received more frequently a 2nd line therapy (89.5% vs 80.9%, p=0.02). For advanced BTC pts, median (m)OS was 17.0 mo vs 16.2 mo (p=0.08) and mPFS was 5.8 mo vs 6.0 mo (p=0.89), in EOBTC vs older pts respectively. Molecular profiling was performed in 72.6% of EOBTC pts vs 52.4% in older pts (p=0.0019), and less actionable alterations were found (e.g. IDH1 mutations, 7.8% vs 16.6%; p=0.029; FGFR2-fusion, 11.7% vs 8.9%; p=0.029). We did not find any usual prognostic factors in BTC (CEA, CA19-9, PS, neutrophile-lymphocyte ratio, number of extra-hepatic metastases) associated with EOBTC survival.

Conclusions: Pts with EOBTC have a more advanced disease at diagnosis, are treated more heavily at an advanced stage, and have similar PFS and OS in comparison to older BTC pts. Molecular profiling was more often performed in EOBTC pts but less actionable alterations were found.

Background: Fibroblast growth factor receptor 2 (FGFR2) fusions or rearrangements (f/r) occur in up to 14% of patients with intrahepatic cholangiocarcinoma (iCCA). PEMIGATINIB, an oral FGFR 1-3 inhibitor, demonstrated significant efficacy in the phase II FIGHT-202 study with a response rate of 37% in heavily pretreated patients. Neither phase III nor phase IV data are currently available but due to the reported efficacy, PEMIGATINIB was FDA and EMA approved and is available in France since July 2020. Our study aimed to evaluate the efficacy and safety of pemigatinib and the disease profile of iCCA with FGFR2 fusions/rearrangements in an unselected population.

Methods: This national multicenter retrospective cohort collected data on demographics, therapeutic management, toxicity profile, objective response rate, progression-free survival and overall survival from French patients with advanced cholangiocarcinoma with FGFR2 f/r who received PEMIGATINIB since July 2020.

Results: From July 2020 to September 2022, 50 patients were included. At diagnosis the mean age was 57 years with 74% female, mainly ECOG 0-1 (82%). 58% had received two or more previous systemic therapies. The objective response rate was 45.3% (3 complete responses and 21 partial responses, n = 24). The median progression-free survival was 9 months (IIQ 6-14) and the median overall survival was 18 months (IIQ 12-NA). Neither clinical nor molecular characteristics were predictive factors for treatment response. The most common toxicities were hyperphosphatemia (58%), nail toxicity (58%) and fatigue (58%). 35% of patients developed grade 3 toxicity at the 13.5 mg daily dose. 57.5% (n = 19) of patients with progression were able to receive at least one subsequent line of treatment, mostly a new FGFR inhibitor (58%). The median overall survival from the locally advanced or metastatic stage was 37 months.

Conclusions: Our study confirms the efficacy of pemigatinib in an unselected population with high response rates and survivals similar to the FIGHT-202 data. It also confirms the good tolerability of pemigatinib and the better prognosis of iCCA with FGFR2 f/r.

122P Largest examination of cholangiocarcinoma (CCA) patients (pts) treated with novel targeted therapies after extended molecular profiling on liquid biopsies

U. Mahmood[1], E. Muhamad Faizul[2], S. Howlett[1], D. Hochhauser[1], K-K. Shiu[1], J.A. Bridgewater[1], K.H. Khan[1]

[1]Department of Gastrointestinal Oncology, UCLH - University College London Hospitals NHS Foundation Trust, London, UK; [2]Department of Oncology, UCL - University College London, London, UK

Background: CCA is associated with poor outcomes with limited treatment options. Targeted therapies have recently gained traction in CCA but data remains sparse in this domain. Here, we present the largest multi-institutional review to date evaluating outcomes following targeted agents in this pt population.

Methods: All consecutive CCA pts receiving systemic therapy between 2010 - 2022 at UCLH were included. Treatment response, survival outcomes and predictors of clinical benefit were evaluated. Pt demographic factors, disease characteristics and survival outcomes were evaluated using the Kaplan-Meier method and Cox proportional-hazards models.

Results: Of the 147 screened pts, 119 (81%) underwent molecular profiling. We identified 48 (40%) eligible CCA pts where 47 received molecularly guided targeted treatment. Most pts received targeted agents in a 2nd treatment line setting (N = 26). Frequently observed genomic alterations occurred in *FGFR* (N = 21), *BRCA* (N = 8), *KRAS* (N = 7), *IDH* (N = 5) and *PIK3* (N = 3) genes. The median progression-free survival (PFS) following 1st, 2nd and 3rd line systemic therapy and overall survival (OS) were: 8.38 (5.45 - 13.50), 5.52 (3.22 - 7.85), 8.15 (2.79 - not reached) and 27.07 (24.21 - 36.63) months, respectively. Median duration of clinical benefit (DoCB) (complete response, partial response and stable disease) in 2nd line treatment setting was 3.10 (2.31 - 4.20) and 5.32 (2.89 - 8.41) months in the chemotherapy and targeted agent (with or without chemotherapy) cohorts, respectively. In a 3rd line setting, the median DoCB was 5.03 (2.63 - 5.42) and 8.34 (2.87 - 14.09) months in the chemotherapy and targeted agent (with or without immunotherapy) cohorts, respectively. This duration extended to 9.66 (3.06 - 14.06) months among futibatinib recipients. Duration of 2nd line targeted treatment was associated with PFS ($P < 0.0001$) and OS ($P < 0.0001$). Duration of 3rd line targeted treatment was associated with PFS ($P = 0.001$) but not OS ($P = 0.14$).

Conclusions: Our study demonstrated the efficacy of novel therapeutic agents in CCA. Liquid biopsies can reliably provide information on extended molecular profiling to aid pt selection for personalised therapeutics.

123P Artificial intelligence (AI)-powered analysis of human epidermal growth factor receptor-2 (HER2) and tumor-infiltrating lymphocytes (TILs) in advanced biliary tract cancer (BTC)

G. Kim[1], C. Kim[2], B. Kang[2], S. Shin[3], T. Lee[3], S. Song[3], S. Kim[3], M. Mostafavi[3], H. Song[3], S. Pereira[3], H. Chon[2]

[1]Department of Pathology, CHA Bundang Medical Center, Seongnam, Republic of Korea; [2]Medical Oncology, Department of Internal Medicine, CHA Bundang Medical Center, Seongnam, Republic of Korea; [3]Oncology, Lunit Inc., Seoul, Republic of Korea

Background: HER2 is overexpressed in a subset of BTC patients, and recent developments in HER2-targeted agents are expanding therapeutic options. However, accurately assessing HER2 expression is challenging in BTC, especially at a low-expression level. We evaluated HER2 expression as well as TILs density through AI models in BTC.

Methods: Whole-slide images (WSI) of pre-treatment HER2 immunohistochemistry (IHC) slides, matched H&E-stained slides and clinicopathological data were obtained from advanced or metastatic BTC patients at CHA Bundang Medical Center in South Korea, between 2019 and 2022. An AI-powered HER2 analyzer classifies tumor cells by HER2 staining intensity (H0, H1, H2, or H3) and quantifies the cells in each staining category. Then, it calculates HER2 categories (0/1+/2+/3+) following the latest ASCO/CAP HER2 IHC guidelines. For evaluating immune landscape, a separate WSI analyzer identified and quantified. TILs within the cancer epithelium or stroma from H&E-stained slides.

Results: In a total of 328 patients, the AI-scored HER2 categories were 0 in 92 (28.9%), 1+ in 137 (43.1%), 2+ in 68 (21.4%), and 3+ in 21 (6.6%). The overall concordance of HER2 categories between the AI and pathologists' readings was 75.3%. HER2 3+ rates by AI in intrahepatic, extrahepatic, gallbladder, and Ampulla of Vater are estimated to be 3.1%, 3.4%, 21.4%, and 5.9%, respectively. HER2-expressing tumors (1+, 2+, and 3+) have significantly higher densities of stromal TILs (983.2 $\pm$ 1347.5 / mm2) than HER2-negative tumors (683.5 $\pm$ 739.7 / mm2, p=0.012) and there were no significant TIL density differences between HER2-high expressing (3+) and low expressing tumors (1+, 2+), which were consistent with either by the AI or pathologists.

Conclusions: AI-powered HER2 scoring showed good agreement with pathologists' scoring, and HER2-expressing tumors harbored high stromal TIL in BTC. Objective expression analysis and the associated differences in immunogenicity will be important for future treatment strategies.

[1]Oncologia Medica, Comprehensive Cancer Center, Fondazione Policlinico Universitario Agostino Gemelli IRCCS, Rome, Italy; [2]Biostatistical Unit, Fondazione Policlinico Universitario Agostino Gemelli IRCCS, Rome, Italy; [3]Medical Oncology, Fondazione IRCCS - Istituto Nazionale dei Tumori, Milan, Italy; [4]Oncology 1, Veneto Institute of Oncology IOV – IRCCS, Padua, Italy; [5]Hepatobiliary Surgery, Comprehensive Cancer Center, Fondazione Policlinico Universitario Agostino Gemelli IRCCS, Rome, Italy; [6]Radiologia Diagnostica e Interventistica Generale, Fondazione Policlinico Universitario Agostino Gemelli IRCCS, Rome, Italy; [7]Department of Precision Medicine, Università degli Studi della Campania Luigi Vanvitelli, Naples, Italy

Background: FGFR2 gene F/R is present in 10-15% of iCCA and FGFR2 inhibitors have demonstrated significant antitumor activity in this population. However, specific clinicopathological features of iCCA patients (pts) harboring FGFR 2 gene F/R have not yet been well clarified. So far, limited literature data seem suggest a correlation between FGFR2 gene F/R and young age and female gender. The aim of this study is to construct a nomogram predicting FGFR2 gene status.

Methods: iCCA pts from four Italian Institutions were retrospectively collected. The following clinicopathological variables were selected: gender; age ($<$ 55 vs $\geq$ 55 years); synchronous vs metachronous metastases (mts); number of metastatic sites (1 vs $>$1), lung/distant lymph-node/peritoneal/bone mts (present vs absent). A multivariate logistic regression model was used to screen out independent predictive factors with a cut-off of 0.10 and a nomogram was established.

Results: Among 464 iCCA pts retrospectively evaluated, 63 (14%) had FGFR2 gene F/R. Univariate and multivariate analysis suggested that age $<$ 55 years [odds ratio (OR): 2.06, 95% confidence interval (CI) 1.15-3.9], bone mts (OR: 2.58, 95% CI 1.28-5.20) and female gender (OR: 1.53, 95% CI 0.88–2.67) were independent predictive factors of FGFR2 gene F/R. A predictive nomogram was established: pts with the highest score (age $<$ 55 years, bone mts, female gender) had a 60% chance to bear FGFR2 gene F/R iCCA [AUC 0.64 (95% CI: 0.57 -0.72)] in comparison to pts with low score (age $\geq$ 55 years, no bone mts, male gender) which had a 7% chance to have FGFR2 positive iCCA.

Conclusions: In the era of molecular characterization, we have developed a simple nomogram for predicting FGFR2 gene status in iCCA. This nomogram might help clinicians to identify pts more likely to harbour FGFR2 gene F/R and increase their therapeutic opportunities. An external validation-set will be analyzed to improve predictive performance.

125P Real-world treatment patterns in patients with biliary tract cancer (BTC): Retrospective chart review survey in Europe (GARNET-2)

J.A. Bridgewater[1], M. Paskow[2], A. Szende[3], P. Messina[4], J. Sah[5], B. Baur[2]

[1]Research Department of Haematology, UCL Cancer Institute, University College London, London, UK; [2]Global Medical Affairs, AstraZeneca, Gaithersburg, MD, USA; [3]Product Development and Market Access Consulting, Fortrea, Leeds, UK; [4]RWE & Analytics, Fortrea, Milan, Italy; [5]Oncology Outcomes Research, AstraZeneca, Gaithersburg, MD, USA

Background: BTC is a diverse group of hepatic and perihepatic malignancies with a 5-year survival rate of $<$20%. This study described real-world treatment patterns and outcomes among patients with advanced and/or unresectable (aBTC) in France, Germany, Italy, Spain, and the United Kingdom (UK).

Methods: In this retrospective, web-based chart review survey, physicians reported anonymized patient-level data for adult patients diagnosed with aBTC between May 2018 and October 2021 who received first-line (1L) systemic therapy (index date). Patients were followed from index date until death or last available date at abstraction. Patient characteristics, treatment patterns, and clinical outcomes were summarized descriptively.

Results: A total of 196 physicians extracted data for 792 aBTC patients who initiated 1L systemic therapy. More patients had intrahepatic cholangiocarcinoma (CCA; 34.8%), than extrahepatic CCA (29.9%), gallbladder (23.5%), and ampullary cancer (10.2%) whereas 1.5% patients had missing information. During follow-up (median=12.4 months), less than half of patients were prescribed gemcitabine + cisplatin (GemCis; 47.9%) as 1L. Median 1L treatment duration was 5.3 months with disease progression (49.2%) being the most common reason for treatment discontinuation. Only 33.1% received 2L and 4.1% received 3L+ of treatment. Median real-world overall survival (rwOS) from index date was 13.4 months, with regional variation (Table).

Table: 125P Key results by country*

	France (N = 167)	Germany (N = 150)	Italy (N = 153)	Spain (N = 167)	UK (N = 155)
Male, %	67.1	66.7	55.6	65.9	57.4
Age ≥60, %	73.1	60.7	76.5	76.0	85.2
Site of primary BTC tumor, %					
Intrahepatic CCA	31.1	35.3	51.0	28.7	29.0
Extrahepatic CCA	30.5	28.0	26.8	29.3	34.8
Gallbladder	23.4	29.3	11.1	28.7	24.5
Ampulla of Vater	13.8	6.0	9.8	13.2	7.7
Unknown	1.2	1.3	1.3	0	3.9
ECOG at diagnosis, %					
0	20.4	14.7	27.5	18.6	32.9
1	52.1	48.0	64.1	67.7	52.3
2+	22.2	22.0	8.5	11.4	11.6
Unknown	5.4	15.3	0	2.4	3.2
GemCis 1L regimen, %	28.7	30.0	69.9	44.3	67.7
Median rwOS (months)	17.8	18.3	14.7	13.1	8.8

*All decimals have been rounded to the nearest tenth, thus the overall % may result in getting a value slightly higher than 100%.

Conclusions: This study demonstrated the unmet needs of patients with aBTC, with less than half of the patients receiving standard-of-care – GemCis (ESMO recommendation) and a median rwOS of just over one year suggesting the need for new

treatments that extend survival. With the recent approval of immunotherapy for aBTC patients, exploration of the benefits in real-world is needed. Additional efforts in the earlier detection of BTC are essential to improve survival.

Virgen del Rocío, Seville, Spain

Background: BTC constitutes a heterogeneous group of invasive tumors, including intrahepatic, perihilar, and extrahepatic cholangiocarcinoma, and gallbladder carcinoma (GC). We aimed to characterize the epidemiology, clinical management, and survival outcomes of BTC pt in our environment.

Methods: We evaluated a large real-world cohort of pt diagnosed with BTC from 1st January 2017 to 31st December 2022 from the Spanish RETUD registry. We described the demographic and clinical features, therapies received and outcomes. We assessed progression-free survival (PFS) and overall survival (OS) using the Kaplan-Meier method in different settings.

Results: A total of 1,285 evaluable pt were included in 28 Spanish sites. The median age was 69.2 years, and 56.2% were men. At primary diagnosis, tumors were mostly intrahepatic (54.8%), followed by extrahepatic (28.5%), and GC (14.6%). Overall, 48.7%, 22.6%, and 28.6% pt were diagnosed with metastatic, locally advanced, and resectable disease, respectively. Only 29.5% of pt underwent surgical resection and 9.6% locoregional procedures. Most pt (74.8%) received systemic treatment as a first-line strategy (86.2%), mainly gemcitabine-based combinations (90%), with 62.7% of pt receiving cisplatin plus gemcitabine (CISGEM). At the database cut-off, 945 pt had died because of disease progression. The median OS at the advanced setting was 9.2 months (m) (95% confidence interval [95CI]: 8.3-10.3). The median PFS in pt with advanced BTC exposed to first-line CISGEM was 5.5 m (95CI 5.0-6.0) with a median OS of 11.6 m (95IC 10.8-12.5). For pt with resectable BTC, OS was analyzed based on whether they received adjuvant treatment (ADJ) and developed metastases (met) during follow-up (see table)

Table: 126P

Group of pt		Median OS (m)	95% CI
No ADJ	No met	36.6	22.8-57.3
	met	21.6	17.8-29.0
ADJ	No met	45.7	33.7-not reached
	met	25.4	21.4-32.6

Conclusions: This study provides insights into the clinical characteristics and management of BTC in the real-world framework in Spain. Our results are consistent with the literature, nevertheless, they must be considered in the context of a currently evolving scenario.

127P Prognostic significance of intratumoral and peritumoral budding in distal extrahepatic bile duct carcinoma

S-Y. Jun[1], S-M. Hong[2], S. An[1]

[1]Pathology, Incheon St. Mary's Hospital, College of Medicine, The Catholic University of Korea, Incheon, Republic of Korea; [2]Pathology, Asan Medical Center - University of Ulsan, Seoul, Republic of Korea

Background: Although tumor budding (TB) has been recognized as a representative adverse prognosticator in gastrointestinal malignancies, it is not well elucidated in distal-extrahepatic bile duct carcinoma (DBDC).

Methods: Herein, we investigated the prognostic significance of peritumoral (PTB) and intratumoral (ITB) budding according to the modified DBDC staging of the 8th edition of the American Joint Committee on Cancer. PTB and ITB were independently evaluated in a cohort of DBDC patients (n=410) based on the 2016 International Tumor Budding Consensus Conference (ITBCC).

Results: High levels of PTB (PTB^{High}, $\geq$ grade 2) and ITB (ITB^{High}, $\geq$ grade 3) were identified in 316 (77%) and 238 (58%) cases, respectively. In univariate analysis, PTB^{High} and ITB^{High} (both P=0.001); larger size and sclerosing tumor growth pattern (both P<0.001); higher histologic grade (P=0.006); extrapancreatic location (P=0.015); adenocarcinomas unrelated to intraductal papillary neoplasm of the bile duct (IPNB) (P=0.008); pancreatic, duodenal, and lymphovascular invasion (all P<0.001); perineural invasion (P=0.003); cancer involvement of the bile duct resection margin, nodal metastasis, and higher T and N categories and disease stages (all P<0.001) were associated with shorter patient overall survival (OS) times. In

multivariate analysis, PTB^{High} and ITB^{High} remained poor independent prognostic indicators of OS in DBDC patients. Specifically, ITB^{High} could predict poor prognosis (P=0.025) in patients with stage I (T1N0) DBDC.

Conclusions: Both PTB^{High} and ITB^{High} were strong prognostic indicators in patients with DBDC. Thus, ITB could be used to predict worse prognoses in patients with DBDC, in which PTB is difficult to assess, especially for patients with stage I (T1N0) DBDC.

128P Biliary tract cancers: Epidemiological and prognosis trends of Latin American population

M.D.C. Diaz Romero[1], G. Calderillo Ruiz[1], E. García[1], B. Carbajal[2], D.A.G. Padilla[3], G.E. Trejo-Duran[4], P. Morales Esponda Mendoza[6], D.L. Guerra Figueroa[6]

[1]Medical Oncology Department, INCAN - Instituto Nacional de Cancerologia, Mexico City, Mexico; [2]Clinical Research, INCAN - Instituto Nacional de Cancerologia, Mexico City, Mexico; [3]Dept. Cirugía Oncológica, INCAN - Instituto Nacional de Cancerologia, Mexico City, Mexico; [4]Radiation Oncology, The National Cancer Institute, Mexico City, Mexico; [6]Facutlad de Medicina, UNAM - Universidad Nacional Autonoma de Mexico, Mexico City, Mexico

Background: Biliary tract cancers are heterogeneous tumors defined by the anatomical location, intrahepatic, cholangiocarcinoma (ICC), extrahepatic (ECC), gallbladder and ampulla of Vater cancer (AVC).The outcome of treatment by location remains unclear in Latin American population, resulting in inconsistently data to enhance treatment decisions and outcome. The aim of this study is to describe the epidemiological features and prognosis of overall survival of Latin American population with biliary tract cancers.

Methods: Retrospective, observational study. Included patients treated at the National Cancer Institute between 2008 and 2022. Statistical analysis required: X^2 *and t* test, Kaplan Meier, Log Rank and Cox Regression. Statistical significance differences were assessed when p was bilaterally <0.05.

Results: A total 786 of patients diagnosed with biliary tract cancer were included in the analysis. Patients had a median age of 61 years (24-96). Alcohol consumption and smoking were observed in 22% and 29% respectively. Regarding comorbidities, 22% had Type2DM, 27% HAS, and obesity & overweight was present in 13% and 32% respectively. Anatomical location included ICC (19%;n=151), ECC (22%;n=172), gallbladder (33%;n=259) and AVC (26%;n=204). Female were more prevalent in gallbladder and ICC (79% & 71%) ($p<0.001$). Median time to diagnosis was 3 months (0–120); extent of disease was observed as localized (18%;n=144), local-advanced (20%;n=158), and metastatic (60%;n=472). In metastatic patients, mean number of metastasis was 1 (1-7), being liver (66%), retroperitoneum (7%), and lung (6%) the most frequent sites. Comparing Chemotherapy and extent of disesase, 35%, 53%, and 55% patients received treatment for localized, unresectable, and metastatic **(p =0.001).** An OS analysis was conducted considering location, ICC patients showed a median-OS of 9months, ECC a median-OS of 12months, gallbladder a median-OS of 1months and AVC did not reach median-OS **(p<0.001).**

Conclusions: Prognosis and outcome for patients with biliary tract cancer differ depending on the anatomical subsite. This is one of the main studies describing epidemiological features, and outcome in Latin American patients with biliary tract.

129P Prognostic factors associated with survival in resected biliary tract cancers: A multicentre Italian experience

M. Ghidini[1], M. Paccagnella[2], M. Salati[3], F. Bergamo[4], M. Ratti[5], B. Galassi[1], O. Garrone[1], M. Rovatti[6], L. Caccamo[7], E. Gringeri[8], A. Zerbi[9], G. Torzilli[10], S. Bozzarelli[11], L. Rimassa[12]

[1]Oncology Unit, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy; [2]Fondazione ARCO - Cuneo, Azienda Ospedaliera St. Croce e Carle, Cuneo, Italy; [3]Medical Oncology Dept, Azienda Ospedaliero - Universitaria Policlinico di Modena, Modena, Italy; [4]Oncology 1, Veneto Institute of Oncology IOV — IRCCS, Padua, Italy; [5]Oncology Department, ASST Cremona - Azienda Socio-Sanitaria Territoriale, Cremona, Italy; [6]Surgery Unit, ASST Cremona - Azienda Socio-Sanitaria Territoriale, Cremona, Italy; [7]Liver Transplant Unit, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy; [8]Hepatobiliary Surgery and Liver Transplantation Unit, Azienda Universitaria Ospedaliera di Padova, Padua, Italy; [9]Pancreatic Unit, IRCCS Humanitas Research Hospital, Department of Biomedical Sciences, Humanitas University, Milan, Italy; [10]Department of Hepatobiliary and General Surgery, Department of Biomedical Sciences, Humanitas University, Milan, Italy; [11]Medical Oncology and Hematology Unit, Humanitas Cancer Center, IRCCS Humanitas Research Hospital, Milan, Italy; [12]Medical Oncology and Hematology Unit, Humanitas Cancer Center, IRCCS Humanitas Research Hospital, Department of Biomedical Sciences, Humanitas University, Milan, Italy

Background: Biliary tract cancers (BTC) are classified as gallbladder tumours (GBC) and intrahepatic (iCCA) or perihilar and distal extrahepatic cholangiocarcinomas (eCCA). BTC's 3-year recurrence rate is up to 80%. Capecitabine (CAP) is the standard for adjuvant (adj) chemotherapy (CT). We collected a retrospective multicentre Italian series of resected BTC and analysed the impact of adj CT on survival.

Methods: Main variables were ECOG performance status (PS), pre-surgical (SUR) Ca 19.9 value, type of SUR, site, histology, invasion (T), nodal status (N), vascular invasion (V) resection margins (R), grade (G). Median follow-up (FU) was estimated with reverse Kaplan-Meier (KM) approach; median RFS (RFS) and median overall survival (OS) were estimated by KM method.

Results: We included 142 all-stages BTC resected from 2005 to 2022, adj CT was given to 69 BTC. With median FU of 89 months (mo), overall RFS and OS were 17 and 30 mo. Lower ECOG PS was associated with longer RFS and OS ($p<0.001$). A pre-SUR Ca19.9 $\leq$ 29 was associated with longer RFS in iCCA ($p=0.001$) and OS both in iCCA ($p=0.010$) and GBC ($p=0.019$). Lower T was associated with longer RFS ($p=0.002$) and OS ($p<0.001$) in iCCA and GBC but not in eCCA. N0 status correlated with longer RFS in iCCA ($p<0.001$) and OS both in iCCA and GBC ($p<0.006$). R0 status was associated with longer RFS in eCCA ($p=0.043$) and GBC ($p<0.001$), showing longer OS only in GBC only ($p<0.001$). V0 status was associated with longer RFS ($p=0.017$) and OS ($p=0.009$) in iCCA . Adj CT didn't impact both on RFS ($p=0.539$) and OS ($p=0.978$) in the whole cohort. After stratification by site, eCCA showed an advantage given by adj CT on mRFS ($p=0.047$). Comparing all adj CT, CAP performed better in iCCA, with a mRFS of 19 mo. Multivariate Cox regression analysis for RFS and OS was stratified for iCCA, eCCA and GBC: ECOG PS, R and N status retained significant correlation with RFS ($p<0.001$, $p<0.001$ and $p=0.034$, respectively) and OS ($p<0.001$, $p<0.001$, $p=0.013$, respectively). Pre-SUR Ca19.9 value correlated with OS ($p=0.001$).

Conclusions: In our series, adj CT didn't impact on survival except for eCCA. Evaluation of multiple prognostic variables (including T, N, R and V status and pre-SUR Ca19.9) is necessary to identify a subgroup of BTC that can benefit more from adj CT.

130P Phase I study evaluating KIN-3248, a next-generation, irreversible pan-FGFR inhibitor, in patients with advanced cholangiocarcinoma, urothelial carcinoma and other solid tumors harboring FGFR2 and/or FGFR3 gene alterations

B. Garmezy[1], M. Borad[2], C-C. Lin[3], L-T. Chen[4], C.A. Perez[5], S. Kato[6], B. Tam[7], P. Severson[8], C.S. Quah[9], J.J. Harding[10]

[1]Research, Sarah Cannon Research Institute, Nashville, TN, USA; [2]Oncology Department, Mayo Clinic Cancer Center, Scottsdale, AZ, USA; [3]Department of Oncology, NTUH - National Taiwan University Hospital, Taipei, Taiwan; [4]Hematology Department, Kaohsiung Medical University Chung-Ho Memorial Hospital, Kaohsiung, Taiwan; [5]Medical Oncology, Florida Cancer Specialists, Fort Myers, FL, USA; [6]Medical Oncology, University of California San Diego - UCSD, La Jolla, CA, USA; [7]Clinical Sciences, Kinnate Biopharma, San Diego, CA, USA; [8]Translational Medicine, Kinnate Biopharma Inc., San Diego, CA, USA; [9]Clinical Development, Kinnate Biopharma, San Diego, CA, USA; [10]Medicine, Memorial Sloan Kettering Evelyn H. Lauder Breast Center, New York, NY, USA

Background: Preclinical and clinical evidence indicates that activating FGFR1-4 gene alterations drives oncogenesis and tumor growth. Pharmacological inhibition of FGFR1-4 leads to tumor shrinkage and disease control, supporting development of FGFR inhibitors. A critical limitation of currently approved, clinical-stage FGFRi is the

emergence of secondary, on-target resistance mutations (mutn) that reduce duration of response. About 70% of cholangiocarcinoma (CCA) patients treated with FGFRi exhibit secondary FGFR2 kinase domain resistance mutn at the time of relapse. KIN-3248 is a next-generation, selective, irreversible, small molecule pan-FGFRi, designed to inhibit primary FGFR oncogenic alterations as well as secondary kinase domain mutn associated with disease progression. Preclinically, KIN-3248 has favorable pharmaceutical properties, is well-tolerated with continuous, daily oral administration in GLP toxicology studies and is efficacious against primary FGFR2 and FGFR3 oncogenic driver alterations as well as secondary FGFR2 resistance mutn (eg, gatekeeper and molecular brake) in human cancer cells and PDX models.

Trial design: KN-4802 (NCT05242822) is a first in human, multicenter, Ph1 study of KIN-3248 in pts with advanced and metastatic solid tumors (AMST) harboring FGFR2 and/or FGFR3 gene alterations. KIN-3248 is given continuously in 28-day cycles until drug intolerance or disease progression. The study is conducted in 2 parts: Part A is a dose escalation of KIN-3248 to MTD/RP2D. Part B evaluates a selected dose of KIN-3248 in previously treated intrahepatic cholangiocarcinoma (ICC) or urothelial carcinoma (UC), treatment naïve ICC or UC, or other AMST. Enrollment criteria include ECOG PS 0-1 and prior standard treatment with clinical benefit, if appropriate. Primary endpoints are safety and preliminary antitumor activity. Secondary objectives include pharmacokinetic and pharmacodynamic assessments including measures of FGFR pathway modulation. Planned sample size is 140 pts and the study is enrolling patients in the US, EU and globally.

Clinical trial identification: NCT05242822.

ANNALS OF ONCOLOGY driving innovation in oncology

BIOMARKERS (AGNOSTIC)

131O A composite biomarker for evaluation of homologous recombination repair deficiency in a pan-cancer cohort

M. Rübsam[1], M. Rheinnecker[1], B. Hutter[1], M. Fröhlich[1], C.E. Heilig[2], N. Paramasivam[1], M. Oleś[1], C. Ball[3], H. Glimm[3], M. Hlevnjak[1], M. Zapatka[4], P. Lichter[4], S. Fröhling[2], R.F. Schlenk[5], D. Hübschmann[1]

[1]Computational Oncology Group, Molecular Precision Oncology Program, German Cancer Research Center (DKFZ) and National Center for Tumor Diseases (NCT) Heidelberg, Heidelberg, Germany; [2]Division of Translational Medical Oncology, German Cancer Research Center (DKFZ) and National Center for Tumor Diseases (NCT) Heidelberg, Heidelberg, Germany; [3]Department for Translational Medical Oncology, National Center for Tumor Diseases (NCT/UCC) Dresden, German Cancer Research Center (DKFZ) Heidelberg, Faculty of Medicine and University Hospital Carl Gustav Carus, Technische Universität Dresden, and Helmholtz-Zentrum Dresden-Rossendorf (HZDR), Dresden, Germany; [4]Division of Molecular Genetics, German Cancer Research Center (DKFZ) and National Center for Tumor Diseases (NCT) Heidelberg, Heidelberg, Germany; [5]Clinical Trial Center, National Center for Tumor Diseases (NCT) Heidelberg, German Cancer Research Center (DKFZ), and Heidelberg University Hospital, Heidelberg, Germany

Background: Assessing the functional state of homologous recombination repair (HRR) is crucial to predict an effective response to *PARP* inhibitor (PARPi) treatment or platinum-based chemotherapy in cancer patients. Drug approvals are currently mostly based on mutations in *BRCA1* and *BRCA2* or genomic scarring alone. Composite biomarkers may extend the discriminative power and make targeted treatment approaches available to a wider range of patients and entities.

Methods: Whole-genome or -exome sequencing (WGS or WES) data from 739 patients including various rare cancers were evaluated for germline and somatic alterations in one of 183 genes related to HRR as well as for genomic patterns of HRR deficiency (HRD), i.e. exposure to single-base substitution signature 3, quantification of HRD-derived loss of heterozygosity (LOH-HRD), and the number of large-scale state transitions (LST). The individual markers were integrated into a composite biomarker, the TOP-ART score, with a scoring system (0-7) and compared to the other published HRR biomarkers. Currently, this biomarker is used to determine eligibility for the TOP-ART trial (ClinicalTrials.gov identifier: NCT03127215, olaparib/trabectedin vs. physician's choice, estimated study completion: December 2023).

Results: The occurrence and severity of HRD predicted by the TOP-ART score varies between entities. Strong associations were found between genomic patterns of HRD and mutations affecting several genes, including but not limited to *BRCA1* and *BRCA2*. The phenotypic susceptibility to *BRCA1* and *BRCA2* impairment varies between entities and depends on zygosity. TOP-ART score positivity (score $\geq$3; 312 cases) overlaps with but is more inclusive than HRDetect (55 cases) and CHORD (26 cases). In particular, we identify patients who were biomarker-negative for HRDetect and CHORD, but positive in the TOP-ART score, and achieved long-lasting disease control upon treatment with olaparib/trabectedin.

Conclusions: The TOP-ART score is a novel composite HRR biomarker developed and validated in an observational precision oncology cohort. It has the potential to broaden access to targeted treatments and is prospectively used to determine eligibility for the TOP-ART trial.

Clinical trial identification: NCT03127215 Study of Olaparib/Trabectedin vs. Doctor's Choice in Solid Tumors (NCT-PMO-1603) Estimated Primary Completion Date: December 2023 Estimated Study Completion Date: December 2023.

Background: Within the EORTC-SPECTA platform, the ARCAGEN collaborative study between EORTC and EURACAN was initiated in June 2019 and aimed to assess the prevalence of genomic alterations, high tumor mutational burden (TMB) and microsatellite instability (MSI), as well as actionability in patients diagnosed with advanced rare cancers (defined with an incidence$<6/10^5$/y).

Methods: Patients with a rare adult solid tumor of one of the 10 domains or EURACAN in advanced phase were proposed for the ARACAGEN study as part of the SPECTA program.

Results: Within 3.5 years, 991 patients were enrolled within 14 countries in Europe, 918 were evaluable, receiving a molecular profile (92.60% success rate), with a median turn-around time of 13.25 days [range 11.5-17]. Molecular profiling was preferentially performed on FFPE material (FoundationOne, 73.5%), if not feasible, liquid biopsy was used as a rescue (FoundationOne Liquid, 26.5%). The 3 most common histotypes were cancer of unknown primary (CUP, 103, 11.2%), mesothelioma (80, 8.7%), cholangiocarcinoma (72, 7.8%). Clinically relevant molecular alterations were identified in 606 patients (66%), with top alterations seen in *TP53* (28.5% of all enrolled patients), *CDKN2A/B* (16.8%), *KRAS* (9.2%). The TMB was above 10 for 53 patients (5.3%) and 9 MSI-high patients were identified. A differential profile was seen between FFPE and blood analysis due to CHIP identification (DNMT3A, MLL2, TET2 for example). Altogether, 456 patients (46%) received a therapy recommendation based on the molecular analysis: 63 (6.8%) patients for an already approved treatment (ESCAT 1A); 232 (25.3%) for an off-label use of an approved treatment in another indication with similar molecular alteration (ESCAT IC, II or III); and 161 (17.5%) for a clinical trial. Response rate, duration of response and survival will be presented.

Conclusions: Close to 50% of patients with rare cancers received a therapeutic recommendation based on molecular characterization, a majority within clinical trials. Molecular characterization should be recommended routinely for rare cancers in advanced phase.

Clinical trial identification: SPECTA NCT02834884.

133MO Differentiation of malignant and benign lung nodules using epigenetically modified nucleosomes in plasma

P-H. Chen[1], T-M. Tsai[2], D. Pamart[3], T. Bygott[3], M. Herzog[3], J. Micallef[3], J-S. Chen[2]

[1]Surgery, National Taiwan University Hospital Hsin - Chu Branch, Hsinchu City, Taiwan; [2]Surgical Oncology, NTUCC - National Taiwan University Cancer Center, Taipei, Taiwan; [3]Research and Development, Belgian Volition SRL, Isnes, Belgium

Background: Recent lung cancer screening trials indicate that low-dose computed tomography (LDCT) has been successful in reducing mortality in high-risk patients. Nonetheless, the high frequency of false-positives leads to expense and possible harm, emphasizing the necessity for complementary biomarkers. To address this, we aimed to enhance the accuracy of lung cancer screening by utilizing a lung cancer-specific immunoassay panel for epigenetically modified nucleosomes in plasma to help differentiate between benign and malignant nodules.

Methods: During the years 2021 and 2022, a total of 806 individuals who had a positive result from LDCT screening and underwent surgery or biopsy were included in the study. Plasma samples from these participants were analyzed for nucleosomes containing histone modifications including H3K27Me3, H3K36Me3, or the H3.1 histone isoform by quantitative immunoassay (Nu.Q®, Belgian Volition SRL). Among these individuals, 648 were diagnosed with either lung cancer or a pre-cancerous lesion, while 158 were diagnosed with a benign lesion based on pathological reports. Logistic regression was used to analyze the assay data, and a simple algorithm was developed to predict whether a nodule was benign or malignant. The algorithm was created using samples collected in 2021 (n=561) as a training set and validated using samples collected in 2022 (n=245).

Results: The plasma epigenetic nucleosome assay for detecting lung cancer showed a diagnostic sensitivity of 92% and a specificity of 82% using a simple regression algorithm, trained on data from the 2021 group. The AUC for differentiating between cancerous and benign nodules was 88%. When the assay was applied to data from 2022, it achieved an AUC of 77% for distinguishing between cancer and benign nodules, with a sensitivity of 60% and a specificity of 84%. The validation test revealed that the algorithm correctly identified patients with stage I cancer and carcinoma in situ in 58% and 61% of cases, respectively.

Conclusions: This large validation study indicates that the epigenetic nucleosome assay has predictive, diagnostic, and prognostic value and could reduce the false-positive rate of LDCT.

134P TERT-associated DNA polymerases genes link CAF and CD8+ T cells to improve immunotherapy response rate across multiple cancers

Z. Luo[1], Y. Xie[2], Y. Deng[1], Y. Che[3], X. Bi[2], H. Zhao[1], X. Bi[1]

[1]Department Of Hepatobiliary Surgery, Chinese Academy of Medical Sciences and Peking Union Medical College - National Cancer Center, Cancer Hospital, Beijing, China; [2]Department of Urology, National Cancer Center - Cancer Hospital, Chinese Academy of Medical Sciences, Beijing, China; [3]Thoracic Surgery, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China

Background: Cancer cells exhibit heightened basal levels of responses to DNA breaks, accumulating DNA polymerases family (DNA-pol) as repair protein, thereby increasing DNA mutation and neoantigens. Based on this, we investigated the potential of DNA-pol as an immunotherapy biomarker and its underlying mechanism.

Methods: We conducted a pan-cancer analysis of DNA-pol gene dysregulation in 6366 samples. Normal fibroblast, cancer-associated fibroblast, and CD8+ T cells were cultured from cancer patients (3 esophagus, 5 lung, 5 renal, and 3 liver cancer), then treated them with PD-L1 inhibitor or overexpressing TERT for RNA-seq and proteomics. 996 multiple cancer cases with ICIs were collected to test biomarker efficiency. A phase II clinical trial is evaluating our biomarker prospectively.

Results: We defined a distinct signature score of DNA-pol genes upregulated in cancer (DNA-pol-up) and linked to worse prognosis (HR=1.2). DNA-pol-up program dysregulation led to immune processes alteration and was related to upstream activation of TERT signaling (z-score=3.6) in ingenuity pathway analysis and linked to immunologically active tumors by recruiting CD8+ T cell and downregulating CAF. DNA-pol-up score was elevated in PD-L1-treated CAF and TERT-overexpressed CD8+ T cell, in MSI-H cancer, also related to more neoepitope peptides, TMB (Rho=0.54), cancer stemness (Rho=0.78), and tumor purity (Rho=0.29). Cancers that activate this program carried distinct genomic profiles with PIK3CA, KRAS, and TP53 mutations. This signature was an independent predictor for ICIs response (OR=2.52), even outperforming cytolytic activity, MSI, TMB (OR=0.9). In 12 clinical trial datasets, this signature could stratify the responding patients (maxAUC=0.762). In our phase II clinical trial, 34 liver cancer were enrolled with 3-year follow-up, it also has a satisfactory performance in predicting the ORR (AUC=0.699) and classifies mortality rate (HR=2.3).

Conclusions: Our findings identify a distinct transcriptional pattern of DNA-pol genes across cancers, which highlighted the role of DNA-pol family genes in predicting the immunotherapy response for the first time, and TERT could be a novel vaccine candidate for improving immunotherapy response.

135P The lymphocyte stability index (LSI) forms a pan-cancer peripheral biomarker for overall survival post initiation of immune checkpoint blockade (ICB)

R.A. Watson[1], O. Tong[1], C. Taylor[1], G. Vallance[2], F. Matos Santo[1], M. Little[3], B. Sun[4], B. Shine[5], M.R. Middleton[2], N.A. Coupe[2], M. Payne[2], B.P. Fairfax[1]

[1]Department of Oncology, The MRC Weatherall Institute of Molecular Medicine Oxford, Oxford, UK; [2]Oncology and Haematology, Oxford University Hospitals NHS Foundation Trust - Churchill Hospital, Oxford, UK; [3]Medical Oncology, Churchill Hospital - Oxford University Hospitals NHS Foundation Trust, Oxford, UK; [4]Nuffield Department of Clinical Neuroscience, John Radcliffe Hospital University of Oxford, Oxford, UK; [5]Clinical Biochemistry, John Radcliffe Hospital University of Oxford, Oxford, UK

Background: Robust, pan-cancer peripheral blood biomarkers for response to immune checkpoint blockade (ICB) are lacking. We have previously shown that a single nucleotide polymorphism at rs16906115 (intronic to *IL7*) associates with increased risk of ICB toxicity, but promotes increased lymphocyte count stability post-initiation of treatment. Individuals with a stable lymphocyte count had improved progression-free (PFS) and overall survival (OS) in metastatic melanoma (MM). We hypothesise that the Lymphocyte Stability Index (LSI) can predict outcome to ICB across a range of cancers.

Methods: We retrospectively collected treatment, blood count and survival data on all individuals treated with ICB since 2014 at Oxford University Hospitals NHS Foundation Trust (n=706). We performed survival analysis based on lymphocyte stability. The LSI was calculated by dividing the post-treatment lymphocyte count by the pre-treatment count.

Results: Using a replication cohort, we validated our previous finding that patients with stable LSI (>0.8) had significantly improved overall survival in MM. This was also the case for those with stable LSI and a diagnosis of non-small cell lung cancer (NSCLC) or metastatic renal cell carcinoma (mRCC) with previous pre-treatment. Using a Cox proportional hazards model to control for a range of covariates including age and number of prior treatments, a stable LSI was associated with a hazard ratio for death of 0.38 (95% CI: 0.26-0.56, p<0.0001) for MM (combined cohorts), 0.49 (95% CI: 0.33-0.77, p<0.001) for NSCLC and 0.33 (95% CI: 0.14-0.89, p=0.013) for pre-treated mRCC. Patients with MM and stable LSI treated with single-agent PD-1 blockade had equivalent survival to those treated with combination ICB.

Conclusions: The LSI is an extremely simple dynamic peripheral biomarker for survival following ICB treatment across multiple cancers with an underlying molecular and genetic association. Application of LSI in MM permits effective patient stratification, delineating those who single-agent ICB provides equivalent benefit to combination anti-PD1 and anti-CTLA-4 treatment, potentially sparing them of the associated toxicity burden.

Background: The multicohort KEYNOTE-158 (NCT02628067) trial supported the US FDA and EMA approval of pembrolizumab across multiple microsatellite instability-high (MSI-H)/mismatch repair deficient (dMMR) advanced solid tumors. The incidence of MSI-H/dMMR advanced cancer in patients (pts) of Chinese descent is similar to that reported in Western populations (Liu et al 2019, Cancer Research 79:616). In cohort L of KEYNOTE-158, we evaluated the efficacy and safety of pembrolizumab in pts of Chinese descent with MSI-H/dMMR solid tumors.

Methods: In this nonrandomized, phase 2, open-label trial, pts aged ≥ 18 years of Chinese descent were enrolled. These pts had to have confirmed MSI-H/dMMR unresectable or metastatic cancers who had ≥1 prior lines of therapy. Eligible pts received 200 mg pembrolizumab Q3W for up to 35 cycles, until progression, unacceptable toxicity, or pt/investigator withdrawal. MSI-H/dMMR status was assessed centrally by PCR or ICH. The primary endpoint was ORR per RECIST 1.1 by independent central review. Secondary endpoints were DOR, PFS, OS and safety. The database cut-off date was July 26, 2022.

Results: At data cut-off, a total of 24 pts were enrolled of which 20 pts were for efficacy evaluation having at least 6 months (mo) of follow-up. The overall ORR was 70.0% (95% CI: 45.7%- 88.1%) for the 20 pts. The median DOR was not reached (NR) (range, 2.1+ - 19.3+) with a 12-mo DOR rate of 85.7%. Median PFS was NR (95% CI: 15.8-NR) with an 18-mo PFS rate of 68.0%. The median OS was NR (95% CI: 9.5, NR) with an 18-mo OS rate of 80.2%. Treatment-related adverse events (AE) were reported in 19 (79%) of the 24 pts enrolled. Grade ≥3 treatment-related AEs occurred in 4 (17%) pts with no grade 5 AEs. Immune-mediated AEs occurred in 8 pts (33%). Of these pts, 2 (8%) had grade 3 AEs (myositis or rash in 1 pt each). No grade 4 or 5 immune-mediated AEs occurred.

Conclusions: Pembrolizumab provided clinically meaningful antitumor activity and durable responses in pts of Chinese descent with MSI-H/dMMR tumors, with a manageable safety profile. No new safety signals were identified. These results are consistent with those reported for patients in the global population.

Clinical trial identification: NCT02628067; first posted on December 11, 2015.

137P VEGFR-3 expression profiling by histology and mRNA signature to classify patient population for the selective VEGFR-3 inhibitor EVT801

C.A. Gomez-Roca[1], P. Fons[2], P-B. Ancey[2], P. Cassier[3], J-P. Delord[4], L. Davenne[2], M. Fitzgerald[5], M. Mandron[6], M.R. Paillasse[7], J. Friend[8], P. Rochaix[9]

[1]Medical Oncology and Clinical Research Department, Institut Universitaire du Cancer -Toulouse- Oncopole, Toulouse, France; [2]Translational Biomarkers, Evotec, Toulouse, France; [3]Medical Oncology Department, Centre Léon Bérard, Lyon, France; [4]Medical Oncology Department, IUCT - Institut Universitaire du Cancer de Toulouse - Oncopole, Toulouse, France; [5]Kazia Therapeutics Limited, Sydney, NSW, Australia; [6]Clinical Development Solution, Evotec (France) Sas, Toulouse, France; [7]Innovate Oncology, Evotec (France) Sas, Toulouse, France; [8]Medicine, Kazia Therapeutics Limited, Sydney, NSW, Australia; [9]Histopathology Department, Institut Universitaire du Cancer -Toulouse- Oncopole, Toulouse, France

Background: EVT801 is a highly selective small molecule inhibitor of VEGFR-3 and acts by inhibiting tumor lymphangiogenesis and angiogenesis. A phase I clinical study (NCT05114668) has started to characterize safety, tolerability, pharmacokinetics of EVT801. Clinical samples from these patients will be used to explore preliminary signals of clinical efficacy and investigate the biological activity of the drug using several biomarkers. Among them, we have investigated VEGFR3 expression profiling by histology.

Methods: We validated a highly specific protocol for VEGFR-3 immunohistochemistry labelling and a VEGFR-3 mRNA signature, readily transferable to clinical centers.

Results: Initially, VEGFR-3 expression was assessed in 29 primary kidney cancer samples and 23 metastatic kidney cancer samples with CD34 to stain vessels and D2-40 to track lymphatics. We detected VEGFR-3 expression in the endothelial cells within the kidney tumor but not in the tumor cells. Remarkably, we observed a very distinct delineation between the kidney tumor vasculature, which showed high VEGFR-3 expression, and the normal adjacent tissue, which was devoid of VEGFR-3 expression. In addition, we found that VEGFR-3 expression in metastases from kidney tumors matched the expression pattern of the primary tumor. Then, We have demonstrated that it exists a strong correlation between VEGFR-3 expression by histology and VEGFR-3 mRNA signature. We applied both VEGFR-3 signatures in different indications of interest like soft tissue sarcomas and lung cancers.

Conclusions: We were able to quantify VEGFR-3 expression by histology and mRNA signature in the kidney and soft tissue sarcoma cohorts plus several others, such as

hepatocarcinoma and non-small cell lung cancer. This enables us to select indications that might benefit from EVT801 as a monotherapy (e.g., clear cell renal cell carcinoma and soft tissue sarcomas) or in combination with standard of care. Accordingly, VEGFR-3 expression is retrospectively quantified during the EVT801 phase 1 clinical trial and may be used to stratify patients in the future.

Clinical trial identification: NCT05114668.

138P Precision medicine phase II study evaluating the efficacy of olaparib in patients with progressive solid cancers and carriers of homologous recombination repair genes alterations

M. Polito[1], C. Le Tourneau[2], A. DeMontfort[1], S. Cousin[3], M. Toulmonde[3], C.A. Gomez-Roca[4], K. Bourcier[3], I. Korakis[4], F. Bertucci[5], E. Mitry[5], C. Mazza[3], P. Cassier[1], C. Coutzac[1], A. Italiano[3], V.K. Attignon[1], R. Mayet[1], D. Perol[1], M.P. Sablin[2], J-Y. Blay[1], O. Tredan[1]

[1]Medical Oncology, Centre Léon Bérard, Lyon, France; [2]Department of Drug Development and Innovation (D3i), Institut Curie, Paris, France; [3]Medical Oncology Department, Institut Bergonie - Centre Régional de Lutte Contre le Cancer (CLCC), Bordeaux, France; [4]Medical Oncology and Clinical Research Department, Institut Universitaire du Cancer -Toulouse- Oncopole, Toulouse, France; [5]IPC - Institut Paoli-Calmettes, Marseille, France

Background: The improved understanding of the biological mechanisms of the homologous recombination repair and the emergence of PARP inhibitors has opened new therapeutic options for patients with progressive cancers on standard treatments. The MOST study was designed to treat patients with metastatic solid tumors according to specific molecular alterations. We present here the results of the olaparib cohort.

Methods: The MOST trial is an ongoing multicenter, prospective, randomized study conducted in six French university hospitals. Patients known to have germline or somatic alterations in the homologous recombination genes received olaparib (300mg, BID) outside standard recommendations, until disease progression, unacceptable toxicity, patient's or investigator's decision. Disease response was evaluated at 12 weeks of treatment per RECIST criteria.

Results: Amongst the 213 included patients (63.4% female, median age: 58 years [26-85], median number of prior lines of treatment: 3 [1-16]) e.g. platinium 63%), the main initial tumor sites were breast (25.8%), pancreas (19.2%), colorectal (7.5%), sarcoma (6.1%) and brain (5.2%). Tumor response after 12 weeks (W12) according to main HRD genes altered (>5%) are presented in table. Patients with PALB2 mutations showed the best disease control rate. Grade 3 or higher adverse events were reported in 81 patients (38%).

Table: 138P Tumor status at week 12 for the main molecular alterations (>5%)

Tumor status	CR or PR	SD	PD	Treatment discontinuation
All patients (n=213)	n=14 (6%)	n =34 (16%)	n=161 (76%)	n=4 (2%)
Gene altered, N (% of population)				
BRCA1, N = 26 (12.2%)	0 (0.0%)	3 (11.5%)	23 (88.5%)	0 (0.0%)
BRCA2 N= 49 (23%)	8 (16.3%)	5 (10.2%)	36 (73.5%)	0 (0.0%)
PALB2 N= 15 (7%)	4 (26.6%)	2 (13.3%)	8 (53.3%)	1 (6.6%)
ATM N= 49 (23%)	1 (2%)	11 (22.4%)	37 (75.5%)	0 (0.0%)
BAP1 N= 14 (6.6%)	1 (7.1%)	3 (21.4%)	10 (71.4%)	0 (0.0%)

CR/PR/SD/PD according to RECIST. Treatment discontinuation before W12 was due to toxicity or patient decision.

Conclusions: Overall, only a minority of patients benefit from olaparib treatment after 12 weeks of treatment even though their tumor harbor HRD gene alterations, with a 3-month PFS rate of 23% (48/213). Translational research is ongoing to explore which genomic signature is associated with olaparib response.

Clinical trial identification: NCT02029001.

139P The characteristics in Chinese NSCLC patients with different BRAF mutation classes

Q. Wang[1], D. Fu[2], X. Li[2], L. Zhang[3], X. Dong[4], F. Pang[2]

[1]Respiratory Medicine, The Second Affiliated Hospital of Nanjing Medical University, Nanjing, China; [2]Medical Department, Shanghai OrigiMed Co., Ltd, Shanghai, China; [3]Operational Department, OrigiMed Shanghai Co., Ltd., Shanghai, China; [4]Pathology and Production center, Shanghai OrigiMed Co., Ltd, Shanghai, China

Background: Compared with *BRAF* Class II and Class III mutations in non-small cell lung cancer (NSCLC), *BRAF* Class I mutations can be effectively targeted by inhibitors. However, the characteristics of Chinese NSCLC with different *BRAF* mutation types are still unclear. Thus, the more comprehensive exploration of *BRAF* mutation profile in Chinese NSCLC was investigated to guide the development of personalized treatment strategies.

Methods: Data was collected on a total of 2,030 cases of NSCLC throughout China between October 2018 and October 2021. Next Generation Sequencing (NGS) is based on the sequencing of tissue samples on the YUANSU™ panel (OrigiMed, Shanghai, China) with 706 cancer-related genes. Wilcoxon Rank Sum Test were applied to significance statistics.

Results: Among the samples, *BRAF* mutations were detected in 82 cases (4.0%, 82/2030), including 19 Class I (0.9%, 19/2030, V600E), 13 Class II (0.6%, 13/2030, K601E, L597R/Q, G464V, G469A/V), and 11 cases Class III (0.5%, 11/2030, G466A/E, N581I, D594G/N). In addition, 39 cases (1.9%, 39/2030) remained unclassified: 22 (1.0%, 22/2030) with potential significance. The *BRAF* mutations were more commonly observed in primary tumors (p=0.066) and the Class I mutations were more prevalent in female patients (63.2%, 12/19, p=0.005). In addition, the median TMB (7.21 mut/Mb) of Class I mutations tumor was significantly lower than that of Class II mutations (median TMB =12.69 mut/Mb), III mutations (median TMB =22.32 mut/Mb) and unclassified BRAF mutations (median TMB =10.33 mut/Mb)(p = 0.033), implying that the patients with Class I mutations may not be suitable for immunotherapy compared with patients with Class II and III mutations. Furthermore, *TP53*, *LRP1B*, *STK11*, *SPTA1*and *MAGI2* were significantly over-mutated in Class II and III ($p<0.06$) and *SETD2* is over-mutated in Class I ($p<0.001$), might suggesting relatively poor prognosis in NSCLC patients.

Conclusions: The characteristics of Chinese NSCLC were further explored, including BRAF mutation types, the incidence of related co-mutations and TMB value, which is helpful to formulate targeted therapy strategies to adapt to different types of *BRAF* mutation functions according to their genomic and clinical characteristics.

140P Colorectal adenoma subtypes exhibit distinct molecular profiles- implications to early detection

F.M. Mancuso[1], P. Canal Noguer[1], K. Kruusmaa[2]

[1]R&D Department, Universal Diagnostics S.A., Seville, Spain; [2]R&D Department, Universal Diagnostics d.o.o., Ljubljana, Slovenia

Background: Colorectal adenomas (AA) are pre-cursors for 85% of the cancers. Methylation and copy-number alterations are well described in colorectal cancer (CRC) context. We aimed to investigate these signals on AA sub-types.

Methods: Whole-genome Enzymatic Sequencing was performed on advanced adenoma (AA) and adjacent control (CNT) tissues of serrated (14), tubular (26), tubulovillous (24) and villous (10) patient samples, alongside colorectal cancer (CRC) stage I samples (23). Differential methylation analysis pipeline was applied, first to identify regions that are significantly altered between all AA subgroups and CNT tissue and then further investigated for sub-type and CRC I level differences. Additionally, mutation and copy-number alteration (CNA) detection were performed, alongside pathway enrichment.

Results: Initial differential methylation analysis revealed 7725 regions significantly altered between AA and CNT tissue. 137 and 2093 and 91 of those were

hypermethylated between serrated vs tubular, serrated vs tubulovillous, tubular vs tubulovillous sub-types respectively. Main pathways, differentiating serrated adenomas from the rest, belong to cAMP signalling, regulation of pluripotency of stem cells, while regions separating tubular and tubulovillous were enriched for WNT signalling. These differential signals could not be seen in stage I CRC samples, which presented CNT-like methylation. The CNA signals were mostly present in tubular or tubulovillous samples. The most frequent signals could be seen in chr7, 12, 19 and 20. Majority of CRC I exhibited CNA in chr 7, 8 and 20, indicating difference processes to be in place between AA and CRC I progression. Differences could also be observed on sub-type level, when looking at tumour mutational burden and specific mutations in APC and KRAS genes.

Conclusions: Colorectal adenoma histological subtypes show distinctly different methylation, CNA and mutational signals, between groups and compared CRC I. These findings are especially important when developing early detection or cancer prevention tests trying to capture adenoma (sub-type level) signatures. These results have been followed by plasma-based biomarker detection studies for pre-cancer screening intent.

141P Microsatellite instability and its relationship with systemic inflammation as prognostic factors in localised colorectal cancer

J.H. Yeo[1], J.H. Park[2], H.K. Ahn[3], I. Park[4], Y.S. Kim[5], E.K. Cho[2], D. Shin[3], W-S. Lee[6], J.H. Baek[7], S.J. Sym[8]

[1]Hemato-Oncology, Hanyang University College of Medicine, Myongji Hospital, Goyang, Republic of Korea; [2]Internal Medicine, Gachon University Gil Hospital, Incheon, Republic of Korea; [3]Medical Oncology, Gachon University Gil Hospital, Incheon, Republic of Korea; [4]Medical Oncology, Asan Medical Center - University of Ulsan, Seoul, Republic of Korea; [5]Internal Medicine, Gil Medical Center, Gachon University College of Medicine, Incheon, Republic of Korea; [6]Colon and Rectal Surgery, Gil Medical Center, Gachon University College of Medicine, Incheon, Republic of Korea; [7]Colon and Rectal Surgery, Gachon University Gil Hospital, Incheon, Republic of Korea; [8]Medical Oncology & Internal Medicine Dept., Gachon University Gil Hospital, Incheon, Republic of Korea

Background: Microsatellite instability-high (MSI-H) is a well-known favorable prognostic marker in localized colorectal cancer (CRC) patients, mainly due to local anti-tumor immunity of cytotoxic T cells. The tumor-induced systemic inflammation is also proven to be responsible for pro-tumor immunity. Despite the importance of tumor microenvironment, the relationships between MSI status, systemic inflammation, and their prognostic effects in CRC patients have not been widely studied.

Methods: We retrospectively analyzed a total of 1130 patients who had diagnosed as stage I to III CRC and had surgical resection from Jan 2007 to Oct 2016 at Gil Medical Center in South Korea. MSI status was evaluated by polymerase-chain reaction (PCR) of mononucleotide repeats. Neutrophil-lymphocyte ratio (NLR), from the blood cell count drawn before any treatment, was used to represent systemic inflammation. Univariable and multivariable analysis were performed with Cox's proportional hazard model to identify prognostic factors in localized CRC patients.

Results: Among 1130 patients of stage I to III CRC, 84 (7.4%) patients had MSI-H CRC, and the majority of MSI-H CRCs were found in stage II patients (12.2%, n=46/378). MSI-H was significantly associated with high NLR (20.2% vs 7.4%, $p<0.001$) as well as right-sided (67.4% vs 20.9%, $p<0.001$), poorly differentiated (17.4% vs 2.8%, $p<0.001$), less perineural invasion (11.6% vs 22.4%, p=0.020), and low BMI (5.8% vs 14.3%, p=0.028). Combining MSI and NLR, MSS/NLR$\geq$5 group showed worst PFS and OS consistently throughout stage I to III (p=0.017). Interestingly, MSI-H/NLR$\geq$5 group showed worse PFS and OS than MSS/NLR$<$5 group in stage II patients (p=0.006). In multivariable analysis, MSS/NLR$\geq$5 group was related significantly with poor PFS (HR 4.19, 95% CI 1.37-12.83, p=0.012), and showed a trend toward poor OS (HR 4.42, 95% CI 0.84-23.11, p=0.079).

Conclusions: MSI-H was significantly associated with high NLR, and its prognostic effect outweighed that of MSI-H, especially in stage II CRC. Therefore, we should consider more about factors of tumor microenvironment such as high NLR, as one of criteria to classify high-risk stage II CRC, which needs adjuvant chemotherapy.

142P Correlating total tumor volume on CT-Scan and liquid biopsy ctDNA in 1017 patients with metastatic cancer: A novel study

Y. Belkouchi[1], L. Dawi[2], L. Lawrance[3], S. Ammari[3], D. Vasseur[4], F. Wirth[2], O. Gautier[2], P-H. Cournede[3], J. Hadchiti[2], C. David[2], F. Bidault[2], C. Balleyguier[5], M. Kind[6], H. Talbot[7], A. Italiano[8], N. Lassau[9]

[1]OPIS Inria, CentraleSupélec - Paris-Saclay Campus, Gif Sur Yvette, France; [2]Imaging, Gustave Roussy, Paris, France; [3]Imaging, Gustave Roussy - Cancer Campus, Villejuif, France; [4]Molecular Biology, Gustave Roussy - Cancer Campus, Villejuif, France; [5]Imaging, Institut Gustave Roussy, Villejuif, France; [6]Imaging, Institut Bergonie, Bordeaux, France; [7]Imaging, CentraleSupélec - Paris-Saclay campus, Gif Sur Yvette, France; [8]Early Phase Trials Unit, Institute Bergonié, Bordeaux, France; [9]Gustave Roussy - Cancer Campus, Villejuif, France

Background: Liquid biopsy is an emerging technology capable of detecting cancer, while CT-imaging is the gold standard. We aim to correlate imaging features from CT-scans to liquid biopsy ctDNA tumor fraction (TF) and blood Tumor Mutational Burden (bTMB).

Methods: This retrospective multicentric study included 1017 patients with metastatic cancer who underwent a variety of treatments. Liquid biopsy and contemporaneous CT-scans were collected. TF and bTMB values were computed using FoundationOne Liquid CDX solution by Roche, with high tumor fraction being over 10%. Two expert radiologists outlined all cancerous lesions in the largest axial diameter. Total tumor volume (TTV) was defined as the sum of estimated lesion volumes. Training set consisted of data from several imaging centers, while the validation set was single-center. Continuous value distributions by category were tested using the Mann-Whitney U-test, and a threshold was set with ROC curve analysis using Youden's Index. This cutoff defined high and low groups, and a X^2 test of independence was used to examine the correlation. Sensitivity and specificity were reported with imaging features taken as the gold standard. Subanalyses were run on patients with liver lesions.

Results: Overall, 55294 lesions were annotated, most commonly located in the lung (n=20074), liver (n=11297) and lymph nodes (n=10222). The train and validation sets included 599 and 418 patients. Preliminary analyses were performed on the train set. Patients with low TF had significantly less TTV than those with high TF ($p<0.001$). ROC analysis yielded an AUC of 0.63 with a threshold of 106 cm3. Correlation was significant between TTV and TF categories (X^2 test: $p<0.001$). The sensitivity and specificity were 76% and 42%. For patients with liver lesions (n=253) , TTV threshold was 108 cm3 with an AUC of 0.66. Correlation was significant between TTV and TF categories (X^2 test: $p<0.001$). The sensitivity and specificity were 82% and 42%.

Conclusions: Analysis showed significant correlation between TTV and ctDNA TF. Sensitivity was higher for patients with liver lesions, suggesting that some organs shed tumoral DNA more than others. The study of tumor heterogeneity on imaging and its correlation to bTMB is in progress.

[1]Drug Development Department (DITEP), Gustave Roussy - Cancer Campus, Villejuif, France; [2]Molecular Biology, Gustave Roussy - Cancer Campus, Villejuif, France; [3]Medical Oncology Department, Institut Gustave Roussy, Villejuif, France; [4]Breast Unit, Gustave Roussy - Cancer Campus, Villejuif, France; [5]Medical Biology and Pathology Department, Gustave Roussy - Cancer Campus, Villejuif, France

Background: Within the last decade, immunotherapy revolutionized cancer treatment and patients (pts) prognosis. MSI is a validated biomarker of response to immune checkpoint blockers (ICB). In daily practice, Immunohistochemistry (IHC) and polymerase chain reaction (PCR) are the most recommended techniques for MSI detection. Lately, next generation sequencing (NGS) performed on liquid biopsy emerged as a new tool for MSI detection and can be used as an alternative to IHC/PCR analysis on tissue. We aim to describe the characteristics of a cohort of pts with MSI solid tumors detected by liquid biopsy and to evaluate the concordance with IHC and NGS testing.

Methods: Data was collected from medical records and molecular profile reports (Foundation One Liquid CDx Assay — 324 genes) performed within the STING trial (NCT04932525) between June 2021 and April 2023.

Results: Among 4535 pts who underwent liquid biopsies, we found 1.5% (n=70) pts with a MSI positive status. The main characteristics were: 51% (n=36) were male with a median age of 68 years [32-89]. 24% of pts (n=17) had a known Lynch Syndrome. Most common tumor locations were colorectal (23%) and endometrial (16%). Median tumor fraction was 26% [10%-73%] and median tumor mutational burden (TMB) 113

mut/Mb [4-1450]. 40% (n=28) of pts had MSI positive tumor assessed by IHC and 55% (n=39) by NGS, with a concordance of 41%. A proportion of 58% (n=41) received ICB for advanced disease; pembrolizumab was the most frequent ICB administered and 66% (n=27) had received a median of 3 [1-8] prior lines of cytotoxic drugs. Median progression free survival (PFS) for concordant MSI status was 25 months (m) vs 9 m for non-concordant MSI (p=0.03), respectively.

Conclusions: MSI concordance on liquid biopsy with MSI on tumor were considerably lower than reported in the literature. However, PFS was better in pts with a concordant status than those with either MSI/IHC or MSI/NGS alone or in tissue.

144P Artificial intelligence supported treatment decisions for precision oncology

D.T. Rieke[1], X. Wang[2], M. Schmidt[1], D. Soll[1], G. Hilfenhaus[1], M. Nassir[1], C. Sigler[1], M. Knoedler[1], U. Keilholz[1], U. Leser[2], M. Benary[3]

[1]Charité Comprehensive Cancer Center, Charité - Universitätsmedizin Berlin, Berlin, Germany; [2]Wissensmanagement in der Bioinformatik, Humboldt-Universität zu Berlin, Berlin, Germany; [3]Core Unit Bioinformatics/Comprehensive Cancer Center, Charité - Universitätsmedizin Berlin, Berlin, Germany

Background: Clinical interpretation of complex biomarkers for personalized treatment decisions requires extensive manual investigations of literature and databases. Recent progress in artificial intelligence (AI) and conversational large language models (LLM) suggests that these might be useful for assisting with automated screening and integration of large biomedical datasets. To better define their role in this application, we investigated several recent LLM as a support tool for precision oncology.

Methods: We generated ten fictional cases of patients with advanced cancers and genetic alterations. Each of the cases was submitted to four LLM (ChatGPT, Galactica, Perplexity, BioMedLM) and one physician as expert human annotator to identify personalized treatment options (TO). TO were blinded and presented to a molecular tumor board (MTB) if they were a) identified by a human, b) identified by more than one LLM or c) identified by a LLM and associated with clinical evidence. MTB members were asked to rate the likelihood of TO to come from an AI on a scale from 0 to 10 (0 extremely unlikely, 10 extremely likely) and to rate their usefulness.

Results: A median number of 4 and 3, 7.5, 11.5, and 13 TO per patient were identified by the human expert and four LLM, respectively. When considering the expert as gold standard, the four LLM reached median F1 scores of 0.04, 0.17, 0.14, and 0.19 over all patients combined. Combined TO by LLM reached a precision of 0.29 and a recall of 0.29 for a F1 score of 0.29 over all patients. When rated for recognizability as AI-generated, LLM-generated TO achieved a median of 8 (range 1 to 10) in contrast to 2 points (range 0 to 6) for manually annotated cases. At least one LLM-generated TO per patient was generally considered useful by MTB members. Two unique useful TO (including one unique treatment strategy) were identified only by a LLM.

Conclusions: Treatment recommendations of LLM in PO cases do not yet reach the quality and credibility of human experts. However, they can already generate useful ideas. Considering the speed of technological progress, LLM could increasingly assist with the screening and selection of relevant biomedical literature to support evidence-based, personalized treatment decisions.

Background: In this study, we use KEM® (Knowledge Extraction and Management) explainable Artificial Intelligence (xAI) platform to systematically explore association rules in a heterogeneous patient database accounting for above 30 cancer types and thus identify biomarkers characterizing patients with higher chances of survival. The list of candidates' biomarkers included drug scores generated by OncoKEM®, an AI-transcriptional-based therapeutic recommendation-tool that computes scores for up to 205 drugs based on the drug's transcriptional signatures and the tumor transcriptional profile. The goal was to demonstrate the biological relevance of OncoKEM® by confronting its results with the findings obtained through a standard pathway analysis.

Methods: Data was retrieved from the PROFILER study (NCT01774409), a molecular screening program, and aggregated into a consolidated database totaling 247 patients and 215,670 variables that included survival, baseline descriptors, gene expression, derived REACTOME pathway dysregulations, and OncoKEM® scores. KEM® xAI platform extracted 55,335 relations associating candidate biomarkers and survival. These results were then filtered based on Support (number of examples), Lift (relative probability) and statistical significance. The remaining relations were finally split into 2 sets to study the associations between survival and respectively pathways dysregulations or OncoKEM® scores.

Results: Our analysis first identified 4 pathway dysregulations that were associated with the overall survival (hazard ratio ranged from 2.36 to 2.80). 3 of these pathways were related to tubulin. Consistently, 4 OncoKEM® scores were then identified as associated with survival (hazard ratio ranged from 2.20 to 2.52) and all 4 corresponded to microtubule inhibitor drugs: ixabepilone, cabazitaxel, vinflunine and brentuximab vedotin.

Conclusions: Our analysis enabled the identification of biomarkers of survival across cancer types. The consistency of the findings both demonstrated the biological relevance of OncoKEM® for microtubule inhibitor drugs and paved the way for the use of this tool as a prognostic marker for refractory cancers.

Clinical trial identification: NCT01774409.

147P Non-small cell lung cancer: Artificial intelligence enables the identification of survival signatures complementary to an Immunologically active gene expression signature involving previous therapies

P. Saintigny[1], P. Iriso[2], M. Afshar[2], V.K. Attignon[3], J. Auclair[4], J. Boulahfa[2], M. Boussageon[4], J. Fayette[4], J-P. Foy[5], A. Karabajakian[3], M. Kindermans[2], M. Lamkhioued[1], S. Lantuejoul[6], L. Michon[6], S. Ortiz-Cuaran[7], F. Parmentier[2], M. Pérol[4], A. Swalduz[4], T. Turcat[8]

[1]CRCL Department, Centre Léon Bérard, Lyon, France; [2]Data Science, Ariana Pharma, Paris, France; [3]Translational Research Department, Centre Léon Bérard, Lyon, France; [4]Medical Oncology, Centre Léon Bérard, Lyon, France; [5]Medical Oncology, Assistance Publique - Hopitaux De Paris, Paris, France; [6]Medicine Dept, Centre Léon Bérard, Lyon, France; [7]Cancer Cell Plasticity, Centre Léon Bérard, Lyon, France; [8]Oncology, OmiCure, Paris, France

Background: Non-small cell lung cancer (NSCLC) is one of the most prevalent cancers worldwide. Centre Léon Bérard, Lyon, France has developed a 27-gene expression-based HOT score that predicts outcome in patients with advanced stage treated with immunotherapy. Yet, this signature could be complemented with additional models involving a smaller set of genes. In this study, we used KEM® (Knowledge Extraction and Management) explainable Artificial Intelligence platform, a tool that systematically extracts relations within the variables of a database, to refine the HOT score, shortening the signature and improving performances.

Methods: Starting from GEO warehouse (GSE161537), 2,568 variables were aggregated into a consolidated database with 82 NSCLC patients. Analysis focused on the associations between combinations of genes, previous treatment lines and overall survival (OS): KEM® extracted 194,349 relations that were filtered on the number of involved genes, statistical significance and specificity.

Results: We identified 5 genes, DKC1, HPGD, MLPH, ABCC4 and MVP, combined into two 4-gene signatures with similar performances that predicted survival with a significant interaction between previous treatment lines and gene expression: patients who carry these signatures and that had undergone at least two treatment lines before immunotherapy showed an improved OS in both models (hazard ratio = 0.45 and 0.36). Compared to the HOT score, the number of genes retained was reduced from 27 to 4, and performances improved: balanced accuracy increases from 0.62 (HOT score) to 0.78.

Conclusions: Our analysis enabled the preliminary identification of signatures that complement the HOT score: the impact of previous lines of therapy was included into the model, the number of markers was reduced and performances increased. These findings are currently being confirmed using Cancer Research Institute iAtlas, a database that contains gene expression for over 1,100 cancer patients across five different tissue types. Specific adjustments may be required to account for differences in gene expression measurements between the training and testing tests.

148P DESTINY-PanTumor02 study of trastuzumab deruxtecan (T-DXd) in patients (pts) with HER2-expressing solid tumors: Exploratory biomarker analyses of HER2 expression and gene amplification in tissue and plasma

V. Makker[1], J-Y. Lee[2], D-Y. Oh[3], A. Oaknin[4], S.D. Puvvada[5], F. Cecchi[5], R. Mcewen[6], F. Michelini[7], F. Meric-Bernstam[8]

[1]Department of Medical Oncology, Memorial Sloan-Kettering Cancer Center, Weill Cornell Medical Center, New York, NY, USA; [2]Obstetrics and Gynecology, Yonsei University College of Medicine, Seoul, Republic of Korea; [3]Department of Internal Medicine, Seoul National University Hospital Cancer Research Institute, Seoul National University College of Medicine, Seoul, Republic of Korea; [4]Gynaecologic Cancer Programme, Vall d'Hebron University Hospital, Vall d'Hebron Institute of Oncology (VHIO), Barcelona, Spain; [5]Translational Medicine, AstraZeneca, Gaithersburg, MD, USA; [6]Oncology, AstraZeneca - Oncology R&D, Cambridge, UK; [7]Translational Medicine, Oncology R&D, AstraZeneca, Waltham, MA, USA; [8]Department of Investigational Cancer Therapeutics, MD Anderson Cancer Center, University of Texas, Houston, TX, USA

Background: HER2 expression is prevalent in a range of solid tumors. Testing for HER2 is not routine outside breast and gastric cancers, and no HER2 assays are currently validated in all cancers. We evaluated the concordance between local and central HER2 immunohistochemistry (IHC) and between *HER2* amplification in tissue and in baseline plasma circulating tumor DNA (ctDNA).

Methods: In this open-label, multicenter, multicohort, phase 2 study (NCT04482309), T-DXd (5.4 mg/kg q3w) was evaluated in pts with HER2-expressing (IHC 2+/3+ by local or central testing) locally advanced or metastatic disease after ≥1 systemic Tx or without Tx options. HER2 IHC status was assessed centrally using HER2 HercepTest™ (DAKO) and scored according to gastric-specific criteria. *HER2* amplification was evaluated centrally using Ventana dual in situ hybridization (ISH) on archival tissue and detected in baseline plasma ctDNA using Guardant Health OMNI assay.

Results: Agreement between local and central HER2 IHC score was 59% for IHC 3+ and 55% for IHC 2+. *HER2* amplification was 35% by ISH and 18% by ctDNA. The table shows concordance between HER2 status by ISH or IHC and ctDNA; agreement with *HER2* focal amplification detected in plasma was 42% and 39%, respectively.

Table: 148P

Plasma *HER2amp*	Central ISH: HER2 ISH+	HER2 ISH-	N/A	Total
Detected	32	7	9	48
Not detected	44	136	32	212
N/A	2	2	3	7
Total	78	145	44	267
	PPA (95% CI): 42% (31–54%)	**NPA (95% CI): 95% (90–98%)**		

Plasma *HER2amp*	Central HER2* status: HER2+	HER2-	N/A	Total
Detected	35	7	6	48
Not detected	54	140	18	212
N/A	3	2	2	7
Total	92	149	26	267
	PPA (95% CI): 39% (29–50%)	**NPA (95% CI): 95% (90–98%)**		

*HER2+: IHC3+ and IHC2+/ISH+
HER2-: IHC2+/ISH- and IHC1+/0
PPA and NPA were calculated excluding N/A samples (failed/unprofiled/undetectable ctDNA); CI calculated using Clopper-Pearson method CI, confidence interval; *HER2*-amp, focal *HER2* amplification; N/A, not available; NPA, negative percent agreement; PPA, positive percentage agreement

Conclusions: The moderate concordance between local and central HER2 IHC results can be ascribed to multiple factors, including different assays/algorithms, tumor heterogeneity, and inter-pathologist variability, highlighting the need for a standardized method to score HER2 across indications. Detection of *HER2* amplification in plasma was accurate, as indicated by the low rate of false positives; however, sensitivity was poor. This suggests that ctDNA testing may help identify pts with *HER2* amplification but is not yet a substitute for tissue-based HER2 ISH and IHC testing.

Clinical trial identification: NCT04482309.

Background: HER2 blockade in ERBB2+ BC can boost the immune system and inhibit cell proliferation and survival. Here, we aimed to identify early molecular changes following a single dose of HP and its association with subsequent pCR following neoadjuvant HP-based chemotherapy.

Methods: Patients (pts) with stage I-III ERBB2+BC were treated with neoadjuvant pertuzumab+trastuzumab+paclitaxel (THP)x16w. Paired tumor biopsies were obtained at baseline (D1) and at day 8 (D8) following a loading-dose of HP, prior to weekly paclitaxel addition. HER2DX gene expression signatures and the expression of 185 genes were evaluated in both timepoints. Paired SAM analyses (FDR<5%) and t-tests determined significant changes between D1-D8. Logistic regression analyses identified associations with pCR (ypT0/isN0).

Results: Gene expression was evaluated in paired samples in 49 out of 52 pts (94%). cT1-2 disease represented 85% of cases, cN0 59%, and 67% were HR+. The overall pCR rate was 45.6% and 55.3% when ypT1miN0 was considered. In all pts, HP induced a significant decrease in HER2DX proliferation, HER2 amplicon, pCR, risk and *ERBB2* scores, and in 81 (43.8%) genes including *KRT18, SPDEF, MUCL1* or *FOXA1;* and a significant increase in the HER2DX IGG signature and 84 (45.4%) genes including *GPNMB, CD68, CD86* or *CD4*. At D8, the HER2DX IGG signature (p=0.002) and 61 (33.0%) genes including *LY9* (p<0.001), *CD8A* (p<0.001), *CD27* (p<0.001) or *GZMA* (p<0.001) were significantly associated with pCR. At D1, pCR rates in HER2DX IGG-high, medium and low were 71.4%, 22.2% and 25.0%, respectively. At D8, pCR rates in HER2DX IGG-high, medium and low were 81.0%, 33.3% and 6.3%, respectively. The ratio between D8 and D1 of HER2DX pCR (p=0.006) and risk (p=0.026) scores and 38 (20.5%) genes including *S100A9* (p=0.006), *TRPV6* (p=0.008), *GPNMB* (p=0.013) or *LY9* (p=0.016) were significantly associated with pCR.

Conclusions: In early-stage ERBB2+ BC, a single dose of HP induces significant biological changes that may better predict pCR. At day 8, pts with high expression of HER2DX immune signature and immune-related genes have a higher probability of achieving a pCR following THP.

Background: HER2DX is a prognostic (risk-score) and predictive (pathological complete response [pCR]-score) genomic assay in early-stage HER2+ BC. Here, we evaluated the ability of HER2DX following (neo)adjuvant HP-based therapy.

Methods: HER2DX was evaluated on baseline FFPE tumors from PHERGain (NCT03161353). Patients (pts) with newly diagnosed stage I-IIIA HER2+ BC and PET evaluable lesions were randomized (1:4) to receive either docetaxel (T), carboplatin (C), and HP (group A) or HP ± endocrine therapy (ET) (group B). PET was performed prior to randomization and after 2 cycles. Group A received TCHPx6 regardless of on treatment PET response. Group B received HP ± ETx2 and PET-responder (RX) pts continued with HP ± ETx6, while PET-non-RX pts received TCHPx6. After surgery, PET-RX without a pCR received TCHPx6. All pts completed HPx18. Primary objective was the association of HER2DX with pCR (ypT0/is ypN0). Secondary objective was the association of HER2DX risk-score with invasive disease-free survival (iDFS).

Results: HER2DX was evaluated in 292 (82.0%) pts. Clinical T2-4 and node-negative disease represented 84.6% and 49.3%, respectively, and 66.4% of tumors were hormone receptor (HR) positive. The overall pCR rate was 38.0% (56.4% in group A and 33.8% in group B). In the multivariable analysis, HER2DX pCR-score (as a continuous variable) was significantly associated with pCR (odds ratio [OR] per 10-unit increase=1.29 (1.5-1.8), p<0.001), after adjusting for treatment and clinicopathological factors such as HR status, treatment group, or PET response. In the overall population, the pCR rates in HER2DX pCR-high, med, and low groups were 50.4%, 35.8%, and 23.2% (pCR-high vs pCR-low OR=3.37, p<0.001), respectively. HER2DX low-risk showed a numerically better 3-year iDFS than HER2DX high-risk pts (100% vs 93.5%; hazard ratio= 0.37 [0.1-1.7]) after adjusting by pCR status. Eight out of 9 pts with metastatic progression had HER2DX high-risk prognostic score.

Conclusions: HER2DX predicts pCR following neoadjuvant HP-based therapy (with or without chemotherapy) and identifies pts with a higher risk of recurrence. This assay might help individualize HP-based therapy in early HER2+ BC.

Clinical trial identification: NCT03161353.

Background: DESTINY-Lung01 (NCT03505710) showed encouraging and consistent antitumor activity for T-DXd in heavily pretreated patients with HER2-overexpressing (immunohistochemistry [IHC] 3+/2+) NSCLC. We investigated associations between baseline gene mutations using ctDNA and clinical outcomes in these patients (data cutoff, May 2021).

Methods: Among 90 patients in the DESTINY-Lung01 HER2-overexpressing cohorts, 85 had baseline ctDNA samples analyzed at Guardant Health OMNI. Activating mutations in key oncogenes (*EGFR*, *RAS*, *BRAF*) and other genes of interest at baseline were assessed for their association with clinical efficacy (objective response rate [ORR] and progression-free survival [PFS]) with T-DXd treatment (cohort 1, 6.4 mg/kg [N = 49]; cohort 1a, 5.4 mg/kg [N = 41] every 3 weeks); analyses were not adjusted for baseline characteristics.

Results: The 85 evaluable patients had an ORR of 27.1% (95% CI, 18.0-37.8) and a median PFS (mPFS) of 5.9 months (95% CI, 4.5-7.4). Activating mutations were identified in *EGFR* (15 patients [17.6%]: 7 T790M, 7 L858R, 1 S768I, 4 E746_A750del, 2 G719A), *KRAS* (20 patients [23.5%]), *NRAS* (1 patient [1.2%]), and *BRAF* (1 patient [1.2%]). 13 of the 15 patients with *EGFR*-activating mutations had prior *EGFR* tyrosine kinase inhibitor treatment. No clear effects of *EGFR*- and *RAS*-activating mutations on ORR and mPFS were observed; however, mutations in *STK11* and *KEAP1* were associated with significantly shorter mPFS (Table).

Conclusions: Baseline ctDNA analysis showed that the presence of activating mutations in *EGFR*, *KRAS*, or *NRAS* did not impact the clinical efficacy of T-DXd in patients with HER2-overexpressing NSCLC whereas mutations in *STK11* and *KEAP1* were associated with shorter mPFS. Updated results will be presented (data cutoff, December 2021).

152P Efficacy of olaparib in advanced cancers with germline or somatic tumor mutations in BRCA1, BRCA2, CHEK2 and ATM: A Belgian precision tumor-agnostic phase II study

S.R. Joris[1], H. Denys[2], J.J. Collignon[3], M. Rasschaert[4], D. T'Kint de Roodenbeke[5], F.P. Duhoux[6], J-L. Canon[7], S. Tejpar[8], J. Mebis[9], L. Decoster[10], P.G. Aftimos[11], J. De Grève[12]

Background: The Belgian Precision initiative aims to maximize the implementation of tumor-agnostic NGS in patients with advanced cancer and enhance access to molecularly-guided treatment options (MGTOs). Academic tumor-agnostic basket phase 2 studies are part of this initiative. The current investigator-driven trial aimed to investigate olaparib efficacy in advanced cancers with a pathogenic or likely pathogenic mutation (germline or somatic) in a gene that plays a role in homologous recombination (HR).

Methods: Open-label multi-cohort phase 2 study that examines the efficacy of olaparib in patients with an HR gene mutation in their tumor and failed SoC. Patients with a somatic or germline mutation in the same gene define a cohort. For each cohort, a Simon minimax two-stage design was used. If a response was observed in the first 13 patients, 14 additional patients were included (type I error rate of 5% and a power of 80% when the true response rate is 20%). Here, we report the results on four completed cohorts: patients with a *BRCA1*, *BRCA2*, *CHEK2* or *ATM* mutation.

Results: The overall objective response rate across different tumor types was 11% in the *BRCA1* (N=27) and 21% in the *BRCA2* (N=27) mutated cohorts. Partial responses were seen in pancreatic cancer, gallbladder cancer, endocrine carcinoma of the pancreas and parathyroid cancer. One patient with a *BRCA2* germline mutated colon cancer has an ongoing CR with 19+ months on treatment. mPFS in responding patients is 14+ months (5-34+ months). The clinical benefit rate was 63% in the *BRCA1* and 46% in the *BRCA2* mutated cohorts. No clinical activity was observed in the ATM (N=13) and CHEK2 (N=14) cohorts. Safety data were consistent with the known profile of olaparib.

Conclusions: Olaparib showed efficacy in different cancer types harboring somatic or germline mutations in the *BRCA1/2* genes but not in *ATM* and *CHEK2*. Patients with any cancer type harboring *BRCA1/2* mutations should have access to olaparib with real-world documentation of efficacy in a retrospective register.

Clinical trial identification: NCT03967938.

153P Descriptive analysis of the location of point mutations in BRCA and the risk of breast or ovarian cancer diagnosis

P. Torres-Mozas, F. Galvez Montosa, N. Luque Caro, F.J.G. Verdejo, A.L.O. Ortega Granados, J. Requena Aguilar, J.Z. Benoit Perejón, R. Garcia Munoz, G.P. Vinueza Hidalgo, I. Fernández Ros, P. Sanchez-Rovira

Medical Oncology, Hospital Universitario de Jaén, Jaén, Spain

Background: Within BRCA carriers, there are data suggesting that not all alterations confer the same risk of breast or ovarian cancer. In addition, the localization of the mutation as a biomarker of response to targeted therapies such as iPARP is in the process of being validated. The distribution of mutations according to the functional domain in which they are located may be a good method for establish their role in cancer risk.

Methods: We included all carriers from the registry of the Hereditary Cancer Unit. Functional domains (dom) of BRCA1 were defined as: Really Interesting New Gene (RING) from aa 8-96; DNA-binding dom (DBD) from aa 452-1092; and BRCA1 C terminal (BRCT) from aa 1650-1863 Functional doms of BRCA2 were defined as: PALB2-BD dom from aa 21-39, RAD51-binding dom (RAD51-BD) from aa 900-2000, and DBD from aa 2459-3190.

Results: 284 carriers were located. 66% women, 55% BRCA1 mutation carriers (mc). Of these, 63% healthy carriers (hc), half of whom were women. Among the BRCA1 muts, 55% of breast cancer (bc) were associated with BRCT muts compared with 5.5% in DBD. In the BRCT dom, the mean age at diagnosis (dx) of bc was 44 years, with 35% of luminal tumors. Among hc, only 33% were older than the mean age at dx. Among the BRCA2 muts, 61% of the cases with bc were associated with the RAD51-BD dom compared to 10% in the DBD dom. In the RAD51-BD dom, the mean age at dx of bc was 51 years, with 11% of cases being Her-2 positive and 29% triple negative. Among hc, only 40% were older than the median age at dx. As for ovarian cancer, a more heterogeneous pattern was observed, although again, the doms with the most cases were BRCT and RAD51-BD.

Conclusions: The characterization of the mut population can provide data for the personalization of follow-up. In our population, the age of hc is shown as a bias for the definition of risk, so more follow-up and multicenter studies are needed to validate the results.

154P Highly sensitive serum volatolomic biomarkers for pancreatic cancer diagnosis and prognosis

A. Martínez[1], A. Martín-Carnicero[2], M.T. Tena[3], M.P. Martínez-Moral[1]

[1]Oncology, Center for Biomedical Research of La Rioja (CIBIR), Logroño, Spain; [2]Medical Oncology, Hospital San Pedro, Logrono, Spain; [3]Department of Chemistry, Universidad de la Rioja, Logroño (La Rioja), Spain

Background: Pancreatic adenocarcinoma (PAC) is one of the most lethal kinds of cancer. PAC is usually diagnosed very late, thus limiting treatment options and leading to low survival rates. Volatile organic compounds (VOCs) are final metabolism products that can be detected in a number of fluids. Our goal was to identify and validate diagnostic and prognostic PAC biomarkers in serum samples.

Methods: Twenty PAC patients and a sex/age matched control group (n=19) were recruited. A second group of 5 patients and 5 healthy volunteers was used for validation. IRB approval was provided by "Comité de Ética de Investigación con Medicamentos de La Rioja (CEImLar)" and all subjects signed the informed consent. A Varian CP-3800 gas chromatographer coupled to a Saturn 2200 ion trap mass spectrometer was used for the non-targeted analysis of VOCs. Surrogate standards were added to all serum samples, that were heated at 50°C and VOCs were collected into a 50/30 µm CAR/PDMS/DVB fiber (Supelco). Desorption was done at 250°C for 30 seconds in the injection port. MassHunter software (Agilent) was used for chromatogram processing including deconvolution of the signals.

Results: The volatolomic profile identified 433 VOCs in serum. Of these, 40 were able to distinguish cases from controls (diagnostic biomarkers). Unsupervised PCA and heatmaps, as well as supervised PLS-DA, showed a clear separation of cases vs controls. ROC curves indicated that 19 VOCs showed excellent predictive potential, with AUC $>$ 0.90. The validation cohort confirmed the predictive value of 11 VOCs. Prognostic VOCs were identified by comparing patients that survived more than one year after diagnosis with those who did not. Sixteen VOCs showed prognostic discrimination and 3 of them had ROC with AUC $>$ 0.86. Furthermore, the chemical structure of 4 of the main VOCs was confirmed by comparison with standards.

Conclusions: We have identified a panel of VOCs that correctly classify patients from controls and predict patient survival with high specificity and sensitivity. Reliable biomarkers may open the door to new technologies and the early detection of PAC.

155P Exploring the utility of serum anti-tNASP antibodies as a screening biomarker in prostate, pancreatic, and ovarian cancer

O. Alekseev[1], X. Yi[2], M. Kasmenn[2], S. Kundu[2], M. Rogers[2], Z. Vaskalis[2]

[1]Physiology and Pathophysiology Department, Campbell University, Buies Creek, NC, USA; [2]CUSOM, Campbell University School of Osteopathic Medicine, Lillington, NC, USA

Background: Nuclear auto-antigenic sperm protein (NASP) is a histone chaperone and a facilitator of chromatin assembly. One of two NASP splice variants, tNASP, is specific to the testis, where it is sequestered by the blood-testis barrier and also present in cancer cells. Exposure of tNASP from the cancer cells to the immune system induces a robust humoral immune response. We hypothesized that the autoantibodies produced against tNASP may be used as a supplementary diagnostic marker for prostate, pancreatic, and ovarian cancer.

Methods: Sera from patients with pancreatic cancer (74), prostate cancer (63), and ovarian cancer (19) were tested for the presence of antibodies against tNASP using enzyme-linked immunosorbent assay (ELISA) with a recombinant tNASP fragment as bait. Correlation analysis was used to determine correlations between anti-tNASP antibody level and the age, ethnicity, TMN staging, and diagnostic marker levels (PSA in the prostate cancer and CA19-9 in pancreatic cancer).

Results: Level of anti-tNASP antibody in prostate cancer patients ranged from 426 to 3810 µg/mL and was significantly higher compared to healthy individuals ($p<0.01$). The cutoff for anti-tNASP antibody thus was established at 400 µg/mL. Combined analysis of anti-tNASP and PSA tests demonstrated that 18% of PC patients with PSA higher than 4 ng/mL had a low level of anti-tNASP antibody (false positive PSA, supported by negative biopsy); 11.4% of PC patients with PSA lower than 4 ng/mL had high levels of anti-tNASP antibodies (false negative PSA, proved histologically). Level of anti-tNASP antibody in pancreatic cancer patients ranged from 564 to 2751 µg/mL and was significantly higher compared to healthy individuals ($p<0.01$). Correlations between expression of tNASP antibody and levels of CA19-9 are not conclusive. There is a significant difference in tNASP antibody concentrations between serum from patients with ovarian cancer and serum from the control group of patients.

Conclusions: Expression of serum anti-tNASP antibody is not a specific screening marker for prostate, pancreatic, or ovarian cancer. Combined use of PSA with anti-tNASP antibody analysis reveals significant elimination of false positive and false negative PSA test results.

156P The association between fibrotic endotypes, determined by pre-treatment serum levels of collagen metabolites, and survival outcomes in patients with pancreatic cancer

R.S. Pedersen[1], J. Thorlacius-Ussing[2], N.I. Nissen[2], A. Johansen[3], I. Chen[3], C. Jensen[2], C. Hansen[4], M. Karsdal[2], J.S. Johansen[3], N. Willumsen[2]

[1]Department of Biomedical Sciences, Copenhagen University, Copenhagen, Denmark; [2]Biomarkers and Research, Nordic Bioscience A/S, Herlev, Denmark; [3]Department of Oncology, Herlev and Gentofte Hospital, Herlev, Denmark; [4]Department of Surgery, Rigshospitalet, Copenhagen, Denmark

Background: Abnormal collagen fiber architectures in tumor fibrosis affect prognosis and treatment response in pancreatic cancer (PC) patients. Increased fibrotic activity releases collagen metabolites into the bloodstream. The aim was to explore these metabolites to cluster PC patients into tumor fibrosis endotypes and evaluate overall survival (OS).

Methods: Serum was collected from patients with PC prior to chemotherapy or resection and included in the BIOPAC Study (ID: NCT03311776) (stage I (n=15), Stage II (n=201), stage III (n=164) and stage 4 (n=434)). Principal component analysis was performed on the levels of five collagen metabolites (Table) measured by ELISAs. K-means clustering was used to discover clusters and Kaplan-Meier curves and the cox proportional hazards model used to dicover associations with OS.

Table: 156P

Biomarker name	collagen metabolite
C3M	Neo-epitope of MMP-9 mediated degradation of type III collagen
PRO-C3	Released N-terminal pro-peptide of type III collagen
PRO-C5	Released C-terminal pro-peptide of type V collagen
PRO-C6	C-terminal of released C5 domain of type VI collagen α3 chain (endotrophin)
PRO-C11	Released N-terminal pro-peptide of type XI collagen

Results: Three putative endotypes (cluster A, B, C) were identified. Patients in cluster B had higher C3M, PRO-C5 and PRO-C11 levels compared to cluster A, whereas patients in cluster C had higher PRO-C3 and PRO-C6 levels compared to cluster A. Patients with endotype A had a median OS of 332 days vs. 185 and 144 days for endotype B and C ($p<0.001$). Compared to endotype A, both endotype B (HR=1.56, 95% CI 1.28−1.91, $p<0.001$) and endotype C (HR=1.69, 95% CI 1.26−2.26, $p<0.001$) were predictors of poor OS when corrected for age, sex, performance status, body mass index, diabetes, cachexia, stage, number of metastatic sites, and CA19-9.

Conclusions: Clustering of patients with PC based on five collagen-derived metabolites measured in serum identifies 3 distinct endotypes that were associated with poor OS independent of other common risk factors. These findings indicate that non-invasive collagen biomarkers can be used to identify fibrotic endotypes in patients with PC and that such endotypes may inform on patient prognostication.

157P CLDN18 fusions rather than expression is a biomarker related to the efficacy of paclitaxel in patients with ovarian metastasis of gastric cancer

P. Yu[1], Y. Cao[1], X. Chen[1], W. Wu[2], Q. Xu[3], J. Fang[1], X. Huang[1], X. Shi[4], W. Zhizheng[4], Z. Ye[1], F. Pang[5], Y. Du[6], X. Cheng[1]

[1]Department of Gastric Surgery, Cancer Hospital of the University of Chinese Academy of Sciences/ Zhejiang Cancer Hospital, Hangzhou, China; [2]Department of Pathology, Cancer Hospital of the University of Chinese Academy of Sciences/ Zhejiang Cancer Hospital, Hangzhou, China; [3]Department of Oncology, Cancer Hospital of the University of Chinese Academy of Sciences/ Zhejiang Cancer Hospital, Hangzhou, China; [4]Medical Products Department, Shanghai OrigiMed Co., Ltd., Shanghai, China; [5]Medical Department, OrigiMed, Shanghai, China; [6]Department of Gastric Surgery, Zhejiang Cancer Hospital - Cancer Research Institute, Hangzhou, China

Background: Paclitaxel inhibits cellular microtubule depolymerisation and has anti-tumor effects in patients with ovarian metastases from gastric cancer. CLDN18 is aberrantly expressed in gastric cancer and plays an important role in tumor invasion and metastasis. However, the relationship between CLDN18 and the efficacy of paclitaxel is lacking in research.

Methods: A total of 74 GC patients with ovarian metastasis treated with paclitaxel were included in the study. 65 primary gastric and 73 ovarian metastatic tumor samples were collected from the enrolled patients, including 64 pairs of matched primary gastric and metastatic ovarian tumor samples. WES was performed with a mean coverage depth of 187x (range: 108-344x) for tumor samples. Immunohistochemistry (IHC) was performed on tissue samples to detect CLDN18 expression.

Results: Of 74 patients, 41 responded to paclitaxel (the "effective" group), while 33 did not respond (the "ineffective" group). Statistical analysis revealed that mutations in RHOA ($p = 0.037$), AFF2 ($p = 0.028$), PIK3CD ($p = 0.028$), and TAF1L ($p = 0.028$) were associated with the ineffectiveness of paclitaxel treatment, while mutations in SALL4 ($p = 0.036$), CCDC105 ($p = 0.018$), and CLDN18 ($p = 0.036$) were associated with a positive response to paclitaxel treatment. IHC was performed on six CLDN18 fusion patients and twelve patients with different responses to paclitaxel. Of CLDN18 fusion patients, four were CLDN18-positive and two were CLDN18-negative, indicating that CLDN18 fusion did not correlate with CLDN18 expression. CLDN18 expression was positive in nine patients who responded to paclitaxel treatment and four patients who did not, and negative in two patients who responded and three who did not. Statistical analysis indicated that there was no significant correlation between the effect of paclitaxel treatment and the expression of CLDN18 (9/11 vs. 4/7, $p = 0.17$).

Conclusions: We have identified potential biomarkers, including CLDN18, that could predict the efficacy of paclitaxel treatment based on the differential response to treatment. We have also confirmed that CLDN18 fusion is a potential predictive biomarker for paclitaxel treatment response, independent of CLDN18 expression.

158P In silico analysis of HER2 enriched subtype and a HER2 index based on transcriptomic data of breast cancer compared to gastric and uterine serous carcinomas

A. Gonzalez-Vilanova[1], T.C. Fleitas[2], L. Gaba Garcia[3], S. Zuniga-Trejos[1], J.A. Perez Fidalgo[4]

[1]Biostatistics, INCLIVA Instituto de Investigación Sanitaria, Valencia, Spain; [2]Medical Oncology Department, Hospital Clinico Universitario de Valencia, Valencia, Spain; [3]Dept. Medical Oncology, Hospital Clinic y Provincial de Barcelona, Barcelona, Spain; [4]Dept. Medical Oncology, Hospital Clinico Universitario de Valencia, Valencia, Spain

Background: In Breast cancer (BC) PAM50 platform has identified a HER2-enriched (HER2E) subgroup with predictive and prognosis implications. Our study aimed to perform an *in-silico* analysis to confirm the prognostic role and the association of two genomic signatures (HER2E and HER2index) with the HER2 expression in gastric (GC) and Uterine serous carcinoma (USC) in comparison to BC.

Methods: We extracted clinical, transcriptomic, and proteome data of primary tumors from 3 publicly available databases: 1) TCGA-BRCA of BC (n=1095), 2) TCGA-STAD of GC (n=412), and 3) TCGA-UCEC (serous subtype) of USC (n=138). Patients were classified according to the PAM50 definition of breast cancer. Moreover, we calculated the correlation of the tumor expression profiles with the HER2 index signature (Li et al 2020). The association of the HER2-related, expression-based biomarkers with overall survival was calculated with independent Cox Proportional Hazard models, separately for each TCGA cohort.

Results: In the BC dataset, HER2E subtype was positively correlated with HER2mRNA and HER2protein (HER2p) ($p<0.001$) with a trend towards a correlation with HER2phospoprotein (pp). HER2 index in BC was correlated with HER2pp ($p<0.001$) and non-signifcantly with HER2mRNA ($p=0.069$), and HER2p ($p=0.087$). Both HER2E and HER2index showed an impaired survival in BC ($p=0.032$ and $p=0.002$ respectively). In GC cohort, no correlation was found between HER2E and HER2mRNA. HER2 index was correlated only with HER2mRNA ($p<0.001$). HER2E and HER2 index were not associated with survival. For the USC cohort, HER2E and HER2index were not correlated with HER2mRNA, HER2p, or HER2p, although HER2E showed a trend towards a positive association with HER2mRNA and HER2p ($p=0.059$ and 0.053 respectively). These signatures were not prognostic in terms of PFS in the USC cohort (HER2E $p=0.284$ and HER2 index $p=0.771$).

Conclusions: HER2E subtype of PAM50 and HER2 index signatures showed significant correlations with HER2 expression and survival in BC, however when these signatures were applied to other HER2 tumors such as GC or USC the prognostic role and correlation with the HER2 protein expression is limited.

159P Better performance of pan-claudin18 antibodies on claudin18.2 detection in gastric adenocarcinoma than claudin18.2 specific antibody

S. Ni[1], W. Sheng[1], W. Su[2], H. Lu[3], Q. Yan[3], J. Xu[3], C. Hua[3], Z. Huang[2], L. Ruan[3], C. Zhu[2]

[1]Department of Pathology, Fudan University Shanghai Cancer Center, Shanghai, China; [2]Department of Translational Medicine, Amoy Diagnostics Co., Ltd., Xiamen, China; [3]Department of Research and Development, Amoy Diagnostics Co., Ltd., Xiamen, China

Background: The claudin18 isoform 2 (CLDN18.2), a member of the tight junction protein family, is a highly selective target for development of novel therapies in various primary malignant tumors. Due to the interference of CLDN18.1, which is highly homologous to CLDN18.2, selection of appropriate antibodies still need to be further identified.

Methods: Expression of CLDN18.2 was evaluated in a total of 66 gastric adenocarcinoma samples by immunohistochemistry(IHC) using the pan-CLDN18 antibodies (clone 43-14A and clone MM02), which recognizes both CLDN18.2 and CLDN18.1, and the CLDN18.2-specific antibody (clone EPR19202-244). The results were further verified by qPCR and CLDN18.1-specific antibody respectively.

Results: The CLDN18.2 expression evaluated by 43-14A and MM02 showed highly consistentat in different eligibility criterions ($\geq$ 2+ membrane staining intensity in $\geq$ 40% or $\geq$ 75% of tumor cells) with 95.45% and 90.91% overall percent agreements(OPA) respectively. While EPR19202-244 showed low sensitivity (84.38%) compared with 43-14A, even after readjusting the optimal threshold according to the ROC curve and Youden index. *CLDN18*, *CLDN18.1* and *CLDN18.2* mRNAs were further measured via quantative real-time PCR and IHC for CLDN18.1 was applied. It was verified that all those samples determined to be negative for CLDN18.2 by EPR19202-244 but positive for CLDN18 by pan-CLDN18 antibodies should be identified as true positive for CLDN18.2.

Table: 159P Comparison of clone 43-14A, clone MM02, and clone EPR19202-244

		43-14A/MM02/EPR19202-244							
		+/+/+	+/+/-	+/-/-	-/+/-	-/-/+	-/+/+	**-/-/-**	**Total**
Samples		29	7	0	2	2	1	25	**66**
Samples were verified		20	5	/	2	1	0	9	**37**
qPCR	**pan-CLDN18**	19	4		2	0	/	1*	
	CLDN18.2	19	4		2	0		0	
	CLDN18.1	0	0		0	0		1*	
IHC	**CLDN18.1-specific**	0	0		0	0		0	

Note: $\geq$2+ intensity in $\geq$40% tumor cells defined as CLDN18.2-positive for 43-14A and MM02, and $\geq$2+ $\geq$25% for EPR19202-24. * : Possibly due to technical differences in qPCR and IHC

Conclusions: Our results clarify the differences between EPR19202-244, 43-14A and MM02, and suggesting a higher sensitivity and specificity of pan-claudin18 antibodies, which should be used for the dectction of CLDN18.2.

160P Real-world practices and physician perspectives on biomarker testing and treatment patterns in patients with locally advanced unresectable or metastatic (La/m) gastric/gastroesophageal junction (G/GEJ) adenocarcinoma in the US

K. Lewis[1], R. Fuldeore[2], S. Braun[3], G. Gourgioti[4], A. Lambert[1], G. Thomason[1], K. Bernacki[2], J. Yang[5]

[1]Oncology and Rare Diseases, Adelphi Real World, Bollington, UK; [2]Medical Affairs, Astellas Pharma Global Development, Inc., Northbrook, IL, USA; [3]Medical Affairs, US Oncology, Astellas Pharma Global Development, Inc., Northbrook, IL, USA; [4]Biostatistics, Astellas Pharma Europe Ltd, Addlestone, UK; [5]Department of Medicine, Memorial Sloan Kettering Cancer Center, Weill Cornell Medical College, New York, NY, USA

Background: Human epidermal growth factor receptor 2 (HER2)-targeted therapy and immunotherapy have improved survival outcomes for patients with La/m G/GEJ adenocarcinoma. Biomarker testing for mismatch repair (MMR) or microsatellite instability (MSI), HER2, and programmed-death ligand 1 (PD-L1) is critical for determining appropriate therapy. We describe real-world data on testing and treatment patterns using the Adelphi Disease Specific Program (DSP).

Methods: Data was collected using the Adelphi's DSP, a cross-sectional survey of US physicians taken between Sept 2022 and Feb 2023. Patients included those diagnosed with La/m G/GEJ adenocarcinoma on or after Jan 2021. Current biomarker testing treatment patterns, and physician attitudes were analyzed descriptively.

Results: Of the 438 pt records received from 60 treating physicians, 338 pts (77%) had La/m G/GEJ adenocarcinoma. Most pts had de novo (85%) disease, 71% were on first-line (1L) therapy and 29% on second line. Fluorouracil-based regimens were most common in 1L. MSI/MMR testing increased over time. Regardless of disease stage, almost all physicians (97%) reported biomarker testing at initial diagnosis to be "important" to "extremely important". However, only a subset of patients had testing performed (Table): HER2 (69%), PD-L1 (51%), and MSI/MMR (44%); 18% had no biomarker testing.

Table: 160P Biomarker testing patterns

Biomarkers tested, patient n (%)	Total		Year of advanced diagnosis received					
			2021		2022		2023	
Overall	**338**		**44**		**207**		**17**	
HER2	234	(69)	24	(55)	157	(76)	11	(65)
PD-1	110	(33)	8	(18)	70	(34)	9	(53)
PD-L1	172	(51)	16	(36)	115	(56)	8	(47)
MSI/MMR IHC	148	(44)	11	(25)	103	(50)	9	(53)
VEGFR-2	54	(16)	4	(9)	34	(16)	5	(29)
CDH-1	35	(10)	3	(7)	18	(9)	5	(29)
CLDN 18.2	25	(7)	2	(5)	15	(7)	5	(29)
NTRK gene fusion	60	(18)	4	(9)	40	(19)	5	(29)
EBV	48	(14)	6	(14)	32	(15)	5	(29)
NTRK	58	(17)	4	(9)	39	(19)	5	(29)
FGFR2	61	(18)	3	(7)	40	(19)	5	(29)
FGFR2b	46	(14)	3	(7)	31	(15)	5	(29)
No biomarker/genetic tests conducted	60	(18)	9	(20)	31	(15)	5	(29)

Conclusions: This study describes potential gaps in biomarker testing in real-world practice for pts with La/m G/GEJ adenocarcinoma. Despite most physicians reporting biomarker testing to be important at the time of diagnosis, only a subset of patients had testing reported. This outcome highlights a need to understand barriers to testing in clinical practice and to establish routine testing as standard of care.

161P Biomarkers of neoadjuvant combinational therapy for locally advanced gastric or gastroesophageal junction adenocarcinoma

Y. Wang[1], J. Yang[1], X. Zhou[2], Q. Liu[1], Y. Yang[1], W. Guan[3], B. Liu[1], J. Wei[1]

[1]The Comprehensive Cancer Centre of Drum Tower Hospital, Medical School of Nanjing University & Clinical Cancer Institute of Nanjing University, Nanjing, China; [2]The Comprehensive Cancer Centre, Nanjing Drum Tower Hospital Clinical College of Traditional Chinese and Western Medicine, Nanjing University of Chinese Medicine, Nanjing, China; [3]General Surgery Department, Medical School of Nanjing University & Clinical Cancer Institute of Nanjing University, Nanjing, China

Background: Gastric or gastroesophageal junction (G/GEJ) cancers is one of the most common lethal malignancies in the world. Nearly half of the G/GEJ cancers are locally advanced at diagnosis and with poor prognosis. Several clinical trials demonstrated that perioperative anti-PD-1 therapy in combination with concurrent chemoradiotherapy (cCRT) for locally advanced G/GEJ cancers could raise the pCR rate over 30%. However, the biomarkers for patients with pCR are nor clear.

Methods: 34 patients with locally advanced G/GEJ cancer received neoadjuvant sintilimab in combination with cCRT followed by gastrectomy and adjuvant sintilimab and chemotherapy in our center. Baseline tumor biopsies and post-treatment surgical tissues were collected for multiplex immunofluorescence (mIF), next-generation sequencing (NGS) and mass cytometry (CyTOF).

Results: Our results met the pre-specified primary endpoint, with a pCR rate of 38.2% and median DFS of 17.0 months. Biomarker analysis by mIF showed that patients with positive PD-L1 expression showed a numerically higher pCR rate. Also, higher levels of infiltrating $CD3^+$ T cells, $CD4^+$ T cells, and $CD56^+$ natural killers (NKs) were found in patients achieving pCR than those not achieving pCR (non-pCR). Moreover, the proportion of $CD127^+CD27^+$HLA-DR^-CD38^-CD4 TCM defined by CyTOF was significantly lower in pCR patients. Also, tumor mutation burden (TMB) analyzed by NGS was significantly higher in the pCR group. Clone evolution can explain the therapy efficacy, and could be deployed to overcame therapy resistance. Deletion of cytoband 7q35, where TPK1 locates, was significantly enriched in pCR groups while deletion of 11q14.3, which TRIM family sitting, was significantly enriched in non-pCR groups.

Conclusions: It is consistent with the acknowledged prognostic biomarker of immunotherapy that positive PD-L1 expression, higher T cell infiltration and TMB could be predictive biomarkers of perioperative anti-PD-1 therapy in combination with cCRT for locally advanced G/GEJ. Furthermore, we found a new TCM subtype defined with $CD127^+CD27^+$HLA-DR^-CD38^- and deletion of cytoband 7q35 or 11q14.3 could be novel biomarkers.

Clinical trial identification: The study protocol was published previously. Wei, J. *et al.* Efficacy and Safety of Sintilimab in Combination with Concurrent Chemoradiotherapy for Locally Advanced Gastric or Gastroesophageal Junction (GEJ) Adenocarcinoma (SHARED): Study Protocol of a Prospective, Multi-Center, Single-Arm Phase 2 Trial. *Cancer Manag Res* **14**, 2007-2015, https://doi.org/10.2147/CMAR.S355687 (2022).

162P MR imaging biomarkers profiles in patients with prostate cancer treated with androgen deprivation therapy

A.L. Sanchez Iglesias[1], V. Morillo Macías[1], A. Nogué Infante[2], M. Domingo[2], V. Aznar[1], R. Yebana[2], C. Puerto Frances[1], A. Fuster-Matanzo[2], P. Plaza Ortega[1], F. Bellvis Bataller[2], R. Muelas Soria[1], A. Alberich Bayarri[2], C. Ferrer Albiach[1]

[1]Radiation Oncology, Consorcio Hospitalario Provincial De Castellon, Castellon, Spain; [2]Quibim - Quantitative Imaging Biomarkers in Medicine, Valencia, Spain

Background: Radiomics has emerged as a potential tool to predict clinical outcomes in prostate cancer (Pca). MRI has a fundamental role in staging and radiotherapy planning, being affected in the case of receiving prior androgen deprivation treatment (ADT). The aim of this study was to determine imaging biomarker profiles that allow to identify patients with a worse prognosis and a higher risk of biochemical relapse (BQR).

Methods: A single-center, retrospective, observational study was designed. Baseline MRIs (T2w, DWI and/or DCE sequences) from PCa patients treated with ADT and radiotherapy were included. Using Quibim's QP-Prostate ® solution, subregions (Transition + Central Zone [TZ + CZ], Peripheral zone [PZ] and seminal vesicles [SV]) were automatically segmented. For each subregion and for the whole prostate (WP), computed using the weighted biomarkers averaging, 105 radiomic features (shape and textures) from T2w, apparent diffusion coefficient (ADC) variables from DWI and perfusion parameters from DCE were extracted.

Results: A total of 128 T2w, 107 DWI and 62 DCE MRIs from 128 PCa patients (32 [25%] low or favourable intermediate risk [group 1] and 96 (75%) high or unfavourable intermediate risk [group 2]) were included, of whom 20 (16%) experienced BQR (18 [19%] from group 2). According to risk stratification, patients from group 1 presented more homogeneous textures in PZ and WP than group 2. Regarding BQR, the ADC mean was higher in the TZ in those who did not relapse, while patients with greater major axis length in the PZ, WP and SV were more likely to relapse. In SV and WP heterogenicity-related feature values were significantly higher in BQR. In group 2, diffusion parameters and shape variables in the SV were significantly different in those experiencing BQR.

Conclusions: Imaging biomarker profiles in this PCa population may help to better stratify patients at risk based on baseline MRIs. High-risk patients may be identified by the heterogeneity of textures. Diffusion and texture parameters may determine a higher probability of relapse.

Background: Several solid tumors, including colorectal cancer (CRC), overexpress c-Met. The antibody-drug conjugate ABBV-400 comprises the c-Met—targeting antibody telisotuzumab conjugated to a potent topoisomerase 1 inhibitor payload. ABBV-400 is being evaluated in a phase 1 trial (NCT05029882) in patients (pts) with advanced solid tumors. We analyzed correlations between genomic alterations and response of pts in this study.

Methods: Adults with advanced solid tumors and no validated treatment option were enrolled. Intravenous ABBV-400 was administered once every 3 weeks. ctDNA was isolated from plasma and analyzed using the GuardantINFINITY™ assay that evaluated various parameters including single-nucleotide variants and insertion-deletion mutations (753 genes), amplifications (415 genes), tumor mutational burden (TMB), and microsatellite instability (MSI) status. Molecular response (based on ctDNA variant allele frequencies) and radiographic response (RECIST v1.1) were assessed.

Results: As of 3 April 2023, 57 pts were efficacy evaluable, including 27 pts with CRC. The objective response rate was 25% (14/57; all confirmed partial responses [cPR]) in all pts and 22% in pts with CRC (6/27; all cPR). Most prevalent gene alterations were *TP53* (67%), *LRP1B* (43%), *APC* (41%), and *KRAS* (41%) mutations and *PTPRT* (45%) and *TOP1* (43%) amplifications. The table shows the correlation between response and select biomarkers (at baseline) in the 45 pts (22 CRC) who had both ctDNA and radiographic response data. A molecular response was observed in 48% (14/29) of all evaluated pts and 47% (8/17) of pts with CRC; median change from baseline tumor size was -22.5% and -20.3%, respectively.

Table: 163P Pts with molecular response and correlation between baseline biomarker status and radiographic response

	All pts		CRC pts			
N (pts with both ctDNA and radiographic response data)	45		22			
Pts with confirmed PR, n/N (%)	11/45 (24)		4/22 (18)			
Pts with molecular response, n/N (%)	14/29[a] (48)		8/17[b] (47)			
	High TMB	High MSI	High TMB	High MSI	*KRAS* mut	*BRAF* mut
Pts with confirmed PR with biomarker positivity, n/N (%)	3/20 (15)	0/3 (0)	3/13 (23)	0/1 (0)	2/16 (13)	1/3 (33)

[a]29 pts were evaluable for molecular response. [b]17 CRC pts were evaluable for molecular response. CRC, colorectal cancer; MSI, microsatellite instability; mut, mutations; PR, partial response; pts, patients; TMB, tumor mutational burden.

Conclusions: ABBV-400 showed promising preliminary efficacy, with molecular and radiographic responses in pts with advanced solid tumors with heterogeneous genomic profiles, including in pts with high TMB and *KRAS* mutations.

Clinical trial identification: NCT05029882.

Background: After curative surgery for stage II colon cancer (CC-II), only patients with high-risk features (pT4 tumor and MSS status) are offered adjuvant chemotherapy (ACT) in the Netherlands. Nevertheless, 15% of CC-II patients develop a recurrence. Post-operative circulating tumor DNA (ctDNA) is a prognostic biomarker that could improve selection of patients that may benefit from ACT. We performed an early evaluation of the effectiveness and cost-effectiveness of ctDNA-guided selection for ACT in CC-II in the Netherlands.

Methods: The validated PATTERN model, which simulates the course of disease from diagnosis till death in CC-II, was supplemented with data on the prognostic value of ctDNA from the Dutch PLCRC-MEDOCC study. Five strategies for selecting patients for ACT were evaluated: current guideline strategy (pT4 and MSS), ctDNA-only strategy, and three combination strategies of ctDNA in addition to pT4 and MSS status. For each strategy, we estimated costs, (quality-adjusted) life-years (QALYs), recurrences and CC deaths. The impact of uncertainty concerning strategy adherence, treatment effect of ACT, costs of ctDNA testing, and test performance on cost-effectiveness was assessed in sensitivity analyses.

Results: Model predictions showed that the ctDNA-only strategy was less effective (more recurrences, less QALYs) and that the combination strategies were more effective (less recurrences, more QALYs) than the current guideline strategy. From the viewpoint of cost-effectiveness, using a willingness-to-pay threshold of €50.000/QALY, the current guideline strategy was most favorable. Sensitivity analyses showed that the combination strategies could be cost-effective if the costs of ctDNA testing are lower than €1500, and/or if ACT is more effective in ctDNA+ than in ctDNA- patients. Improved ctDNA test had limited impact on the cost-effectiveness.

Conclusions: Selecting patients based on ctDNA status in addition to pT4 and MSS status for ACT can improve patient selection in terms of effectiveness, and can also potentially become a cost-effective strategy. However, more research is needed to investigate the prognostic and predictive value of ctDNA to accurately evaluate the (cost)effectiveness.

Background: Trop-2 is a transmembrane calcium signal transducer widely expressed in multiple tumor types on the membrane surface of epithelial cells. Antibody-drug conjugates targeting Trop-2 are currently being developed for the treatment of breast cancer. However, there is little data regarding the therapeutic implications of Trop-2 expression in HER2-positive breast cancer.

Methods: Trop-2 expression, as determined by immunohistochemistry (IHC) and its relationship with clinicopathologic features and pCR, was retrospectively analyzed in patients (pts) with HER2-positive EBC treated with upfront neoadjuvant docetaxel, carboplatin, trastuzumab, and pertuzumab in the PHERGain study (Pérez-García et al, Lancet Oncol 2021). Trop-2 expression was classified into low, medium, and high groups according to a histochemical score (H-score) based on staining intensity and percentage of stained cells.

Results: A total of 41 pts were included. Of these, 31.7% (13/41) had node-positive disease and 63.4% (26/41) were estrogen receptor-positive. 68.3% (28/41) of the tumors showed Trop-2 expression (low [29.3%]; medium [17.1%]; and high [21.9%]). No relationship was found between Trop-2 expression and different clinicopathologic features, but there was a trend toward higher progesterone receptor negativity among Trop-2-expressing tumors ($p = 0.098$). pCR was achieved in 63.4% (26/41) of the pts. According to Trop-2 expression, pCR rates were 50.0% (14/28) and 92.3% (12/13) in pts with and without Trop-2 expression, respectively ($p=0.015$).

Conclusions: Trop-2 expression by IHC was identified in approximately two thirds of HER2-positive EBC pts. Trop-2 appears to be a potential mechanism of resistance in this patient population and may become a strategic target for future combinations.

Background: Long term treatment related toxicity is a major issue for breast cancer patients in the adjuvant setting. Predicting toxicities may allow us to adapt the treatment strategy. We assessed whether the metabolomic profile of patients may predict long-term toxicities.

Methods: High-resolution untargeted metabolomics was performed at baseline for 857 ER-positive, HER2- breast cancer patients from the CANTO prospective cohort. Four metabolomic profiles per patient were produced: (i) shared and annotated metabolites (n=224), (ii) annotated but not always common metabolites (n=456), (iii) annotated but not always shared metabolites (n=766) and (iv) all metabolites (n=1693, *FullMet*). Samples were split into a discovery and validation set. We benchmarked algorithms adapted for high dimensional analysis (LASSO, Adaptive LASSO, machine learning, and deep learning) in order to select best models for prediction.

Results: 30.0% of patients were >65 years old, 24.4% <50 years old, 20.4% had BMI>30, 12.7% had previous history of neurological disorders, 6.1% had diabetes. 69.6% presented with pT1, 25.7% with pT2 and 3.4% with pT3; 11.1% had lymph node involvement. Among all benchmarked, adaptive LASSO was the most interesting statistical method with limited optimism bias. It also allows the selection of a subset of metabolites of particular interest. The addition of rare metabolites as well as non-annotated metabolites significantly increase the predictive power of models. Metabolic toxicity prediction mainly relied on endogenous metabolites while neurological toxicities were partly predicted using exogenous/environmental metabolites. In the validation set, compared to clinical data alone (AUC 0.50-0.54), addition of metabolomics data shows moderate (AUC = 0.55-0.60) but significant ($p<0.05$ adjusted for multiple comparison) predictive ability for neurological and metabolic toxicities.

Conclusions: Breast cancer patient metabolomic profile at baseline improves toxicity prediction after adjuvant chemotherapy, similar to what is reported for genomic fingerprints. Untargeted metabolomics allows the achievement of higher performance by taking into account environmental exposure, metabolites linked to microbiota as well as rare and uncommon metabolites.

Clinical trial identification: NCT01993498.

167P A tumor immune microenvironment-based model for prediction of everolimus efficacy in premenopausal women with hormone receptor-positive/human epidermal growth factor receptor 2-negative advanced breast cancer: Preliminary results from MIRACLE trial

T. Yujing[1], Y. Guan[2], Y. Chen[1], D. Ji[1], J. Wang[1], F. Ma[1], Y. Luo[1], P. Zhang[1], X. You[3], W. Xi[3], Y. Song[3], B. Xu[1], Y. Fan[1]

[1]Medical Oncology, Chinese Academy of Medical Sciences and Peking Union Medical College - National Cancer Center, Cancer Hospital, Beijing, China; [2]Oncology, Beijing Chao-Yang Hospital, Beijing, China; [3]Bioinformatics, Jiangsu Simcere Diagnostics Co., Ltd, Nanjing, China

Background: Everolimus (EVE), a mammalian target of rapamycin (mTOR) inhibitor, has been proven beneficial for patients with $HR^+/HER2^-$, advanced breast cancer (ABC) with endocrine resistance. Preclinical studies showed mTOR has close relationships with the tumor immune microenvironment (TME). Therefore, this study aimed to identify TME-related markers to predict efficacy of EVE in patients with $HR^+/HER2^-$ ABC.

Methods: Tumor tissues of patients from Miracle trial receiving EVE were collected for NanoString RNA expression analysis. TME cell type and TME signatures associated with efficacy were identified using the 289-immuno-gene panel of NanoString nCounter platform. Multiple statistical approaches were applied for enrichment analyses, survival estimation and validation.

Results: Mast cell scores significantly increased in patients who did not respond to EVE ($P = 0.031$) and those who had progression-free survival (PFS) < 6 months ($P = 0.029$). CD8 T cells were highly infiltrated in tumor tissue from patients with PFS < 1 year ($P = 0.035$). Patients with PFS > 1 year had lower scores of chemokines ($P = 0.032$) and Teff ($P = 0.028$) than those with PFS < 6 months did. Histidine decarboxylase (HDC), TNF receptor superfamily member 1A (TNFRSF1A), and RAD51 correlated with PFS and EVE response. Patients with HDC ($P = 0.013$) or TNFRSF1A ($P = 0.0031$) overexpression showed shorter PFS, whereas patients with RAD51 overexpression showed prolonged PFS ($P = 0.049$). A predictive model comprising HDC, TNFRSF1A, and RAD51 was established, and the receiver operating characteristic curve demonstrated its superiority (AUC = 0.96). The results also showed that patients whose tumors were non-responsive to EVE ($P = 0.00021$) or whose PFS was poor ($P = 0.0025$) were at a higher risk in the model.

Conclusions: The immune-related gene model consisting of HDC, TNFRSF1A, and RAD51 could potentially predict the efficacy of EVE in premenopausal patients with $HR^+/HER2^-$ ABC with endocrine resistance, which could help stratify responders to EVE and guide the choice of EVE in clinical practice.

168P HUWE1 inhibition has tumor suppressive effect in triple-negative breast cancer cell lines by modulating glycolytic and immune modulatory markers

S. Kahol, S. Mathur

Department of Pathology, AIIMS - All India Institute of Medical Sciences, New Delhi, India

Background: The E3 ligase HUWE1 is a key regulator of the DNA damage response, transcription, autophagy, apoptosis and metabolism in a variety of cancers. Due to its pivotal role in conferring substrate specificity, HUWE1 has attracted enormous attention as a promising anticancer drug target. In this study, we have studied the role of HUWE1 in triple-negative breast cancer (TNBC) cell lines and evaluated its role on aerobic glycolysis which is upregulated in cancer cells and immune modulatory markers for their roles in immunotherapy. TNBC subtype neither express hormone receptors nor Her2/neu. TNBC are highly aggressive, with poor prognosis and no well-defined treatment regimen. Therefore, considering HUWE1 as an oncogene its role has been explored on glucose metabolism and immune modulation in TNBC cell lines.

Methods: Two TNBC cell lines i.e. MDA-MB-231 and MDA-MB-468 were used in the present study. These cell lines were treated with HUWE1 inhibitor: BI8622 for 24 h and the effect of inhibition was seen on its substrate (c-myc), aerobic glycolytic (HK-2, GLUT-1) and immune checkpoint markers (PDL-1, CD-47) using western blotting approach. Wound healing assays and clonogenic assays were also performed in BI8622 treated cells to check the effects of HUWE1 inhibition on migration and colony forming ability of TNBC cells in both the cell lines.

Results: As expected, there was a decrease in the protein expression levels of c-myc after the HUWE1 inhibition. Furthermore, there was decrease in protein expression of glycolytic markers i.e. HK-2 and GLUT-1 as well as immuno modulatory markers i.e. PDL-1 and CD-47. Additionally, the HUWE1 inhibition in TNBC cells was positively associated with the inhibition of migration and clonogenic potential.

Conclusions: In this study for the first time, we have demonstrated that HUWE1 acts as a tumor suppressor in TNBC by regulating the glucose metabolism and immune

checkpoint inhibitors. HUWE1 inhibition could functionally suppress TNBC development possibly by regulating aerobic glycolysis and immune checkpoints through c-myc.

169P Integration of metabolomics and transcriptomics to reveal potential biomarkers associated with treatment response of neoadjuvant therapy in HER2+ breast cancer

N. Zhang, Y. Xiang, Z. Jing, F. Yu, J. Zeng, X. Pan, W. Zhou, X. Liang, Y. Yue, H. Zhang, Y. Deng, S. Deng, S. Mo, X. Jiang, X. Zeng

Breast Cancer Center, Chongqing University Cancer Hospital, Chongqing, China

Background: This study aimed to explore potential indicators associated with neoadjuvant efficacy of TCbHP regime (taxane, carboplatin, trastuzumab and pertuzumab) in HER2+ breast cancer.

Methods: LC-MS and GC-MS platform-based untargeted metabolomics were performed to determine the metabolic profiles of plasma samples from HER2+ breast cancer patients, who received and completed neoadjuvant therapy (NAT) with TCbHP regime and subsequent surgery at Chongqing University Cancer Hospital. Random forest (RF) was used to establish predictive models based on pre-therapeutic metabolic traits. Transcriptome analysis was performed in available samples to identify differentially expressed genes (DEGs) before treatment. Metabolic and transcriptomic data were integrated to uncover significantly perturbed pathways potentially involved in drug resistance.

Results: From July 20, 2020 to May 28, 2021, a total of 40 HER2+ breast cancer patients with 120 plasma samples were eligible and recruited for this study. Of whom 21 (52.5%) patients achieved pCR and 19 (47.5%) achieved non-pCR. There were significant differences in plasma metabolic profiles between non-pCR and pCR groups before and during treatment. A total of 100 differential metabolites were identified between pCR and non-pCR patients at pre-therapeutic period, which were significantly enriched in 40 metabolic pathways. Four key metabolites [sophorose, N-(2-acetamido)iminodiacetic acid, taurine and 6-hydroxy-2-aminohexanoic acid] were selected by RF analysis. The AUC value to discriminate pCR and non-PCR group to NAT of the single potential metabolite or combined panel of these metabolites were more than 0.910. 18 metabolites had potential value in monitoring effect. A total of 163 DEGs were identified between biopsy tissue samples from pCR and non-pCR patients. 39 altered pathways aberrantly expressed at both metabolic and transcriptional levels.

Conclusions: Metabolomics integrated with transcriptomics analysis could assist for gaining more insights into biochemical pathophysiology and facilitate the development of novel therapeutic targets for insensitive patients.

170P Clinical significance and functional role of GPR56 (ADGRG1) in breast cancer

H. Chen[1], X. Hu[1], W. Ouyang[1], D. Wang[2], Y. Wang[1], Y. Yu[1], H. Yao[1]

[1]Breast Tumor Centre, Department of Medical Oncology, Phase I Clinical Trial Centre, Guangdong Provincial Key Laboratory of Malignant Tumor Epigenetics and Gene Regulation, Sun Yat-sen Memorial Hospital, Sun Yat-sen University, Guangzhou, China; [2]Department of Radiation Oncology, State Key Laboratory of Oncology in South China, Collaborative Innovation Center for Cancer Medicine, Sun Yat-Sen University Cancer Center, Guangzhou, China

Background: The clinical significance and functional role of adhesion G protein-coupled receptors (aGPCRs) in breast cancer remain largely unknown. We aimed to comprehensively analyze the prognostic potential of aGPCRs in breast cancer, identify the key prognostic GPCRs, and comprehend their functional roles.

Methods: A total of 1593 breast patients were analyzed using RNA-seq and clinical data from four independent public datasets, including 1064 patients from TCGA, 198 from GSE7390, 327 from GSE20685, and 104 from GSE42568. We also analyzed the mutated landscape based on exome and copy number alteration data from TCGA. In addition, single-cell RNA-seq (scRNA-seq) data from three breast cancer patients from GSE198745, and data on mammary gland tissue from the Tabula Muris, were used to measure the variation of the candidate GPCRs across diverse cell types. The CellMiner database was used to examine drug sensitivity.

Results: Among the 33 aGPCRs, GPR56 was the only significant prognostic factor in all four datasets. High GPR56 expression was significantly lined to worse relapse-free survival and overall survival. GPR56 expression was higher in younger, high-grade, and triple-negative breast cancers. GPR56-related genes were involved in several pathways, including cell division, DNA replication, cell cycle, protein binding, and others. GPR56 also participated in the activation of multiple cancer signaling pathways. High GPR56 expression was correlated with higher levels of several immune cells, immune checkpoints, and immune-related scores. scRNA-seq analysis revealed that GPR56 was mainly expressed in tumor cells, tumor stem cells and endothelial cells. In normal breast tissues, GPR56 expression was higher in basal cell subsets than in luminal epithelial cell subsets, suggesting that GPR56 may interact with breast stem cells. In addition, there were some differences in the mutant landscape between the high and low GPR56 expression groups. Furthermore, GPR56 was significantly associated with sensitivity to multiple antitumor drugs.

Conclusions: GPR56 was significantly linked to the molecular pathology and prognosis of breast cancer. GPR56 may serve as a promising novel therapeutic target in breast cancer.

171P Combined expression of MKI67, FOXC1 and PDL1 is a pan-tumor tissue-agnostic predictor of PD1/PDL1 inhibitor efficacy in metastatic renal cell cancer: Validation in checkmate 009, 010 and 025 clinical trial cohorts

P.S. Ray[1], T. Ray[2], C. Taylor[3], R. Hussa[2]

[1]Surgical Oncology, Onsite Healthcare, Lincolnwood, IL, USA; [2]Research & Development, Onconostic Technologies, Inc., Evanston, IL, USA; [3]Pathology, Keck School of Medicine - University of Southern California USC, Los Angeles, CA, USA

Background: Accurate prediction of PD1/PDL1 inhibitor therapeutic efficacy (TE) as well as any resultant durable clinical benefit (improved progression-free survival (PFS), overall survival (OS)) is not consistently achieved with existing biomarkers like PDL1 or tumor mutational burden(TMB). We hypothesized that a multi-marker (MM) predictive biomarker strategy that tracks plasticity using FOXC1 expression, in parallel to tumor proliferation and immune evasion, using expression of MKI67 and PDL1, respectively, may demonstrate superior TR prediction, and also enable accurate prediction of risk for hyperprogressive disease (HPD).

Methods: Metastatic renal cell carcinoma (mRCC) patients enrolled in Checkmate (CM) 009, 010 and 025 clinical trials (n=35, 168, 803) with available pre-treatment tumor RNA-Seq data (n=16, 45, 250 respectively) were analysed for FOXC1, MKI67 and PDL1 expression, and correlated with overall response rate (ORR), PFS, OS and HPD, the latter defined as time-to-treatment-failure <=2 months post-treatment initiation. Optimized biomarker cut-off values based on model area-under-curve were leave-one-out cross validated and prediction algorithms derived to predict Predicted Responders (PR) and Non-Responders (NR). The unmodified strategy was then validated in independent datasets.

Results: In CM025 ORR prediction by MM was specific to the Nivolumab arm [ITT CR %=22.5%, PR CR%=41.8%, NR CR%-3.6% OR=19.4 (4.3- 87.8)95%CI, p<0.0001, n=111] and not the Everolimus arm [ITT CR%=4.6%, PR CR%=3.3%, NR CR%= 5.4%, n=109]. This was confirmed further in combined CM009+CM010 cohorts (OR=9.63 (0.98-94.54) 95%CI, p=0.03). MM-predicted PR consistently displayed superior PFS (p<0.0001) and OS (p=0.03) compared to predicted NR who displayed either Progressive Disease or Hyperprogressive Disease, and were superior to results with PDL1.

Conclusions: Tracking multiple dimensions of cancer biology using our MM approach again proved its superiority in predicting PD1/PDL1 inhibitor efficacy in advanced/metastatic tumors, this time in mRCC patients. This approach merits further testing in prospective clinical trials.

Clinical trial identification: NCT01358721 - October 28, 2021 NCT01354431 - May 12, 2022 NCT01668784 - August 9, 2022.

172P T cell-derived circulating DNA and tumour inflammatory microenvironment in EGFR-mutant advanced non-small cell lung cancer: Correlation with the outcome of EGFR TKI treatment

N. Zungsontiporn[1], S. Santisukwongchote[2], P. Sitthideatphaiboon[1], N. Leelayuwatanakul[3], K. Korphaisarn[4], P. Chantranuwat[2], V. Sriuranpong[1], C. Vinayanuwattikun[1]

[1]Division of Medical Oncology, Department of Medicine, King Chulalongkorn Memorial Hospital - Thai Red Cross Society, Bangkok, Thailand; [2]Department of Pathology, King Chulalongkorn Memorial Hospital - Thai Red Cross Society, Bangkok, Thailand; [3]Division of Pulmonary and Critical Care Medicine, Department of Medicine, King Chulalongkorn Memorial Hospital - Thai Red Cross Society, Bangkok, Thailand; [4]Division of Medical Oncology, Department of Medicine, Faculty of Medicine Siriraj Hospital, Mahidol University, Bangkok, Thailand

Background: We previously reported paradoxical impact of T-cell derived circulating DNA (T-cirDNA) in-term of prognosis marker in advanced non-small cell lung cancer (NSCLC). Longer durability of EGFR tyrosine kinase inhibitor (EGFRi) was correlated with undetectable T-cirDNA/cirDNA. This study aimed to confirm the finding in a larger cohort, correlated with tumor immune microenvironment (TIME).

Methods: Pretreatment plasma of patients with advanced *EGFR*-mutant NSCLCs who received EGFRi were collected. The semi-quantitative T-cirDNA /cirDNA was conducted by multiplex real-time polymerase chain reaction. Correlation with clinical outcome and TIME, including programmed cell death ligand-1 (PD-L1 clone 22C3), CD8 tumor infiltration lymphocyte (TIL), and Treg/FOXP3 were conducted.

Results: One-hundred and thirty-nine patients were divided according to T-cirDNA/cirDNA into undetectable (30%), low ($\leq$1% ratio; 38.1%), and high (>1% ratio; 31.6%). The median progression-free survival (PFS) was 13.1 [95% CI 8.8 − 17.4], 9.0 [95% CI 6.7 − 12.5], and 13.2 [95% CI 8.8 − 19.3] months respectively, which was longest in undetectable and high T-cirDNA/cirDNA. Sixty-eight available tissue blocks for TIME study revealed decremental proportion of high PD-L1 ($\geq$15% TPS) in high (21%), low (13%) and undetectable T-cirDNA/cirDNA (4%). While high intra-tumoral CD8 TIL ($\geq$1%) had lowest proportion in low T-cirDNA/cirDNA (17%) contrary to undetectable (36%) and high T-cirDNA/cirDNA (47%). Multivariate cox-regression analysis revealed that high PD-L1 and high intra-tumoral CD8 TIL were independent factors correlated with shortened PFS. Good ECOG performance status (0-1) and undetectable T-cirDNA/cirDNA were solely independent prognostic factor to overall survival.

Conclusions: Undetectable T-cirDNA/cirDNA represents inactivated naïve T-cell and indicated favorable prognosis in *EGFR*-mutant NSCLCs who received EGFRi. Inflammatory TIME including high PD-L1 and high intra-tumoral CD8 indicated shorted disease control with EGFRi. The interaction of active T-lymphocyte and TIME in *EGFR* alteration advanced NSCLC received EGFRi is warranted.

173P Expression of programmed death-ligand 1 and EGFR on circulating tumour cells in advanced lung cancer patients

J. Khandare[1], G. Aland[1], M. Garbhe[2], S. Gosavi[2], G. Khutale[3], M. Patil[2], V. Tulpule[2], P. Lokhande[2], A. Ashturkar[2], V. Jadhav[2], A. Vasudevan[2], S. Jayant[2], A. Bharde[4]

[1]CTC, Actorius Innovations and Research, Pune, India; [2]CTC, Actorius Innovations and Research USA and India, Pune, India; [3]CTC, OneCell Dx, Pune, India; [4]CTC, OneCell Diagnostics India Pvt Ltd, Pune, India

Background: Targeted molecular therapy and immunotherapy have revolutionized the treatment of advanced lung cancer (ALC). Although therapeutically significant, the outcome of ICI or TKI is dependent on the presence of their respective targets in tumor cells. Evaluating targets based on solid biopsy may be often misleading, particularly in progressive patients despite therapy administration. Additionally, tissue biopsy provides a static signature of a target protein expression from the evolving tumor. The unmet need for dynamic detection and monitoring of actionable targets could be addressed by circulating tumor cells (CTCs). Here we report on the utility of CTCs to detect actionable targets from advanced lung cancer (ALCs) patients.

Methods: We retrospectively analyzed 193 ALC patients for Programmed Death - Ligand 1 (PD-L1) and EGFR expression on CTCs from. CTCs were isolated from Drug Controller General of India-approved OncoDiscover technology based on immunomagnetic targeting using anti EpCAM antibody, and immuno-staining with anti EGFR and PD-L1 antibodies. CTCs were detected based on the expression of CKs, absence of CD45, and prominent DAPI-stained nuclei. The presence or absence of EGFR and PD-L1 was determined with automated immunofluorescence microscopy.

Results: Among the evaluated cohort, 67 % patients showed the presence of CTCs with a mean value of 4.2 (Range: 1 to 62, SD =10.65). The absence of CTCs from the remaining 33 % of patients could be due to the therapy response of the clinically stable disease. From all patients showing the presence of CTCs, 66 % showed the detectable expression of PD-L1, while 42 % showed a strong expression of EGFR. The presence of PD-L1 was a significant association with CTCs. Similarly, the expression of EGFR among the detected CTCs showed high significance compared to the reported data on tissue biopsy from the literature.

Conclusions: Detection of therapeutic targets on CTCs obtained from ALC strongly indicate these patients qualify for anti-EGFR and PD-L1 therapies. Systematic studies with larger samples are required to strengthen the liquid biopsy-based detection of actionable targets. This could immensely help ALC patients showing progressive disease on chemo/radiotherapy.

174P Frequency and prognostic value of circulating tumor cells in cancer of unknown primary

M. Pouyiourou[1], S. Riethdorf[2], T. Bochtler[3], C. Coith[2], B. Kraft[1], T. Hielscher[4], A. Stenzinger[5], K. Pantel[2], A. Krämer[6]

[1]Clinical Cooperation Unit Molecular Hematology/Oncology, German Cancer Research Center (DKFZ) and Department of Internal Medicine V, University of Heidelberg, Heidelberg, Germany; [2]Institute for Tumor Biology, UKE Universitätsklinikum Hamburg-Eppendorf KMTZ, Hamburg, Germany; [3]Medical Oncology, NCT - Nationales Zentrum für Tumorerkrankungen, Heidelberg, Germany; [4]Division of Biostatistics, German Cancer Research Center (DKFZ), Heidelberg, Germany; [5]Institute of Pathology, University Hospital Heidelberg, Institute of Pathology, Heidelberg, Germany; [6]Clinical Operation Unit Molecular Hematology/Oncology, German Cancer Research Center (DKFZ) and University of Heidelberg, Heidelberg, Germany

Background: Cancer of unknown primary (CUP) is defined as a primary metastatic malignancy, where the primary tumor remains elusive in spite of a comprehensive diagnostic workup. Patients with CUP have a poor prognosis, making the need for the development of novel therapeutic and prognostic tools urgent. The frequency and prognostic value of circulating tumor cells (CTCs), which are considered to be the source of metastasis, has not yet been systematically evaluated in CUP.

Methods: 92 patients with a confirmed diagnosis of CUP according to the ESMO guidelines, who presented to our clinic between 07/2021 and 03/2023 provided blood samples for CTC enumeration using CellSearch® methodology. CTC counts were correlated with demographic, clinical and molecular data generated by comprehensive genomic profiling of tumor tissue.

Results: CTCs were detected in 35% of all patients. The highest CTC frequency was observed among patients with unfavorable CUP (18/53, 34%), while patients with single-site/oligometastatic CUP harbored the lowest CTC frequency (4/28, 14%). Disease burden and the number of affected organs had no significant effect on the CTC detection rate (P=0.251 and P=0.805). CDKN2A alterations were slightly more common in CTC-negative patients (P=0.086). High CTC levels (5 CTCs/7.5 ml) predicted for adverse overall survival (OS) compared to negative or low counts (median 74 vs. 19 months; Log-rank P=0.002; HR 3.73; 95% CI 1.54-9.00). Progression-free survival was also affected by CTC status, the effect did not, however, reach statistical significance (median 7.4 vs 3.6 months, Log-rank P=0.1). CTC dynamics over the course of the disease were prognostic for OS, with patients that were either consistently CTC-negative or turned negative during treatment demonstrating the best prognosis.

Conclusions: The number of CTCs is a predictor of survival in patients with CUP. Measurement of CTCs provides a useful prognostic tool in the management of these patients.

175P Radiomic biomarker of vessel tortuosity for monitoring treatment change: Preliminary findings in prospective evaluation of ECOG-ACRIN EA5163

P. Mutha[1], F. Duan[2], V.S. Viswanathan[1], M. Khorrami[1], N. An[3], V. Velcheti[4], A. Gupta[5], S.S. Ramalingam[6], K. Kelly[7], K. Sandler[8], H. Borghaei[9], A. Madabhushi[1]

[1]Wallace H. Coulter Department of Biomedical Engineering at Emory University and Georgia Tech, Emory University, Atlanta, GA, USA; [2]Department of Biostatistics, Brown University, Providence, RI, USA; [3]Center for Statistical Sciences, Brown University, Providence, RI, USA; [4]Thoracic Oncology, NYU Langone Medical Center and School of Medicine, New York, NY, USA; [5]Department of Radiology, Case Western Reserve University / University Hospitals, Cleveland, OH, USA; [6]Department of Hematology and Medical Oncology, Winship Cancer Institute, Emory University School of Medicine, Atlanta, GA, USA; [7]Hematology Oncology Department, UC Davis Comprehensive Cancer Center, Sacramento, CA, USA; [8]Department of Radiology, Vanderbilt University Medical Center, Nashville, TN, USA; [9]Hematology/Oncology Department, Fox Chase Cancer Center - Main Campus, Philadelphia, PA, USA

Background: EA5163 is a phase 3 randomized trial investigating first-line mono immunotherapy (IO) or IO with chemotherapy in advanced non-small cell lung cancer (NSCLC). Previous work has retrospectively validated a CT based radiomic signature of tumor associated quantitative vessel tortuosity (QVT) for prognosticating outcomes in IO treated NSCLC (Alilou et al. Sci Adv 2022). In this study, we report initial results of evaluating QVT in assessing IO related treatment changes in EA5163, specifically associating changes in QVT (Δ-QVT) with changes in tumor volume (Δ-TV) between baseline (B) and 6 week post-treatment scans (TP1).

Methods: CT scans from 29 patients enrolled in EA5163 with measurable lung lesions at B and TP1 were included. Vasculature was automatically segmented in a 25mm region around manually annotated tumors in CT using MATLAB R2022b. 84 QVT features measuring tortuosity, curvature and angle statistics were extracted. No information on outcomes, survival, or treatment arm assignment was available due to the ongoing nature of the trial. Spearman correlation and false discovery rate corrected p-values were computed to associate Δ-QVT with Δ-TV in an unsupervised setting. A risk score (QRS) was generated as the output of a classifier previously trained on 5 Δ-QVT features prognostic of RECIST v1.1 response.

Results: 14 Δ-QVT features were significantly ($p<0.05$) correlated with Δ-TV with an absolute range of 0.45 and 0.76. 4 features in the QRS signature were significantly correlated with Δ-TV (Table). QRS based stratification showed net decrease in TV in low risk patients, whereas a net increase in high-risk patients at TP 1 ($p<0.001$). The Δ-QVT features were not associated with baseline tumor volume.

Table: 175P

Feature	Correlation	p-value
Vessel volume	0.71	<0.001
1st bin of tortuosity histogram	0.65	0.002
12th bin of angles histogram	0.61	0.004
2nd bin of curvature histogram	0.65	0.002
Vessel volume to tumor volume ratio	-0.48	0.053

Conclusions: This study demonstrated an association between CT derived radiomic biomarker Δ-QVT and Δ-TV in an ongoing prospective clinical trial. Validation of these results upon interim analyses or trial completion is warranted.

Clinical trial identification: NCT03793179.

Background: The growing need for better predictive biomarkers in immunotherapy has driven the development of AI models across various fields. Despite this progress, most studies focus on single modalities, such as pathology or radiology. This study emphasizes the importance of multimodal biomarkers, combining radiology and pathology data, to optimize treatment outcomes and advance personalized medicine in immunotherapy.

Methods: We developed weakly-supervised deep learning (DL) models for CT and PDL1-stained immunohistochemistry (IHC) images. We trained a CT-based model to predict immunotherapy clinical benefit (PFS > 5 months) in a pan-cancer cohort from VHIO(n=369). Simultaneously, we trained a DL method to predict PD-L1 status from IHC images in an open source NSCLC cohort (n=233), validated in a pan-cancer cohort from VHIO (n=106). The model predictions of both modalities were aggregated and utilized for patient stratification in immunotherapy response. In the overlapping subset with both modalities' data (n=75), we explored the association between PFS and the combination of predicted clinical benefit by CT and predicted PDL1 status by IHC using Cox regression and log-rank test.

Results: The CT-based and IHC-based DL models exhibited effective performance in predicting PFS for immunotherapy response in the pan-cancer cohort, with hazard ratios (HR) of 0.62 [95% CI 0.5-0.78], $p<0.05$ and 0.66 [95% CI 0.44-1], $p<0.05$, respectively. In the multi-modal data subsets, patients classified as clinical benefit prediction by the CT-based model and PDL1 high by the IHC-based model ($n = 20$) exhibited better immunotherapy response (HR 0.44 [0.25-0.78], $p<0.05$) with longer PFS (median PFS 4.08 [2.70-10.91] months) compared to the rest (median PFS 1.81 [1.68-2.96] months).

Conclusions: Integrating radiology and pathology data improves response prediction compared to single modality models, emphasizing the potential of a multimodal approach for better patient stratification in immunotherapy.

177P Revealing differences in radiosensitivity of advanced non-small cell lung cancer (NSCLC)through single-cell sequencing data

P. You[1], H. Zhou[2], Q. Li[2], D. Xie[2], L. Yao[2], S. Liu[3]

[1]Radiotherapy, Nanchang University, Nanchang, China; [2]Department of Thoracic Surgery, Guangdong Province People's Hospital, Guangzhou, China; [3]Guangdong Province People's Hospital, Southern Medical University Hospital of Integrated Traditional Chinese and Western Medicine, Guangzhou, China

Background: Radiotherapy resistance is a major therapeutic difficulty for advanced NSCLC patients because not all patients can benefit from radiation therapy. Identifying disparities in radiosensitivity of advanced lung cancer and antagonizing the radiotherapy resistance are the challenges for clinical oncologists.

Methods: We analyzed the scRNA-seq transcriptome data of 42 patients with advanced NSCLC, including lung adenocarcinoma and lung squamous cell carcinoma, used the radiosensitivity index (RSI) to calculate the radiosensitivity intensity (RSI ^{high} and RSI ^{low}) of each cell of 11 cell types, and drew the radiosensitivity difference map of different cell types in the system. The core role of malignant cells in radiosensitivity differences in advanced NSCLC was revealed using cell cycle inference, tumor cytoTRACE score, GO/KEGG enrichment, cell-cell interactions, cellular metabolic activity, and quasi temporal trajectory joint analysis, all in accordance with the "4R" principle of radiobiology (Repair, Reoxygenation, Redistribution, Regeneration).

Results: Malignant cells differ significantly from other types of radiosensitive cells in processes such as cell cycle, aging, apoptosis, chromosomal alterations, and cellular metabolic activity. RSI ^{high} cells make up the majority of cells in the G2/M and S phases, and the quantity and intensity of RSI ^{high} cell ligand receptors increases considerably. RSI ^{low} cells, as an exposure factor, tend to shift from epithelial to malignant cells, leading in alterations in ligand receptor input and output patterns. Furthermore, we discovered considerable changes in the metabolic activity of RSI ^{low} cells in lung squamous cell carcinoma.

Conclusions: Our findings show that radiosensitivity varies in advanced NSCLC. RSI ^{low} cells could be a subset of malignant cells with radiotherapy resistance, driving clinical researchers to delve deeper into the detailed mechanism of advanced NSCLC.

Background: IO revolutionized NSCLC treatment paradigm, but only a relatively small proportion of pts shows benefits. Since available biomarkers demonstrated only limited predictive efficacy, novel models are urgently needed. Radiomics, through machine learning (ML) and deep learning (DL) techniques, allows to extract features from raw images to build predictive models. This study aimed to develop and test 2 type of radiomics models in predicting IO efficacy on advanced NSCLC, one ML-based, other through an end-to-end DL pipeline.

Methods: We collected CT scans and RWD from 295 consecutive pts with advanced NSCLC pts receiving any-line anti-PD(L)1 therapy either alone or in combination with CHT at our Institution from 23/04/2013 to 12/05/2022 within APOLLO 11 study. ML workflow consisted of image preprocessing, feature extraction, 3 step feature selection, correlation, algorithm training and evaluation of 6 ML classifiers. ML models were trained using radiomics +/- RWD. Models were evaluated on independent test set and SHAP values used to explain model predictions. We compared developed model with novel DL end-to-end model, a 3D convolutional neural network.

Results: 15 image features were selected to build radiomic model, achieving ACC of 0.61 and AUC of 0.58. Combining it with additional RWD features, accuracy and AUC of LR reached 0.71 and 0.76. SHAP analysis for best-performing models showed RW (ECOG PS, therapy line, concomitant CHT, PDL1) and radiomics features (tumor shape and intensity/distribution of gray-level values) that most influenced models. DL model achieved an ACC of 0.69 and a Loss value of 0.773. A high proportion of higher GLSZM and a high value of large area size zones were associated to a higher response to therapy.

Conclusions: The developed and validated ML-based model includes radiomic and RW features, demonstrating ability to predict IO efficacy and potential future applicability for treatment selection. We firstly demonstrated that a radiomics-based DL model outperform the all radiomics ML-based models highlighting the importance of this approach in image data. SHAP analysis provided valuable insights to explore features that most influenced the models' predictions

179P Molecular tumor board directed treatment for patients with advanced stage solid tumors: A case-control study

D. Bansal[1], M.T. Roth[1], C. Ward[1], L. Douglass[1], B. Buzard[1], B. Gustafson[1], T. Pluard[1], J. Subramanian[2]

[1]Medical Oncology, Saint Luke's Cancer Institute, Kansas City, MO, USA; [2]Thoracic Oncology Center for Precision Oncology, Suite 4000, Saint Luke's Primary Care Plaza, Kansas City, MO, USA

Background: Interpreting next-generation sequencing (NGS) results and directing treatment based on those results can be challenging. Molecular tumor boards (MTBs) can help by establishing collaborative frameworks to deliver patient care plans with the appropriate incorporation of genomic data.

Methods: This retrospective observational study evaluates the impact of MTB on the outcomes of adult patients diagnosed with advanced-stage cancer. Patients were grouped into those who received at least one treatment recommended by MTB or those who did not receive treatment recommended by MTB. Kaplan- Meier analysis was performed for overall survival (OS) and progression-free survival (PFS). Cox proportional hazard model was fit for PFS, OS, and time on treatment (ToT) with multivariate adjusting for age, stage, line of therapy, and primary site of diagnosis.

Results: Of 238 evaluable patients, 138 (58%) received at least one treatment recommended by MTB. Patient characteristics were well balanced between the cohorts except for a statistically significantly higher proportion of lung adenocarcinoma (33% v 14%, p=0.0009) & melanoma (9% v 2%, p=0.030) in the matched cohort and more glioblastoma in the unmatched cohort (8% v 1%, p=0.017) (Table). Median ToT was 4.3 months for patients on matched treatment versus 2.8 months for patients who received therapy of provider's choice (HR 0.58, 95% CI [0.41-0.83], p=0.0027). Median PFS was 9.7 months versus 4.3 months for MTB-matched treatment versus provider's choice of treatment (HR 0.64, 95% CI [0.42-0.97],p=0.035). Median OS was 18.5 months for patients on MTB-recommended therapy versus 9.1 months for patients who received therapy of provider's choice (HR 0.64, 95% CI [0.43-0.96],p=0.030).

Conclusions: MTB treatment recommendations improved survival outcomes for patients with cancer even after correcting for imbalances between the two cohorts. Our findings show that MTBs in community cancer centers are feasible and valuable in cancer care.

Table: 179P Histology

	Matched		Unmatched	
	No.	(%)	No.	(%)
	138		100	
Lung Adenocarcinoma	45	(33%)	14	(14%)

180P An HLA-diet-oriented system unveiling organ-specific occurrence of multiple primary cancers (MPC) with prevention strategy: A large cohort study of 47,550 cancer patients

Z. Rong, Z. Dong, S-C. Ma, J. Lin, D. Han, X. Cai

Department of Radiation Oncology, Southern Medical University Nanfang Hospital, Guangzhou, China

Background: Along with the prolonged survival of cancer patients in recent years comes another dilemma, multiple primary cancers (MPC), which rob cancer patients of their privilege to optimal treatments. Nonetheless, understanding the hereditary and postnatal predisposition of MPC is still in its infancy.

Methods: We included 47,550 cancer patients in UK Biobank. Hazardous and protective HLA alleles concerning MPC were recognized leveraging stepwise logistic regression, which was further validated by log-rank test and Cox proportional hazard model. Logistic regression was used to investigate the organ-specific association between HLA and MPC. Cox proportional hazard model was used to explore potential interventions.

Results: Two protective (DPA1*02:02 and DRB1*04:03) and four hazardous (A*26:01, A*24:03, DPB1*20:01 and DQB1*06:01) HLA alleles are significantly associated with MPC risk for male, whereas one protective (DRB5*01:01) and four hazardous (A*03:02, DRB1*08:03, DQB1*05:04, and DPB1*11:01) for female. Compared with patients without MPC-related HLA alleles, both male and female patients carrying protective HLA alleles have lower risk of MPC (HR, 0.67 [95% CI, 0.53-0.83] and HR, 0.84 [95% CI, 0.73-0.97], respectively), while those carrying hazardous HLA alleles have higher risk of MPC (HR, 1.31 [95% CI, 1.09-1.57] and HR, 1.55 [95% CI, 1.25-1.93], respectively). HLA alleles are associated with organ-specific MPC occurrence. Lower animal fat intake subsided (HR, 0.46 [95% CI, 0.26-0.82]) while unqualified vegetable fat intake increased MPC risk (HR, 2.23 [95% CI, 1.22-4.07]) for male cancer patients carrying hazardous HLA alleles. Lower free sugar intake subsided the risk of MPC for female patients carrying hazardous HLA alleles (HR, 0.34 [95% CI, 0.15-0.74]).

Conclusions: HLA alleles might help to understand the predisposition and organ-specific incidence of MPC. Intervention on diet could counteract the risk.

Klina, Brasschaat, Belgium; [11]GI Oncology, UZ Leuven - University Hospitals Leuven - Campus Gasthuisberg, Leuven, Belgium; [12]Medical Oncology, UZA - University Hospital Antwerp, Edegem, Belgium; [13]Department of Oncology-Hematology, GHdC - Grand Hopital de Charleroi - Site Notre Dame, Charleroi, Belgium; [14]Medical Oncology, AZ Nikolaas Hospital, Sint-Niklaas, Belgium; [15]Medical Oncology Department, Jesse Ziekenhuis - Campus Virga Jesse, Hasselt, Belgium; [16]Department of Medical Oncology, UZ Gent - University Hospital Ghent, Gent, Belgium; [17]Medical Oncology Department, Vrije Universiteit Brussel - Faculty of Medicine & Pharmacy, Brussels, Belgium

Background: Several targeted therapies are available through reimbursed organ-specific next-generation sequencing (NGS). Agnostic comprehensive genomic profiling (CGP) covering all classes of genomic alterations could improve access to molecularly-guided therapies (MGTs).

Methods: PRECISION is an initiative launched by the Belgian Society of Medical Oncology (ESMO Open. 2022 Aug;7(4):100524). In the prospective GeNeo trial, CGP (FoundationOne CDx or Heme) was centrally done on tumor samples for patients with advanced solid tumors (NCT04641676). In parallel, organ-directed NGS panel testing was mandatory if reimbursed. Patients with no tissue sample were enrolled with a liquid biopsy. Results were discussed at a national molecular tumor board (MTB). Reasons for non-initiation of the recommended treatment were recorded. Clinical and genomic data are stored in the PRECISION database, with prospective follow-up up to 2 years.

Results: From October 2020 to April 2022, 1000 patients were enrolled at 13 sites. CGP results were available for 937 (843 tissue and 94 liquid biopsies) patients, out of which 918 were discussed at the MTB. The largest cohorts were breast (n=137), colorectal (n=128) and rare cancers (n=100). Turnaround-time from sample received to MTB recommendation was $\leq$ 28 days for 45% of cases and $\leq$ 37 days for 80%. 576 patients (63%) received at least one recommendation for CGP-based therapy. Cohorts with most treatment recommendations (>75% of cases) were bladder, biliary tract, skin and thyroid cancers. 72% of 469 patients who also had an organ-directed NGS test received at least one additional treatment recommendation based on CGP testing. Among the patients who received at least one MTB recommendation, 123 (21%) were treated accordingly. Reasons for non-compliance include patient ineligibility (26%), physician decision (23%) and treatment unavailability (22%). Follow-up continues.

Conclusions: Tumor-agnostic CGP provides more treatment options to patients with advanced solid tumors when compared to organ-directed NGS panel testing. The national MTB provides recommendations within a clinically relevant timeframe and enhances the uptake of MGTs.

Clinical trial identification: NCT03873103.

H. Lurie Cancer Center of Northwestern University, Chicago, IL, USA; [9]Hematology/Oncology, University Hospital of Virginia (UVA), Charlottesville, VA, USA; [10]Medicine Department, Moores Cancer Center - UC San Diego Health, La Jolla, CA, USA

Background: While DNA NGS can detect clinically actionable fusions in tumors, technical and biological limitations may lead to false negatives, preventing patients from receiving approved therapies associated with outcome benefit. RNA NGS is recommended by ESMO guidelines to maximize fusion detection but is not widely used clinically. In a large, real-world dataset, we quantify the benefit of RNA concurrent with DNA NGS for ALK fusion detection in NSCLC.

Methods: We retrospectively analyzed de-identified stage IIIB-C and IV NSCLC samples sequenced with the Tempus xT assay (DNA and whole-exome capture RNA NGS). ALK fusion prevalence was compared to public DNA-seq-based data from Dana Farber Cancer Institute (DFCI, N=4,497) and Memorial Sloan Kettering Cancer Center (MSKCC, N=5,317) with one-sided proportion tests. ALK fusions were limited to known oncogenic partners detectable by FISH or IHC (EML4, KIF5B, KLC1, and PICALM). Therapeutic adoption was analyzed in cases with ≥90 days of first-line medication data.

Results: Among 7,428 NSCLC patients, 2.9% had ALK fusions (n=217), with 83% (n=180) detected by both DNA and RNA, 15% (n=33) from RNA alone, and 2% (n=4) from DNA alone. ALK fusion prevalence in the Tempus Database was higher than the combined MSKCC and DFCI rate (2.4%, n=236/9,814, P=0.036). To investigate RNA vs DNA discordance, we examined exonic EML4-ALK breakpoint locations (n=32). Most cases had canonical breakpoints in RNA (n=26), where 18 had no DNA support in these breakpoints, suggesting complex ALK rearrangements in DNA. The remaining 8 had limited DNA support but were below the clinical threshold for reporting. Of those with medication data (n=7), 6 patients with EML4-ALK fusions detected by RNA alone received targeted therapy post-testing and 5 remained on therapy for ≥100 days.

Conclusions: This large, real-world dataset demonstrates that RNA NGS increases ALK fusion detection by 18% over DNA alone for patients with advanced NSCLC. This increase is likely to translate to a larger number of patients matched to and receiving targeted therapy. Consequently, RNA NGS should be considered for more widespread adoption in the clinic.

183P Frequency of actionable fusions in 7,735 patients with solid tumors

K.J. McDonnell[1], J.R. Hoag[2], C. Flannery[2], D. Hall[3], M.C. Evans[4], A. Akkunuri[4], S. Thakkar[3], J.R. Lobello[3], G.D. Basu[3], R.F.L. Baehner[3], J.D. Bonner[1], S.S. Lindsey[1], C. Hong[1], X. Xia[1], S. Gray[1], S.B. Gruber[1]

[1]Center for Precision Medicine, City of Hope Comprehensive Cancer Center, Duarte, CA, USA; [2]Clinical Biostatistics, Exact Sciences Corporation, Madison, WI, USA; [3]Precision Oncology, Exact Sciences Corporation, Redwood City, CA, USA; [4]Bioinformatics, Exact Sciences Corporation, Madison, WI, USA

Background: Identifying rare oncogenic gene fusions can be challenging. Comprehensive genomic profiling (CGP) approaches that include RNA sequencing can improve fusion detection versus exome or targeted DNA sequencing alone. Here, we characterize gene fusions in solid tumors detected with the OncoExTra™ tumor-normal, whole-exome (WES), whole-transcriptome (WTS) CGP assay.

Methods: The study included oncology patients with solid tumor samples tested with the OncoExTra assay between May 2018 and November 2022. We quantified the frequency of all potentially clinically-relevant fusions, including those with therapeutic, clinical trial eligibility, prognostic or diagnostic implications, and the subset of these with FDA-approved therapies at the time of testing.

Results: Overall, 7,735 patients and 33 tumor types were included. We identified 931 (12.0%) patients with clinically-relevant fusions, 224 (2.9%) of whom had a fusion associated with an FDA-approved therapy, with large variation in frequency across tumor types (Table). Sarcomas had one of the highest proportions (34.4%) of fusions identified, many of which are diagnostic or prognostic: *PAX3/7-FOXO1* (n=17), *SS18-SSX* (n=10), *CIC-DUX4* (n=8), and *MDM2* (n=6). We also detected fusions in 189 (9.5%) breast (including 43 with *ESR1*, 13 with *ERBB2*, 12 with *FGFR* family), 33 (3.4%) colorectal (including 5 *RSPO*, 3 *RET*), and 29 (9.9%) non-small cell lung (including 10 *ALK*, 5 *RET*, 3 *ERBB2*) cancer patients. Across all cancers, *ERG* (3.0%) was the most common fusion partner, found predominantly in prostate cancer patients. Other notable fusions involved *ESR1* (n=64); *RAF* family (n=30); *NTRK* family (n=27); and *RSPO* family (n=12).

Conclusions: Oncogenic gene fusions, including those with FDA-approved therapies, were identified with varying frequency across solid tumors. Sarcomas had a high proportion of fusions, including those with therapeutic, diagnostic and prognostic relevance.

Table: 183P Gene fusions in select tumor types

Tumor type	Patients, n (%)	Total fusions, n (% of patients)	Fusions with FDA-approved therapies, n (% of patients)
Breast	1989 (25.7%)	189 (9.5%)	65 (3.3%)
Colorectal	975 (12.6%)	33 (3.4%)	9 (0.9%)
Prostate	582 (7.5%)	277 (47.6%)	7 (1.2%)
Ovary	389 (5.0%)	21 (5.4%)	4 (1.0%)
Sarcoma	326 (4.2%)	112 (34.4%)	16 (4.9%)
NSCLC	293 (3.8%)	29 (9.9%)	18 (6.1%)
Brain	274 (3.5%)	41 (15.0%)	22 (8.0%)
Bladder	197 (2.5%)	14 (7.1%)	6 (3.0%)
Thyroid	132 (1.7%)	17 (12.9%)	15 (11.4%)
Biliary	93 (1.2%)	16 (17.2%)	11 (11.8%)
All Cancers	7735 (100.0%)	931 (12.0%)	224 (2.9%)

184P Patient-specific HLA-I genotypes predict response to immune checkpoint blockade

K.S. Shohdy[1], J. Atherton[2], J. Longland[2], J.L.E. Allison[2], M. Pillai[2], F. Thistlethwaite[1]

[1]Division of Cancer Sciences, The Christie NHS Foundation Trust and The University of Manchester, Manchester, UK; [2]Experimental Cancer Medicine Team, The Christie NHS Foundation Trust, Manchester, UK

Background: Specific shared HLA Class 1 alleles have been linked to the response to immune checkpoint blockade (ICB). In this study, we aimed to identify the HLA-A subtypes associated with maximum benefit from ICB.

Methods: We compiled a prospectively maintained clinical dataset of patients who underwent CLIA-approved germline HLA status testing as part of various advanced immune and cell therapy trials undertaken at the Christie NHS Foundation Trust. The probability of overall survival (OS) or progression-free survival (PFS) was estimated by the Kaplan-Meier method, and their associations with the HLA-A alleles were tested with Cox regression analysis.

Results: A total of 285 patients from 11 immune and cell therapy clinical trials were eligible for final analysis. The median age at diagnosis was 57 years (range: 19 − 82). The tumor categories were NSCLC (n=93), melanoma (n=60), and other cancers (n=123). We identified 15 HLA-A subtypes, the most common alleles being HLA-A02 (42.2%), HLA-A01 (35.4%), and HLA-A03 (26.0%). A total of 145 patients received ICB either as first-line (56.5%) or as second or later-line (43.5%). Of these, 136 patients had evaluable clinical response status. 24.2% were positive for HLA-A02:01 and were eligible for screening for our HLA-specific trials. Patients with the HLA-A01 and HLA-A30 subtypes were significantly associated with a higher likelihood of clinical response to ICB (odds ratio = 2.58, 95%CI: 1.20 − 5.62, p = 0.017 and 1.80, 95% CI: 1.58-2.18, p= 0.011, respectively). In the NSCLC subgroup, patients with HLA-A01 subtypes were significantly associated with better OS (hazard ratio (HR): 0.42, 95%CI: 0.22-0.81, p= 0.010); meanwhile, HLA-A02 was associated with worse OS (HR: 1.95, 95%CI: 1.09-3.49, p= 0.024). In the other cancers subgroup, HLA-A11 and A24 were associated with better OS (HR: 0.20, 95%CI: 0.05-0.85, p= 0.030 and HR: 0.31, 95% CI: 0.10-0.89, p= 0.029, respectively).

Conclusions: HLA-A status predicted clinical outcomes of patients receiving ICB. HLA genotyping could be incorporated early into the diagnostic work-up of patients with solid cancers as a predictive and selective biomarker.

185P Real-world data analysis of genomic profiling-matched targeted therapy outcomes in patients with fusion-positive NSCLC

J. Patel[1], R. Ben-Shachar[2], K. Nadhamuni[3], M. Carty[3], R. Pelossof[4], I. Klein[5], H. Nimeiri[6], C. Aggarwal[7], R.D. Gentzler[8]

[1]Hematology and Oncology, Northwestern University Feinberg School of Medicine, Chicago, IL, USA; [2]Clinical Development, Tempus Labs, Inc., Chicago, IL, USA; [3]Data Science, Tempus Labs, Camarillo, CA, USA; [4]Tempus Labs, Inc., Chicago, IL, USA; [5]Medical Affairs, Tempus Labs, Inc., Chicago, IL, USA; [6]Oncology Department, Robert. H. Lurie Cancer Center of Northwestern University, Chicago, IL, USA; [7]Medicine - Hematology/Oncology Department, University Of Pennsylvania, Philadelphia, PA, USA; [8]Hematology/Oncology, University Hospital of Virginia (UVA), Charlottesville, VA, USA

Background: While clinical oncology societies such as ESMO have recommended the use of Comprehensive Genomic Profiling (CGP) to identify patients eligible for targeted treatment, full utilization of the potential benefits of CGP has not yet occurred in routine clinical practice. Here we assess the compliance to ESMO targeted therapy recommendations and associated outcomes for CGP-based ALK, RET, ROS1, and NTRK fusions detected in a large real-world, observational dataset of advanced NSCLC patients.

Methods: We retrospectively analyzed de-identified stage IV or metastatic NSCLC records from the Tempus database which encompasses molecular and clinical data from hundreds of clinics across the United States sequenced with the Tempus xT assay (DNA and whole-exome capture RNA NGS) from 2018-2022. Therapeutic adoption was analyzed in cases with ≥30 days of medication data post-sequencing. Real-world overall survival (rwOS) was defined as the interval from start of medication prescribed after sequencing to date of death, censored on the last known physician encounter. A cox proportional hazards model was fit to evaluate the relationship between matched targeted therapy compliance and rwOS in fusion-positive patients.

Results: Among 1,950 patients that met study inclusion criteria, N= 65 (3.3%) had a fusion detected by CGP (N=38 ALK fusions, N=15 RET fusions, N=11 ROS1 fusions and N= 1 NTRK fusion). The overall compliance rate of targeted therapy was 82% (N=53). The median time from sequencing to start of targeted therapy was < 1 month. Fusion-positive patients receiving matched therapy had significantly longer rwOS than those that did not receive matched therapy (HR=0.13, p<0.001). ALK-positive patients receiving matched therapy had significantly longer rwOS than those that did not receive matched therapy, (HR=0.12, p<0.05).

Conclusions: This study demonstrates that in a real-world, retrospective cohort, most oncologists utilized CGP to timely treat patients with ESMO-recommended targeted therapy for fusion-positive advanced NSCLC. More importantly, CGP-matched guideline-recommended treatment is associated with improved rwOS. Future studies are needed to understand the gap in compliance with matched targeted therapy.

Orsola-Malpighi, Bologna, Italy; [5]Cancer Medicine Department, Gustave Roussy and Paris-Saclay University, Villejuif, France; [6]Department of Oncology and Hematology, IRCCS Policlinico San Martino Hospital, Genoa, Italy; [7]Medical Oncology Department, Institute Jules Bordet − Hôpital Universitaire de Bruxelles, Brussels, Belgium; [8]Cancer Medicine Department, Gustave Roussy, Villejuif, France; [9]Pulmonary Diseases Department, Maastricht University Medical Center (MUMC), Maastricht, Netherlands

Background: Among patients (pts) with *ALK*+ advanced non-small cell lung cancer (NSCLC) naïve to ALK-inhibitors, A significantly prolonged progression-free survival (PFS) over C. We present results of a post-hoc patient-level pooled analysis at interim data cut-off of the randomized phase III trials ALEX (NCT02075840) and J-ALEX (JapicCTI-132316), exploring new prognostic factors.

Methods: In both studies, the primary endpoint was PFS by RECIST v1.1. Treatment crossover was only allowed in the J-ALEX trial. Multivariate analysis was performed by Cox's model, the independence of the two trial data sets was managed by random effects models. Survival outcomes were correlated with baseline characteristics including high tumor burden (hTB, i.e. > median sum of diameter of target lesions) and body mass index (BMI).

Results: The pooled set included 500 pts (A=249, C=251) with data available for survival and safety analysis. There was no imbalance between A and C groups in age (median 58 *vs* 56), sex (female 58% *vs* 59%), brain metastases (29% *vs* 34%), BMI (<25 70% *vs* 67%). At a median follow-up of 17.1 months, A provided prolonged PFS over C (median not reached vs. 10.2 months, HR 0.41, 95% CI 0.31-0.55, p<0.001), with median OS not reached in any arm (HR 0.80, 95% 0.50-1.28, p=0.353). In the multivariate analysis with correction for ethnicity, hTB (>55mm) was linked to worse PFS regardless of the treatment received (HR 1.66, 95% CI 1.26-2.20, p<0.001), and BMI ≥25 was correlated with better OS compared to BMI <25 (HR 0.50, 95% 0.29-0.88, p=0.025). Treatment effectiveness in subgroups is shown in table. Significant interaction between treatment and TB (p=0.002) was found in subgroup PFS analysis.

Grade ≥3 adverse events occurred in 36% of pts with A *vs* 51% with C, 15% of pts discontinued A *vs* 20% C.

Table: 186P Subgroup analysis

	HR for PFS A vs C (95% CI)	p value for PFS	HR for OS A vs C (95% CI)	p value for OS
Ref. A vs C whole cohort	0.41 (0.31-0-55)	<0.001	0.80 (0.50-1.28)	0.353
Sum diam ≤55mm	0.25 (0.16-0.41)	<0.001	0.79 (0.35-1.80)	0.572
Sum diam >55mm	0.52 (0.36-0.76)	0.001	0.87 (0.49-1.55)	0.645
BMI <25	0.44 (0.32-0.62)	<0.001	0.99 (0.58-1.71)	0.976
BMI ≥25	0.35 (0.19-0.63)	0.001	0.39 (0.12-1.21)	0.103

Conclusions: hTB is a prognostic and predictive factor in patients with advanced *ALK*+ NSCLC under ALK-inhibitors, while a BMI ≥25 is linked to a reduced risk of death. Escalation strategies could be explored for hTB.

Clinical trial identification: This is a pooled analysis of ALEX (NCT02075840) and J-ALEX (JapicCTI-132316) trials. This abstract is based on research using data from data contributor F. Hoffmann—La Roche that has been made available through Vivli, Inc. Vivli has not contributed to or approved, and is not in any way responsible for, the contents of this publication.

Background: CRAFT (Continuous ReAssessment with Flexible ExTension in Rare Malignancies) is an open-label, 7-arm, cross-entity phase 2 trial investigating the efficacy of combinations of molecularly targeted agents and PD-L1 inhibition with atezolizumab in cancers with targetable molecular alterations (PMID: 34808524). We report the interim efficacy analysis of ipatasertib and atezolizumab in cancers with increased PI3K-AKT pathway activity.

Methods: Adult patients with locally advanced/metastatic cancer refractory to ≥1 medical treatment and selected molecular tumor characteristics (arm 1: BRAF V600E/K mutations; arm 2: ERBB2 amplification/overexpression, activating ERBB2 mutations; arm 3: ALK rearrangements/ALK mutations; arm 4: aberrations predicting increased PI3K-AKT pathway activity; arm 5: activating PIK3CA mutations; arm 6: aberrations predicting increased RAF-MEK-ERK pathway activity; arm 7: alterations predicting anti-PD-L1/anti PD-1 sensitivity) were eligible. Main exclusion criteria were hematologic/primary brain cancers. In arm 4, ipatasertib 400 mg q.d. was given in a 21-days-on/7-days-off schedule, and atezolizumab was administered every 3 weeks. Statistics are based for each arm on a Simon's optimal 2-stage design with 14 patients accrued in stage 1 and 11 additional patients if ≥4 patients achieve the primary endpoint, i.e., disease control (complete/partial remission [PR] or stable disease [SD]) at day 110.

Results: Until 04/2023, 51 patients were registered, and 28 were treated. Thirteen patients with various cancers and PI3K-AKT-activating alterations (PTEN deletion/loss-of-function mutation: n=8; activating PIK3CA mutation: n=2; activating AKT1 mutation: n=3) were enrolled in arm 4. One patient with breast cancer and a homozygous AKT1 E17K and one patient with prostate cancer and PTEN loss achieved a PR and SD, respectively. None of the remaining 11 patients reached the endpoint. Toxicity was mainly gastrointestinal and manageable.

Conclusions: Ipatasertib and atezolizumab were ineffective in this patient population with PI3K-AKT-altered tumors. More stringent molecular selection criteria and an addition trial arm were implemented (arm 5).

Clinical trial identification: NCT04551521, EudraCT 019-003192-18.

188P The landscape of SMARCA2 genomic alterations in Chinese cancer patients

C. Jiaqi[1], Y. Dong[2], T. Han[2], D. Guo[2], R. Kong[2], M. Wang[2], S. Chen[3], R. Ding[2], W. Deng[3], F. Bu[4]

[1]Department of Medical Oncology, The Second Affiliated Hospital of Zhejiang University College of Medicine, Hangzhou, China; [2]The Medical Department, Jiangsu Simcere Diagnostics Co., Ltd., Nanjing, China; [3]Bioinformatics Department, Jiangsu Simcere Diagnostics Co., Ltd., Nanjing, China; [4]Operations Department, Jiangsu Simcere Diagnostics Co., Ltd, Nanjing, China

Background: Alterations of the *SMARCA2* gene primarily promote cell proliferation and tumorigenesis by impacting the function of the SWI/SNF complex and activating multiple oncogenic signaling pathways. Previous studies have shown that selective inhibition of *SMARCA2* can induce death of tumor cells with *SMARCA4* mutations, providing a theoretical basis for *SMARCA2* as a therapeutic target for tumors. In addition, differences in mutation profiles in pan-cancer can help understand pathogenesis, identify targets for therapy and promote precision medicine.

Methods: We retrospectively analyzed genomic DNA alterations in tissue samples from 21206 patients by next-generation sequencing (NGS). The *SMARCA2* alterations were divided into functional or unfunctional mutations according to the OncoKB database.

Results: In total, 2.79% (592/21206) of pan-cancer patients carried *SMARCA2* mutations. A total of 710 *SMARCA2* alterations were identified in 592 patients, including missense mutations (60.56%), nonsense (4.51%), frameshifts (1.83%), splicing (21.83%), copy number variations (7.04%), non frameshift mutations (4.23%). Compared the genomic landscape among the *SMARCA2*-functional (S-F), *SMARCA2*-unfunctional (S-UNF) and *SMARCA2*-wide type (S-WT) patients. The results showed the S-F group have higher TMB (55.82 vs. 27.78 vs. 6.33, $p<0.05$) and higher proportion of MSI-H patients (31.15% vs. 22.48% vs. 1.72%, $p<0.05$). Additionally, 13.34% (n=79) of patients carried 2 (n=57) or more than 2 (n=22) *SMARCA2* mutations. Compared with carriers of single mutation, they presented significantly higher TMB (141.40 vs 27.18) and higher proportions of MSI-H (73.42% vs. 34.62%). It is worth noting that in the *SMARCA2* mutation cohort, 24.16% of patients also carried *SMARCA4* mutation, and patients with co-mutation have significantly higher TMB (105.52 vs. 21.78) and a higher proportion of MSI-H (59.44% vs. 22.80%). Based on our results, immunotherapy may be an alternative strategy, which needs more clinical explorations.

Conclusions: *SMARCA2* mutations are diverse, and patients with multiple *SMARCA2* mutations or both *SMARCA2*-*SMARCA4* mutations tumors had higher TMB and a higher proportion of MSI-H may more sensitive to immunotherapy, which may enable new therapeutic options in the future.

189P Design and enrollment for a classifier development study for a blood-based multi-cancer early detection (MCED) test

C. Douville[1], L. Hogstrom[2], V. Gainullin[2], H.J. Hwang[3], S. Chowbina[2], Y. Zhang[2], M. Gray[3], C. Nobles[2], M. Kumar[2], M. Manesse[3], F. Zhuang[3], V. Fa[3], X. Chen[2], J. Garces[4], A. Mcelhinny[3], G. Cerqueira[2], G.A. Silvestri[5], S. Rego[6], T.M. Beer[7], F. Diehl[3]

[1]Oncology, Johns Hopkins Medicine - The Sidney Kimmel Comprehensive Cancer Center, Baltimore, MD, USA; [2]Bioinformatics, Exact Sciences Corporation, Madison, WI, USA; [3]Research & Development, Exact Sciences Corporation, Madison, WI, USA; [4]Science Office, Exact Sciences Corporation, Madison, WI, USA; [5]Medicine, Medical University of South Carolina, Charleston, SC, USA; [6]Clinical Affairs, Exact Sciences Corporation, Madison, WI, USA; [7]Medical Affairs, Exact Sciences Corporation, Madison, WI, USA

Background: The aim of the Ascertaining Serial Cancer patients to Enable New Diagnostic 2 (ASCEND 2) case-control study is to develop a classifier algorithm for a refined version of a multi-analyte blood-based MCED test. Here, we report the study design, enrollment, and sample selection from this large, multi-center, prospective, case-control study of clinically characterized participants.

Methods: The ASCEND 2 study engaged 151 sites within the US and Europe for subject enrollment. Samples consisted of blood collected using LBgard® tubes for plasma and buffy samples. The study population includes male and female subjects ≥50 years old with known cancer, suspicion of cancer, and controls without cancer. All subjects provided informed consent and were assessed for study participation eligibility.

Results: Over 11,000 subjects were enrolled in this study. A subset of 6361 samples was selected to develop and refine a multi-analyte cancer detection classifier. The subset includes 1440 cancer subjects, from more than 18 organ sites reflective of US cancer incidence by tumor type, and 4921 age-matched subjects without suspicion of cancer. Demographics are reported in in the table. Cancer cases include stage I (388), stage II (301), stage III (374), stage IV (317), stage unknown (60). The samples will be partitioned into training and independent test sets. The performance of one or more locked cancer detection models developed in the training phase will be tested.

Table: 189P Demographics

	Overall (6361)
Mean Age (SD)	65.5 (8.3)
Sex, n (%)	
Female	3579 (56.3%)
Male	2782 (43.7%)
Race, n (%)	
White	5198 (81.7%)
Black/African American	817 (12.8%)
American Indian/Alaska Native	29 (0.5%)
Asian	203 (3.2%)
Multiracial	13 (0.2%)
Native Hawaiian/Other Pacific Islander	6 (0.1%)
Unknown	95 (1.5%)
Ethnicity, n (%)	
Hispanic/Latino	828 (13.0%)
Not Hispanic/Latino	5452 (85.7%)
Unknown	81 (1.3%)
Region, n (%)	
Midwest	1184 (18.6%)
Northeast	833 (13.1%)
South	3059 (48.1%)
West	1069 (16.8%)
Outside US	93 (1.5%)
Unknown	123 (1.9%)
Cigarette Smoking Status, n (%)	
Current	801 (12.5%)
Former	1756 (27.6%)
Never	3787 (59.5%)
Unknown	17 (0.3%)

Conclusions: The ASCEND 2 study selected cancer types in an incidence-targeted manner, including rare and common cancers and evenly distributed stages. By enrolling a racially, ethnically, and geographically diverse cohort, the current study enables MCED test development with a representative cohort.

190P Quantitative serum tumor markers (CEA, CA19-9, and CA-125) are independently predictive of survival in patients with appendiceal adenocarcinoma

J.P. Y-C. Shen[1], A. Yousef[1], M.M.G. Yousef[1], M. Zeineddine[1], S. Chowdhury[1], M. Knafl[2], K. Raghav[1], M.G. White[3], K. Alfaro-Munoz[1], B. Helmink[4], K.F. Fournier[4], M.J. Overman[1]

[1]Gastrointestinal Medical Oncology, University of Texas MD Anderson Cancer Center, Houston, TX, USA; [2]Biostatistics, The University of Texas MD Anderson Cancer Center, Houston, TX, USA; [3]Colon & Rectal Surgery, The University of Texas MD Anderson Cancer Center, Houston, TX, USA; [4]Surgical Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX, USA

Background: Although grade is strongly predictive of survival, no other prognostic or predictive biomarkers have been validated to help guide therapeutic decision making in Appendiceal adenocarcinomas (AA). Here we investigated the clinical utility of the serum tumor markers CEA, CA19-9, and CA-125 by association with survival and tumor molecular features.

Methods: The MD Anderson patient database was queried to identify a total of 1,322 patients diagnosed with of AA between 1997 to 2022 with at least one TM measured. Elevation of TM defined as above laboratory ULN (CEA $>$ 3 ng/mL, CA 19-9 $>$ 37 U/mL, and CA-125 $>$ 37 U/mL, highly elevated defined as top 10th percentile (CEA $>$ 100.4 ng/mL, CA 19-9 $>$ 337.5 U/mL, and CA-125 $>$ 41.8 U/mL).

Results: CEA, CA19-9 and CA125 were elevated in 56%, 34%, and 37% of patients, respectively, 63.8% had at least one elevated. The proportion of patients with elevation of each TM did not differ in high- vs low-grade tumors or by histologic subtype (mucinous, colonic, goblet, signet ring). CEA stratified patients by survival with median not-yet-reached for patients with normal CEA vs 182 mo for those with elevated CEA vs 96 mo for those with highly elevated CEA (log-rank p $<$ 0.0001), 5-year OS was 95% vs 82% vs 61% for normal, elevated, and highly elevated, respectively. The prognostic effect of CEA was independent of grade, with 5-year OS (99%, 93%, 69%, log-rank p $<$ 0.0001) for low-grade and (91%, 73%, 55%, log-rank p $<$ 0.0001). Similar survival stratification was seen for CA19-9 (92%, 84%, 66%, log-rank p $<$ 0.0001) and CA-125 (93%, 70%, 60%, log-rank p $<$ 0.0001). CEA was more correlated with CA-19-9 (pearson r $=$ 0.62) than CA-125 (r $=$ 0.29). Elevation of multiple TM was associated with worse prognosis; HR relative to patients with no TM elevated was 4.9 (p $=$ 6.0e-6), 8.9 (p $=$ 6.5e-12), and 16.2 (p $=$ 8.0e-16), for 1, 2, or all 3 TM in multivariate cox model of survival including gender, race, age, grade, and histologic subtype.

Conclusions: Elevation of CEA, CA19-9 and CA125 are independently associated with poor prognosis in patients with appendiceal cancer, all three should be measured. Future efforts to evaluate incorporation of TM into clinical staging are warranted.

191P Novel approach to proficiency testing demonstrates wide gaps in biomarker quality for colon cancer treatment

K.R. Bisson[1], A. Beharry[1], M.D. Carter[2], S. Dudani[3], J.G. Garratt[4], J.M. Loree[5], S. Snow[6], S. Yip[7], J.R. Won[4], B.S. Sheffield[1]

[1]Department of Laboratory Medicine, William Osler Health System - Brampton Civic Hospital, Brampton, ON, Canada; [2]Department of Pathology and Laboratory Medicine, Queen Elizabeth II Health Sciences Centre, Halifax, NS, Canada; [3]Division of Medical Oncology, William Osler Health System - Brampton Civic Hospital, Brampton, ON, Canada; [4]Department of Molecular Pathology, Canadian Pathology Quality Assurance - Assurance Qualité Canadienne en Pathologie (CPQA-AQCP), Richmond, BC, Canada; [5]Division of Medical Oncology, BC Cancer, Vancouver Centre, Vancouver, BC, Canada; [6]Division of Medical Oncology, Queen Elizabeth II Health Sciences Centre, Halifax, NS, Canada; [7]Department of Pathology, Vancouver General Hospital, Vancouver, BC, Canada

Background: Biomarkers are fundamental to oncology, closely tying this practice to that of laboratory medicine. Results are required to be accurate, timely, comprehensive, and comprehendible. External proficiency testing is a key tool in maintaining quality. Traditional schemes test analytic accuracy. Here, we demonstrate the feasibility and utility of a novel end-to-end proficiency testing exercise examining the *entire* process of biomarker testing.

Methods: Challenge specimens were made using resected colon cancer tissue, each paired with a clinical vignette and distributed to participating labs. Participants were asked to provide all molecular testing required, which could include pre-analytic preparation, immunohistochemistry, gene sequencing, or other methodologies, and to draft and return a final report for each case upon completion. Reports were redistributed to an assessor team including oncologists, who chose therapy based on each lab's biomarker report. Finally, participants were graded based on their ability to guide oncologists to the most appropriate treatment. Gold standard treatments for each case were decided by assessors prior to the exercise, based on reference results and clinical vignettes.

Results: Eight laboratories participated. Three laboratories were found to have suboptimal results, two leading oncologists to incorrect therapeutic prescriptions (Table) and one withdrawn. Turnaround time ranged from 6-86 days (median 24).

Table: 191P Resulting number of medical oncologist assessors prescribing the optimal treatment choice based on reported results

	Lab ID							
Sample ID	**2**	**3**	**4**	**5**	**6**	**7**	**8**	**Gold Standard Treatment**
1	3	3	***0***	3	3	3	3	Immune Checkpoint Inhibitor
2	3	***0***	3	3	3	3	3	Anti-*EGFR* mAb
3	3	*2*	*2*	3	*2*	*2*	3	*BRAF* Inhibitor + Anti-*EGFR* mAb
Turnaround Time (Days)	24	***63***	***86***	20	29	21	6	14 Days

Conclusions: This is the first report of *end-to-end* proficiency testing, providing valuable insights into biomarker quality beyond analytic accuracy, including specimen management, communication, and turnaround time. Here, significant quality gaps were identified, generating opportunities for improvement. This paradigm shift in quality assurance to focus on the complete specimen journey is a promising tool in assessing and improving modern cancer care.

192P Impact of oncogenic fibroblast growth factor receptor (FGFR) alterations in patients with advanced solid tumors in a real-world setting

H. Sweiti[1], L. Demirdjian[2], S. Triantos[1], K. Standish[2], S. Thomas[3], J. Greshock[2], Q. Xia[4], J. Paone[5], P. Sheridan[5], S. Pant[6], C. Massard[7], D.A. Reardon[8], Y. Loriot[9], M.H.H. Schuler[10]

[1]Oncology, Janssen R&D, Springhouse, PA, USA; [2]Data Sciences, Janssen Pharmaceutical Companies of Johnson & Johnson, Titusville, NJ, USA; [3]Translational Research Department, Johnson & Johnson Pharmaceutical - Research and Development, Spring House, PA, USA; [4]Statistics, Janssen R&D, Springhouse, PA, USA; [5]Delivery, Aetion, Inc, New York, NY, USA; [6]Gastrointestinal Medical Oncology, MD Anderson Cancer Center, Houston, TX, USA; [7]DITEP, Gustave Roussy - Cancer Campus, Villejuif, France; [8]Medical Oncology, Dana Farber Cancer Institute, Boston, MA, USA; [9]Cancer Medicine Department, Institut Gustave Roussy, Villejuif, France; [10]Department of Medical Oncology, WTZ - Westdeutsches Tumorzentrum Essen, Essen, Germany

Background: Selective FGFR inhibitors are approved for treatment (tx) of FGFR+ advanced urothelial cancer (UC) and cholangiocarcinoma (CCA). The prognostic FGFR+ impact in solid tumors shows mixed results for select solid tumor types (TT). This study assessed the real-world (RW) prognostic impact of FGFR+ on overall survival (OS) of patients (pts) in a tumor agnostic (TA) setting.

Methods: This retrospective study used the Flatiron/Foundation Medicine, Inc Clinico-genomic database (FMI), including data from ∼280 US cancer centers. Pts (age ≥18 y) had advanced/metastatic (adv/met) disease (except UC), evidence of FGFR testing, and started first-line (1L) systemic tx in the adv/met setting. All pts had FMI's tissue-based genomic profiling. Pts with prior selective FGFR inhibitor tx were excluded. FGFR+ was defined as ≥1 of 81 prespecified FGFR oncogenic mutations or any FGFR fusion involving an intact kinase domain. Pts with wildtype FGFR (FGFR-) were matched 3:1 with pts with FGFR+ on TT, age, sex, date of adv/met disease diagnosis, and FMI test version. The statistically powered primary objective assessed differences in TA RW OS from 1L tx initiation in pts with FGFR+ vs FGFR- adv/met disease treated with standard of care systemic tx. Secondary objectives assessed differences in tumor specific RW OS and in time to tx discontinuation or to next tx. Delayed entry models and covariate-adjusted stratified Cox models were used to mitigate bias.

Results: Data from 253 FGFR+ and 759 FGFR- pts were analyzed. Demographics, baseline disease and clinical characteristics were balanced between groups. There were no significant differences in TA RW OS from 1L between groups (HR, 0.97 [FGFR+ vs FGFR-]; p=0.78). Median RW OS from initiation of 1L tx was 1.13 y (95% CI, 0.92-1.52) and 1.01 y (95% CI, 0.89-1.15) for FGFR+ and FGFR- pts, respectively. There were no significant differences in RW OS between groups in tumor-specific comparisons, including CCA, breast cancer, and NSCLC.

Conclusions: There was no statistically significant difference in RW OS between pts with FGFR+ or FGFRadv/ met solid tumors, with a median OS of ∼1 year in both groups. These results highlight the poor prognosis and high unmet need for novel, targeted tx.

194P Early kinetics of C-reactive protein for cancer-agnostic prediction of therapy response and mortality in patients treated with immune checkpoint inhibitors: A multi-center cohort study

D. Barth[1], F. Moik[1], S.M. Steinlechner[1], F. Posch[2], V. Schlintl[1], L. Koch[3], N. John[4], R. Wurm[4], M. Pichler[1], T. Bauernhofer[1], P. Reimann[5], C. Wohlkönig[4], E. Richtig[3], T. Winder[5], M. Preusser[6], P.J. Jost[1], C. Ay[7], A. Gerger[1], A. Terbuch[1], J.M. Riedl[1]

[1]Division of Oncology, Department of Internal Medicine, Medical University of Graz, Graz, Austria; [2]Division of Hematology, Department of Internal Medicine, Medical University of Graz, Graz, Austria; [3]Department of Dermatology, Medical University of Graz, Graz, Austria; [4]Division of Pulmonology, Department of Internal Medicine, Medical University of Graz, Graz, Austria; [5]Oncology Department, Landeskrankenhaus Feldkirch, Feldkirch, Austria; [6]Division of Oncology, Department of Medicine I, Medical University of Vienna, Vienna, Austria; [7]Department of Medicine I, Clinical Division of Haematology and Haemostaseology, MedUni Wien - Medical University of Vienna, Vienna, Austria

Background: C-reactive protein (CRP) kinetics have recently been suggested as predictive biomarkers for the efficacy of immune checkpoint inhibitor (ICI) therapy in selected cancer types. The aim of this study was to characterize early CRP kinetics as a tumor-agnostic biomarker for ICI treatment outcomes.

Methods: In this multicenter retrospective cohort study, two independent cohorts of patients with various cancer types undergoing palliative ICI treatment at Austrian academic centers served as the discovery (n=562) and validation cohort (n=474). Four different patterns of CRP-kinetics in the first 3 months of ICI therapy were defined (CRP-flare responders, CRP-responders, CRP non-responders, patients with all-normal CRP). Objective response rate (ORR), progression-free- (PFS) and overall survival (OS) were defined as co-primary endpoints. Uni-and multivariable logistic regression, Landmark analysis and Cox-regression including CRP kinetics as time-dependent variable were performed.

Results: The ORR in patients with all-normal CRP, CRP responders, CRP flare-responders and CRP non-responders was 41%, 38%, 31% and 12%, respectively. The median OS and PFS estimates were 24.5 months (95%CI 18.5 – not reached) and 8.2 months (95%CI 5.9-12.0) in patients with all-normal CRP, 16.1 months (95%CI 12.6-19-8) and 6.1 months (95%CI 4.9-7.2) in CRP-responders, 14.0 months (95%CI 8.5-19.4) and 5.7 months (95%CI 4.1-8.5) in CRP flare-responders and 8.1 months (95%CI 5.8-9.9) and 2.3 months (95%CI 2.2-2.8) in CRP non-responders (log-rank p for PFS and OS <0.001). These findings prevailed in multivariable analysis and could be fully confirmed in our validation cohort. Pooled subgroup analysis suggested a consistent predictive significance of early CRP kinetics for treatment efficacy and outcome independent of cancer type.

Conclusions: Early CRP kinetics represent a tumor-agnostic predictor for treatment response, progression risk and mortality in patients with cancer undergoing ICI therapy.

195P Identification of biomarkers associated with checkpoint inhibitor pneumonitis based on serum proteomic approach and construction of an online interactive visual prediction model

X. Jia, H. Guo, Y. Zhang, Y. Li, X. Fu, X. Yu

Department of Medical Oncology, The First Affiliated Hospital of Xi'an Jiaotong University, Xi' An, China

Background: Checkpoint inhibitor pneumonitis(CIP) is one of the most common fatal adverse events in the new era of immune checkpoint inhibitor(ICI). Screening the high risk group of CIP is a major clinical challenge to improve the safety of ICI therapy. However, there are lack of effective biomarkers to predict CIP. The practical difficulties of early screening highlight the need to explore new biomarkers. The aim of this study is to determine predictive biomarkers of CIP through proteomics methods, and then build a prediction model, so as to improve the safety of ICI therapy.

Methods: This study prospectively recruited 98 tumor patients. Fasting peripheral blood was collected from patients before ICI therapy for the first time. Patients were dynamically followed up and assessed for CIP. Serum protein spectrum was analyzed and identified by MALDI-TOF mass spectrometry(MALDI-TOF-MS) and LC-MS. Confirmatory studies were conducted by ELISA to quantitatively evaluate the expression of serum protein. R language is used to construct online interactive prediction model. This study was approved by the Ethics Committee of the First Affiliated Hospital of Xi'an Jiaotong University (XJTU1AF2021LSK-001).

Results: 31 patients with CIP constituted the case group. A total of 88 peptide peaks were detected by MALDI-TOF-MS. 15 protein polypeptides with the most significant differences were selected for further identification. After quantitative verification by ELISA analysis, it was found that plasma serine protease inhibitor (SERPINA5), A-kinase anchor protein 6 (AKAP6), tubulin alpha-4A chain (TUBA4A) were significantly highly expressed in CIP patients. Based on this, online interactive visual prediction model was constructed (https://mass-cip.shinyapps.io/DynNomapp/). Harrell's C-indices of the training set and validation set were 0.974 and 0.968, respectively. The calibration curve and clinical decision curve showed satisfactory predicted value.

Conclusions: SERPINA5, AKAP6 and TUBA4A are considered useful biomarkers for predicting CIP. The predictive model has the potential to be a convenient, intuitive, and personalized clinical tool for assessing the risk of CIP.

196P Serum metabolomics to determine survival of immunotherapy for advanced non-small cell lung cancer: Metabolomic analysis based on two cohorts

Y. Xu, K. Ding, Z. Peng, Y. Fan

Medical Thoracic Oncology, Zhejiang Cancer Hospital, Institute of Basic Medicine and Cancer (IBMC), Chinese Academy of Sciences, Hangzhou, China

Background: Noninvasively collected samples are attracting significant interest as new areas of biomarker study in immune checkpoint inhibitors (ICIs) field, and metabolomics is one of these growing ones. We focused on the added value of the metabolomic profile as a means of distinguishing long-term survival from short-term survival in NSCLC patients treated with ICIs.

Methods: We prospectively recruited 97 patients with stage IV NSCLC who were treated with anti-PD-1 inhibitor, including patients treated with monoimmunotherapy as second-line treatment (Cohort 1), and patients treated with combination immunotherapy as first-line treatment (Cohort 2). Each cohort was divided into two groups, long-term survival and short-term survival. All blood samples were collected before beginning immunotherapy. Metabolomic profiling of serum was performed by UHPLC-Q-TOF MS analysis. Multivariate data analysis, including Pareto-scaled principal component analysis (PCA) and orthogonal partial least-squares discriminant analysis (OPLS-DA), was performed.

Results: A total of 41 differential metabolites in Cohort 1 and 47 in Cohort 2 were screened. Among them, 8 common metabolites in ESI^- mode and 11 in ESI^+ mode were significantly associated with both PFS and OS in cohort 1. In cohort 2, 3 metabolites in ESI^- mode and 6 in ESI^+ mode were significantly associated with both PFS and OS. In cohort 1, the top 3 enriched KEGG pathways, as determined through significant differential metabolic pathway analysis, were primary bile acid biosynthesis, african trypanosomiasis, and choline metabolism in cancer. In Cohort 2, the top 3 enriched KEGG pathways were the citrate cycle (TCA cycle), PPAR signaling pathway, and primary bile acid biosynthesis. The primary bile acid synthesis pathway had significant differences in the long-term survival and short-term survival groups in both Cohort 1 and Cohort 2.

Conclusions: Our study suggests that peripheral blood metabolomic analysis is critical for identifying metabolic biomarkers and metabolic pathways responsible for the NSCLC patients treated with ICIs, and the primary bile acid synthesis pathway may be the important one.

197P Clinical benefit of HER2-targeted therapies versus prior chemotherapy in refractory HER2 expressing and mutant gastrointestinal malignancies

V. Khanna[1], A.S. Henry[2], T.P. Johnson[1], G. Heestand[1], S. Shaheen[1], C. Chong[1], G.A. Fisher, Jr.[1], C. Chen[1]

[1]Stanford Cancer Institute, Stanford Cancer Center Palo Alto, Palo Alto, CA, USA; [2]Department of Biomedical Data Science, Stanford University School of Medicine, Stanford, CA, USA

Background: HER2-directed drugs are established therapies for patients with advanced HER2+ gastroesophageal (GEJ) cancers. However, while various anti-HER2 agents including antibodies, antibody-drug conjugates, and tyrosine kinase inhibitors are active in non-GEJ HER2+ GI tumors, the optimal integration/sequencing of these agents with conventional chemotherapy is unclear.

Methods: We assessed the outcomes of patients with metastatic HER2-expressing or mutated non-GEJ GI cancers who received anti-HER2 drugs at our institution from 2010 −2021. We measured the growth modulation index (GMI) − the ratio of progression-free survival (PFS) of the anti-HER2 drug to the time-to-progression on the immediately prior therapy − for each line of HER2 therapy. GMI $\geq$1.3 is considered meaningful clinical benefit, and we classified patients with GMI $\geq$2.6 as exceptional benefiters.

Results: Forty-one patients with adenocarcinomas (19 colorectal, 13 biliary tract, 3 intestinal, 3 pancreatic, 2 ampullary, and 1 appendiceal) were identified; 59% received $\geq$2 lines of therapy before their first anti-HER2 agent. Twenty-two patients who received $\geq$1 line of HER2-directed therapy were GMI evaluable. Fifty percent benefited from therapy and 36% derived exceptional benefit. The median PFS to the first anti-HER2 therapy was 5.5 (0.4 − 53.0) months. All HER2 benefiters were either *HER2*-amplified, 3+ by IHC, or 2+/ISH+; none (0/3) with *HER2* mutations derived benefit. Three patients had exceptional benefit to second-line HER2 drugs after deriving no benefit on their first HER2 therapy, with a median GMI of 4.9 (4.7 − 6.5) and a median PFS of 11.0 (4.3 − 13.7) months. One patient remains alive over 60 months since diagnosis and has received 5 lines of anti-HER2 therapy (median PFS of 8.8 months per agent).

Conclusions: Anti-HER2 drugs in later lines can provide durable benefit relative to earlier-line chemotherapy in a large proportion of patients with HER2+ non-GEJ GI malignancies. Patients not benefiting from initial anti-HER2 drugs may still achieve sustained benefit from subsequent HER2-directed regimens. Early and continued incorporation of anti-HER2 agents throughout a patient's treatment course may optimize clinical outcomes.

198P Detection of ERBB2 (HER2) amplification by next-generation sequencing (NGS) in patients (pts) with gastrointestinal (GI) cancer

Y. Qi[1], L. Huang[2], Y. Jin[3], F. Ruan[2], H. He[2]

[1]Radiotherapy Center, Sichuan Cancer Hospital and Institute/The Affiliated Cancer Hospital School of Medicine, UESTC, Chengdu, China; [2]Department of Medicine, Zhejiang Shaoxing Topgen Biomedical Technology Co., Ltd., Shanghai, China; [3]Department of Bioinformatics, Zhejiang Shaoxing Topgen Biomedical Technology Co., Ltd., Shanghai, China

Background: Recent advances have transformed care for HER2-positive gastrointestinal cancer. However, the clinical utility of NGS-based techniques for determining HER2 status in GI cancer has been limited. Here, we detail our experience regarding the assessment of HER2 alterations in GI cancer.

Methods: 626 colorectal cancer (CRC) samples, 80 esophageal cancer (ESCA) samples, 153 esophagogastric junction cancer (EGJC) samples, and 286 gastric cancer (GC) samples were collected from August 2021 to April 2023. Among them, there were 82 CRC plasma samples, 33 GC plasma samples, 7 ESCA plasma samples, and 22 EGJC plasma samples. All specimens were detected by OncoDrug-Seq 603-gene panel assay through NGS using Illumina NovaSeq 6000. For plasmas, HER2 amplification defined as HER2 copy number >2.22 was identified. For tissues, HER2 amplification defined as HER2 copy number >6.00 was identified.

Results: For tissue samples, ERBB2 amplification was detected in 0.74% of CRCs, 3.56% of GCs, 1.37% of ESCAs, and 3.05% of EGJCs. Only 2 GC cases (6.06%) were found to have ERBB2 amplification for plasma samples. No ERBB2-amplified CRCs showed mismatch-repair deficiency. ERBB2 amplification is anti-correlated with RAS/RAF mutations in CRCs (p=0.047). Interestingly, ERBB2 amplification was associated with microsatellite stability in GCs (p=0.00078). Other driver alterations were not present in the ERBB2-amplified cases that currently have targeted therapies approved by the FDA including NTRK fusion, RET fusion, and BRAF V600E mutation.

Conclusions: The proportions of ERBB2 amplification in GCs and EGJCs were relatively high. The high positive rate in GC plasma samples is worthy of attention. The mutational landscape of ERBB2-amplified cases provides novel insights that can help guide further patient-personalized therapy.

199P Novel machine learning (ML) algorithm to predict immunotherapy response in small cell (SCLC) and non-small cell (NSCLC) lung cancer

L. Sharma[1], S. Choi[1], V. Balaji[2], A. Joshi[3], I. Mporas[4], J. Shi[5], Y. Zhao[3], V. Tailor[6], G. Powell[2], D. Alrifai[7], R. Shah[8], J.S.C. Waters[9], O.M. Adeleke[2]

[1]GKT School of Medical Education, King's College London, London, UK; [2]Curenetics Ltd, London, UK; [3]School of Medicine, Imperial College London - Hammersmith Campus, London, UK; [4]School of Physics, Engineering & Computer Science, University of Hertfordshire, Hatfield, UK; [5]Department of Oncology, St George's Hospital NHS Trust, London, UK; [6]CurenX, Precision Health, Atlanta, GA, USA; [7]Cancer Department, Guys and St Thomas NHS Trust, London, UK; [8]Medical Oncology, Maidstone Hospital, Maidstone, Kent, UK; [9]Kent Oncology Centre, Maidstone Hospital - Maidstone and Tunbridge NHS Trust, Maidstone, UK

Background: Immune checkpoint inhibitors (ICI) are used to manage patients with SCLC and NSCLC lung cancer. Yet, response rates are often low and identifying patients that will benefit from ICIs can be challenging. Accurate and accessible tools that predict ICI responses could enable a precision medicine approach that improves patient outcomes. This study aimed to use ML to predict response to ICI therapies in patients with lung cancer based on clinically available data.

Methods: 334 eligible records were reprocessed using one hot encoding. 161 patients had complete datasets available. Differences in data distribution were handled using the Synthetic Minority Oversampling Technique. Six ML algorithms were trained, including Linear regression, Support Vector Classifier, XGBoost Classifier, Random Forest, Decision Tree and Gaussian Naïve Bayes Classifier. The algorithms used 80% of the training data, were tested on 20% of validation data and used the Grid Search Cross-Validation technique for hyperparameter optimization.

Results: Of the 161 patients, 9% had SCLC and 80% had NSCLC. Patients receiving Pembrolizumab, Nivolumab and Atezolizumab comprised 62%, 11% and 25% respectively. XGBoost Classifier predicted response with the most accuracy, 64%. The artificial intelligence (AI) algorithm predicted and stratified ICI response better than PD-L1 levels alone (Table). The model showed good performance status, female gender and adenocarcinoma sub-type predicted response to ICI. Conversely, M1, N2 staging, male gender, squamous cell carcinoma sub-type and receiving Atezolizumab were predictive of disease progression.

Table: 199P

		Response (R) %	Stable Disease (SD) %	Disease Progression (DP) %	AI-predicted validation cohort %		
					R	SD	DP
Total *N=161*		29	8	63	33	6	61
PD-L1 levels	**<1%** *N=23*	13	9	78	33.3	0	66.6
	1-50% *N=19*	42	0	58	66.6	0	33.3
	>50% *N=33*	33	11	56	50	14	36

Conclusions: Multiple novel ML models, developed using clinically available data, showed that ICI type, histopathology sub-type and TMN staging impact ICI response in lung cancer. Future studies will seek to include more SCLC cases and compare the prediction accuracy among the three ICIs.

200P Precise tumor & patient selection for CDR404: A bispecific & bivalent MAGE-A4 T cell engager

G. Giacomazzi[1], M. Liivrand[2], R. Hieta[2], N. Dupuis[3], D. Rondas[4], P. Swatkowski[5], M. Vrohlings[6], D. Lenherr-Frey[7], L. Borras[8], S. Biswas[9], R. Leidner[10], E. Calvo[11]

[1]Assay Development, CellCarta, Antwerpe, Belgium; [2]Bioinformatics Core, Genevia Technologies, Tampere, Finland; [3]Scientific Business Development, CellCarta, Antwerpe, Belgium; [4]Clinical Operations, CellCarta, Antwerpe, Belgium; [5]Global Regulatory Affairs, CellCarta, Naperville, IL, USA; [6]Translational Science, CDR-Life Inc., Horgen, Switzerland; [7]Project Management, CDR-Life, Horgen, Switzerland; [8]Research, CDR-Life, Horgen, Switzerland; [9]Clinical, CDR-Life Inc., Horgen, Switzerland; [10]Earle A Chiles Research Institute, Providence Cancer Institute, Southfield, MI, USA; [11]Dept. Early Clinical Drug Development, Hospital Madrid Norte San Chinarro - Centro Integral Oncologico Clara Campal, Madrid, Spain

Background: A phase 1 trial of CDR404, an antibody-based T-cell engager (TCE) targeting MAGE-A4, is planned for 2024. CDR404 binds to a MAGE-A4 peptide presented on cancer cell surface HLA-A2. There are no validated assays to measure HLA peptide presentation. RNA sequencing or immunohistochemistry (IHC) for total MAGE-A4 can be used as surrogates. To identify tumors for trial inclusion and enable precise patient selection, we performed bioinformatic analyses and compared two IHC antibodies.

Methods: 32 solid tumors were selected from the TCGA dataset and ranked based on MAGE-A4 mRNA prevalence and expression (high to low). To assess protein expression, we compared specificity of two commercial MAGE-A4 antibodies for patient selection: an anti-rabbit E7O1U clone and an anti-mouse OTI1F9 clone. Cross reactivity to MAGE-A family members was confirmed using IHC of individually transfected HEK293 cells.

Results: In ranking order, we identified 6 (RNA^{HIGH}) tumors: squamous lung (LUSC), squamous head & neck (HNSC), bladder (BLCA), uterine carcinosarcoma (UCS), testicular germ cell (TGCT) and squamous cervical (CESC), which had both MAGE-A4 mRNA highest prevalence and median expression. Both parameters were positively correlated (R^2=0.64, p=0.00012). Mean RNA levels were different for the RNA^{HIGH} group compared to the remaining 26 tumors (RNA_{LOW} group), which consisted mainly of adenocarcinomas (p=$9.1e^{-120}$). Of interest, human papillomavirus (HPV) negative (-VE) HNSC had higher RNA levels vs. HPV-positive (+VE) tumors (p=0.0046). In vitro over-expression experiments demonstrated that E7O1U only bound to MAGE-A4 whereas OTI1F9 cross-reacted widely with MAGE-A3, -A6, -A8, -A10, -A11 and -A12.

Conclusions: Squamous cell carcinomas were enriched in the MAGE-A4 RNA^{HIGH} group. Trial screening efficiency can be optimized by enrolling RNA^{HIGH} tumors especially LUSC and HPV -VE HNSC, two cancers with high unmet medical need. Lack of response reported in another MAGE-A4 TCE trial (NCT03973333) where tumor screening in ovarian cancer was absent confirms that IHC selection will be essential for RNA_{LOW} tumors. In this regard, we have identified E7O1U as a highly specific MAGE-A4 antibody for precise IHC patient selection in the CDR404 trial.

201P Afatinib for EGFR, HER2 or HER3 mutated solid tumors: A phase II Belgian precision study

L. Decoster[1], P.G. Aftimos[2], S. Rottey[3], H. Prenen[4], J.J. Collignon[5], J. Mebis[6], J-L. Canon[7], V. Fastenaekels[8], N. Cappoen[8], S.R. Joris[8], J. De Grève[9]

[1]Department of Medical Oncology, UZ Brussel - Universitair Ziekenhuis Brussel, Jette, Belgium; [2]Clinical Trials Conduct Unit, Institute Jules Bordet, Anderlecht, Belgium; [3]Department of Medical Oncology, UZ Gent - University Hospital Ghent, Gent, Belgium; [4]Oncology Department, UZA - University Hospital Antwerp, Edegem, Belgium; [5]Department of Medical Oncology, CHU Liège Sart-Tilman-Service d'Oncologie, Liège, Belgium; [6]Medical Oncology Department, Jesse Ziekenhuis - Campus Virga Jesse, Hasselt, Belgium; [7]Department of Oncology-Hematology, GHdC - Grand Hopital de Charleroi - Site Notre Dame, Charleroi, Belgium; [8]Medical Oncology, UZ Brussel - Universitair Ziekenhuis Brussel, Jette, Belgium; [9]Medical Oncology Department, Vrije Universiteit Brussel - Faculty of Medicine & Pharmacy, Brussels, Belgium

Background: The Belgian Precision initiative aims to implement tumor-agnostic NGS in advanced cancer patients (pts) and enhance access to genotype-matching drugs. The current study aimed to investigate the efficacy of afatinib in advanced pre-treated solid cancers with an EGFR (excluding non-small cell lung cancer (NSCLC)), HER2 or HER3 mutation.

Methods: Open-label phase 2 study including 3 cohorts for previously treated advanced cancers: EGFR, HER2 and HER3 mutated. The primary endpoint for each cohort was objective response rate (ORR). Response assessment was performed every 8 weeks. For each cohort, a Simon two-stage design was used. The null hypothesis that the true ORR is 10%, was tested against a one-sided alternative that the true ORR is 30%. If two or more ORR were observed in the first ten pts, 19 additional pts were included (type I error 5% and power 80%) Secondary endpoints were disease control rate (DCR), duration of response (DOR), progression-free survival (PFS), overall survival (OS) and safety.

Results: A total of 45 pts were included in the trial with median age 62 years. The EGFR cohort comprised 7 pts: 2 pancreas, 1 head and neck, 1 breast, 1 endocrine tumor, 1 cervix and 1 kidney. The HER2 cohort comprised 30 pts: 11 NSCLC, 8 breast, 3 cervix, 2 colorectal, 2 head and neck, 1 bladder, 1 kidney, 1 liver and 1 pancreas. The HER3 cohort comprised 8 pts: 2 breast, 2 pancreas, 1 colorectal, 1 head and neck, 1 esophagus and 1 stomach. ORR and DCR were respectively 28.6% and 42.9% in the EGFR cohort, 3% and 49% in the HER2 cohort and 0% and 62.5% in the HER3 cohort. Partial responses were observed in a HER2-mutated NSCLC (1/11) with a DOR of 8.5 months, an EGFR-mutated breast cancer (1/1) with a DOR of 6.6 months and an EGFR-mutated pancreas cancer (1/2) with a DOR of 15.4 months. PFS and OS data will be presented at the meeting Safety data were consistent with the known safety profile of afatinib.

Conclusions: Although three pts demonstrated a clinical meaningful benefit, afatinib did not result in a significant ORR improvement in the HER2 cohort, which completed accrual. Recruitment was hampered by a lack of systematic agnostic NGS sequencing and the COVID epidemic. Broader and more systematic agnostic NGS would enable further exploration of HER inhibition in solid tumors

202P Participant perceptions and mammography adherence from DETECT-A: The first prospective interventional trial of a multi-cancer early detection (MCED) blood test

N. Papadopoulos[1], A.M. Lennon[1], P. Elias[2], S. Rego[2], O. Choudhry[2], D. Flake[3], J. Cohen[1], C. Douville[1], A. Honushefsky[4], I. Kinde[5], A. Klein[1], Z. Salvati[4], C. Tomasetti[6], E. Wagner[4], C. Walter[4], E. Fishman[1], K. Kinzler[1], B. Vogelstein[1], T.M. Beer[7], A. Buchanan[4]

[1]Johns Hopkins University School of Medicine, Johns Hopkins University, Baltimore, MD, USA; [2]Clinical Affairs, Exact Sciences Corporation, Madison, WI, USA; [3]Clinical Biostatistics, Exact Sciences Corporation, Madison, WI, USA; [4]Department of Genomic Health, Geisinger Medical Center, Danville, VA, USA; [5]Technology Assessment, Exact Sciences Corporation, Madison, WI, USA; [6]Center for Cancer Prevention and Early Detection, City of Hope Comprehensive Cancer Center, Duarte, CA, USA; [7]Medical Affairs, Exact Sciences Corporation, Madison, WI, USA

Background: MCED tests may improve early cancer detection, but the impact of MCED testing on anxiety and standard of care (SOC) screening adherence is unknown. The DETECT-A trial evaluated the CancerSEEK MCED test in 9,911 women without a cancer history (Science, 359:6499, 2020). DETECT-A participants without a cancer diagnosis were invited to a follow-up observational study involving annual surveys. Here we report on participant satisfaction, anxiety, intent to adhere to SOC cancer screening, and adherence to breast cancer screening.

Methods: The survey, conducted approximately 3 years after DETECT-A enrollment, assessed: a) whether participants regretted DETECT-A participation or would participate again, b) how likely they were to adhere to routine cancer screenings, and c) how participation affected their anxiety. Adherence to biennial mammography screening was assessed at the month of survey completion for screening-eligible participants with evaluable medical records.

Results: Of the 7573 DETECT-A participants contacted, 3,870 (51%) completed a survey. Of the 3,788 respondents who answered all survey questions, 96.9% indicated no participation regret, 98.8% would participate again, 99.5% reported being equally or more likely to adhere to SOC screening, and 98.7% reported no change in or reduced anxiety. Of 1,053 participants eligible for mammography with available health records, 93.4% (n=984) were adherent with mammography screening. 94.3% of participants with false positive (FP) results who completed a survey ($n = 35$) reported no change or a reduction in anxiety; 5.7% (95%CI 1.6%-18.6%) reported an increase in anxiety compared to 1.3% (95% CI 0.9%-1.7%) of participants with true negative results ($p = 0.07$).

Conclusions: A follow-up study of MCED participant survey responses revealed high levels of participant satisfaction, intent to adhere to SOC screening, and mammography adherence. Most participants reported no change or a decrease in anxiety. This data suggest that MCED testing with imaging-based diagnostic resolution does not significantly increase anxiety or negatively impact mammography adherence for most participants, including those with FP results.

203P Genomic characterization of sporadic MET amplified non-small cell lung cancer (NSCLC) and association with real-world outcomes

R.D. Gentzler[1], N. Sharma[2], A. Mitra[3], R. Ben-Shachar[3], M. Stein[2], J. Guinney[4], H. Nimeiri[3], W. Iams[5], C. Aggarwal[6], J. Patel[7]

[1]Hematology/Oncology, University Hospital of Virginia (UVA), Charlottesville, VA, USA; [2]Systems Biology, Tempus Labs, Inc., Chicago, IL, USA; [3]Clinical Development, Tempus Labs, Inc., Chicago, IL, USA; [4]Cancer Genomics, Tempus Labs, Inc., Chicago, IL, USA; [5]Medical Oncology, Vanderbilt Ingram Cancer Center, Nashville, TN, USA; [6]Medicine - Hematology/Oncology Department, University Of Pennsylvania, Philadelphia, PA, USA; [7]Medical Oncology, Northwestern University Feinberg School of Medicine, Chicago, IL, USA

Background: *MET* copy-number amplifications (CNAs) are implicated as a resistance mechanism in patients treated with EGFR-targeted tyrosine kinase inhibitors and are associated with poor outcomes. However, data are limited on associations of immune biomarker and clinical outcomes among patients with sporadic *MET* CNAs — defined as preceding first-line (1L) therapy. This is the first real-world dataset to assess the prevalence of sporadic *MET* amplifications and their association with real-world clinical outcomes.

Methods: We analyzed a de-identified, multimodal dataset of 3,998 NSCLC patients biopsied prior to or within 30 days after the start of 1L therapy. Samples underwent NGS testing with Tempus xT (DNA-seq of 595-648 genes, 500x coverage). *MET* CNAs were identified using a CN threshold of $\geq$ 4 copies and compared to patients that were copy-number neutral (CN-N); patients with *MET* exon14 skipping mutations were excluded.

Results: The prevalence of sporadic *MET* CNAs in NSCLC patients was 5.7% (n=227). Patients with *MET* CNAs were more likely to harbor EGFR mutations compared to CN-N patients (17.6% vs 12.3%; p=0.02). In the subset of *EGFR* mutation-negative patients with PD-L1 data (n=2,230), a higher proportion of patients with *MET* CNAs were PD-L1-H (tumor proportion score $\geq$ 50%) compared to *MET* CN-N patients (45% vs 25.9%; p<0.001). Amongst *EGFR* mutation-negative patients (n=3,494), *MET* CNA-H patients were significantly enriched for High Tumor Mutational Burden (TMB-H, $\geq$ 10 Mut/Mb) compared to CN-N patients (21.4% vs 13.5%, p=0.004). In the subset of *EGFR* mutation-negative patients treated with 1L immune checkpoint inhibitors (ICIs, n=1,464); there was no significant difference in rwOS for patients with *MET* CNAs (median OS 21.5 months) vs CN-N patients (median OS 16.5 months), (HR=0.81, CI=[0.57, 1.14], p=0.22).

Conclusions: The majority of treatment-naive patients with sporadic *MET* CNAs are *EGFR* mutation-negative and enriched with biomarkers that are predictive of immune therapy benefit (PD-L1-H and TMB-H). Future clinical trials evaluating *MET* targeted therapy should account for this genomic heterogeneity and immunogenic therapeutic potential.

204P Performance assessment of a comprehensive genomic profiling (CGP) NGS kit across multiple study laboratories

J. Choi[1], A. Fellowes[2], E. Pikarsky[3], M. Teixeira[4], I. Vogl[5], A. Ahmed[1], K. Bi[1], K. Kirkconnell[1], C. Yin[1], M. Shin[1], N. Shrestha[1], J. Blau[1], S. Li[1], Y. Li[1], G. Kumar[1], R. Chien[1], S.E. Trabucco[6], W. Wen[1], M. Javey[1], Z. Li[1]

[1]Molecular Labs, Roche Diagnostics Solutions, Pleasanton, CA, USA; [2]Molecular Diagnostic Development, Peter MacCallum Cancer Center, Melbourne, VIC, Australia; [3]Department of Pathology, The Hebrew University of Jerusalem, Jerusalem, Israel; [4]Department of Pathology, Instituto Portugues de Oncologia do Porto Francisco Gentil, EPE, Porto, Portugal; [5]Laboratory Operations, FMI GmbH, Penzberg, Germany; [6]Oncology Genomics Dept., Foundation Medicine, Inc, Cambridge, MA, USA

Background: Precision oncology is a rapidly evolving field. Reliable tools are required for comprehensive genomic profiling (CGP) in clinical and research settings. NGS provides capabilities to detect multiple alterations, but complex workflows may be difficult to implement. Roche Diagnostics and Foundation Medicine have developed the AVENIO Tumor Tissue CGP Kit, a streamlined and easy to implement Research-Use-Only CGP assay to enable translational research labs.

Methods: The AVENIO Tumor Tissue CGP Kit profiles 324 genes for cancer alterations, tumor mutation burden (TMB), microsatellite instability (MSI), and genomic loss of heterozygosity (gLOH)). The kit contains reagents to create libraries. A software provides access to Foundation Medicine's bioinformatics pipeline. Five laboratories tested 160 samples, consisting of cell line and formalin fixed paraffin embedded (FFPE) tumor specimens. To assess reproducibility, 144 samples were evaluated across operators, lots, and instruments. To evaluate diagnostic sensitivity and specificity, 314 FFPE samples were tested and positive and negative predictive agreements determined against an orthogonal NGS method.

Results: Across five labs, pass rate was 98.1%. Sequencing quality metrics were high, with most samples reaching 1500x-2500x median coverage. Sites had 99.7% agreement for short variants. In the 144 sample reproducibility study, samples were highly uniform across variables, achieving >90% on-target rate. In the 314 sample concordance study, pass rate was 99.06%, with most samples achieving 2000x-2500x median coverage. Out of 314 samples, PPA to an orthogonal NGS-based method were: 98.3% short variants, 90.5% rearrangements, 94.8% copy number, 100% MSI, 100% TMB, and 96.8% gLOH. NPA reached 99.97% across short variants. Detected alterations included EGFR T7090M, BRAF V600E, KRAS 12/13 mutations, and EML4-ALK fusions.

Conclusions: CGP tests are being utilized in precision oncology, but NGS workflows and bioinformatics pipelines can be difficult to implement. The AVENIO CGP Tumor Tissue Kit is highly reproducible across sites and operators, achieving high sequencing quality metrics and diagnostic sensitivity.

205P A novel immunoprecipitation/PCR method for detection of plasma cfDNA fragments selectively occupied by CTCF in cancer

D. Pamart, J-V. Turatsinze, B. Cuvelier, M. Herzog, J. Micallef

Research and Development, Belgian Volition SRL, Isnes, Belgium

Background: CTCF-binding site (BS) occupancy is plastic, tissue specific and altered in cancer. This principle underlies some fragmentomics methods. We hypothesized that ChIP-Seq of plasma CTCF-cfDNA might identify CTCF-BSs selectively occupied in cancer and that, having removed all nucleosomes or other non-CTCF bound cfDNA by CTCF immunoprecipitation (IP), the presence of cfDNA fragments corresponding to sites selectively CTCF occupied in cancer may be tested for by PCR. We now report a novel liquid biopsy method, and initial results, based on this principle.

Methods: (i) Identification of CTCF-BSs selectively occupied in cancer samples. Plasma samples were collected from healthy volunteers (n=5), and patients with inflammatory conditions (n=5) or cancer (n=5). IP was performed using anti-CTCF coated magnetic beads and immunoprecipitated cfDNA was extracted, amplified and sequenced on an Illumina platform. (ii) We developed specific qPCR assays for 10 CTCF-BS sequences that we observed to be preferentially bound in the plasma of cancer patients vs either inflammatory conditions or healthy subjects. The panel of qPCR assays was tested on CTCF associated cfDNA isolated from plasma samples (1ml) obtained from patients diagnosed with a variety of common solid cancer diseases (n=48).

Results: We observed that specific CTCF IP resulted in isolation of cfDNA fragments with a frequency peak in the 30-80bp range that was not present in negative controls (mouse-IgG). These short cfDNA fragments included previously described CTCF binding sites. Moreover, CTCF binding sites were not randomly distributed on cfDNA fragments but located at the centre of each fragment. Among the CTCF occupied binding sites observed, we identified 29 sites that were significantly differentially bound in cancer. We observed highly sensitive and specific qPCR test results for a number of common solid cancer diseases including high sensitivity at disease stage I and II.

Conclusions: This is the first demonstration of IP of plasma CTCF-cfDNA. IP followed by multiplex PCR may form the basis of a rapid, low cost liquid biopsy method that obviates expensive library preparation and NGS.

206P WAYFIND-R: A global, real-world database of patients (pts) with a solid tumour profiled with next-generation sequencing (NGS)

J-Y. Blay[1], A. Hackshaw[2], C. Le Tourneau[3], J. Geissler[4], A. Ferro[5], E. Schirgruber[6], O. Skatkova[7], R. Dienstmann[8]

[1]Medicine Department, Centre Léon Bérard, Lyon, France; [2]Clinical Trials, Cancer Research UK & University College London Cancer Trials Centre, London, UK; [3]Department of Drug Development and Innovation (D3i), Institut Curie, Paris, France; [4]Patvocates Network, Patvocates GmbH, Riemerling (Hohenbrunn), Germany; [5]RWD Oncology, PD Data Science, Roche Products Limited, Welwyn Garden City, UK; [6]Global Product Development Medical Affairs, F. Hoffmann-La Roche Ltd, Basel, Switzerland; [7]Global Product Development Medical Affairs Operations, F. Hoffmann-La Roche AG - Switzerland, Basel, Switzerland; [8]Oncoclínicas Precision Medicine, Oncoclínicas Group, Sao Paulo, Brazil

Background: WAYFIND-R is a global, multicentre, prospective pan-cancer registry collecting long-term data from pts diagnosed with a solid tumour profiled with NGS. The goal is to advance precision medicine by providing high-quality real-world data (RWD) to researchers internationally.

Methods: WAYFIND-R data are electronically collected into a centralised database with standardised forms and high quality data management procedures. To ensure reliability/accuracy and a fit-for-purpose data source, data are periodically evaluated. Enrolment began in Sep 2020. Sites submit baseline pt, tumour, biomarker, NGS and molecular tumour board (MTB) decision making at enrolment, and treatment and outcome data at routine follow up.

Results: As of 31 Mar 2023, 855 pts had complete baseline data collection and cancer-related information; 755 carried on to the next data collection, 119 had died and 18 had ended participation. Pts were enrolled at 61 sites across 23 countries, mostly at academic institutions/university hospitals. The median age was 65 years (range: 20—93), 50% were female, 49% were retired and 62% had government insurance. WAYFIND-R had 109 cancer types and 160 subtypes (most common: adenocarcinoma [n = 389]). The most commonly detected genes were *TP53*, *KRAS*, *EGFR*, *BRAF* and *APC*. The most commonly screened non-NGS biomarkers were cytokeratin 7 (CK7/KRT7), PD-L1, CA19-9, CEA and Ki67. Table shows data for the most common cancer types in the registry.Many pts (n [341; 40%) had not been evaluated by an MTB. The most frequent MTB recommendation after NGS testing (n [213; 25%) was to start other treatment (chemotherapy: 63%; immunotherapy: 19%; targeted therapies: 18%).

Conclusions: The WAYFIND-R registry captures precision oncology data using a standardised approach globally. WAYFIND-R can enable further insights into clinical decision making, the timeliness of NGS testing and access to therapy.

Clinical trial identification: NCT04529122, first posted 27 August, 2020.

Background: TAPUR is a phase II basket study evaluating antitumor activity of commercially available targeted agents in pts with advanced cancers with specific genomic alterations. Results from 2 cohorts of pts with solid tumors with *CDK4* or *CDK6* amp treated with P are reported.

Methods: Eligible pts had measurable disease, ECOG performance status (PS) 0-2, adequate organ function and no standard treatment (tx) options. Genomic testing was performed in CLIA-certified, CAP-accredited labs. Amp cut-offs were defined per NGS providers. Recommended dosing was 125 mg P orally once daily for 21 days on followed by 7 days off, until disease progression. Low accruing histology-specific cohorts with *CDK4* or *CDK6* amp were collapsed into 2 histology-pooled cohorts for analysis. Primary endpoint was disease control (DC) defined as investigator assessment of complete or partial response (PR) or stable disease (SD) of at least 16+ weeks (wks) duration (SD16+) per RECIST v1.1. The hypothesized null DC rate of 15% was evaluated by a 1-sided exact binomial test ($\alpha = 0.10$; power 65% and 58%, respectively). Secondary endpoints were progression-free survival (PFS), overall survival (OS), objective response (OR), duration of response (DOR) and SD, and safety.

Results: Pts with solid tumors with *CDK4* amp (N=16) or *CDK6* amp (N=15) were enrolled. 1 pt from each cohort was not evaluable for efficacy. Table shows demographics and outcomes. For the *CDK4* cohort, 2 pts had SD16+ for a DC rate of 13% (p=0.72); the null DC rate was not rejected. Of pts with SD16+, duration of SD was 28 (ovarian) and 52 (adrenal) wks. For the *CDK6* cohort, 1 pt had a PR (pancreatic, DOR = 8 wks) for a DC rate of 7% (p=0.897) and OR rate of 7%; the null DC rate was not rejected. 6/31 pts had ≥1 tx-related grade 3-4 adverse or serious adverse event of neutropenia or thrombocytopenia.

Conclusions: P did not show antitumor activity in heavily pretreated pts with advanced solid tumors with *CDK4* or *CDK6* amp.

208P Identification of BCOR mutation as a novel predictor of immunotherapy efficacy in gastrointestinal tumors

W. Wang[1], Q. Zhang[2], C. Zhu[2], D. Chen[2]

[1]Department of Thoracic Surgery, Xi'an International Medical Center Hospital, Xi'an, China; [2]The Medical Department, Jiangsu Simcere Diagnostics Co., Ltd., Nanjing, China

Background: Immune checkpoint inhibitors (ICIs) have become an important therapeutic option for gastrointestinal cancer (GC). *BCOR* (BCL6 Corepressor) is an epigenetic regulator, whose mutation has been found to be associated with the development of various tumors, while evidence in GC remains limited.

Methods: We analyze genomic data from 236 GC patients receiving immunotherapy from Memorial Sloan Kettering Cancer Center (MSKCC) to assess the relationship between *BCOR* mutation status and efficacy of immunotherapy. The prognostic value and RNA mechanism exploration of *BCOR* mutations are explored in 914 GC samples from The Cancer Genome Atlas (TCGA) database. CIBERSORT is used to evaluate the infiltration status of 22 immune cell types in TCGA GC cohort. Survival is estimated by Kaplan-Meiercurves, with the P-values are determined by log-ranktest.

Results: The TMB levels of *BCOR*-mutant (Mut) patients are higher than *BCOR*-wildtype (WT) patients in both TCGA (Median: 24.25 [0.55 - 245.56] *vs.* 2.78 [0.05 - 1296.91], $P < 0.001$) and MSKCC (Median: 54.65 [2.95 - 203.64] *vs.* 6.14 [0.00 - 93.04], $P < 0.001$) cohort. *BCOR*-Mut patients receiving ICIs achieve prolonged OS than *BCOR*-WT patients (median OS: 14 months *vs.* not reach; HR 95% CI: 0.28 (0.09-0.90); $P = 0.03$); moreover, a multivariable analysis using Cox proportional-hazards regression demonstrated that *BCOR*-Mut was associated with better OS (HR = 0.29; 95% CI: 0.092-0.93; $P = 0.036$), after adjusting for age, gender, metastasis and treatment. In TCGA cohort, there is no significance in OS between *BCOR*-wildtype and *BCOR*-mutant patients (median OS: 55.4 vs 61.8 months, $P = 0.94$). Based on the analysis of immune cell infiltration status, the mechanism of the predictive value of *BCOR* mutation to ICIs efficacy may be related to the greater abundance of activated CD4 memory T cell, CD8 T cell, follicular helper T cell and Macropghages M1, and lower abundance of Monocytes and CD4 memory resting cells in *BCOR*-mutant tumors.

Conclusions: Survival analysis of MSKCC shows *BCOR* mutation is an independent predictor of ICIs treatment in GC, rather than a prognostic factor, and may be associated with better immune cell infiltration.

209P Molecular atlas of copy number variation(CNV) in lung cancer with brain metastases

X. Zhang[1], T. Han[2], D. Guo[2], R. Kong[2], S. Chen[3], R. Ding[2], W. Deng[3], F. Bu[2]

[1]Department of Neurosurgery, The First Hospital of Jilin University, Changchun, China; [2]The Medical Department, Jiangsu Simcere Diagnostics Co., Ltd., Nanjing, China; [3]Bioinformatics Department, Jiangsu Simcere Diagnostics Co., Ltd., Nanjing, China

Background: Patients (pts) with lung cancer had high rates of brain metastasis (BM). Genetic alterations were associated with the metastatic spread of lung cancer cells in recent study, lung cancer driver genes, such as *EGFR*, *ALK*, and *RET* are risk factors for brain metastasis in advanced lung cancer pts. The number of CNV regions was markedly higher in the secondary metastatic tumor than the primary tumor in the lung. However, the precise mechanisms in BM were still unclear. In this study, we explored the clinical and molecular features of lung cancer with brain metastases in Chinese real word.

Methods: This study retrospectively analyzed the genomic alteration of Chinese lung cancer with brain metastases pts during 2019-2022. Next-generation sequencing (NGS) was performed to detect gene mutations in tumor. Lung cancer driver genes set, as *EGFR*, *ALK*, *ROS1*, *BRAF*, *ERBB2*, *MET*, *KRAS* and *RET* were evaluated in those pts.

Results: 193 lung cancer with brain metastases pts were enrolled. Male:Female ratio: 128:65. Median age 61 years(Min-Max: 38-78). 79% of pts had CNV, and tumors with CNV had higher TMB values than those without CNV (7.7 vs. 2.8, $p<0.001$). The top3 amplification genes were: *EGFR*(n=25), *MYC*(n=11), *ERBB2*(n=10), and the three most frequently deletion genes were: *CDKN2A* (n=69), *CDKN2B* (n=69), *PTEN* (n=15). Among pts with TMB≥10, the proportion of pts with CNV was higher than that of pts without CNV (24% vs. 5%, $\chi 2=7.22$, $p < 0.05$). The numbers of pts with driver gene mutation and pts without driver gene mutation were 145 and 48, respectively, and there was no significant difference in age between the two groups. Pts with CNV and no driver gene mutation had higher TMB values (average TMB=9.6). The proportion of pts that carrying CNV in driver gene mutation tumors was similar to those without driver gene mutation (82% vs. 68%).

Conclusions: 79% of pts with brain metastases had CNV. The top3 amplification genes were: *EGFR*, *MYC*, *ERBB2*, and the three most frequently deletion genes were: *CDKN2A*, *CDKN2B*, *PTEN*. The proportion of pts that carrying CNV in driver gene mutation tumors was similar to those without driver gene mutation. Pts with CNV and no driver gene mutation had higher TMB values, indicating the pts may have more clinical benefits from immunotherapy.

210P Lung tumour vascularity is a risk factor for survival in NSCLC patients undergoing surgery

A.R. Filippi[1], F. Blistein[2], F. Belmans[2], S. Goffart[2], L. Libert[2], R. Narasimhan[2], A. Corsi[3], W. Vos[2], M. Occhipinti[3]

[1]Department of Clinical, Surgical, Diagnostic and Paediatric Sciences, University of Pavia, Pavia, Italy; [2]R&D, Radiomics SA, Liège, Belgium; [3]Medical, Radiomics SA, Liège, Belgium

Background: Vascularization is known to be linked to tumour growth. We explored the potential of automated lung tumour vascularity assessment as risk factor for landmark survival.

Methods: 131 CT scans from the NSCLC Radiogenomics dataset were evaluated. All patients underwent surgery, with or without other therapies. Primary lung tumour (PLT) is segmented by a radiologist. Vessels segmentation (arteries and veins) is performed by an in-house deep learning segmentation model. Vascularity features extracted for the PLT include: amount of blood vessel connections, % of the tumour surface connected to vessels (%area), and basic statistics on the surface area of the connections. A generalized linear model (GLM) to predict landmark survival was trained with these features, tumour volume, and clinical factors. Stepwise feature reduction was performed to arrive to the final model. We present the odds ratio (OR) as well as a combined risk score for the remaining independent predictors.

Results: Landmark survival was reached for 86/131 (66%) patients. GLM analysis showed 4 independent risk factors related to landmark survival: %area (OR= 1.69 for >2.5%), age (OR=1.57 for >70 years), gender (OR=2.10 for male) and radiation therapy (OR=1.51 for yes). Smoking status and tumor volume were not retained in the final model. We also showed that risk of dying before landmark survival increased with increased number risk factors (0%, 18%, 40%, 48% and 100% for 0, 1, 2, 3, 4 risk factors, respectively).

Conclusions: Lung tumour vascularity is an independent risk factor for landmark survival. We showed an approach were it can be used as additional prognostic factor to inform clinical decision making and therapy planning.

211P Cost-efficient detection of NTRK1, NTRK2 and NTRK3 gene rearrangements using the test for 5′/3′-end unbalanced expression: The analysis of 8075 patients

E. Imyanitov, A. Romanko, E. Preobrazhenskaya, V. Tiurin, A. Venina, R. Mulkidjan, A. Anuskina, A. Togo, A.O. Ivantsov, A.G. Iyevleva

Department of Tumor Growth Biology, N.N. Petrov National Medical Research Center of Oncology, St. Petersburg, Russian Federation

Background: The majority of NTRK1, NTRK2 and NTRK3 rearrangements result in the increased expression of the kinase portion of the gene due to its fusion to an actively transcribed gene partner. Consequently, the analysis of 5′-/3′-end expression imbalance is potentially capable of detecting the entire spectrum of NTRK gene fusions.

Methods: Formalin-fixed tissue specimens were subjected to manual dissection of tumor cells, followed by DNA/RNA isolation and cDNA synthesis. 5′-/3′-end expression imbalance in NTRK genes was analyzed by real-time PCR. Further identification of gene rearrangements was performed by variant-specific multiplexed PCR for 42 common NTRK fusions, and, whenever necessary, by RNA-based next-generation sequencing (NGS).

Results: The study initially included 8075 tissue specimens; 651 (8.1%) of these samples failed to pass the quality control. NTRK rearrangements were detected in 7/6436 (0.1%) lung carcinomas, 11/137 (8.0%) pediatric tumors, and 13/851 (1.5%) adult non-lung malignancies. The highest incidence of NTRK translocations was observed in pediatric sarcomas (7/39, 17.8%). Relatively high frequency of NTRK fusions was seen in microsatellite-unstable colorectal tumors (6/48, 12.5%) and salivary gland carcinomas (5/93, 5.4%). None of 1293 lung carcinomas with driver alterations in EGFR/ALK/ROS1/RET/MET oncogenes had NTRK 5′/3′-end expression imbalance. Variant-specific PCR was performed for 744 tumors with normal 5′/3′-end expression ratio: there were no rearrangements in 172 EGFR/ALK/ROS1/RET/MET-negative lung cancers and 125 pediatric tumors, while NTRK fusions were detected in 2/447 (0.4%) non-lung adult malignancies.

Conclusions: This study describes a robust pipeline for the detection of NTRK1, NTRK2 and NTRK3 gene fusions, which may be considered as a cost-efficient alternative to conventional methods of NTRK analysis.

212P Extracellular vesicle miRNA as effective biomarkers for predicting antitumor efficacy in lung adenocarcinoma treated with chemotherapy and checkpoint blockade

S. Sun, H. Yu, X. Wu, X. Zhao, Z. Hu, J. Wang

Thoracic Medical Oncology, Fudan University Shanghai Cancer Center, Shanghai, China

Background: Immune checkpoint inhibitors (ICIs) have improved the care of patients in metastatic lung adenocarcinoma (LUAD). However, PD-L1 status, high Tumor Mutational Burden (TMB), and mismatch repair deficiency are the only validated biomarkers of efficacy for ICIs. These markers remain imperfect, and new predictive markers represent an unmet medical need. MicroRNAs (miRNAs) encapsulated within plasma-derived extracellular vesicles (EVs) may be suitable for use as noninvasive diagnostic biomarkers for aggressive malignancies, including LUAD. Here, we assessed the possibility of plasma EVs derived miRNAs as potential biomarkers for predicting and identifying the beneficiaries of combined immunochemotherapy.

Methods: A total of 31 patients with metastatic LUAD who received pembrolizumab combined with pemetrexed and carboplatin were enrolled. After efficacy evaluation. 25 patients had durable clinical benefits from combined immunochemotherapy, and the rest patients showed disease progression. MiRNA profiles of plasma-derived EVs from these patients were investigated using unsupervised hierarchical clustering.

Results: 46 differentially expressed miRNAs (DEMs) were identified between responders and non-responders. Interestingly, we found that miR-6815-5p, miR-15a-5p, miR-92a-3p, and miR-107 were obviously down regulated in non-responder group. However, miR-769-5p, and miR-589-5p showed a trend of significantly increased expression. In addition, all these findings were further confirmed by clinical imaging assessment.

Conclusions: In conclusion, EVs miRNAs derived from patients with lung cancer showed promising application scenarios for effectively identifying true responders treated with combined immunochemotherapy.

Clinical trial identification: NCT04427475, release date is June 11, 2020.

Background: Targeted cancer treatment has been developed at a rapid pace, but implementation of precision cancer medicine (PCM) has met several challenges. Key challenges are: 1) lack of clinical evidence within and across tumor groups 2) lack of predictive biomarker 3) access to medication and 4) regulatory and economic factors. These are interconnected, and PCM trials are needed to address most of them. To meet the need for tailored diagnostics for PCM trials, we designed a national Infrastructure for Precision Diagnostics — InPreD-Norway.

Methods: In 2020, the CEOs of the four Norwegian health regions allocated funding to the six university hospitals to form a collaborative network, InPreD, with dedicated environments (nodes) at each site for implementing next-generation cancer diagnostics. The first task has been to build a complete program for Comprehensive Gene Profiling (CGP), including a national virtual tumorboard, for patients eligible for experimental cancer treatment and trial inclusion.

Results: The InPreD nodes were gradually built at the six university hospitals. The largest hospital, Oslo University Hospital, was initiated first, built a transdisciplinary environment and implemented a complete pipeline for CGP testing (TSO500). These solutions were used by the other nodes when they were initiated. In spring 2023, the InPreD nodes had completed CPG profiling of 1000 patient cases. A new treatment opportunity was found for 34% of the patients, where referral to the national PCM trial IMPRESS-Norway trial dominated (21%). The National molecular tumorboard meets virtually twice weekly to discuss the analysed cases with the InPreD nodes and the referring physicians, providing both an advisory but also and educational role. InPreD now plan novel diagnostics such as drug sensitivity screening and digital pathology biomarkers for planned trials.

Conclusions: The national Infrastructure, InPreD, secures competence building and standardised service in CGP testing nationwide, providing new treatment opportunities for cancer patients. Beyond strengthening the ability to identify patients to clinical trials, it serves as a united interaction partner for national stakeholders such as governmental bodies, health authorities and industry.

214P PESSA: A shiny app for pathway enrichment score-based survival analysis in cancer

Y. Shi, H. Yang, A. Lin, J. Zhang, P. Luo

Department of Oncology, Zhujiang Hospital of Southern Medical University, Guangzhou, China

Background: The activation levels of biologically significant gene sets are innovative molecular markers for tumours and play an irreplaceable role in the diagnosis, staging, prognosis evaluation and treatment of tumours; however, there is still a scarcity of web-based tools for prognosis analysis that use gene set activation levels as molecular markers for tumours. We have developed a web-based tool for survival analysis using gene set activation levels.

Methods: All data analysis within PESSA is implemented via R. Activation levels of MSigDB gene sets were assessed using the single-sample gene set enrichment analysis (ssGSEA) method based on microarray and high-throughput sequencing data from the Gene Expression Omnibus (GEO) and The Cancer Genome Atlas (TCGA). PESSA was used to perform median and best cut-off dichotomous grouping of ssGSEA scores for each dataset, relying on the survival and survminer packages for survival-related analysis and visualisation. The web pages were built relying on Shiny.

Results: PESSA is an open-access online tool for visualising prognostic analysis based on the activation levels of biologically significant gene sets as molecular markers of tumour prognosis. A total of 214 datasets from the GEO and TCGA covering 51 different cancer types and 13 different survival status types were included; 13,434 tumour-related gene sets were obtained from the MSigDB for pre-grouping. For survival analyses, the gene set of interest was selected; Kaplan−Meier analyses and visualisation were conducted based on the median and best dichotomous cut-off, plus continuous variables were subjected to univariate Cox regression analyses.

Conclusions: PESSA (https://smuonco.shinyapps.io/PESSA/) is a large, interactive, easily accessible web-based analysis tool covering a large amount of data; it can creatively use predefined gene set activation levels as molecular markers of tumours and facilitate survival analysis for cancer patients.

215P Identifying predictors of overall survival among TMB-low cancer patients treated with immune checkpoint inhibitors

C.B. Xavier[1], G. Guardia[2], J.P. Alves[3], C.D.H. Lopes[1], B. Awni[1], E.F. de Campos[1], A.A. Camargo[2], D.L.F. Jardim[1], P. Galante[2]

[1]Oncology Center, Hospital Sírio-Libanês, São Paulo, Brazil; [2]Molecular Biology Center, Hospital Sírio-Libanês, São Paulo, Brazil; [3]Data Science, Innovation Intelligence AI, San Francisco, CA, USA

Background: Dichotomizing tumors into tumor mutational burden (TMB)-high and TMB-low is common practice but may not determine which patients will benefit from immune checkpoint inhibitors (ICI). This study examines the impact of somatic mutations on overall survival (OS) for TMB-low metastatic cancer patients (MCP) treated with ICI.

Methods: Genomic (MSK-IMPACT) and clinical data from 1,172 TMB-low (<10mut/Mb) MCP were collected. OS accordingly to single-genemutations was assessed by Kaplan-Meier (KM) method. For genes exhibiting a correlation with OS, we conducted a Cox multivariate analysis (CMA) stratified by TMB, sex, age, microsatellite instability (MSI), and histology. KM and CMA were also performed to investigate the relation between insertions and deletions (InDels) and OS. Linear regression (LR) investigated the relation between TMB and InDels burden. Decision tree modeling (DTM) aimed to predict whether patients that received ICI harbored OS shorter or longer than the median OS of 15 months. The discriminative features (DF) for DTM were TMB (continuous), gene mutations, sex, and histology.

Results: Mutations in 25 genes were related to OS. CMA confirmed 9 genes associated with superior (*VHL*) and inferior (*CTNNB1, DAXX, H3C2, HLA-A, IGF1R, KMT2D, SMARC4, TP53*) OS ($P < 0.05$). MSI, age, and gender did not affect OS. Melanoma, bladder, and RCC endowed patients with better OS ($P < 0.01$). TMB and InDels exhibited a R-squared of 0.38 - low (or absent) relation. The InDels burden was unrelated to OS ($P = 0.21$). *VHL* mutation was a predictor of better OS in uni- and multivariate levels for RCC (N=149; $P < 0.01$). At DTM, RCC histology was the first DF (gini 0.492). For RCC patients, VHL mutation was the second (gini 0.349). For non-RCC patients, melanoma histology was the second. At the third layer, a TMB threshold of 5.095 mut/Mb for *VHL* wild-type patients and *TP53* mutation for non-RCC and non-Melanoma patients were the following DF.

Conclusions: Tumor histology, mutated genes, and a better adjusted TMB cutoff (5.095 mut/Mb) are important for predicting ICI treatment outcomes in TMB-low patients. Among RCC patients, VHL mutations predict better OS. Individualized profiling is needed for a tailored ICI treatment strategy.

216P PTCH1 mutation as a potential predictor of immune checkpoint inhibitors in gastrointestinal cancer

Y. Tang[1], Q. Zhang[2], Y. Qi[2], D. Chen[2]

[1]Department of Surgical Oncology, The Second Afliated Hospital Zhejiang University School of Medicine, Hangzhou, China; [2]The State Key Lab of Translational Medicine and Innovative Drug Development, Jiangsu Simcere Diagnostics Co., Ltd, Nanjing, China

Background: The association between genetic alterations and benefit of immunotherapy is well documented, but evidence for gastrointestinal cancer (GC) remains limited. Patched1 (PTCH1) mutation, a frequently altered gene in GC, lead to dysregulation of Hedgehog signaling. However, the efficacy of *PTCH1* mutations in immunotherapy in patients with GC remains unclear. Herein, we aimed to analyze the association between *PTCH1* mutations and immune checkpoint inhibitors (ICIs) efficacy in patients with GC.

Methods: We screened the following 3 cohorts: (1) MSKCC cohort (N=236) of GC (including esophageal, gastric and colorectal cancers) who received ICIs. (2) Peking University Cancer Hospital (PUCH) GC cohort (N=92) who received ICIs. (3) the TCGA cohort (N=914) of GC. The patients were divided into *PTCH1* mutant type (*PTCH1*-MT) group and *PTCH1* wild type (*PTCH1*-WT) group. We analyzed the differences in overall survival (OS) and TMB between the two groups. Tumor immune microenvironment (TIME) was evaluated by calculating the cell infiltration score as the arithmetic mean analysis of the constituent genes.

Results: In MSKCC cohort, *PTCH1*-MT group (9.3%) had significantly better OS ($p=0.017$, median OS, 34m vs. 13m) and higher TMB ($p<0.01$). The results of the multivariate analysis showed that *PTCH1* had a significant effect on OS, with the *PTCH1*-MT group had better OS ($p=0.035$; HR=0.37; 95%CI: 0.15-0.93). Furthermore, we consistently observed in the PUCH cohort that the *PTCH1*-MT group (7.6%) significantly prolonged OS ($p=0.036$). Additionally, in the TCGA cohort, we similarly observed a trend towards longer OS ($p=0.63$, mOS, 70.2m vs. 61.8m) and higher TMB ($p<0.01$) in *PTCH1*-MT group (5.8%). It shows that *PTCH1* is a predictor, but not a prognostic factor. Subsequently, we assessed the abundance of 22 predefined immune cells. The score of CD4 T cells, CD8 T cells, NK cells, mast cells, and M1 cells were all significantly higher in the *PTCH1*-MT group ($p<0.05$). It shows that the *PTCH1*-MT group has a higher activation TIME.

Conclusions: Our study demonstrated that *PTCH1* mutation could act as a potential predictor for ICIs therapy in GC. In the future, relevant prospective clinical trials need to be designed to verify this conclusion.

217P Clinical and molecular features of PTCH1 mutant in solid tumors

X. Li[1], T. Han[2], D. Guo[2], R. Kong[2], S. Chen[3], R. Ding[2], W. Deng[3], F. Bu[2]

[1]Center for Integrative and Translational Medicine, Shandong Public Health Clinical Center, Jinan, China; [2]The Medical Department, Jiangsu Simcere Diagnostics Co., Ltd., Nanjing, China; [3]Bioinformatics Department, Jiangsu Simcere Diagnostics Co., Ltd., Nanjing, China

Background: *PTCH1*, a tumor suppressor and inhibitor of the hedgehog pathway. Hh signaling was reported to modulate the tumor microenvironment by increasing immune checkpoint expression and promoting an inflammatory environment. Mutations of *PTCH1* are potential therapeutic targets, Hh pathway inhibitor has been developed as a treatment for patients with advanced solid tumors. It is thus important to understand the genomic landscape of *PTCH1* mutation. Here, we explored *PTCH1* mutation profiles in Chinese solid tumors.

Methods: Next-generation sequencing of 551-gene profiling was performed to analyze postoperative tissues from 22312 Chinese solid tumors in 2019-2022. Somatic mutations and copy number variations were detected following the standard operating procedure.

Results: *PTCH1* mutations were present in 3.1% of patients with advanced solid tumors, a total of 791 *PTCH1* somatic mutations were detected in 684 tumor samples. The higher frequency cancer type contained lung cancer(n=239), colorectal cancer(n=137), and stomach cancer(n=60). Of 791 *PTCH1* mutations, missense mutations(65%,n=514) were more observed, and 25% were loss of function (LOF) mutations, including frameshift(n=124), nonsense(n=50), splicing(n=23) mutations. Exon 23, exon1 and exon22 of *PTCH1* were the main mutational hotspot regions found, with p.S1203Afs*52 (n=26), p.R1308Efs*64 (n=22), p.R602* (n=11), p.Y1316Tfs*56 (n=11) being the most frequent mutations in our study. There was a significant statistical difference in TMB values that the *PTCH1* mutant group was higher than the *PTCH1* wild-type group (39 vs. 5, $p < 0.001$), and patients who presented with two or more *PTCH1* mutations with higher compared with those patients carried only a single mutation (129 vs. 29, $p < 0.001$). TMB in *PTCH1* frameshift_variant tumors (53, 0−672) was significantly higher than TMB in *PTCH1* splice

variant tumors (15, 0—60; $P < 0.05$). The proportion of *PTCH1* alterations in MSI-H tumors was higher than those without mutations (22% vs. 1%, $p < 0.001$).

Conclusions: In our study, *PTCH1* mutations are present in 3.1% of solid tumors, and mostly occurred in exon 23, exon1, and exon22. *PTCH1* mutant tumors tended to be associated with higher TMB values (39 vs. 5), therefore, Hh pathway inhibitor combined immunotherapy may be considered in the future.

218P Peripheral T cell activation phenotype is associated with clinical outcomes and immune-related adverse events of ipilimumab-nivolumab in advanced hepatocellular carcinoma

W.S. Lee[1], H. Yang[1], S.J. Lee[1], S.J. Kong[1], B. Kang[1], I. Kim[2], H. Kim[3], C. Kim[1], H. Chon[1]

[1]Medical Oncology, CHA Bundang Medical Center, Seongnam, Republic of Korea; [2]Internal Medicine, Inje University Haeundae Paik Hospital, Busan, Republic of Kora; [3]Internal Medicine, Ulsan University Hospital, Ulsan, Republic of Korea

Background: Although combination immunotherapies have become a mainstay of treatment for patients with advanced hepatocellular carcinoma (HCC), studies of circulating biomarkers for immunotherapy in HCC are still limited. Therefore, we aimed to evaluate the peripheral T-cell activation phenotype as a biomarker for clinical outcomes of immunotherapies for HCC.

Methods: Baseline blood samples from 86 patients with advanced HCC in three tertiary cancer centers in Korea (ipilimumab-nivolumab [Ipi/Nivo], n=55; nivolumab [Nivo], n=31) were prospectively collected and analyzed.

Results: In the discovery cohort of the Ipi/Nivo group, the peripheral T-cell activation phenotype (IFN-γ^+TNF-α^+) at baseline was significantly higher in patients with partial response or stable disease compared with those with progressive disease. The cut-off value for high-peripheral T-cell activation phenotype was set to 5.55% using maximally selected rank statistics for optimally predicting survival outcomes. In both the discovery and validation cohorts, the patients with high-peripheral T-cell activation phenotypes showed an increased ORR and more favorable PFS (discovery cohort: hazard ratio [HR], 0.35; 95% CI, 0.16—0.74; $P = 0.004$; validation cohort: HR, 0.22; 95% CI, 0.04—1.11; $P = 0.046$) and OS (discovery cohort: HR, 0.44; 95% CI, 0.20—0.99; $P = 0.042$; validation cohort: HR, 0.20; 95% CI, 0.04—1.02; $P = 0.036$) than those with low levels. These results were consistent in the Nivo cohort. Regarding immune-related adverse events (irAEs), patients with high-peripheral T-cell activation phenotype showed higher incidence of irAEs compared with those with low levels (14.3% vs. 37.0%). Of note, comparing baseline peripheral blood cytokine levels according to irAEs, the patients with irAEs had significantly lower serum levels of IL-6 at baseline.

Conclusions: Baseline peripheral T-cell activation phenotype was a predictor of clinical outcomes and irAEs in patients with advanced HCC receiving Ipi/Nivo immunotherapy. Patients with lower serum IL-6 levels at baseline might experience more frequent irAEs during Ipi/Nivo treatment in advanced HCC.

219P Multicentric evaluation of amplicon-based next-generation sequencing solution for local comprehensive molecular tumor profiling

E. Jantus Lewintre[1], A. Rappa[2], D. Ruano[3], S. Gallach Garcia[4], C.J.C. Camps Herrero[5], L. Lacroix[6], K. Kashofer[7], T. van Wezel[3], M. Barberis[1]

[1]Biotechnology, Universitat Politècnica de València, Valencia, Spain; [2]Pathology, IEO - Istituto Europeo di Oncologia IRCCS, Milan, Italy; [3]LUMC-Leiden University Medical Center, Leiden, Netherlands; [4]Molecular Oncology Department, FIHGUV - Fundación de Investigación Hospital General Universitario de Valencia, Valencia, Spain; [5]Oncology, Hospital General Universitario Valencia, Valencia, Spain; [6]Institute Gustave Roussy, Villejuif, France; [7]Medical University of Graz, Graz, Austria

Background: Molecular profiling of tumors is an essential step in the management of cancer patients, enabling personalized treatment decisions. Oncomine Comprehensive Assay Plus (OCA+) is an amplicon-based next-generation sequencing solution that can detect multiple biomarkers, including complex biomarkers, in a single assay. Here, we aimed to evaluate the sensitivity, specificity, and concordance of this comprehensive genomic profiling solution in detecting various types of biomarkers in a multicentric study using a cohort of 190 pre-characterized clinical tumor samples.

Methods: DNA and/or RNA were obtained from formalin-fixed paraffin-embedded (FFPE) tumor samples from patients with different cancer types from 5 different centers. Samples studied addressed the complete variety of genomic alterations targeted by the Oncomine Comprehensive Assay Plus. OCA+ was used to generate libraries that were sequenced using the Ion S5 Prime system and analyzed using Ion Reporter Oncomine Comprehensive Plus - w3.0 workflow. Single nucleotide variants (SNVs), insertions/deletions (indels), copy number alterations (CNAs), gene fusions, tumor mutation burden (TMB), microsatellite instability (MSI) and Genomic instability (GIN related to HRD) results were compared to orthogonal and gold standard methods.

Results: OCA+ demonstrated a total success rate of 97.2%. High sensitivity and specificity were obtained in detecting multiple biomarkers, including complex biomarkers. The assay detected >95% of SNVs and indels with a variant allele frequency (VAF) of ≥5%, and identified gene fusions, TMB, MSI and GIN with high concordance to orthogonal methods, 90%, 70%, 84% and 93% respectively.

Conclusions: OCA+ is a sensitive and specific platform for molecular tumor profiling, including the detection of complex biomarkers. The high concordance rate with orthogonal methods highlights the assay's potential in guiding clinical decision-making for personalized cancer care. OCA+ may provide comprehensive genomic information for cancer management and may be a valuable tool for further implementing precision medicine in oncology.

220P Biomarker of blood age and inflammation in older cancer patients might predict outcome

M.H.F. Vetter[1], C. Ewald[2], E. Burri[3], R. Rosenberg[4], S. Subotic[5], S. Mitrovic[6], E.D. Chiru[7], M. Knufinke[7]

[1]Medical Oncology Hematology and Immunotherapy, KSBL - Kantonsspital Baselland Liestal, Liestal, Switzerland; [2]Molecular Science, ETH Zurich - Inst. f. Molecular Health Sciences, Zurich, Switzerland; [3]Gastroenterology, KSBL - Kantonsspital Baselland Liestal, Liestal, Switzerland; [4]Surgical Oncology, Cancer Center, KSBL - Kantonsspital Baselland Liestal, Liestal, Switzerland; [5]Urology, KSBL - Kantonsspital Baselland Liestal, Liestal, Switzerland; [6]Lab Medicine, KSBL - Kantonsspital Baselland Liestal, Liestal, Switzerland; [7]Oncology, KSBL - Kantonsspital Baselland Liestal, Liestal, Switzerland

Background: Two-thirds of all cancers are diagnosed in patients above the age of 65 years, often associated with worse outcomes. The aim of this cohort study was to identify the predictive value of blood markers of inflammation, cell activity, and aging in older patients with solid malignant tumors.

Methods: Patients diagnosed with solid tumors were included at the Cancer Center Baselland, Switzerland. We investigated the predictive value on overall survival of blood markers sampled by clinical routine, including CRP (C-reactive protein), NLR (Neutrophil-to-lymphocyte ratio), LDH (Lactate dehydrogenase), Albumin, and Vitamin B12 (Cobalamin). The study analyzed the median value of each blood marker in all patients diagnosed after January 1, 2018, and calculated the survival curves and hazard ratios.

Results: From Jan 2018 to Feb 2022, a total of 510 patients were included with a median age at diagnosis of 72 years (57-91 years). Among these patients, 246 had localized disease, and 262 had advanced disease at primary diagnosis. The diagnoses included NSCLC (n=158, 31%), CRC (n=98, 19%), breast cancer (n=58, 11%), prostate cancer (n=82, 16%), pancreas cancer (n=42, 8%), urothelial cancer (n=42, 8%) and SCLC (n=30, 6%). Patients with abnormal median blood values had a significantly increased risk of poor outcomes. NLR>4 ($p<0.001$, HR=2.37), CRP >5mg/l ($p=0.021$, HR=1.6), CRP>10mg/l ($p<0.001$, HR=4.0-6.6), Albumin<35g/l ($p<0.001$, HR=3.05), LDH>250U/l ($p<0.001$. HR=2.24), and Vitamin B12>810pmol/l ($p<0.002$, HR=2.96) were associated with increased hazard ratios.

Conclusions: Older cancer patients with abnormal inflammation and aging markers had worse outcomes. This highlights the potential role of these blood markers in predicting outcomes in cancer patients with solid tumors. It is important to note that these blood markers are not cancer-specific, and their levels can be affected by other factors, such as infection, inflammation, and nutritional status. However, when used in conjunction with other clinical and pathological factors, they may provide additional information for risk stratification and treatment planning. Overall, our study adds to the growing body of evidence on the potential role of blood biomarkers in predicting outcomes in cancer patients.

221P Peripheral T cell activation phenotype predicts clinical outcomes of atezolizumab-bevacizumab therapy in unresectable hepatocellular carcinoma

C. Kim[1], W.S. Lee[1], H. Yang[1], S.J. Lee[1], S.J. Kong[1], B. Kang[1], I. Kim[2], H. Kim[3], H. Chon[1]

[1]*Medical Oncology, CHA Bundang Medical Center, Seongnam, Republic of Korea;* [2]*Internal Medicine, Inje University Haeundae Paik Hospital, Busan, Republic of Korea;* [3]*Internal Medicine, Ulsan University Hospital, Ulsan, Republic of Korea*

Background: Atezolizumab plus bevacizumab (Ate/Bev) has demonstrated superior efficacy to sorafenib, thereby becoming the new standard first-line treatment in patients with unresectable hepatocellular carcinoma (HCC). However, there is a lack of reliable biomarkers that could predict clinical outcomes of Ate/Bev. In this study, we aimed to assess the clinical and immunological implications of peripheral T-cell activation phenotype as a biomarker in patients with HCC treated with Ate/Bev.

Methods: This study prospectively enrolled 106 patients with unresectable HCC treated with Ate/Bev (discovery cohort: 50 patients from one center; validation cohort: 56 patients) as the first-line systemic treatment in three tertiary cancer centers in Korea. Baseline blood samples were analyzed using multiplex flow cytometry.

Results: The optimal cut-off value for baseline peripheral T-cell activation phenotype (IFN-γ^+TNF-α^+), 2.50%, was determined using maximally selected rank statistics. In the discovery cohort, the patients with high-peripheral T-cell activation phenotype at baseline had an increased objective response rate (ORR) than those with low activation levels (15.4% vs. 35.1%). Moreover, progression-free survival (PFS) and overall survival (OS) were significantly longer in patients with high-peripheral T-cell activation phenotype than those with low levels (hazard ratio [HR], 0.37; 95% CI, 0.18−0.79; $P =$ 0.008 for PFS; HR, 0.18; 95% CI, 0.07−0.41; $P < 0.001$ for OS). In the validation cohort, these findings were consistently observed. The patients with high-peripheral T cell activation phenotype at baseline were associated with a higher ORR (15.0% vs. 38.9%) and longer PFS (HR, 0.43; 95% CI, 0.22−0.85; $P = 0.012$) and OS (HR, 0.41; 95% CI, 0.18−0.96; $P = 0.035$) compared with those with low activation levels.

Conclusions: Highly activated peripheral T-cell phenotype was associated with favorable clinical benefit in patients with unresectable HCC treated with Ate/Bev. Therefore, peripheral T-cell activation phenotypes could be used as a potential predictor of Ate/Bev treatment.

222P Therapeutic opportunities for porcupine inhibition in gastrointestinal cancer

N. Cook[1], S. Wu[2], C. Maksymiuk[2], C. Phillips[3], J. Robertson[4], S.A. Woodcock[3]

[1]*Department of Medical Oncology, The Christie NHS Foundation Trust, Manchester, Cambridgeshire, UK;* [2]*Clinical and Translational Research, Caris Life Sciences - Headquarters, Irving, TX, USA;* [3]*Redx Oncology, Redx Pharma Plc, Macclesfield, UK;* [4]*Clinical Development Department, Redx Pharma Plc, Macclesfield, UK*

Background: Gastrointestinal (GI) cancer (Upper/Lower GI and Hepatobiliary) causes more cancer deaths than any other body system. Wnt pathway activation promotes common GI cancers, but safely targeting this pathway is challenging. Inhibition of Porcupine, an enzyme essential for Wnt ligand activity, has clinical potential to suppress Wnt in a safe and tolerated manner. Preclinically, GI tumors with upstream Wnt pathway variants (RNF43 loss of function (LoF), RSPO gain of function (GoF)) are Wnt ligand dependent and exquisitely sensitive to RXC004, a small molecule Porcupine inhibitor. Using Caris data, 278,649 human tumor samples (across all 58 solid tumor lineages) were analysed for the prevalence of upstream Wnt pathway variants and associated features.

Methods: Human tumors were analysed by next-generation sequencing of DNA (592 genes, NextSeq; WES, NovaSeq) and RNA (WTS, NovaSeq) by Caris. Molecular profiles and prevalence of RNF43_LoF and RSPO2/3_GoF cases were compared with negative (WT) cases using Fisher-Exact analysis. Real world overall survival was obtained from insurance claims data and Kaplan-Meier estimates were calculated for defined cohorts from time of tissue collection to last contact.

Results: Prevalence of RNF43_LoF, RSPO2_GoF and RSPO3_GoF were 1.3%, 0.1% and 0.3% in all lineages; increasing to 3.6%, 0.2% and 0.9% in GI lineages. The top lineages by combined Wnt ligand dependent prevalence were GI: Small Bowel (9.6%), Colorectal (CRC; 5.9%), Pancreatic (5.4%) and Gastric (4.3%) cancers. Of 15,025 CRC cases, 13,886 (92%) were Microsatellite stable (MSS). Within MSS CRC cases, prevalence of RNF43_LoF was 2.6% and RSPO2/3_GoF was 1.6%; hence total prevalence was 4.2%. BRAF_V600E had high co-occurrence with Wnt ligand dependent (42%), compared to WT (3.4%), MSS CRC cases. In MSS CRC, upstream Wnt pathway variants were associated with poor prognosis in either all cases (HR 1.64; $p<0.0001$) or BRAF_WT cases (HR 1.52; $p<0.0001$) versus WT cases.

Conclusions: Upstream Wnt pathway variants are enriched in GI cancer, in particular Small Bowel cancer, a rare subtype of high unmet need. In MSS CRC cancer, the poor prognosis and high BRAF_V600E co-occurrence with upstream Wnt pathway variants suggests benefit of co-targeting Wnt and MAPK pathways in this population.

Background: The backbone chemotherapy of first-line standard of care (SOC) for microsatellite stable (MSS) metastatic colorectal cancer (mCRC) combines 5-Fluorouracil to oxaliplatin and/or irinotecan. There are no biomarkers to predict response, which is complete or long-lasting (CR/LLR) in ∼25% of patients, while ∼15% are primary refractory. Our study aims at developing an accurate response predictor via a pathomics model based on Hematoxylin & Eosin (H&E)-stained digital slides (WSI).

Methods: We trained an unsupervised bag-of-words artificial intelligence (AI)-based model on 62 patients classified as response outliers as follow: i) *super-sensitive* if they achieved CR or LLR >10 months to any SOC (N=20); ii) *refractory* if progression occurred at first disease reassessment (N=42). WSIs of the resected primary tumors were tiled into patches of 224x224 pixel (0.5µm/pixel). First-order and texture features were subsequently extracted from all tumoral tiles, and grouped into homogenous clusters through a 3x3 self-organized map. For each patient, the percentage of tiles belonging to each tiles' cluster was computed and used by a dendrogram to create clusters of similar patients. Patients' survival was calculated by landmark analysis logrank test. Main clinicopathological features were matched to treatment response by Fisher's exact test.

Results: Primary resistant patients had significantly worse survival [logrank HR 4.2 95% CI (2.7-7.3)]. While outliers showed similar clinicopathological features (including stage, *RAS/BRAF* status, histotype and sidedness), pathomics signatures were significantly associated to primary resistance (p=.005). According to the unsupervised clustering, we classified as resistant patients belonging to four out of eight clusters obtaining an 88% (23/26) negative predictive value. We observed that patients classified as belonging to one of the four resistant clusters were predominantly characterized by a specific pattern of patches.

Conclusions: We demonstrated that a pathomics signature has the potential to predict resistance to SOC in MSS mCRC. Validation of these preliminary findings on a further cohort of 125 patients is ongoing.

224P Germline HLA-I/II is not associated with clinical outcome but the absence of HLA-A01 or the presence of HLA-B27 supertypes were correlated with improved clinical outcome among patients with NSCLC treated with pembrolizumab in combination with chemotherapy

A. Abed[1], A. Reid[2], M. Millward[3], E.S. Gray[4]

[1]Centre for Precision Health, Edith Cowan University, Joondalup, WA, Australia; [2]Centre for Precision Health, Edith Cowan University, Perth, WA, Australia; [3]School of Medicine, University of Western Australia, Perth, WA, Australia; [4]School of Medical and Health Sciences, Edith Cowan University, Perth, WA, Australia

Background: Maximal heterozygosity on the human leukocyte antigen (HLA) loci was found to be associated with improved survival among NSCLC patients treated with immune checkpoint inhibitors (ICI). Here we aimed to investigate the effect of germline HLA-I/-II zygosity on clinical outcomes among NSCLC patients treated with first-line pembrolizumab in combination with chemotherapy. We explored the correlation between different HLA-A/-B supertypes and clinical outcome among the same cohort.

Methods: We prospectively collected pre-treatment blood from patients with NSCLC treated with first-line pembrolizumab in combination with chemotherapy. DNA was extracted from white blood cells and used for high resolution HLA-I/II typing. Genomic HLA-I/II homozygosity was correlated with clinical benefit. We used Sidney et al to classify genomic HLA-A and -B into supertypes.

Results: Of 65 patients recruited, 53 complied with the inclusion criteria. Of those 76%(40/53) have PD-L1 expression of <50% of their cancer cells. Our analysis did not find any association between HLA-I/-II homozygosity and clinical outcome among patients with NSCLC treated with pembrolizumab in combination with chemotherapy. However, the absence of HLA-A01 was associated with favourable PFS (HR=2.09, 95% CI 1.03-4.27, P=0.22) and improved OS (HR=2.58, 95%CI 0.96-6.89, P=0.038). the presence of HLA-B27 was associated with improved PFS (HR=0.24, 95%CI 0.12, P=0.004) but not OS.

Conclusions: The absence of association between genomic HLA-I/-II homozygosity and clinical outcome among patients with advanced NSCLC treated with pembrolizumab in combination with chemotherapy might reflect a diminished role for HLA molecules among patients with low or no PD-L1. HLA-A01 and HLA-B27 might have a role in predicting clinical outcome among this cohort of patients. Further studies are needed to explore biomarkers for this group of patients.

225P Utility of next-generation sequencing (NGS) in patients with advanced cancer in a low-middle income country

M. Lombana Quinonez[1], J.C. Avila Valencia[2], M. Garcia[2], M.A. Ortiz[2], A.M. Torres Paredes[3]

[1]Oncology Department, Clinica de Occidente, Cali, Colombia; [2]Statitics, Clinica de Occidente, Cali, Colombia; [3]Clinical Research, NALT SAS, Cali, Colombia

Background: NGS use improve outcomes in cancer patients. However, approved drugs in differents countries is a concern. The impact in intermediate-low income populations is less studied. We report the results about the utility of NGS at a comprehensive cancer center in Cali, Colombia. Country with less approved drugs by the national regulator (INVIMA) compared to populations such as in Europe (EMA) or United States (FDA).

Methods: Retrospective study of patients with advanced cancer who underwent NGS either by tissue or liquid biopsy, between March 2019 and March 2023 at The Comprehensive Cancer Center Clinica de Occidente in Cali-Colombia. Relevant sociodemographic, clinical, and molecular variables were included. We performed descriptive, Kaplan Meier and cox regression analysis. The study was approved by the institutional ethics committee. The information was analyzed with Stata 16.

Results: 156 patients were identified. Median age was 66 years (20-89), 51% men. 18 different tumors types were included, with lung (39.1%), prostate (22.4%), breast (7.0%), colorectal (6.3), ovarian (5.1%), gastroesophageal (5.0%), between the principals. Actionable alterations (ESCAT I-V) were found in 49.6% of the patients, most were evidence I in 81% of them. 90% had FDA approval, 84% EMA, and 59% national approval by INVIMA. After the NGS result, clinical decision was modified in 46.4% of cases and match therapy was used in 57.5% of them. In those patients, there was better clinical benefit with OR 6 (95% CI 1.31-29.39, P=0.0059) and objective response OR 12 (95% CI 1.88-88.38, P=0.0012) There was significant improvement of PFS HR 0.27 (95% CI 0.13-0.56, P=0.000) and OS HR 0.34 (95% CI 0.15-0.73, P=0.002)

Conclusions: Genomic profiling through NGS had a significant impact on decision-making and patient prognosis, despite the fact that only 59% of the indicated matched drugs had national approval for their use.

Background: Yttrium-90 (Y90)-resin microspheres radioembolization followed by nivolumab (Nivo) has shown encouraging response rate in advanced hepatocellular carcinoma (HCC), but only a subset of patients benefit from it. Predictive biomarkers help to identify patients for the treatment.

Methods: Longitudinal plasma and peripheral blood mononuclear cells (PBMCs) collection from HCC patients who received sequential Y90-RE followed by nivolumab (CA209-678; NCT03033446) allowed assessment of dynamics changes. Predictor selection procedure includes individual timepoint comparison, average analysis, trajectory description, responsiveness prediction, and combined modalities validation. 65-plex Human ProcartaPlex Luminex panel was employed to examine the concentration of cytokines and chemokines in 187 plasma samples collected at eight timepoints (responder [R]=11, non-responder [NR]=22). Immunomonitoring of PBMCs (NR=12, R=5) was assessed with a 39-plex Cytek panel followed by dimension reduction analysis. CXCL9 was reported impacting the immune treatment response, thus we focused on CXCL9+ CD8 cluster. Mixed models were fitted for responsiveness represented by Luminex analytes and CD8 phenotypes. Logistic regression and Cox model were fitted for the association between analytes and treatment response and 3-year overall survival (OS). Biomarkers showed significant association ($P<0.05$) and AUC > 0.7 were selected as the potential predictors.

Results: All Luminex biomarkers showed difference between the R and NR groups 14 days after Y90 treatment ($P<0.05$). The higher increment of IL-18, IL-12p70, and CCL24 after Y90 treatment related to better treatment response and 3-year OS. CXCL9+ and CXCR3+ CD8 clusters differed between R and NR on the 21st and 35th day after Y90-RE, respectively. IL-18 and IL-12p70 were significantly associated with CXCL9+ and CXCR3+ CD8 clusters in the Rs, but not NRs.

Conclusions: IL-18, IL-12p70, and CCL24 were potential predictors for treatment response as well as 3-year OS for HCC patients treated by Y90-Nivo.

227P Biomarkers for novel NK checkpoint inhibitor anti LLT1 antibody, ZM008: Patient transcriptome analysis

M.S. Madhusudhan[1], I. Garcia Ribas[2], M. Ghosh[3], A. Tiwari[3], A. Dubey[3], S. Bhattacharjee[3], Y. Manjunath[3], S. Kashipathi[3], S. Krishna[3], T. Mandal[3], S. Gnanasegaran[3], G. Rodrigues[1]

[1]Biology Bioinformatics and Structure, Indian Institute of Science Education and Research (IISER), Pune, India; [2]Medical, IGR Consultant, Las Rozas, Spain; [3]R&D, Zumutor Biologics, Bangalore, India

Background: C-type lectin superfamily protein LLT1 interacts with CD161 on NK cells and facilitates tumor immune escape. Disruption of LLT1-CD161 with anti LLT1 antibody, ZM008 activates immune cells and kills cancer cells. This study aims to identify new biomarkers to classify specific patient population in ZM008 clinical studies.

Methods: TCGA transcriptome data was used to understand expression of LLT1 in 33 cancers. Correlation analysis was performed to compare LLT1 expression with immune gene signatures. Genomic cancer markers (TMB, MATH, MMR and MSI) status were determined using "Maftools" and "MSI sensor". Univariate Cox proportional hazard regression analysis (SURVIVAL) was used to measure patient survival.

Results: High expression of LLT1 was found in 11 different cancers. CIBERSORT analysis revealed significant immune cell infiltration (activated NK or CD8+ T) in TME. However, LLT1 expression in multiple cancers is negatively correlated with proinflammatory gene signatures (IL-2, IL-6, EOMES, and LAMP1 etc.), positively correlated with immune exhaustion markers PD1, LAG3, TIM3, TIGIT, ICOS and immune suppressive signals (high Treg cells and CD33+ MDSC; $p<0.05$). These data suggest immune suppressive "Cold tumor" phenotype associated with LLT1 expressing cancers. Further, immune check point predictors analysis in LLT1 positive tumors suggests positive correlation with high TMB score in COAD, UCEC and KICH; MSI score is elevated in PRAD and COAD; MMR genes expression is negatively correlated in COAD, KICH, BRCA, HNSC, KIRC, LUAD and PRAD; lastly, MATH score is correlated for GBM patients only ($p<0.05$). Subsequently, significant hazard ratios of 1.115, 2.114 and 1.067 were observed only for COAD, KICH and KIRC, respectively ($p<0.05$).

Conclusions: The transcriptome data analysis revealed LLT1 expression is associated with immune repressive TME in multiple cancers, suggesting therapeutic significance of ZM008. Multiple anti-inflammatory gene signatures could be useful in stratifying patients for ZM008 treatment. In addition, TMB & MSI scores and MMR gene expression could be monitored as potential biomarkers in phase I clinical trials with ZM008.

228P Biomarker discovery via meta-analysis of immunotherapy clinical trials in cancer

B. Haibe-Kains

Princess Margaret Cancer Centre, UHN - University Health Network - Princess Margaret Cancer Center, Toronto, ON, Canada

Background: Clinical profiling studies have shed light on molecular features and mechanisms that modulate response or resistance to immunotherapy but their predictive value remains largely unclear. We (Bareche et al., Annals of Oncology 2022) and others (Litchfield et al., Cell 2021) have recently curated a compendium of public datasets of DNA, RNA and clinical profiles of patients treated with immunotherapy.

Methods: Leveraging our compendium of immunotherapy clinical datasets, we developed, PredictIO, an open-source meta-analysis pipeline to assess the predictive value of molecular predictors. We first used PredictIO to compute the association between immunotherapy response and established biomarkers, such as tumor mutation burden (TNB) or CD8 gene expression, and a collection of 91 molecular signatures curated from the literature. Second, we used PredictIO for de novo RNA signature discovery pipeline to build a new predictor of immunotherapy response.

Results: Using molecular and clinical profiles of ∼3600 patients across 12 tumor types, our meta-analysis pipeline revealed thatTMB and ∼50% of the gene signatures were significantly predictive of immunotherapy response across tumor types, although their predictive value were strongly dependent on specific tumour types. We next developed a de novo gene expression signature from our pan-cancer analysis and demonstrated its superior predictive value over other biomarkers. To identify novel targets, we computed the T-cell dysfunction score for each gene within PredictIO and their ability to predict dual PD-1/CTLA-4 blockade in mice. Two genes, F2RL1 and RBFOX2, were concurrently associated with worse ICB clinical outcomes, T-cell dysfunction in ICB-naive patients and resistance to dual PD-1/CTLA-4 blockade in preclinical models.

Conclusions: Our study highlights the potential of large-scale meta-analyses in identifying novel biomarkers and potential therapeutic targets for cancer immunotherapy. These initial results, while promising, suffer from severe limitations in terms of data availability for specific cancer types and the lack of frameworks to develop and validate multi-omics predictors of immunotherapy response in a collaborative and scalable way.

Background: *FGFRalts* are present in 1%-20% of all cancers. Erda is an oral selective pan-FGFR inhibitor approved to treat locally advanced or metastatic (adv/met) urothelial carcinoma in adults with susceptible *FGFR3/2alt* who have progressed during or after ≥1 line of platinum-based chemotherapy. Interim results of RAGNAR showed tumor agnostic efficacy in patients (pts) with adv/met solid tumors with predefined *FGFRalt* after failure of standard therapies (Loriot et al, ASCO 2022). Here, we evaluated the *FGFR* co-alt landscape and its impact on response to erda treatment (tx) in RAGNAR.

Methods: Archival tumors from pts with adv/met solid tumors were prospectively screened for *FGFR1-4alts* using FoundationOne (FM) or, for those pts enrolled based on local results, retrospectively tested using FM. 217 pts received erda until progression or intolerable toxicity. The impact of co-alts on erda tx was evaluated with respect to objective response rate (ORR) (primary end point) using Fisher exact test, Kaplan-Meier analysis for duration of response (DOR), and Wilcoxon rank-sum test for maximum tumor shrinkage (MTS).

Results: Of 217 pts, 175 (81%) had tumors with pathogenic co-alts, most prevalent in *TP53* (27%), *PIK3CA* (18%), and *CDK2NA* (15%). Co-alts were histology dependent. *TP53* was altered in 75% of esophageal, 75% of ovarian, and 71% of colorectal; *TERT* mutations were seen in 55% of high-grade gliomas. ORR did not show an association between the presence or burden of co-alts (p=0.51). Of the 12 most prevalent co-alts and pathways, none were significantly associated with response vs non-response. Within each histology, individual co-alts were not associated with response. Among responders, *TP53* alt was associated with shorter DOR (HR=0.29 [95% CI, 0.15-0.58]; p=0.002). Further, RTK-RAS pathway co-alts were associated with less MTS (p=0.034).

Conclusions: High prevalence of *FGFR* co-alts reflects the complex genomic landscape of tx-refractory adv/met solid tumors. Despite most pts having histology-specific co-alts, erda showed clinical activity in these pts, supporting *FGFRalts* as oncogenic drivers in these tumors.

Clinical trial identification: NCT04083976.

231P Time to deterioration of quality of life as a surrogate of OS: A trial-level surrogacy analysis

A. Shahnam[1], U. Nindra[2], J. Desai[1], R. Hui[3], A.M. Hopkins[4], M. Sorich[5]

[1]Medical Oncology, Peter MacCallum Cancer Centre, Melbourne, VIC, Australia; [2]Medical Oncology Department, Liverpool Cancer Therapy Centre, Liverpool, NSW, Australia; [3]The Centre of Cancer Medicine, University Hong Kong, Hong Kong, China; [4]Clinical Pharmacology Department, Flinders Medical Centre, Adelaide, SA, Australia; [5]College of Medicine and Public Health, Flinders University, Adelaide, SA, Australia

Background: Overall survival (OS) is the optimal marker of efficacy for evaluation of treatments in randomized clinical trials (RCTs) but can take a considerable amount of time to mature. Evaluation of changes in tumor size through objective response rate (ORR) and progression free survival (PFS) has served as an early surrogate of OS however they are imperfect. Time to deterioration (TTD) in quality of life (QoL) measures could act as an early alternative patient centered surrogate of OS.

Methods: We utilised published phase 3 RCTs in solid malignancies that reported OS, PFS, ORR, and time to deterioration (TTD) evaluations of overall QoL or physical function (PF) published between 1st of January 2010 and 30th of June 2022. Weighted regression analysis was utilised to assess the relationship between PFS, ORR ratio, TTD QoL and TTD PF with OS. The coefficient of determination (R^2) was used to quantify surrogacy.

Results: After identifying 9109 publications, 138 studies with 86199 patients were included for analysis. 47 RCT involved immunotherapy (IO) whilst 91 investigated non-IO agents. PFS (R^2= 0.19) and ORR (R^2= 0.05) were poor surrogates of OS. TTD QoL and TTD PF was available in 137 and 75 RCTs respectively. In the respected subset of studies, TTD QoL (TTD QoL R^2= 0.18 vs. PFS R^2= 0.19) and TTD PF (TTD PF R^2= 0.10 vs PFS R^2= 0.09) performed similarly to PFS as surrogates of OS. However, for IO agents, TTD PF (R^2= 0.38) had a higher surrogacy to OS compared to PFS (R^2= 0.19). Furthermore, combining PFS and TTD PF enabled improved prediction of OS (R^2= 0.57). Importantly, TTD PF and PFS were not correlated with each other (R^2= 0). TTD PF was not a surrogate endpoint of OS for non-IO trials.

Conclusions: Our trial level analysis identified TTD in PF as a potential marker of early OS in trials that utilized IO agents. It could potentially be used in conjunction with PFS to improve surrogacy in specific tumor types. Our results are based on published results and should be validated using patient-level data.

Background: In recent years, the use of Next Generation Sequencing based gene panels for the management of solid tumours has become almost routine testing in many Cancer Genomics Laboratories. In most cases, the purpose of the analysis is to identify biomarkers with potential predictive value. However, the mutations identified in the tissue may also have a hereditary origin. The objective of this study was to analyse the pathogenic germline variants identified as a somatic secondary finding in genes that have not been established to confer an increased risk for this specific tumour ('off-tumour').

Methods: A retrospective analysis was carried out on 330 patients in whom a tumour genomic analysis (somatic testing) had been performed in our institution between February 2022 and 2023. The genomic analysis tool was *Oncomine™Comprehensive Assay* in all cases (500 gene panel). Germline-focused analysis was performed to variants with a variant allele frequency >30% (or >20% if small insertions/deletions) in genes consistent with hereditary predisposition to cancer.

Results: In the solid biopsies from 330 patients studied, 58 pathogenic variants of potential germline origin were identified in 54 patients (16.3%). In 23 of these patients (42.5%) the pathogenic variant was an 'off-tumour' finding. The median age at diagnosis of these 23 patients was 56 years-old, 21 patients (91.3%) had a metastatic or recurrent tumour and 11 (47.8%) did not meet any criteria of inherited predisposition to cancer. The results of the germline study are available in 10 of these 23 patients and the germline pathogenic variant was confirmed in 7 cases (70%): 4 *BRCA1*, 1 *ATM*, 1 *MUTYH* and 1 *PMS2*. The most frequent related tumour was lung cancer, in 3 cases.

Conclusions: In our series of 330 cases tested for tumour genomics, 23 patients harboured an "off-tumour" pathogenic variant with potential germline origin, that was confirmed in 7 out of 10 patients. Detected germline mutations included high penetrance cancer predisposing genes as *BRCA1*. This detection rate reflects the clinical utility, for patients and their families, of using the somatic genomic analysis as a source of information about a potential hereditary cancer predisposition syndrome.

Gregorio Marañon, Hospital General Universitario Gregorio Maranon, Madrid, Spain; [7]General Surgery Service, Hospital General Universitario Gregorio Marañón. Gregorio Marañon, Hospital General Universitario Gregorio Maranon, Madrid, Spain; [8]Genomics Unit, Hospital General Universitario Gregorio Marañón, Instituto de Investigación Sanitaria Gregorio Marañón, Madrid, Spain; [9]Medical Oncology Service, Hospital General Universitario Gregorio Marañón, Instituto de Investigación Sanitaria Gregorio Marañón, CIBERONC, Hospital General Universitario Gregorio Marañón, Madrid, Spain

Background: Performing rapid genetic testing before consultation in a Hereditary Cancer Unit (HCU) is becoming increasingly common due to its importance in the decision-making of cancer management. There are few studies analyzing this new genetic counseling approach.

Methods: We conducted a retrospective descriptive study in a cohort of patients (pts) who underwent germinal genetic testing during their treatment plan at Hospital Gregorio Marañon since April 2019 to November 2022. Tests were directly ordered by their oncologists with a brief pre-test counseling prior to the formal evaluation in the HCU. Primary objective was to analyze if having these results available prior to formal genetic counseling could impact in the management of the patient's cancer.

Results: 225 pts (32.9% men, 67.1% women) underwent genetic test. Cancer diagnoses were: pancreatic (49.3%), breast (40.4%), ovarian (5.8%), colorectal (2.6%), gastric (2.6%), prostate (1.3%), cholangiocarcinoma (1.3%), renal (1.3%) and endometrial 0.9%. A specific-syndrome genetic panel was performed in 55.1%, multigenetic in 44% and single gene in 0.9%. We found pathogenic/likely pathogenic variants (PV/LPV) in 31 pts (13.8%) and variants of unknown significance (VUS) in 53 (23.5%). 22.6% of the pts with PV/LPV (n=7) didn't meet the Spanish Society for Medical Oncology (SEOM) criteria for hereditary cancer. 40% of the pts (n=90) didnt receive post-test counseling in the HCU: 81.1% due to negative result and non-significant familial background, 10% due to patient's death, 4.4% did not attend the appointment (rest unknown). According to retrospective chart review in 32.3% with PV/LPV (n=10; 4.4% of the total) a change in cancer management was decided (Table).

Table: 233P

Pts with PV/LPV (n=31)		n (%)
Changes in cancer management*	Bilateral mastectomy	8 (25.8%)
	Avoid radiotherapy	1 (3.2%)
	PARP inhibitors	1 (3.2%)
	Platinum-based chemotherapy	2 (6.4%)
	None (due to death)	(22.6%)

*One patient could have more than one change

Conclusions: Genetic testing performance can modify the therapeutic plan of pts with cancer, especially for those with PV/LPV. Rapidity in obtaining the results is essential. The balance between this rapidity and a proper post-test genetic counseling needs to be warranted.

Background: Hamlet.rt (Heuristics, Algorithms and Machine Learning: Evaluation & Testing in Radiation Therapy) is a multi-centre study exploring the role of machine learning in predicting response and toxicity in patients receiving radical radiotherapy for non-small cell lung cancer (NSCLC), Head and Neck Cancer (H&N Cancer) and Prostate cancer. Hamlet.rt Trans is a translational sub-study that leverages the infrastructure of Cancer Research UK RadNet Cambridge to evaluate multiple liquid biomarkers of radiation response. This study aims to investigate biomarkers of treatment response in patients with lung and head and neck cancers and markers of treatment toxicity in patients with prostate cancer.

Trial design: HAMLET.trans is a translational biosampling study of patients undergoing radical radiotherapy for NSCLC, H&N cancer or prostate cancer. Venous samples for ctDNA analysis and senescence-related profiling are collected together with dried blood spot samples before chemotherapy and radiotherapy at multiple time points during radiotherapy and post-treatment. Urine is collected from patients with prostate cancer. Patients are completing toxicity questionnaires during and after radiotherapy. Delivery dose per fraction is assessed based on imaging just before radiotherapy delivery. The trial aims to recruit at least 20 patients per arm. Patient samples are analysed for tumor-specific mutation, methylation profiling of cfDNA as well as cytokine assays to establish markers or response and toxicity and identify optimal sample timings for future studies. Blood spots are analysed for ctDNA tumour content to establish a less invasive way of frequent sampling on therapy. The results of HAMLET.trans will inform ongoing translational work.

Clinical trial identification: NCT04060706.

[1]Department of Thoracic Oncology, National Cancer Center Hospital East, Kashiwa, Japan; [2]Department of Thoracic Surgery, National Cancer Center Hospital East, Kashiwa, Japan; [3]Department of Thoracic Oncology, Osaka International Cancer Institute, Osaka, Japan; [4]Department of Medical Oncology, Japanese Red Cross Medical Center, Tokyo, Japan; [5]Department of Respiratory Medicine, Faculty of Medicine Hokkaido University, Sapporo, Japan; [6]Department of Thoracic Oncology, National Hospital Organization Kyushu Cancer Center, Fukuoka, Japan; [7]Division of Respiratory Medicine, Department of Internal Medicine, Kobe University Graduate School of Medicine, Kobe, Japan; [8]Pulmonary Medicine and Clinical Immunology Department, Dokkyo Medical University, Mibu, Japan

Background: MRD is a potential biomarker for predicting disease relapse or therapeutic response for lung cancer, and it is expected to establish a precise detection system by liquid biopsy. We have been conducting a prospective observational study to evaluate the clinical utility of MRD detection in lung cancer (LC-SCRUM-MRD) since August 2022, in parallel with a multicenter prospective genomic screening project in Japan (LC-SCRUM-Advantage).

Trial design: The main inclusion criteria are pathologically diagnosed treatment-naive lung cancer, 16 years of age or older, performance status 0-1, and normal organ function. A total of 10,680 patients in LC-SCRUM-Advantage/MRD will be enrolled over five years and assigned to one of six cohorts (A1 to B2) according to their histology, stage, and treatment (Table). In the MRD monitoring cohorts A2-B2 of 680 patients, we will analyze MRD every 1-6 months for up to 2 years, and computed tomography scans and serum tumor markers measurement will be performed at each time point. As for MRD analysis, we will perform tissue-based MRD detection systems that require sequencing of tumor tissue to create personalized plasma circulating tumor DNA (ctDNA) assay and liquid-based MRD detection systems that analyze plasma ctDNA by methylation profiling or urinary exosomal microRNA. The

performance of these liquid-based MRD detection systems will be compared with tissue-based MRD detection systems to establish the optimal MRD detection system for lung cancer. As of April 2023, a total of 154 patients have been enrolled in LC-SCRUM-MRD across 40 institutions, and preliminary results will be presented at this meeting.

Table: 236TiP LC-SCRUM-Advantage/MRD

Cohort	Histology	Stage	Treatment	Genomic screening	MRD monitoring	Sample size
A1	NSCLC	I-III	Surgery	○	-	9800
A2				○	○	200
A3		III	Chemoradiotherapy	-	○	100
A4		III/IV	Chemotherapy	-	○	150
B1	SCLC	LD	Chemoradiotherapy	-	○	30
B2		ED	Chemotherapy	-	○	200

Background: An integrated precision oncology approach that can guide the selection of personalized therapy is paramount to achieving improved outcomes in patients while maintaining responsible healthcare economics. Actionable precision oncology requires *in vitro* diagnostic tests that are sufficiently sensitive, accurate, reproducible, and reliable in the real-world setting with minimal risk of patient overtreatment or undertreatment. Liquid biopsies and specifically ctDNA based diagnostics provide a unique opportunity to optimize clinical decisions and thereby improve individual patient care. Such techniques could be particularly valuable in the adjuvant setting where multi-modal therapy (MMT) has curative potential. Multiple studies provide evidence that serial ctDNA monitoring can predict or detect recurrence earlier than conventional surveillance. However, as highlighted in the most recent ESMO ctDNA recommendations, the detection limit of current diagnostics to accurately report ctDNA fragments in peripheral blood remains a challenge. Importantly, it is currently unclear how to incorporate ctDNA as MRD biomarker or as a decision tool for treatment selection to improve cancer outcomes. GUIDE.MRD, a patient-centered precision oncology public-private partnership under the Innovative Health Initiative umbrella, is designed to improve the utility and clinical implementation of ctDNA as MRD biomarker and to evaluate the potential of novel decision tools to match patients to MMTs.

Trial design: Partners from academic, medical technology, pharmaceutical and patient advocacy sectors will join to (a) benchmark available ctDNA assays for sensitivity, specificity, and predictive value using reference material that closely mimic patient samples in the adjuvant setting, (b) to clinically validate the top performing ctDNA assay characteristics in patients with NSCLC, CRC and PDAC and develop patient-centric clinical implementation roadmaps, and (c) determine the utility of ctDNA assays as a prospective decision tool of clinical response and choice of MMT including novel combinations.

ESMO GOOD SCIENCE BETTER MEDICINE BEST PRACTICE

ANNALS OF ONCOLOGY driving innovation in oncology

BREAST CANCER, EARLY STAGE

238MO Long-term residential and workplace exposure to air pollution and breast cancer risk: A case-control study nested in the French E3N cohort from 1990 to 2011

B. Fervers[1], M. Duboeuf[1], A. Amadou[1], T. Coudon[1], L. Grassot[1], E. Faure[2], G. Severi[2], F. Mancini[2], P. Salizzoni[3], J. Gulliver[4], D. Praud[1]

[1]Cancer and Environment Department, Centre Léon Bérard, Lyon, France; [2]Exposome, Hérédité, Cancer et Santé INSERM 1018, Gustave Roussy, Villejuif, France; [3]Mécanique des Fluides, Ecole Centrale, Ecully, France; [4]Centre for Environmental Health and Sustainability, University of Leicester, Leicester, UK

Background: Air pollution, classified as carcinogenic to humans, is a major public health concern. Studies on breast cancer are scarce and remain inconsistent. We studied the association between breast cancer risk and long-term exposure to particulate matters ($PM_{2.5}$, PM_{10}) and nitrogen dioxide (NO_2) estimated at the womens' residential and workplace addresses.

Methods: We conducted a case-control study of 2419 cases and 2984 individually matched controls nested in the French prospective E3N cohort, over the period 1990-2011. Controls were matched to cases on department of residence, age (±1 year); date (±3 months), and menopausal status at blood collection. Annual mean $PM_{2.5}$, PM_{10} and NO_2 concentration levels were estimated using a Land Use Regression (LUR) model (resolution 50m x 50m) and were assigned to women based on their geocoded residential and workplace addresses. The mean exposure was calculated for each woman from their inclusion into the E3N cohort to their index date (date of diagnosis of cases). Odds ratios (OR) and 95% confidence intervals (CI) were estimated using multivariate logistic regression models, for a 10 µg/m^3 increase in $PM_{2.5}$, PM_{10} and NO_2. Adjustment variables were selected from the literature, using a directed acyclic graph.

Results: The results showed a statistically significant linear increase in breast cancer risk related to mean exposure to $PM_{2.5}$ (adjusted OR 1.28; CI 1.00−1.63, for an increment of 10 µg/m^3). A numerically increased risk was observed for PM_{10} (adjusted OR1.09; CI 0.92−1.30) and NO_2 (adjusted OR 1.05; CI 0.97−1.13) for an increment of 10 µg/m^3. No effect modification by menopausal status was observed (p interaction 0.99, 0.90, and 0.86 respectively for $PM_{2.5}PM_{10}$ and NO_2). Analyses by hormone receptor status showed a positive but not significant association for $PM_{2.5}$ for oestrogen receptor positive (ER+) breast cancer cases (adjusted OR 1.32; CI 0.97−1.79).

Conclusions: To our knowledge, this study is the first to investigate breast cancer risk associated with long term air pollution exposure at both, the subjects' residence and workplace, estimated using a very fine spatial resolution LUR model. Future studies should consider exposure during commuting.

239MO Impact of body mass index and its change on survival outcomes in patients with early breast cancer: A pooled analysis of individual-level data from BCIRG-001 and BCIRG-005 trials

H. Chen[1], X. Qian[2], Y. Tao[3], D. Wang[4], Y. Wang[1], Y. Yu[1], H. Yao[1]

[1]Breast Tumor Centre, Department of Medical Oncology, Phase I Clinical Trial Centre, Guangdong Provincial Key Laboratory of Malignant Tumor Epigenetics and Gene Regulation, Sun Yat-Sen Memorial Hospital, Sun Yat-Sen University, Guangzhou, China; [2]Department of Oncology, Henan Provincial People's Hospital, People's Hospital of Zhengzhou University, People's Hospital of Henan University, Zhengzhou, China; [3]Department of Oncology, The Affiliated Hospital of Xuzhou Medical University, Xuzhou, China; [4]Department of Radiation Oncology, State Key Laboratory of Oncology in South China, Collaborative Innovation Center for Cancer Medicine, Sun Yat-Sen University Cancer Center, Guangzhou, China

Background: The relationships between body mass index (BMI) and survival outcomes are complex, and have not been thoroughly investigated in breast cancer patients who received adjuvant chemotherapy.

Methods: We collected data on 2394 patients from two randomized, phase III clinical trials that investigated adjuvant chemotherapy in breast cancer identified in Project Data Sphere. The objective was to examine the effect of baseline BMI, BMI after adjuvant chemotherapy, and BMI change from baseline to post-adjuvant chemotherapy on disease-free survival (DFS) and overall survival (OS). Restricted cubic splines, adjusting for confounding factors, were used to examine potential non-linear associations between continuous BMI value and survival. Stratified analyses involved chemotherapy regimens used.

Results: On multivariate analysis, severe obesity (BMI≥40.0 kg/m^2) at baseline was independently associated with worse DFS (HR=1.48, 95%CI 1.02-2.16, *P*=0.04) and OS (HR=1.79, 95%CI 1.17-2.74, *P*=0.007) compared with underweight/normal weight (BMI≤24.9 kg/m^2). A BMI loss >10% was also an independent prognostic factor for adverse OS (HR=2.14, 95%CI 1.17-3.93, *P*=0.014). When stratified by chemotherapy regimens, the multivariate analysis revealed that severe obesity adversely affected DFS (HR=2.38, 95%CI 1.26-4.34, *P*=0.007) and OS (HR=2.90, 95%CI 1.46-5.76, *P*=0.002) in the docetaxel-based group, but not in the non-docetaxel-based group. Restricted cubic splines revealed a "J-shaped" association of baseline BMI with risk of recurrence (*P* for non-linearity=0.111) or all-cause death (*P* for non-linearity=0.008), and this relationship was more pronounced in the docetaxel-based group (DFS: *P* for non-linearity=0.011; OS: *P* for non-linearity <0.001).

Conclusions: In early breast cancer patients treated with adjuvant chemotherapy, baseline severe obesity was lined to worse DFS and OS, while a BMI loss over 10% from baseline to post-adjuvant chemotherapy also negatively affected OS. Moreover, the prognostic role of BMI might differ between docetaxel-based and non-docetaxel-based groups.

240MO Prognostic and predictive impact of estrogen/progesterone receptor (ER/PR), and Ki-67 expression: An exploratory analysis from the monarchE trial in patients with high-risk, HR+, HER2-, early breast cancer (EBC)

M.P. Goetz[1], N. Turner[2], H. Sasano[3], C. Arteaga[4], S. Chandarlapaty[5], S. Loi[6], J.S. Reis-Filho[5], H. Kreipe[7], N. Harbeck[8], P. Fasching[9], C.S. Rubenstein[10], S. Wijayawardana[10], M. Muñoz[10], L.M. Litchfield[10], S.R.D. Johnston[2]

[1]Department of Oncology, Mayo Clinic, Rochester, NY, USA; [2]Department of Medicine-Breast Unit, Royal Marsden NHS Foundation Trust & Institute of Cancer Research, London, UK; [3]Department of Pathology, Tohoku University Hospital, Sendai, Japan; [4]Simmons Comprehensive Cancer Center, University of Texas Southwestern Medical Center, Dallas, TX, USA; [5]Department of Pathology and Laboratory Medicine, Memorial Sloan Kettering Cancer Center, New York, NY, USA; [6]Division of Research and Clinical Medicine, Peter MacCallum Cancer Centre, Melbourne, VIC, Australia; [7]Institute of Pathology, Hannover Medical School, Hannover, Germany; [8]Breast Center, Department of Gynecology and Obstetrics, Comprehensive Cancer Center Munich, Ludwig Maximilians University Hospital, Munich, Germany; [9]Department of Gynecology and Obstetrics, Universitätsklinikum Erlangen, Erlangen, Germany; [10]Oncology, Eli Lilly and Company, Indianapolis, IN, USA

Background: The monarchE trial demonstrated that the addition of abemaciclib to endocrine therapy (ET) significantly improved invasive disease-free survival (IDFS) and distant relapse-free survival in node-positive, high-risk EBC patients (pts) with benefit deepening beyond the 2-year (yr) treatment (tx) period. Ki-67 ≥20% was prognostic of breast cancer outcomes but not predictive of abemaciclib benefit. Here, we evaluate expression of ER, PR and Ki-67 to determine their prognostic and predictive impact, including analyses as continuous variables.

Methods: ER/PR and Ki-67 expression was determined by immunohistochemistry (IHC). The graphical Subpopulation (subp) Tx Effect Pattern Plot (STEPP) analysis was conducted for each biomarker to robustly assess the tx effect ensuring a balance between subp sample size and enough number of overlapping subp. Cox proportional hazards model was used to estimate hazard ratios (HR) and 95% confidence intervals (CI) for ER/PR status subtypes (positive ≥1%).

Results: Each IHC cohort varied slightly in number of pts and the precise IDFS HR point estimate (abemacilib+ET vs ET), but STEPP analysis revealed consistent abemaciclib tx benefit regardless of ER, PR or Ki-67 expression (Table, A). The IDFS benefit of abemaciclib was also consistent in ER+/PR+ and ER+/PR- tumors (Table, B). The 3-yr IDFS rates of the control arm showed that pts with PR- tumors had a higher risk of recurrence. Pts with ER- tumors followed a similar trend, but the effect could not be robustly estimated due to small numbers..

Conclusions: Consistent IDFS benefit of adjuvant abemaciclib was observed regardless of the level of ER, PR or Ki-67 expression, as well as in ER+/PR+ and ER+/PR- tumors. Similar to Ki-67 ≥20%, PR- status was prognostic of worse outcomes with ET alone.

Table: 240MO Summary of STEPP and IDFS analysis

A. Summary statistics for the deviation of the STEPP Subp, HRs from the overall Tx effect

	Overall IDFS HR	Median of the STEPP HRs (IQR)
ER (n=4520)	0.74	0.75 (0.69 – 0.87)
PR (n=4012)	0.78	0.71 (0.64 – 0.78)
Ki-67 (n=4425)	0.65	0.65 (0.55 – 0.76)

B. IDFS in ER/PR Subtypes

	Abemaciclib+ET			ET			HR (95% CI)	Interaction p-value
	n	events	3-yr rate	n	events	3-yr rate		
ER+/PR+	2405	275	89.9%	2437	392	85.9%	0.698 (0.599, 0.815)	0.2531
ER+/PR-	298	50	83.2%	295	86	73.0%	0.560 (0.395, 0.794)	
ER-/PR+	16	5	NE*	17	8	NE*	NE*	NE*

IQR, Interquartile range. *Not estimated (NE) due to low numbers

Clinical trial identification: NCT03155997.

241MO Patient characteristics and real-world outcomes in HER2 negative/ ER zero and ER low patients treated as triple-negative breast cancer in Sweden 2008-2020

I. Fredriksson[1], B. Acs[2], J. Hartman[2], D. Sönmez[3], H. Lindman[4]

[1]Department of Molecular Medicine and Surgery, Karolinska Institutet & Karolinska University Hospital, Comprehensive Cancer Center, Stockholm, Sweden; [2]Department of Oncology-Pathology & Department of Clinical Pathology and Cancer Diagnostics, Karolinska Institutet & Karolinska University Hospital, Comprehensive Cancer Center, Stockholm, Sweden; [3]Oncology Department, MSD - Merck Sharp & Dohme (Sweden) AB, Stockholm, Sweden; [4]Oncology, University Hospital Uppsala/Akademiska Sjukhuset, Uppsala, Sweden

Background: Estrogen receptor-low (ER-low) Her2-negative breast cancer has similar pathological and molecular characteristics as triple-negative breast cancer (TNBC), and it is questionable whether it should be considered a separate entity. When the international guidelines lowered the cutoffs for ER to ≥1% in 2010, the ≥10% threshold was kept in Sweden. ER-low breast cancer (ER 1-9%) has thus in Sweden been treated as TNBC, which is interesting now that the international community recognize limited data for benefit of endocrine therapy in the ER-low group The benefit of endocrine therapy in these tumors is under debate and discussion. We aimed to describe real-world patient and tumor characteristics, treatment patterns and overall survival in a Swedish population-based cohort of patients with HER2 negative/ ER zero and ER low breast cancer treated as TNBC.

Methods: TNBC cases diagnosed in Sweden 2008-2020 were included in a population-based cohort study. Patient, tumour and treatment characteristics were analysed by ER status (ER-negative 0% vs ER-low 1-9%), and associations between subgroups compared using χ^2 test. Endpoints were overall survival (OS) and distant disease-free survival (DDFS). Kaplan-Meier curves were used to describe time-to-event endpoints and Cox proportional hazards models to estimate adjusted hazard ratios.

Results: Of the 5657 tumors, 90.1% were ER-negative and 9.9% ER-low. In the unadjusted analysis of OS, ER-low disease was associated with a borderline significantly better OS than ER-negative disease (n=3893, HR 0.83 (0.70-1.001), p=0.051), but this was restricted to patients not given chemotherapy (n=1764, HR 0.65 (0.50-0.88), p=0.002). ER-status 0% vs 1-9% did not affect OS in the multivariable analysis (HR 1.09, 95% CI 0.89-1.34). DDFS did not differ by ER-status 0% vs 1-9% (n=1299, HR 0.97 for ER-negative vs ER-low (0.62-1.53)). After preoperative treatment, the importance of pCR for OS did not significantly differ between ER-negative or ER-low disease.

Conclusions: ER-low breast cancer has characteristics and prognosis similar to ER-negative breast cancer when treated as TNBC. The use of ≥10% as threshold for ER positivity is supported by this study.

Background: Oncotype DX represents one of the genomic assays associated with the highest quality of evidence driving a strong recommendation for its use to guide decisions on adjuvant therapy for HR+/HER2- early BC patients. The clinical value of TILs in HR+/HER2- BC may be unearthed by focusing on patients whose tumors exhibit features of higher biological aggressiveness. Here we deepen and describe the correlation between RS and TILs, proposing an immuno-genomic model for HR+/HER2- BC.

Methods: We enrolled T1-T3, N0-N1 BC patients with available RS and TILs in the context of four multicenter, prospective studies primarily aimed at assessing the impact of the Oncotype DX® test on adjuvant treatment decisions in a clinical practice scenario. RS was categorized into: 0-10 (low risk), 11-25 (intermediate risk) and 26-100 (high risk); TILs were categorized into: low (0-10%), intermediate (11-59%) and high (60-100%).

Results: 811 patients were included. RS distribution was (n=810): low risk 22.0%, intermediate risk 61.2%, high risk 16.8%. TIL distribution was (n=455): low TILs 84.6%, intermediate TILs 13.6% and high TILs 1.8%. A significant, weak positive, linear correlation was found between continuous TILs and RS (Pearson coefficient=0.223, $p<0.001$). When considering RS and TILs categories, tumors with intermediate/high TIL levels significantly enriched the high RS subgroup ($p=0.006$). This was confirmed both within Luminal A (Ki67<20% and PgR ≥20%) and Luminal B cohorts (ki67≥20% and/or PgR <20%). Among high-RS patients, 16.7% of Luminal A and 26.7% of Luminal B tumors had intermediate/high TILs.

Conclusions: We observed that RS and TILs capture only slightly overlapping information on the biology of HR+/HER2- tumor microenvironment. We demonstrated the feasibility of combining RS and TILs into a composite immuno-genomic model, which may identify patients simultaneously showing features of high biological/clinical risk and enhanced immunogenicity and may serve the purpose of guiding and focalizing patient selection in the further development of immunotherapy strategies for Luminal-like disease.

Background: Neoadjuvant systemic therapy (NST) for triple-negative breast cancer (TNBC) and HER2+ breast cancer (HER2+BC) yields a pathol-ogic complete response (pCR) in approximately 60% of patients. A pCR to NST predicts an excellent prognosis and can be accurately determined by percutaneous image-guided vacuum-assisted core biopsy (VACB). Radiotherapy alone, without breast surgery after NST among patients who had a VACB−determined pCR was evaluated in the feasibility phase (Johnson et al. *JACS* 2023), 2-year pre-planned primary outcome (Kuerer et al *Lancet Onc* 2022), the 32.4 mo patient reported outcomes (Johnson et al SSO 2023) and now at the preplanned 3-year primary endpoint.

Methods: This multicentre phase II clinical trial enrolled women aged ≥40 years with unicentric cT1-2N0-1M0 TNBC or HER2+BC and a residual breast lesion <2 cm on imaging after NST. One biopsy was obtained by 9G image-guided VACB containing a minimum of 12 cores from the tumour bed. If no invasive/in situ disease was identified, breast surgery was omitted, and patients underwent whole-breast radiotherapy/boost. Primary outcome was ipsilateral breast tumour recurrence (IBTR) rate and secondary outcomes included evaluation of baseline and longitudinal obtained circulating tumor cells (CTCs) in a total of 33 blood samples and patient-reported outcomes.

Results: During 2017-2021 50 total patients were enrolled and underwent VACB following NST. The mean age was 60·4 years (SD 7·8); 21 patients had TNBC and 29 had HER2+BC. Mean imaging final tumour size after NST was 0·90 cm (SD 0·81), and 17 patients (34%) had a complete radiologic response. VACB identified a pCR in 31 patients (62%). Among these 31 patients, median follow-up was 38.4 months (IQR: 22.4-49·5) the 3-year IBTR rate was 0% (primary endpoint) and 3-year DFS and OS rates were 100%. Two patients were CTC-positive at baseline, 2 were positive at 6-months, and 1 at 12-months. No patients had CTCs detected at more than one timepoint.

Conclusions: Eliminating breast surgery in highly selected patients with an image-guided VACB−determined pCR following NST shows promising 3-year results and additional time and clinical trials evaluating this approach are indicated.

Clinical trial identification: NCT02945579; 20-1-2017 release date.

244MO A phase II trial targeting disseminated dormant tumor cells with hydroxychloroquine, everolimus or the combination to prevent recurrent breast cancer ("CLEVER")

A. DeMichele[1], A.S. Clark[1], L. Bayne[1], K. Rohn[1], I. Nivar[1], P. Wileyto[2], L. Berry[3], S. DeLuca[1], J. Savage[4], I. Makhlin[1], T.C. Pan[5], J. Graves[5], G. Belka[5], J. Wang[5], N. Shih[6], D. Berry[3], A. Nayak[6], M. Feldman[7], L. Chodosh[5]

[1]Department of Hematology-Oncology, University of Pennsylvania, Philadelphia, PA, USA; [2]Department of Biostatistics, Epidemiology and Informatics, University of Pennsylvania, Philadelphia, PA, USA; [3]Clinical Trials, Berry Consultants, Austin, TX, USA; [4]Abramson Cancer Center, University of Pennsylvania, Philadelphia, PA, USA; [5]Department of Cancer Biology, University of Pennsylvania, Philadelphia, PA, USA; [6]Department of Pathology, University of Pennsylvania, Philadelphia, PA, USA; [7]Department of Pathology, Indiana University, Indianapolis, IN, USA

Background: Breast cancer (BC) recurrence may follow a dormant phase in which quiescent cells reside in niches such as bone marrow (BM). Dormant BM disseminated tumor cells (DTCs) are independently associated with BC recurrence/death. We investigated whether targeting dormancy through autophagy inhibition (hydroxychloroquine (HCQ), and/or mTOR signaling (everolimus (EVE) in DTC+ BC survivors was feasible, reduced DTCs and/or prevented recurrence.

Methods: The CLEVER trial (NCT03032406) is a randomized, phase II trial in patients (pts) diagnosed within 5 years, with positive nodes, triple-negative disease, high-risk Oncotype/Mammaprint, and/or residual disease post-neoadjuvant therapy who completed all treatment except endocrine therapy. DTCs were detected in BM aspirate (BMA) by IHC with pan-CK antibody AE1/AE3. DTC+ pts were randomized to six 28-day cycles (C) of HCQ (600 mg BID), EVE (10 mg daily) or both (+/- 3-month (m0) observation period). If DTC+ persisted after C6, pts received another 6C HCQ+EVE. DTC assessment was done after C3, C6, C12 (if applicable) and 6-mo after end of treatment. Adverse events (AE) were assessed by CTCAEv4. Primary endpoint was feasibility, defined as >75% completion of C6C without G3/G4 AE. Secondary endpoints were safety, DTC response rate (RR) and 3-year RFS. DTC RR was analyzed with Bayesian Poisson regression models.

Results: 184/197 eligible pts had baseline BMA, 55 (30%) were DTC+, 53 were randomized: HCQ (n=15), EVE (n=15), and HCQ+EVE (n=23). 13 patients had repeat after 3-mo observation. Feasibility endpoint was met. There were no G4/5 toxicities. At a median follow up of 42 mo (range 7-60), 1 pt recurred in lung (after 2 cycles EVE), 1 pt developed new contralateral breast cancer. The posterior probabilities that HCQ, EVE, and HCQ+EVE reduced DTCs by at least 80% after C3 vs observation alone are 99.1%, 98.2%, and 99.9%, respectively.

Conclusions: The CLEVER trial provides proof-of-principle that therapeutic targeting of dormant BC is feasible and active in eliminating DTCs by targeting dormancy-specific mechanisms. Follow up for recurrence and survival is ongoing.

Clinical trial identification: NCT03032406.

Background: Dual HER2-blockade with trastuzumab (T) and pertuzumab (P) plus docetaxel as neoadjuvant therapy showed an improved pathological complete response (pCR) rate and was approved by the FDA and EMA for early HER2-positive breast cancer. QL1209 is a biosimilar of the originator P (Perjeta, Roche). Here we present the results of the phase 3 study comparing the efficacy, safety, immunogenicity of QL1209 with P in the neoadjuvant setting for early HER2-positive breast cancer.

Methods: Eligible patients (pts) had HER2-positive, early (T2-3, N0-1, M0) or locally advanced (T2—3, N2—3,M0 or T4, any N, M0), ER(-) and PR(-) breast cancer with primary tumor larger than 2cm in diameter, and had not received any previous anticancer therapy. Pts were randomly assigned (1:1, stratified by disease stage) to receive neoadjuvant treatment of QL1209 or P (loading dose 840 mg at cycle 1, followed by 420 mg from cycles 2 to 4) plus T and docetaxel once every 3 weeks for 4 cycles. The primary endpoint was tpCR by IRC. Secondary endpoints included tpCR by investigator (INV), bpCR by IRC, bpCR by INV, ORR, safety, immunogenicity etc.

Results: 517 pts were enrolled (52 sites in China) and 516 pts (QL1209/P: n=257/259) received neoadjuvant treatment, of whom 482 (93.2%) underwent surgery (QL1209: 238; P: 244). tpCR (by IRC) was observed in 109 (42.7%) pts with QL1209 and 117 (45.2%) pts with P; ratio of tpCR (QL1209:P) 0.946 (90% CI: 0.8-1.11), p=0.014. Incidences of TEAEs and Gr≥3 TEAEs: (QL1209 vs P) (94.6% vs 96.1%; Gr≥3, 31.9% vs 34.7%). TRAEs: 77.4% vs 78%. Incidences of ADA and Nab were similar between 2 groups (2.3% vs 3.1%; 0.8% vs 0.8%).

Table: 245P

	QL1209 (n=257)	P (n=259)
Overall, n (%)		
No of pts	255*	259
tpCR by INV	108 (42.4)	120 (46.3)
bpCR by IRC	128/256 (50.0)	134 (51.7)
bpCR by INV	124 (48.6)	133 (51.4)
ORR by INV, n (%)	211/257 (82.1)	212/259 (81.9)

*IRC didn't receive the complete specimens for 2 patients

Conclusions: QL1209 demonstrated equivalence to P in efficacy and showed comparable safety profile and immunogenicity in patients with early or locally advanced HER2-positive breast cancer.

Clinical trial identification: NCT04629846.

246P Phase II study of anlotinib combined with taxanes and lobaplatin in the neoadjuvant treatment of triple-negative breast cancer: Efficacy, safety and biomarker analysis from the neoALTAL trial

X. Qi[1], Y. Liang[2], J. Liu[2], Q. Shi[2], K. Zhu[3], J. Jiang[2], Y. Zhang[2]

[1]Breast Surgery, Southwest Hospital, Third Military Medical University (Army Medical University), Chongqing, China; [2]Department of Breast and Thyroid Surgery, Southwest Hospital, Third Military Medical University (Army Medical University), Chongqing, China; [3]Department of Oncology, Chia Tai Tianqing Pharmaceutical Group Co., Ltd. L., Lianyungang, China

Background: Anlotinib, a novel multi-target tyrosine kinase inhibitor, has been proven effective in HER2-negative metastatic breast cancer, but its efficacy in early-stage TNBC is unknown. This phase 2 study aims to evaluate the efficacy and safety of adding anlotinib to neoadjuvant chemotherapy (NCT) in patients (pts) with TNBC.

Methods: Pts with clinical stage II/III TNBC were treated with 5 cycles of anlotinib (12mg, d1-14, q3w) plus 6 cycles of taxanes (docetaxel 75 mg/m^2 or nab-paclitaxel 125 mg/m^2, d1 and d8, q3w) and lobaplatin (30 mg/m^2, d1, q3w), followed by surgery. The primary endpoint was total pathological complete response (tpCR; ypT0/is ypN0) and the secondary endpoints include breast pCR (bpCR), axillary pCR (apCR), survival, and safety. Exploratory endpoints were efficacy biomarkers based on FUSCC classification (IHC-based) and NGS (425 gene panel).

Results: From Jan 2021 to Aug 2022, 48 pts were assessed and 45 were enrolled. All pts received at least one dose of study treatment and underwent surgery. The median age was 50 years (range, 26-65), 71% were nodal involved, and 20% had stage III. In the ITT population, 26 out of 45 pts achieved tpCR (57.8%; 95% CI, 42.2%—72.3%), and 39 achieved RCB 0-I (86.7%; 95% CI, 73.2%-94.9%). The bpCR and apCR rates were 64.4% (29/45) and 71.9% (23/32), respectively. No recurrence or metastasis occurred during the short-term follow-up. Based on the FUSCC IHC-based subtypes, the tpCR rates were 68.8% (11/16) for IM subtype, 58.3% (7/12) for BLIS subtype, and 33.3% (4/12) for LAR subtype, respectively. Next-generation sequencing revealed that the tpCR were 69.2% (9/13) and 53.6% (15/28) in MYC-amplified and wild-type pts, respectively, and 75.0% (9/12) and 51.7% (15/29) in BRCA1/2-mutated and wild-type pts, respectively. In the safety population (N=45), Grade 3 or 4 TEAEs occurred in 29 pts (64%), and the most common events were neutropenia (38%), leukopenia (27%), thrombocytopenia (25%), anemia (13%), and hypertension (13%), respectively. No treatment-related deaths occurred.

Conclusions: The addition of anlotinib to NCT showed manageable toxicity and promising antitumor activity for pts with early-stage TNBC.

247P KN026 in combination with docetaxel as neoadjuvant treatment for HER2+ early or locally advanced breast cancer (BC): A single-arm, multicenter, phase II study

L. Ma[1], B. Yang[1], M. Zhang[2], K. Wang[3], Y. Chen[4], Z. Fan[5], J. Zhang[6], B. Xia[6], J. Wu[1]

[1]Department of Breast Surgery, Fudan University Cancer Institute, Shanghai, China; [2]Surgical Oncology, The First Affiliated Hospital of Bengbu Medical College, Bengbu, China; [3]Department of Breast Oncology, Guangdong Provincial People's Hospital, Guangzhou, China; [4]Breast Surgery, The Second Affiliated Hospital Zhejiang University School of Medicine, HangZhou, China; [5]Breast Surgery, The First Hospital of Jilin University, Changchun, China; [6]Clinical Medicine, Jiangsu Alphamab Oncology Co., Ltd., Suzhou, China

Background: Trastuzumab (H) plus Pertuzumab (P) combined with cytotoxic agents has been the SOC for Her2+BC across perioperative to late stage. Even with high efficacy, optimized treatment strategy still needs to be explored. KN026 is a bispecific monoclonal antibody that targets domain II and IV of HER2. KN026 showed comparable or better efficacy with H+P in preclinical study. The superior efficacy had also been validated in a series of clinical trials in late line Her2+ solid tumors as well as the first-line Her2+ breast cancer and gastric cancer. Here we report the results of KN026 plus docetaxel as neoadjuvant treatment in HER2+ BC pts.

Methods: Treatment naive pts with HER2+ early or LABC were enrolled to receive 4 cycles of KN026 (30mg/kg, ivgtt d1, q3w) and docetaxel (75 mg/m^2, ivgtt d1, q3w) as neoadjuvant treatment. The primary endpoint was tpCR rate. Secondary endpoints were bpCR, ORR, safety, etc. This study is registered in ClinicalTrials.gov, number NCT04881929.

Results: From August 9th, 2021, to July 29th, 2022, a total of 30 pts were enrolled from 5 sites. 16 pts (53.3%) were stage II, and 14 pts (46.7%) were stage III; 26 (86.7%) pts with biopsy-confirmed lymph node metastases; 15 (50.0%) pts were hormone receptor positive. As of Nov 21st, 2022, the study completed the primary outcome. 28 pts completed the surgery followed by pathological evaluation, and 2 pts discontinued from the study earlier due to AEs. In FAS, tpCR rate was 56.7% (17/30, 95% CI: 37.43%-74.53%), bpCR rate was 60% (18/30, 95% CI:40.60%-77.34%), ORR was 90.0% (27/30, 95% CI: 73.47%-97.89%). The incidence of TEAEs and CTCAE Grade ≥3 TEAEs were 100% (30/30) and 53.3% (16/30), respectively. The most common (≥5%) Grade ≥3 TEAEs were neutrophil count decreased (50%, 15/30), white blood cell count decreased (40.0%, 12/30), and lymphocyte count decreased (10%, 3/30). 7 (23.3%) pts required docetaxel dose reduction due to AEs. KN026 and docetaxel related SAEs occurred in only one patient. No Grade 5 TEAEs occurred.

Conclusions: KN026 plus docetaxel as neoadjuvant treatment has shown promising clinical benefit and acceptable safety for pts with HER2+ early or LABC. Further validation in a large-scale randomized controlled trial is warranted.

248P Targeting triple-negative breast cancer metabolism with neoadjuvant chemotherapy plus fasting-mimicking diet plus/minus metformin: The BREAKFAST trial

Background: Cyclic fasting or fasting-mimicking diets (FMDs) enhanced the antitumor activity of chemotherapy (CT) in TNBC mouse models, while the combination of fasting and metformin resulted in impressive antitumor activity in several preclinical tumor models. The BREAKFAST study was designed to investigate if cyclic FMD, plus/minus metformin, improves the antitumor activity of neoadjuvant CT in patients (pts) with localized TNBC.

Methods: BREAKFAST is a randomized, non-comparative, phase II trial originally designed to enrol 90 stage I-III (cT>1cm) TNBC pts candidate to receive neoadjuvant doxorubicin-cyclophosphamide q3w for 4 cycles, followed by weekly paclitaxel for 12 cycles. Pts were randomized 1:1 to receive: CT + triweekly 5-day FMD cycles (arm A), or CT + FMD + daily metformin (1700 mg) (arm B). The primary study objective was to investigate if one or both experimental treatments were able to increase pCR rates when compared to anthracycline-taxane CT alone according to historical data.

Results: We enrolled 30 pts between June 2020 and February 2022, when the study was prematurely interrupted after the introduction of chemo-immunotherapy (CT-IO) as a standard neoadjuvant therapy for early stage TNBC. Of these pts, 13 were randomized to arm A and 17 to arm B; 73.3% of enrolled pts completed the maximum of 8 FMD cycles, with an average number of 6.9 completed FMD cycles. The observed pCR rate was 56.6%, i.e., significantly higher than pCR rates previously reported with CT alone in phase II/III trials (26-39%), and with no significant differences among treatment arms (OR 1.67, 95% CI 0.39-7.43; p=0.49). RNA-seq analysis in tumor specimens revealed higher pCR probability in pts undergoing precocious enhancement of tumor infiltration by activated T and NK cells, as well as precocious downmodulation of glycolysis and oxidative mitochondrial metabolism pathways.

Conclusions: Preoperative CT plus cyclic FMD (plus/minus metformin) results in excellent pCR rates in early TNBC pts. Based on these findings, we recently initiated a phase II, randomized, multicentric trial, namely BREAKFAST-2, to investigate if adding cyclic FMD to neoadjuvant CT-IO increases pCR rates in stage II-III TNBC pts.

Clinical trial identification: NCT04248998.

250P The impact of inter-cycle treatment delays on progression-free survival in early stage breast cancer

L. Steventon[1], E. Kipps[2], K. Man[3], M.D. Forster[4], I. Wong[5], S. Shah[1], R. Miller[4], S. Nicum[4], O. Almossawi[6], P. Chambers[1]

[1]Cancer Services, UCLH - University College London Hospitals NHS Foundation Trust, London, UK; [2]Breast, Royal Marsden Hospital NHS Foundation Trust, London, UK; [3]RDPP, UCL - University College London, London, UK; [4]Medical Oncology Department, UCLH - University College London Hospitals NHS Foundation Trust, London, UK; [5]Department of Pharmacology and Pharmacy, UCL - University College London, London, UK; [6]Population, Policy & Practice Department, Great Ormond Street Hospital for Children NHS Foundation Trust, London, UK

Background: Up to 30% of systemic anti-cancer therapy (SACT) treatments are reported to be delayed within cycle, due to drug toxicity, hospital capacity issues and patient choice; however, the impact on survival is unknown. This study aimed to determine the association of delays on PFS.

Methods: This population-based observational study included stage II-III breast cancer patients in England for whom guidelines recommend SACT, and who received six cycles of treatment from 01/01/2014-31/12/2015 in adjuvant and neo-adjuvant settings. Data were collected by the National Health Service as part of routine care. Cox proportional hazards model was applied to evaluate risk of progression with respect to treatment delays, adjusting for age, stage, histology, Charlson comorbidity index, ethnicity, socioeconomic group, BMI, region of England, hospital type and surgical status. Overall survival at 5 years was assessed. Delays were defined as treatment >7 days after expected date. Progression was defined as time from completion of 1st line to start of 2nd line SACT.

Results: 8680 patients were included. 2211 (25.5%) experienced at least one delay of 7 days or more during a six-cycle drug regimen. PFS probability was significantly lower at 1, 2 and 5 years in delayed patients; 97% (CI 96.6-97.4) vs 95.8% (CI 94.9-96.6), 93.9% (CI 93.3-94.5) vs 91.6% (CI 90.5-92.8) and 86.6% (CI 85.8-87.5) vs 81.5% (CI 79.9-83.2) respectively at each timepoint in patients treated to schedule vs delayed. Cox proportional hazards analysis showed a positive association of delays >7 days with disease progression or death (HR 1.36, CI 1.19—1.55) compared to those treated to schedule. Covariates associated with reduced PFS were triple-negative histology (HR 1.63, CI 1.29-2.06) and BMI>40 (HR 1.55, CI 1.16-2.08). Non-significant associations were seen between treatment at local vs academic hospital (HR 1.15, CI 0.98-1.35), Asian (HR 0.73, CI 0.53-1.01) and Chinese (HR 0.54, CI 0.13-2.19) ethnicity compared to White ethnicity.

Conclusions: Treatment delays were significantly associated with reduced PFS and occur frequently in early-stage breast cancer patients in England. Hospitals must avoid centre-led treatment delays where possible to maximise treatment efficacy in this patient cohort.

Background: Adjuvant anthracyclines and taxanes reduce risk of recurrence and death in Early Breast Cancer (EBC) patients (pts) but the toxicity profile is a major concern. Several studies have shown conflicting results correlating Body Mass Index (BMI) and outcomes in these pts. There are limited data on the efficacy of adjuvant taxanes among BMI categories. The prognostic effect of BMI on disease recurrence between adjuvant Paclitaxel (P)-based Chemotherapy (CT) vs. Docetaxel (D)-based CT has not ever been reported.

Methods: Pt-level pooled analysis of 13,486 EBC pts treated with adjuvant anthracyclines +/- taxanes from 7 GEICAM & TRIO adjuvant randomized controlled trials (RCTs) carried out from 1996 to 2008. Pts were classified in 4 BMI (kg/m2) categories: normal (< 25.0), overweight (25.0 to 29.9), obese (30.0 to 34.9), and severely obese (≥ 35.0), to evaluate BMI as a predictive factor for efficacy and toxicity of adjuvant taxane-based CT. Hazard Ratios (HR) were calculated using a Cox proportional hazard model stratifying by RCT.

Results: Pts distribution based on BMI was: 44% normal, 33% overweight, 16% obese, and 8% severely obese. 79% were treated with taxane-based CT (83% with D and 17% with P). 10y iDFS was 71%, 70%, 68% and 64% in normal, overweight, obese, and severely obese pts who received CT, respectively, being statistically significant in obese (HR 1.15; 95% CI 1.05-1.26; p=0.002) and severely obese (HR 1.29; 95% CI 1.15-1.45; p<0.001). 10y iDFS by type of CT are describe in the table. Relevant toxicity was 5%, 5.5%, 5.9% and 9.3% in normal, overweight, obese, and severely obese pts who received D.

Table: 251P

	Normal	Overweight	Obese	Severely obese
D vs. non- D	70% vs. 62% HR 0.73 95% CI 0.59-0.89 ***p*=0.003**	67% vs. 66% HR 0.83 95% CI 0.66-1.05 *p*=0.124	66% vs. 62% HR 0.84 95% CI 0.61-1.16 *p*=0.285	64% vs. 67% HR 1.12 95% CI 0.70-1.78 *p*=0.646
P vs.non-P	79% vs. 77% HR 0.94 95% CI 0.75-1.17 *p*=0.554	77% vs. 74 HR 0.89 95% CI 0.71-1.13 *p*=0.347	78% vs. 72% HR 0.72 95% CI 0.52-0.98 ***p*=0.039**	71% vs. 65% HR 0.70 95% CI 0.45-1.09 *p*=0.113

Conclusions: Prognosis is worse in heavier vs. leaner EBC pts receiving adjuvant taxane-based CT. Leaner pts receiving D (compared to non-D) achieved a better outcome, while pts who benefited most from P were the obese subgroup (compared to non-P).

252P Adjuvant chemotherapy in T1a/bN0 breast cancer patients with high oncotype DX recurrence scores (RS>25)

D. Katz[1], I. Feldhamer[2], A. Hammerman[3], H. Goldvaser[1], D. Goldstein[4]

[1]Oncology Department, Shaare Zedek Medical Center, Jerusalem, Israel; [2]Division of Planning and Strategy, Clalit Health Services, Tel Aviv, Israel; [3]Medison Pharma Israel, Petah Tikva, Israel; [4]Oncology Department, Rabin Medical Center, Petah Tikva, Israel

Background: RS>25 is prognostic for distant recurrence and predictive for adjuvant chemotherapy (aChem) benefit in ER+HER2-negative early breast cancer (BC), independent of tumor size. For patients with tumors >0.5 cm and candidates for aChem, current NCCN guidelines recommend strongly considering OncotypeDX testing and aChem treatment for RS>25. Herein, we sought to evaluate the benefit of aChem in T1a/bN0 early BC patients with high RS>25 tested. We used the Clalit Health Services (CHS) dataset, the largest HMO in Israel, with more than 4.5 million insurers.

Methods: We identified all CHS patients tested between Feb-2006 and Dec-2019 with T1a/bN0 early breast cancer and a RS>25. Demographic, clinicopathological, and treatment data were extracted from the CHS centralized registry. A propensity score matching method based on nearest neighbor with replacements was used to balance differences. Kaplan-Meier analysis with log-rank test was used to test differences in clinicopathological characteristics. Freedom from recurrence of BC locally and at a distant site and freedom from second primary cancer and death also known as invasive disease-free survival (iDFS) between the treatment groups.

Results: 159 patients were identified of which 76 patients (47.7%) received aChem. Before applying the propensity- score matching aChem was more common among younger patients >50-years-old (25%) compared with patients ≤70-years-old (7.9)%, healthier patients with Charlson comorbidity score 0-1 (70%) compared with 30.2% for score ≥2, among Oncotype RS >30 72.5%. aChem was more often omitted in invasive lobular carcinoma (75%) and grade 1 tumors (72.7%). Propensity score matching balanced discrepancies among both treatment groups and Kaplan-Meier analysis demonstrated no iDFS improvement with aChem in T1a/bN0 early BC patients with high Oncotype DX recurrence scores (RS>25).

Conclusions: Utility of aChem in T1a-bN0 tumors and RS>25 is dependent on clinocopathologic variables beyond RS. After balancing between these variables no iDFS benefit for aChem was observed.

253P Is 6-weekly administration of pembrolizumab in combination with chemotherapy for early triple-negative breast cancer safe? A real-world early comparison of q6w versus q3w administration of pembrolizumab in two large cancer centres in the UK

V. Angelis[1], E. Scott[1], C. Gousis[2], P.E. Hall[1], K.M. Hawkesford[1], R. Nijjar[1], M. Nathan[2], P. Schmid[3], M. Phillips[1]

[1]Medical Oncology, St. Bartholomew's Hospital - Barts Health NHS Trust, London, UK; [2]Medical Oncology, Guys and St Thomas NHS Trust, London, UK; [3]Centre for Experimental Cancer Medicine, Barts Cancer Institute, Queen Mary University of London, London, UK

Background: The KEYNOTE 522 regimen is now established as the gold standard for patients with at least T2N0 or N+ early triple-negative breast cancer. In KEYNOTE 522, Pembrolizumab was administered every 3 weeks at 200mg. Following approval of 6-weekly administration by the FDA and EMA, hospitals could choose to implement q6w (400mg) or q3w (200mg) administration of Pembrolizumab. On implementation of q6w Pembrolizumab at St Bartholomew's Hospital (SBH), we observed a higher-than-expected rate of grade 3-4 hepatotoxicity. This led to this real-world retrospective study, comparing our rates of toxicity with those seen at Guys Cancer Centre using the q3w regime.

Methods: We identified 21 eligible patients treated at SBH, who received at least one of cycle of q6w Pembrolizumab and 17 patients who received it q3w at GSTT from November 2022 — March 2023. Epidemiological and clinical data were collected retrospectively.

Results: In KEYNOTE 522, grade 3-5 transaminitis was seen in 5.5% of patients receiving Pembrolizumab. Of the 21 patients receiving q6w Pembrolizumab at SBH, there was a higher frequency of grade 3 transaminitis (Table). All 4 patients (19%) with G3 transaminitis required hospitalisation for IV steroids, with 2 developing grade 4 hyperbilirubinaemia requiring additional immunosuppression. A liver biopsy was carried out with 1 of 2 patients demonstrating vanishing bile duct syndrome. Pembrolizumab was discontinued in all 4 patients and 1 patient had to discontinue chemotherapy. In comparison, patients who received q3w Pembrolizumab at GSTT experienced no grade 3 toxicities.

Table: 253P

Pembrolizumab frequency	Q6w	Q3w
Patient number	21	17
Mean age	49	50
T2	17 (80%)	10 (59%)
N+	10 (48%)	11 (65%)
HBcAb positive requiring prophylaxis	0	1
Transaminitis		
G1	0	3 (18%)
G2	3 (14%)	2 (12%)
G3	4 (19%)	0

Conclusions: Although this study is limited by short follow-up and small number of patients it suggests that administration of q6w Pembrolizumab may be associated with a higher risk of grade 3 immune related hepatotoxicity. Further studies are required to confirm these findings.

254P Effects of delaying adjuvant chemotherapy initiation on clinical outcomes in early triple-negative breast cancer patients

M.E. Hatzipanagiotou[1], M. Pigerl[1], M. Gerken[2], S. Räpple[1], V. Zeltner[1], M. Hetterich[1], P. Ugocsai[1], E.C. Inwald[1], M. Klinkhammer-Schalke[3], O. Ortmann[1], S. Seitz[1]

[1]Department of Gynecology and Obstetrics, University Medical Centre Regensburg, Regensburg, Germany; [2]Regional Centre Regensburg, Bavarian Health and Food Safety Authority, Bavarian Cancer Registry, Regensburg, Germany; [3]Tumor Center Regensburg - Centre for Quality Management and Health Services Research, University of Regensburg, Regensburg, Germany

Background: TNBC is known for its aggressive nature, with early recurrence and limited treatment options beyond chemotherapy and recently immunotherapy. The optimal time to initiation of adjuvant chemotherapy (TTAC) for triple-negative breast cancer (TNBC) patients remains unclear. We aim to clarify, whether TTAC has an impact on survival in patients with early TNBC.

Methods: Data from a large population-based regional cancer registry covering over 2.2 million people was used for evaluation, including women with diagnoses of TNBC between 2010 and 2018. Data collected included demographics, pathology, treatment, recurrence, and survival. TTAC was defined as days from primary surgery to first dose of adjuvant chemotherapy. Kaplan-Meier and Cox regression methods were used to evaluate impact of TTAC on overall survival (OS).

Results: We identified 37 382 patients with malignant neoplasms of the mammary gland. The final study cohort included 732 patients with early TNBC, of whom 43.6% were treated with neoadjuvant chemotherapy and 40.3% with adjuvant chemotherapy. 245 patients with TNBC treated with adjuvant chemotherapy had a valid TTAC. Treatment given within 22-28 days led to the best outcome with a mean OS of 10.2 years, while later treatment (29-35, 36-42 days, or >6 weeks) had significant reduced survival rates of 8.3, 7.8, and 6.9 years. Patients who received therapy within 22-28 days had significantly better survival than those who received therapy between 29-35 days (p=0.043) or after more than 43 days (p=0.033).

Conclusions: The results in this large population-based study indicate that timing of adjuvant systemic therapy can influence OS in TNBC patients, with reduced OS if adjuvant chemotherapy is applied later than 42 days after surgery. To optimize patients' outcomes, we recommend avoiding a delay of more than 6 weeks when administering adjuvant chemotherapy for early TNBC patients.

[1]Medical Oncology, Centre Georges-François Leclerc, Dijon, France; [2]Biostatistics, Centre Georges-François Leclerc (Dijon), Dijon, France; [3]Pathology, Centre Georges-François Leclerc, Dijon, France; [4]Medical Oncology, Institut Jean Godinot, Reims, France; [5]Medical Oncology, CHU de Reims - Hôpital Robert Debré, Reims, France; [6]Medical Oncology, Centre Francois Baclesse, Caen, France; [7]Medical Oncology, Institut de Cancérologie de Lorraine - Alexis Vautrin, Vandoeuvre-lès-Nancy, France

Background: CPS+EG scoring system properly defined prognosis subgroups of early breast cancer (eBC) patients (pts) treated with neoadjuvant chemotherapy (NACT) with a higher CPS+EG associated with worse outcomes. It remains unknown if CPS+EG similarly stratify prognostic in HER2-low and HER2-zero eBC patients after NACT.

Methods: This pluricenter french retrospective study included eBC pts treated with NACT from 2 cohorts, a monocenter local database at CGFL, Dijon and a pluricenter clinical trial PRIMUNEO (NCT01513408). Molecular features were determined on core biopsies. Threshold for HR positivity was ≥10%. HER2-low/zero status was defined by immunohistochemistry (IHC) HER2 staining. CPS+EG score was calculated for all pts with available data.

Results: 608 patients with HER2-negative eBC that have received NACT were included. Median age at diagnosis was 51.0 y-o. Nearly all pts (98.2%) received >3 NACT cycles. In the overall population, 288 pts (47.4%) were HER2-low. More pts were HR+ than TNBC with 367 (60.3%) and 241 pts (39.7%), respectively. The majority of pts harboring HR+ disease were HER2-low (61.0%) contrary to TNBC eBC pts (26.5%). In the HER2-low and HER2-zero population, CPS+EG was able to well categorized pts within prognosis subgroups (log-rank p <0.0001).

Table: 255P

Score	CPS+EG HER2-low (n =288) 5-year DFS rate (%) (95% CI)	CPS+EG HER2-zero (n =320) 5-year DFS rate (%) (95% CI)
0	100 (100-100)	100 (100-100)
1	92.9 (82.14-97.28)	86.11 (74.1-92.81)
2	71.95 (60.8-80.43)	86.8 (77.89-92.3)
3	69.78 (58.09-78.8)	72.5 (61.18-81.01)
4	48.03 (29.17-64.63)	55.48 (40.12-68.39)
5	38.1 (8.92-68.02)	30.77 (9.5-55.43)

In HR+/HER2-negative pts, CPS+EG still properly separated pts within prognosis subgroups between HER2-low and HER2-zero pts (log-rank p =0.0012 and p <0.0001, respectively). In TNBC population, CPS+EG appears to be less accurate. Within HR+ and TNBC molecular subtypes, there was no difference in 5-year DFS between HER2-low and HER2-zero pts harboring a similar CPS+EG score.

Conclusions: In this study, we show that the CPS+EG scoring system retains its interest for the prognostic stratification of pts treated with NACT for HER2-low and HER2-zero eBC. While it seems especially true for HR+ disease, CPS+EG appears to be less effective for TNBC in isolating different outcomes.

256P Evolution and risk stratification of adjuvant treatment strategies for early breast cancer: A Chinese perspective based on a national cancer database

Y. Fan[1], D. Ji[1], M. Jiang[1], Y. Tan[1], Y. Yang[2], T. Li[2], X. Ma[2], B. Xu[1]

[1]Department of Medical Oncology, Chinese Academy of Medical Sciences and Peking Union Medical College - National Cancer Center, Cancer Hospital, Beijing, China; [2]Lilly China Drug Development & Medical Affairs Center, Eli Lilly and Company, Shanghai, China

Background: HR+, HER2- early breast cancer (EBC) patients (pts) with high-risk clinicopathologic features (CPF) are at increased risk of early recurrence. This is the first study aimed at investigating the evolving adjuvant therapy landscape.

Methods: The study cohort, based on the medical records from 50 major hospitals across China linked with China Vital Registration (death information), included pts with HR+, HER2- stage I-III EBC who received surgery and adjuvant endocrine therapy (AET) from Jan 1, 2013, to Mar 31, 2021. CPF were used to identify a 'high-risk group' (HiR) (including ≥ 4 positive axillary lymph nodes (LN), or LN1-3 with ≥ 1 of the following high-risk CPF: Grade 3, tumor size ≥ 5 cm or Ki-67 ≥ 20%) and 'low-risk group' (LoR) (do not meet above criteria). Survival analysis was performed on invasive disease-free survival (iDFS), distant relapse-free survival (DRFS), and overall survival (OS) with cutoff date of Sep 30, 2021.

Results: Of the 4088 eligible pts (median age: 50 years), 1310 were identified in HiR (46.6% had LN≥ 4 and 53.4% had LN1-3 with high-risk CPF), and 2778 in LoR (90.8% N0 pts). Pts in HiR were more likely to receive adjuvant chemotherapy (74.9% vs 63.7%) and radiotherapy (72.1% vs 45.6%) than LoR. From 2013 to 2021, the use of aromatase inhibitors and ovarian function suppression in AET gradually increased while the use of selective estrogen receptor modulators (tamoxifen/toremifene) decreased. The 5-year iDFS was 75.3% in HiR and 89.9% in LoR, respectively. Pts in HiR had a higher risk of recurrence or death than pts in LoR (Hazard Ratio: 2.38, 95% CI: 1.82-3.12). Similar results were observed for DRFS and OS (Table).

Table: 256P Risk of recurrence and death in HR+, HER2- early breast cancer[1]

Risk groups	HR_{iDFS} (95% CI)	HR_{DRFS} (95% CI)	HR_{OS} (95% CI)
N0, or LN1-3 without risk feature	Ref.	Ref.	Ref.
LN≥4, or LN1-3 with ≥1 risk feature	2.38(1.82,3.12) **	3.20(2.31,4.43) **	3.81(2.34,6.21) **
LN≥4	3.44(2.55,4.65) **	4.86(3.40,6.94) **	6.47(3.84,10.92) **
LN1-3 with ≥1 risk feature	1.50(1.05,2.14) *	1.82(1.19,2.80) **	1.68(0.85,3.30)

*P < 0.05; **P<0.01

CI: Confidence interval; HR: hazards ratio; LN: positive axillary lymph nodes.

[1] HR and 95%CI were estimated from Cox proportional hazards regression models with adjustments for age, menopausal status, neoadjuvant therapy, adjuvant chemotherapy and radiotherapy.

Conclusions: Nearly 25% EBC pts with high-risk CPF experienced recurrence or death within 5 years of initiating AET. Novel treatments are needed to prevent recurrence and death in these pts.

257P The characteristics of HER2-positive microinvasive breast cancer and the necessity of chemotherapy and anti-HER2 therapy in these patients: A real-world study

B. Lan[1], D. Lv[1], C. Guo[2], Z. Feng[2], Y. Fan[1], F. Ma[1], B. Xu[1]

[1]Department of Medical Oncology, Chinese Academy of Medical Sciences and Peking Union Medical College - National Cancer Center, Cancer Hospital, Beijing, China; [2]Department of Pathology, Chinese Academy of Medical Sciences and Peking Union Medical College - National Cancer Center, Cancer Hospital, Beijing, China

Background: The prognosis of microinvasive breast cancer (MIBC) is between ductal carcinoma in situ and T1aN0 stage tumors. We conducted this real-world study to explore the prognosis of human epidermal factor receptor 2 (HER2)-positive MIBC, as well as to find out whether chemotherapy and anti-HER2 therapy could improve outcome in this population.

Methods: Patients who received radical surgery and were diagnosed with lymph node-negative HER2-positive MIBC at the National Cancer Center in China from January 2010 to December 2019 were consecutively enrolled. The invasive components were confirmed HER2-positive by pathologists from our center. The exclusion criteria included: 1) distant metastasis before surgery; 2) HER2 status of the invasive components was unknown. Clinicopathologic characteristics and follow-up outcome data were collected.

Results: A total of 121 patients were included. The median age was 51 years old, and the median follow-up time was 68.3 months. Twenty-four patients (19.8%) received adjuvant chemotherapy (CT), of which 7 patients received CT combined with trastuzumab. Among these 24 patients, 17 patients were aged $\leq$ 50, and 20 patients were estrogen receptor (ER) negative. In total, 5 patients experienced recurrence (2 in situ breast recurrence, 3 distant metastasis), all within 3 years after surgery. The 3-year disease free survival (DFS) rate and 5-year DFS rate were all 95.9%. Univariate analysis showed that patients aged $\leq$ 50 might have worse outcomes than those aged $>$ 50 (5-year DFS rate 92.5% versus 98.5%, p=0.098). Using propensity score matching, patients who received CT with or without trastuzumab were matched with those who did not receive CT in a 1:2 ratio based on age and ER status. Patients who received CT with or without trastuzumab showed a trend of increase in 5-year DFS rate compared to those who did not receive CT (100% vs 89.6%, p=0.106).

Conclusions: HER2-positive MIBC had a relatively good prognosis. For patients with risk factors of relapse, CT and trastuzumab might decrease recurrence, so adjuvant CT and anti-HER2 therapy could be considered in this population.

258P Cost-effectiveness of neoadjuvant pembrolizumab plus chemotherapy followed by adjuvant pembrolizumab for high-risk early-stage triple-negative breast cancer in Colombia

R. Brugés Maya[1], J.C. Urrego[2], C. Marrugo[2], V. Wurcel[3], A. Khandelwal[4], J. Singh[4], M. Huang[5], A. Haiderali[6]

[1]Clinical Oncology, Centro Javeriano de Oncología Hospital San Ignacio, Bogota, Colombia; [2]Market Access, MSD Colombia, Bogota, Colombia; [3]CABA, MSD Argentina, Munro, Argentina; [4]Economic Modeling and Adaptations, CHEORS - Complete Health Economics Outcomes and Research Solutions, North Wales, PA, USA; [5]Economic and Data Sciences, Merck & Co., Inc., Rahway, NJ, USA; [6]Center for Observation and Real-World Evidence, Merck & Co., Inc., Rahway, NJ, USA

Background: In Colombia, 15,509 new cases of breast cancer (BC) were diagnosed in 2020. Furthermore, BC was the leading cause of cancer deaths. Triple-negative breast cancer (TNBC) is an aggressive subtype that represents 15-20% of BC. The KEYNOTE-522 (KN522) trial showed that neoadjuvant pembrolizumab + chemotherapy followed by adjuvant pembrolizumab significantly improved pathological complete response and event-free survival when compared to neoadjuvant placebo + chemotherapy followed by adjuvant placebo in patients with high-risk early stage TNBC (eTNBC). This study evaluated the cost-effectiveness of neoadjuvant pembrolizumab + chemotherapy [paclitaxel + carboplatin followed by anthracycline + cyclophosphamide] plus adjuvant pembrolizumab versus neoadjuvant chemotherapy in high-risk eTNBC, from a third payer perspective in Colombia.

Methods: A Markov cohort model was developed with four mutually exclusive health states: event-free, locoregional recurrence, distant metastasis, and death, to simulate patients' lifetime disease course based on the efficacy and safety data from KN522. Outcomes and costs were discounted at 3% annually. Time on treatment was estimated using observed Kaplan-Meier curves from KN522. Utility inputs were derived from EuroQoL-five-dimension questionnaire in KN522. Costs for initial and subsequent therapies, disease and adverse events management, and terminal care were estimated using drug and healthcare public lists prices of Colombia.

Results: Over a 51-year time horizon, patients receiving pembrolizumab + chemotherapy accrued an additional 2.39 life-years (LYs) and 2.19 quality-adjusted life-years (QALYs) compared to neoadjuvant chemotherapy. The resulting incremental cost-effectiveness ratios (ICER) were COP 65,159,259/LY and COP 71,172,546/QALY, which were lower than the willingness-to-pay threshold of COP 85,093,272 in Colombia (based on 3-GDP per capita).

Conclusions: Neoadjuvant pembrolizumab + chemotherapy followed by adjuvant pembrolizumab is a cost-effective treatment versus neoadjuvant chemotherapy for high-risk eTNBC in Colombia, constituting a novel and key therapy option for those patients.

259P Adjuvant doxorubicin-cyclophosphamide in early-stage breast cancer provides long-term cardiac safety

T. Susiriwatananont[1], N. Poovorawan[1], C. Teerapakpinyo[2], S. Shuangshoti[3], L. Jarutasnangkul[4], M. Tumkosit[4], P. Chattranukulchai[5], N. Theerasuwipakorn[5], S. Manasnayakorn[6], C. Vinayanuwattikun[1], Y. Vorasettakarnkij[7], V. Sriuranpong[1]

[1]Division of Medical Oncology, Department of Medicine, Faculty of Medicine, Chulalongkorn University and The King Chulalongkorn Memorial Hospital, Bangkok, Thailand; [2]Chula GenePro Center, Research Affairs, Faculty of Medicine, Chulalongkorn University and The King Chulalongkorn Memorial Hospital, Bangkok, Thailand; [3]Department of Pathology, Faculty of Medicine, Chulalongkorn University and The King Chulalongkorn Memorial Hospital, Bangkok, Thailand; [4]Department of Radiology, Faculty of Medicine, Chulalongkorn University and The King Chulalongkorn Memorial Hospital, Bangkok, Thailand; [5]Division of Cardiovascular Medicine, Department of Medicine, Faculty of Medicine, Chulalongkorn University and The King Chulalongkorn Memorial Hospital, Bangkok, Thailand; [6]Department of Surgery, Faculty of Medicine, Chulalongkorn University and The King Chulalongkorn Memorial Hospital, Bangkok, Thailand; [7]Division of Hospital and Ambulatory Medicine, Department of Medicine, Faculty of Medicine, Chulalongkorn University and The King Chulalongkorn Memorial Hospital, Bangkok, Thailand

Background: Anthracyclines have been crucial chemotherapy for breast cancer treatment. However, its use has been limited by cardiotoxicity. We investigated the long-term outcomes and potential biomarkers associated with cardiac toxicities in breast cancer survivors who received anthracycline.

Methods: We prospectively collected data from 212 early-stage breast cancer patients who received adjuvant doxorubicin-cyclophosphamide (AC) at KCMH from 2007 to 2012. Echocardiography was performed pre-AC and within 3 months post-AC in 177 patients. Cardiac MRI (CMR) was conducted in asymptomatic patients (n=49) between July and December 2022 to assess long-term cardiac outcomes. We analyzed plasma microRNA expression using the Nanostring platform at pre-AC and before 2nd cycle of AC of 18 patients who had decline of LVEF $>$10% (n= 9) and $\leq$10% LVEF (n =9).

Results: The mean age of breast cancer diagnosis was 51$\pm$9 years with a median follow-up of 11 years [6-12]. The mean cumulative doxorubicin was 223.3$\pm$19.8 mg/m^2. At end-AC evaluation, 43 patients (24.3%) and 15 patients (8.5%) had decreased LVEF by 10-20% and $>$20% respectively. 32 patients (18%) received subsequent anti-HER2 therapy. 8 patients (3.7%) had arrhythmia (n=6) and cardiomyopathy (n=2) in long-term follow-up. The miR-16-5p, miR-25-3p, miR-873-5p, miR-19b-3p, and miR-30d-5p were the top 5 microRNAs that overexpressed in end-AC LVEF decline $>$10% with the fold change of 1.77-2.99. There was no difference in long-term CMR findings, including LVEF, LVEDVI, LVESVI, LV mass index, RVEF, T1 mapping, and strain in asymptomatic patients with end-AC LVEF decline $>$10% vs. $\leq$10%. Abnormal scars

were found in 8 patients who had end-AC LVEF decline >10% (n=7) vs. ≤10% (n=1). All were located at the RV insertion site or mid-wall.

Table: 259P

LVEF at pre-AC, end-AC, and long-term CMR

LVEF	End-AC LVEF decline >10% (n = 16)	End-AC decline ≤10% (n = 30)	p-value
Pre-AC echocardiogram	75.2% +/- 7.2%	68.4% +/- 5.2%	<0.01
End-AC echocardiogram	62.7% +/- 6.5%	68.1% +/- 5.3%	<0.01
Long-term CMR	60.3% +/- 4.9%	60.6% +/- 5.3%	0.87

Conclusions: Our study demonstrated acceptable long-term cardiac outcomes in early-stage breast cancer patients who received ≤4 cycles of AC. Potential plasma micro-RNAs were identified and will be further studied in more patients.

260P Oncology efficacy of gonadotropin-releasing hormone agonist in hormone receptor-positive very young breast cancer patients treated with neoadjuvant chemotherapy

H.J. Choi

Breast Surgery, Samsung Changwon Hospital - Sungkyunkwan University School of Medicine, Changwon, Republic of Korea

Background: Breast cancer in young women has been shown to have an aggressive behavior and poor prognosis. This study aimed to evaluate the outcomes of hormone-receptor (HR)-positive young breast cancer patients treated with neoadjuvant chemotherapy (NAC) and the oncologic efficacy of gonadotropin-releasing hormone (GnRH) agonist.

Methods: This was a retrospective study on a prospectively collected cohort. We included 1123 patients who, between January 2006 and June 2018, were diagnosed with invasive breast cancer and treated with NAC followed by curative surgery at 000. Among patients with HR-positive and human epidermal grow factor 2 (HER2)-negative breast cancer, we analyzed the characteristics and oncology outcomes between the patients equal to or younger than 35 years and the patients older than 35 years.

Results: Among 288 patients with NAC and strong HR-positive/HER2-negative breast cancer, 72 patients were equal to or younger than 35 years of age, and 213 patients were older than 35 years of age. The median follow-up is 74.0 months. There was no statistically significant difference in disease free survival (DFS, $p = 0.261$) and overall survival (OS, $p = 0.625$) between the patients equal to or younger than 35 years and the patients older than 35 years. The two groups differed in that the GnRH agonist was used more frequently in the group of patients equal to or younger than 35 years than in the other group (52.4% vs. 11.2%, $p<0.001$). Interestingly, for the DFS according to the GnRH agonist in the group of patients equal to or younger than 35 years, patients treated with the GnRH agonist had better DFS ($p = 0.016$).

Conclusions: GnRH agonists might improve the DFS rate of HR-positive/HER2-negative breast cancer in the equal to or younger than 35 years group of patients with NAC.

261P Dysregulation of immune checkpoint proteins in newly- diagnosed early breast cancer patients undergoing neoadjuvant chemotherapy: A comparison between TNBC and non-TNBC patients

B.L. Rapoport[1], H. Steel[1], C-A. Benn[2], S. Nayler[3], T. Smit[4], L. Heyman[4], L. Kwofie[1], A. Theron[1], N. Hlatswayo[1], P. Meyer[1], R. Anderson[1]

[1]Department of Health, University of Pretoria, Pretoria, South Africa; [2]Surgery, Breast Care Centre of Excellence, Johannesburg, South Africa; [3]Pathology, Gritzman & Thatcher, Randburg, South Africa; [4]Research, The Medical Oncology Centre of Rosebank, Johannesburg, South Africa

Background: Breast cancer is associated with up-regulation or down-regulation of proteins in the immune system, to evade anti-tumor immune responses. Soluble forms of immune checkpoint molecules (sICMs) can be measured in human plasma. The study aimed to measure the systemic levels of a series ICMs at diagnosis, post-neo-adjuvant chemotherapy (NAC) and post-surgery in newly- diagnosed BC patients (pts) and compare the biological behaviour of these sICMs between TNBC and non-TNBC patients.

Methods: Soluble ICMs were measured using multiplex bead array technology in plasma from 72 BC pts and 45 healthy controls. Data were prospectively obtained and levels were compared between pre-treatment, post-NAC, and post-surgery using non-parametric tests (Mann-Whitney & Kruskal-Wallis).

Results: Following NAC, the plasma levels of six soluble co-stimulatory checkpoints (CD28, CD40, ICOS, CD27, CD80, GITR), all involved in the activation of CD8+ cytotoxic T cells, were significantly increased ($p < 0.04$-$p < 0.00001$). Four of the soluble co-inhibitory checkpoints (LAG-3, PDL1, TIM-3 and HVEM) increased significantly post-NAC. PD-1 remained unchanged, while BTLA and CTLA-4 decreased significantly ($p < 0.03$ and $p < 0.00001$, respectively). Normalization of sICM seemingly indicates a reversal of systemic immune dysregulation following the administration of NAC in early BC. In contrast, recovery of immune homeostasis may explain the increased levels of several negative checkpoint proteins, albeit with the exceptions of CTLA-4 and PD-1.

Conclusions: This study demonstrates low levels of co-stimulatory and co-inhibitory sICMs in newly-diagnosed, non-metastatic BC pts. Following treatment with NAC, the sICMs levels increase substantially, except CTLA-4. In the case of co-stimulatory sICMs, these novel findings are indicative of an immune-restorative mechanism. The pattern of co-inhibitory sICMs (elevated levels of PD-L1, LAG-3, TIM-3 and HVEM), might be indicative of immune-therapeutic resistance, underscoring the augmentative immune-therapeutic promise of targeting these molecules, either individually or in combination, to improve the outcome of pts with early BC.

Background: There is unacceptably low level of oncology clinical trials in Nigeria, the country with the highest burden of breast cancer in Africa. This has been attributed to poor research infrastructure and trained personnel. This study was designed to assess the feasibility of establishing a robust platform for multi-institutional biomarker driven oncology clinical trials to improve quality of cancer care in Nigeria.

Methods: One-stage phase II single arm design in women with HER2-positive breast cancer with clinical stages IIA to IIIC (AJCC 2009). All patients received 4 cycles of docetaxel + Herceptin SC. Breast ultrasound (USS) was done at diagnosis and after

every 2 cycles of neoadjuvant phase. Those with complete clinical response by USS after 4 cycles had surgery. Those with partial response or stable disease (operable) switched to FEC for additional 3 cycles before surgery. All responders received 18 cycles of Herceptin SC. Adjuvant treatment included hormonal therapy as indicated. Radiation therapy was administered as per institutional practice.

Results: Study was initiated in April 2020 at onset of the pandemic and completed accrual in August 2022. Forty-seven of 53 enrolled patients (pts) were evaluable; 4 pts withdrew consent and 2 refused surgery. The median age was 50yrs (range 25-71 yrs.); Fifty-five percent were premenopausal. Majority were clinical stage III (60%), 58% ER- and 60% PR-. Twenty-five of 47 (53.2%) evaluable pts had pathological complete response (pCR) [including 6 pts (12.8%) after 4 cycles of docetaxel + Herceptin SC]. Treatment was well tolerated with Grade 3 toxicities of myelosuppression 6 (12.8%), diarrhea 1 (2.1%) and hepatic toxicity 2 (4.2%). The maximum reductions in LVEF were 20% and 26% in 2 pts respectively but without cardiac symptoms.

Conclusions: The study met its primary endpoint with pCR rate of 53% and manageable toxicity. To our knowledge, this is the first investigator initiated multi-institutional biomarker driven oncology clinical trial ever conducted in sub-Sahara Africa, paving the way for future pragmatic patient-centric biomarker informed clinical trials in populations of African Ancestry.

Background: Neoadjuvant chemotherapy (NAC) with the addition of Pembrolizumab (anti-PD1) is the current standard of care for early-stage II-III triple-negative breast cancer (TNBC). Although immunotherapy improves efficacy, toxicity rates remain a paramount parameter to consider since many of the events are long-lasting for this subset of patients (pts) treated with a curative intent.

Methods: We conducted a retrospective analysis of the medical records of 95 pts with early-stage TNBC treated with NAC and Pembrolizumab, between April 2022 and April 2023 in our institution. At the time of this submission, the toxicity analysis is available for 74 pts and efficacy for 64 pts. A complete analysis of 95 pts will be presented at ESMO. Treatment-related toxicities are reported according to the common terminology criteria for adverse events (CTCAE) v5.0.

Results: The cohort currently comprises 74 female patients, with a median age of 50 years [20-74]; 52% were premenopausal, and 20% harboured a deleterious *BRCA* germline mutation. Efficacy analysis (n=64): Pathologic complete response (pCR) rate was 56 % (n=36). The rate of pCR in pts with BRCA1/2 germline mutations was 80% (n=12). Toxicity analysis (n=74): We reported 376 toxicity events, of which 27% were grade 3-4. Most events were attributed to chemotherapy (55%). The immune-related adverse events (irAE) rate was 26%. A total of 35% of pts discontinued treatment due to toxicity, most commonly: liver toxicity, recurrent severe haematological and severe skin toxicities; while 50% of pts required dose reductions. The most common grade 3-4 AEs were neutropenia in 49% of pts and hepatic toxicity in 30% of cases. Immune-mediated thyroid dysfunction occurred in 25.7%, adrenal insufficiency was witnessed in 5%(4) of pts and hypophysitis in 4%(3). Immune-mediated myocarditis was witnessed in 1 elderly patient.

Conclusions: In this real-life cohort of early-stage TNBC patients treatment with a chemo-immunotherapy combination in the neoadjuvant setting was effective. However, we witnessed an important rate of treatment discontinuation due to toxicity. The impact on the quality of life of these patients should be carefully evaluated, especially in regard to permanent toxicities.

264P Tumor-infiltrating lymphocytes (TILs) for prediction of response to platinum-based neoadjuvant chemotherapy (NACT) in triple-negative breast cancer (TNBC): Final analysis

S. Abdullaeva[1], T.Y. Semiglazova[1], A. Artemyeva[2], A. Kudaibergenova[2], V. Semiglazov[3], P. Krivorotko[4], V. Semiglazov[4]

[1]Department of Innovative Methods of Therapeutic Oncology and Rehabilitation, N.N. Petrov National Medical Research Center of Oncology, St. Petersburg, Russian Federation; [2]Anatomic Pathology Department, N.N. Petrov National Medical Research Center of Oncology, St. Petersburg, Russian Federation; [3]Oncology Department, First Saint Petersburg State Medical University named after I.I. acad. I.P. Pavlova, St. Petersburg, Russian Federation; [4]Breast Cancer Department, N.N. Petrov National Medical Research Center of Oncology, St. Petersburg, Russian Federation

Background: According to several previous trials, event-free survival (EFS) in patients with TNBC is improved when carboplatin is added to NACT. Stromal TILs represent an important predictive and prognostic biomarker in patients with breast cancer. We are now reporting the analysis of EFS in patients with TNBC who received NACT $\pm$ carboplatin regarding TILs status.

Methods: The clinical data were obtained from 132 patients diagnosed with TNBC (ER&PgR<10%) and treated with either anthracycline-taxane NACT (n=68) or carboplatin-based chemotherapy (n=64) from 2017 to 2022 at N.N. Petrov National Medicine Research Center of Oncology. TILs were evaluated in FFPE tumor tissue samples stained with H&E at baseline biopsies according to guidelines from the International TILs Working Group. EFS was estimated by the Kaplan-Meier method and compared between groups by log-rank test. Multivariate analysis for EFS was performed using Cox's proportional hazards regression model, covariates included TILs level (<40 vs. $\geq$40), NACT, nodal status, BRCA status and pCR.

Results: High TILs were associated with significantly higher 5-year EFS (94.3% vs 56.1% HR=0.119, 95%CI 0.02-0.88, p=0.037). Patients with pCR had a significantly better 5-year EFS (74.5% vs 53.2%, HR=0.231, 95%CI 0.09-0.58, p=0.002). 5-year EFS rates were similar for both platinum-based and standard NACT groups (68.6% and 61.9%, respectively HR=0.537, 95%CI 0.24-1.19, p=0.124).
5-year EFS for platinum-based NACT was 100% vs 84.6% in the standard NACT group (HR=1.374, 95%CI 0.66-2.88, p=0.40) in patients with high TILs, compared with patients with low TILs levels EFS was lower 61.3% vs. 56.9%, respectively (HR=1.602, 95%CI 0.71-3.61, p=0.256). In univariate analysis, the nodal status, pCR, and TILs level were significant predictors of EFS. In multivariate analysis, only pCR (p=0.006) and TILs level (p=0.048) are two independent predictors of EFS.

Conclusions: EFS is numerically lower in the low TILs tumors which justifies the escalation of the NACT regimen. Treatment de-escalation may be considered in patients with high TILs level. Further research in larger datasets is needed to validate these hypothesis generating findings.

265P Effect of HER2-low-positive status on neoadjuvant chemotherapy and survival outcome of breast cancer: A 10-year dual-center retrospective study

Y. Li, H. Zhang

Breast Surgery, The First Affiliated Hospital of Xi'an Jiaotong University, Xi'an, China

Background: Various novel HER2-targeted antibody-conjugated drugs (ADCs) have shown satisfactory antitumor activity in HER2-low-positive breast cancer (BC). The effect of HER2 status on neoadjuvant chemotherapy (NAC) and survival outcome is controversial. It is urgent to clarify whether HER2-low-positive tumors have unique biological behavior and should be considered a new molecular subtype. In our study, a 10-year dual-center retrospective research was conducted to analyze the effect of HER2-low-positive status on NAC and survival outcome of BC.

Methods: We screened eligible BC patients and collected relevant information at the First Hospital of Jilin University and the the First Affiliated Hospital of Xi'an Jiaotong University from January 2010 to December 2020. The primary outcome indicator was pathologic complete response(pCR). The secondary outcome indicators were overall survival (OS) and disease-free survival (DFS).

Results: A total of 1027 patients were included in our study cohort, and 66.0% (678/1027) had HER2-low-positive tumors. Compared to HER2-zero, HER2-low-positive patients tended to have more lymph node metastasis, a larger proportion of hormone receptor (HR)-positive tumors, and a lower proliferation rate (Ki-67). The pCR rate of HER2-low-positive was lower than that of HER2-zero patients (19.3% vs 21.6%), especially in the HR-positive subgroup (12.00% vs 20.29%). However, multivariate logistic regression analysis showed that HER2 status was not an independent factor for predicting pCR. HER2-low-positive patients had a higher OS rate in the HR-positive subgroup. The Cox regression model analysis suggested that HER2-low-positive status did not affect the survival outcomes, regardless of DFS (p=0.308) or OS (p=0.066).

Conclusions: HER2-low-positive tumors have unique clinical and pathological characteristics, with a lower pCR rate in the HR-positive subgroup and better survival in the HR-negative subgroup compared to HER2-zero tumors. However, HER2-low-positive status is not an independent predictor of pCR or survival outcome. The authors have equally contributed to the study.

266P Discontinuation rate and serious adverse events of chemoimmunotherapy as neoadjuvant treatment for triple-negative breast cancer: A systematic review and meta-analysis

F.M. Schipilliti[1], A. Rizzo[2], F. Di Costanzo[3], S. Acquafredda[4], G. Arpino[5], F. Puglisi[6], L. Del Mastro[7], F. Montemurro[8], M. De Laurentiis[9], M. Giuliano[10]

Breast and Thoracic Oncology, Istituto Nazionale Tumori IRCCS - Fondazione G. Pascale, Naples, Italy; [10]Oncology Department, AOU "Federico II", Naples, Italy

Background: Combination of chemotherapy plus immune checkpoint inhibitors (ICIs) has recently shown efficacy in triple-negative breast cancer (TNBC), and thus, has been introduced in clinical practice in both the advanced and early disease stage. However, few data are available regarding the extent and the potential consequences of discontinuation rate and serious adverse events of these treatments, especially in the neoadjuvant setting. Herein, we performed a comprehensive systematic review and meta-analysis to assess discontinuation rate and serious adverse events of chemoimmunotherapy compared to chemotherapy alone in phase II and III neoadjuvant clinical trials in TNBC.

Methods: Following the Preferred Reporting Items for Systematic Reviews and Meta-analyses (PRISMA) guidelines, EMBASE, Cochrane Library, and PubMed/ Medline were searched for articles published from June 2008 to March 2023. The outcomes of interest were discontinuation rate, serious adverse events, and grade 3-4 adverse events.

Results: Overall, 4 studies were included in the analysis. The pooled Odds Ratios (ORs) for discontinuation rate and serious adverse events were 1.26 (95% CI, 0.78-2.06) and 1.79 (95% CI, 1.4-2.28), respectively, in patients receiving chemoimmunotherapy versus chemotherapy alone as neoadjuvant treatment for TNBC. A higher risk of grade 3-4 adverse events was reported in the chemoimmunotherapy group (OR 1.30; 95% CI, 1.07-1.59). The analysis was associated with substantial heterogeneity and the risk of discontinuation rate was strongly conditioned by the KEYNOTE-522 trial.

Conclusions: Our findings support the design of clinical trials which could be specifically focused on safety and treatment adherence, as well as the potential impact on outcome and quality of life in TNBC patients receiving neoadjuvant treatment. Careful monitoring of tolerability remains a crucial need in this clinical setting.

267P Pathological complete response after neoadjuvant chemotherapy plus pertuzumab and trastuzumab for HER2+ early breast cancer: Real-world data from NeoPowER study

F. Canino[1], M. Barbolini[2], U.F.F. De Giorgi[3], L. Gianni[4], A. Maestri[5], L. Moscetti[2], C. Omarini[2], C. Zamagni[6], R. Cuoghi Costantini[7], F. Tamburrano[1], G. Antonelli[1], F. Baglio[1], L. Belluzzi[1], G. Martinelli[1], S. Natalizio[1], O. Ponzoni[1], M. Dominici[1], F. Piacentini[1]

[1]Division of Medical Oncology, Department of Medical and Surgical Sciences for Children and Adults - University Hospital of Modena, Azienda Ospedaliero - Universitaria Policlinico di Modena, Modena, Italy; [2]Division of Medical Oncology, Department of Oncology and Ematology - University Hospital of Modena, Azienda Ospedaliero - Universitaria Policlinico di Modena, Modena, Italy; [3]Department of Medical Oncology, IRCCS Istituto Romagnolo per lo Studio dei Tumori (IRST) "Dino Amadori", Meldola, Italy; [4]Oncology and Haematology Department, Ospedale Infermi, Rimini, Italy; [5]Department of Medical Oncology, Ospedale Bellaria Carlo Alberto Pizzardi, Bologna, Italy; [6]Oncology&Haematology Dept., AOU Policlinico S. Orsola-Malpighi, F.Addarii, Bologna, Italy; [7]Unit of Clinical Statistics, Azienda Ospedaliero - Universitaria Policlinico di Modena, Modena, Italy

Background: The addition of pertuzumab (P) to trastuzumab (H) and standard chemotherapy (CT) as neoadjuvant treatment (NaT) for patients (pts) with HER2 positive (HER2+) breast cancer (BC), has shown to increase the pathological complete response (pCR) rate, without main safety concerns. The aim of multicentric NeoPowER trial is to evaluate safety and efficacy of P+H+CT in a real world population.

Methods: We retrospectively reviewed the electronic medical records of stage II-III, HER2+ BC pts treated with preoperative CT+H±P. The pts who received P+H+CT in 5 Emilia Romagna oncology centers (Modena, Bologna Bellaria, Bologna S.Orsola, Meldola, Rimini) between 2017-2022, were compared with a historical group who received H+CT (control) at Modena Cancer Center between 2007-2021. Clinicopathological variables were collected. Univariate and multivariate analysis were performed to assess the impact of covariates on pCR. Results were expressed as odds ratios (OR).

Results: 259 pts were included in the analysis, 125 (48%) received P+H+CT. Median age was 52 years, 63% were node-positive and 62% had hormone receptors positive (HR+). Features were balanced in the two groups, 62% of pts in the P+H+CT cohort had a Ki67 $\geq$ 30%, vs 43% in the control. All pts received preoperative taxane-based CT: 82% and 45% of pts also received anthracyclines, in the control and P+H+CT respectively. P+H+CT pts achieved higher pCR rate than the control: 46% vs 40% (p=0.462). At univariate analysis, HR negative (OR=3.79 p<0.001), Ki67 $\geq$ 30% (OR=1.29 p=0.04) and the use of preoperative anthracyclines (OR=1.72 p=0.04), were statistically related to pCR. Only ER expression (OR: 0.97 p=0.004) confirmed its statistical relation to pCR at multivariate analysis.

Conclusions: NeoPowER study confirms the efficacy of neoadjuvant chemotherapy combined with dual HER2 directed therapy: a higher pCR rate is achievable in case of HR negative and ki67$\geq$30% in pts receiving neoadjuvant P+H+CT, when compared to H+CT.

268P Evaluating the efficacy of adjuvant capecitabine in triple-negative breast cancer patients with residual disease: A real-world evidence study

M.J. Kim[1], H.J. Kim[1], S. Park[2], Y.H. Park[3]

[1]Digital Health, Samsung Advanced Institute for Health Science & Technology (SAIHST), Sungkyunkwan University, Seoul, Republic of Korea; [2]Health Sciences and Technology, Samsung Medical Center (SMC) - Sungkyunkwan University School of Medicine, Seoul, Republic of Korea; [3]Hematology-Oncology Dept, Samsung Medical Center (SMC) - Sungkyunkwan University School of Medicine, Seoul, Republic of Korea

Background: In early breast cancer, residual disease after neoadjuvant chemotherapy is considered an important prognostic factor, especially for triple-negative breast cancer (TNBC) and HER2-positive patients. The CREATE-X study demonstrated a survival benefit of adjuvant capecitabine (adjC) for these patient groups, particularly in TNBC. Researchers have been trying to find the appropriate population for adjC as Real-World Evidence (RWE). However, RWE in the Asian population was lacking, and previous RWE studies were limited in number. In addition, these studies did not include patients who received neoadjuvant immunotherapy treatment, while the Keynote-522 trial demonstrated the benefit of immunotherapy in early TNBC. Therefore, we evaluated the advantages of adjC in non-pCR TNBC patient group by using RWD.

Methods: We conducted a retrospective analysis of 1,033 TNBC patients who received neoadjuvant treatment at Samsung Medical Center between 2018 and 2023, using de-identified, anonymous data from the institutional Clinical Data Warehouse. Among these patients, we identified 403 patients who received at least one cycle of adjC, while 36 received no adjuvant treatment. Residual Cancer Burden (RCB) classification were available for 399 patients. The primary outcome of the study was Disease-Free Survival (DFS). We conducted a survival analysis using Kaplan-Meier method.

Results: The median DFS has not yet been reached. The disease risk of the adjC group tended to be lower than that of the no adjuvant treatment group, but the difference was not statistically significant (Hazard ratio(HR), 0.52; p-value=0.083). At 36 months, 86% of patients in the adjC group were disease-free or alive, compared to 76% of patients in the no adjuvant treatment group. Compared to the RCB-I group (n=114, 28.4%), the HR for the RCB-II group (n=233, 58.5%) was 1.40, and the for the RCB-III group (n=52, 13.1%), it was 5.88 ($p<0.0001$). The DFS at 36 months was 90%, 89%, and 67% for the RCB-I, II, and III groups, respectively.

Conclusions: In this study, adjC demonstrated a potential survival benefit for non-pCR TNBC patients. Subgroup analysis based on RCB classification indicated a higher risk associated with higher RCB class.

269P Achieving treatment goals in elderly breast cancer patients with neoadjuvant chemotherapy: A remarkable insight

E. Caliskan Yildirim[1], H.S. Semiz[1], O.U. Unal[2], E. Atag[1], A. Karaoglu[1]

[1]Medical Oncology, Dokuz Eylul University - Faculty of Medicine, Izmir, Turkey; [2]Medical Oncology, Tepecik Education and Research Hospital, Izmir, Turkey

Background: Neoadjuvant chemotherapy (NAC) is widely used for locally advanced breast cancer, including HER2-positive and triple-negative subtypes. However, the impact of age on treatment response remains uncertain. This study aims to investigate treatment outcomes in elderly breast cancer patients receiving neoadjuvant chemotherapy.

Methods: A retrospective analysis was conducted on breast cancer patients who underwent neoadjuvant treatment at two tertiary centers between 2010 and 2021. Patients were divided into two groups based on age: $\geq$65 years and $<$65 years. Pathologic response and surgical outcomes were compared between the groups.

Results: A total of 535 patients were included in the study, with 12% aged $\geq$65 years. There were no statistically significant differences in the clinicopathological characteristics between older and younger patients. The overall rate of receiving anthracycline-based chemotherapy (CT) in the entire population was 97.6%, with ddAC used more in the younger patients (71.7% vs 38.5%, $p<0.001$). Breast-conserving surgery and sentinel lymph node dissection were comparable between the groups. In older patients, the rate of breast downstaging was 73.5% and the rate of axillary downstaging was 70.6%, with no statistically significant difference compared to younger patients. A comparison of the groups in terms of pathological complete response revealed rates of 26.6% in younger patients and 33.3% in older patients ($p>0.05$). The rate of grade 3-4 toxicity was statistically higher in elderly patients (71% vs. 46.4%, $p<0.01$). No treatment-related deaths were observed. The median follow-up period was 50 months. Recurrence occurred in only 84 (17%) patients, with a recurrence rate of 10.4% in elderly patients compared to 17% in the other group ($p=0.17$).

Conclusions: The study suggests that elderly patients achieve similar outcomes to younger patients, indicating that age alone should not be a basis for undertreatment. Further research focusing on personalized approaches for the geriatric population is needed.

270P Influence of neoadjuvant chemotherapy-induced short-term amenorrhea on pathologic response and treatment outcome in ER+HER2- breast cancer

S.E. Lee[1], Y. Kook[2], B. Seung Ho[2], S. Moon[1], J. Kim[1], M.J. Kim[1], S.J. Bae[2], J. Jeong[2], S.B. Lee[3], S.G. Ahn[2]

[1]Department of General Surgery, Gangnam Severance Hospital, Yonsei University College of Medicine, Seoul, Republic of Korea; [2]Department of Surgery, Gangnam Severance Hospital, Yonsei University College of Medicine, Seoul, Republic of Korea; [3]Department of Surgery, Asan Medical Center - University of Ulsan, Seoul, Republic of Korea

Background: Premenopausal women experience temporary ovarian function suppression (OFS) during the period of chemotherapy. In ER+ breast cancer, chemotherapy-induced temporary OFS may offer anti-estrogenic effect in addition to direct cytotoxic anti-tumor effect. It is unclear whether anti-estrogenic effect by temporary OFS during neo-adjuvant chemotherapy (NAC) enhance anti-tumor effect. Based on pathologic complete response (pCR) and complete cell-cycle arrest (CCCA), we compared pathologic response and outcomes between younger and older patients with ER+HER2- breast cancer treated with NAC.

Methods: Between 2007 January and 2021 June, we retrospectively identified 1,178 patients with ER+HER2- breast cancer who underwent NAC in the Gangnam Severance Hospital and the Asan Medical Center. We compared the pCR rate according to age under 45 and over 55 and investigated durations of NAC, clinical stage, and Ki-67. Pathologic complete response was defined as no invasive residual disease in both breast and axillae. In addition, we collected available Ki67 expression in surgical specimen after NAC. We defined low Ki67 with a cutoff of 2.7%. The recurrence-free survival was evaluated in patients with post-NAC Ki67.

Results: In all 1,178 patients, the pCR rate was 1.9% (22/1,178). The rate was 1.4% (8/552) in younger patients (age $\leq$45), whereas it was 3.6% (9/250) in older patients (age $\geq$55) ($p=0.063$, Chi-square test). In 524 patients who received NAC consisting of anthracyclines and taxanes with a duration of NAC longer than 6 months, the pCR rate did not differ between the younger patients and the older (2.1%, 5/243 vs. 2.8%, 3/106; $p=0.703$). In patients with post-NAC Ki67, the CCCA rates were 66.2% (307/464) in the younger and 39.8% (86/216) in the older, respectively ($p<0.001$). Survival analyses showed that, compared to patients with CCCA, those without CCCA experienced a significant decrease in RFS in both younger and older women.

Conclusions: While short-term OFS resulting from NAC led to a higher rate of CCCA in premenopausal women, younger women had notably poorer survival outcomes compared to older women. Among premenopausal women, achieving CCCA was associated with a slight improvement in treatment outcomes.

Background: Structural remodeling of cells and extracellular matrix (ECM) during cancer initiation and progression are accompanied by substantial biomechanical alterations, which can be measured by Atomic Force Microscopy (AFM). Increasing (pre)- and clinical evidence demonstrate the importance of cancer biomechanics in mediating therapy response. Incorporating AFM measurements of clinical biopsies within standard of care is thus a promising avenue to leverage tissue mechanics as prognostic and predictive biomarker for solid cancers.

Methods: We conducted a single center, blinded, prospective study to measure a multiparameter nanomechanical signature (NS) of response to neoadjuvant therapy (NAT) in breast cancer (BC). Between 2016 and 2019, 588 fresh, baseline, clinical breast biopsy samples from 545 patients were measured using the AFM based Automated and Reliable Tissue Diagnostics (ARTIDIS) investigational device — ART-1, within routine clinical setting in the Breast Clinic, University Hospital Basel. 35 patients received NAT: combination chemotherapy (CHT) (n=30) and endocrine NAT (n=5). Study endpoints were radiological complete response (rCR) prior and pathological complete response (pCR) after surgery. NS data has been analyzed in an automated manner using proprietary ARTIDISNet software platform. 10 y follow up is ongoing.

Results: The ARTIDIS NS of response to NAT in BC showed 100% negative predictive value (NPV) and 89% positive predictive value (PPV) with 93% of accuracy for patients receiving CHT, independent of molecular subtype or treatment regimen. Sensitivity was 100% and specificity was 85% (AUC=0.91). When 5 patients with endocrine NAT were included, performance was decreased, meaning: NPV=92%, PPV=91, Sensitivity = 95 and Specificity = 85 (AUC=0.83).

Conclusions: NS can be prospectively used in clinical settings to predict response to NAT in BC. Mechanistically, these results highlight the importance of cell and TME mechanics in modulating therapy response. Furthermore, these results are being validated in a multicenter prospective study (ANGEL) currently enrolling 2706 patients with the aim to support implementation of the ARTIDIS NS into routine clinical practice.

Gemelli, Rome, Italy; [13]Medical Direction, IRCCS Ospedale Sacro Cuore Don Calabria, Negrar Di Valpolicella, Italy

Background: High rate of clinical fractures was reported during adjuvant HT trials (9-14% in BIG 1-98, ATAC, IES). Since 2015, in Italy, bisphosphonates and denosumab are reimbursed for prevention of bone fractures in EBC HR+ postmenopausal pts receiving HT, regardless of T-score values (Note 79 of AIFA-Agenzia Italiana del Farmaco). In 2019, these drugs were administered only in 25% of potentially beneficiary pts. The P&P is a nationwide Bone Health (BH) management project designed to improve adherence to recommendations regarding fracture risk assessment and risk prevention measures in pts receiving HT for HR+ EBC.

Methods: The BH management model P&P was developed in 10 Italian cancer centres and includes: 1- training of multidisciplinary team and presentation of a BH management model by the oncologist (with referral to the Bone Specialist if osteoporosis); 2- implementation of this model in every centre; 3- evaluation, after 12 months, of rate of EBC HR+ pts in postmenopausal status (natural, surgical, secondary to chemotherapy or hormonal blockage) assessed for BH within 30 days from the start of adjuvant HT; 4- evaluation, after 12 months, of rate of EBC HR+ pts receiving therapy within 90 days from the start of adjuvant HT, according to the criteria for reimbursement by AIFA.

Results: At 12 months after implementation of P&P, data are available from 6 centres (IRCCS Negrar, Ancona Hospital, IRCCS San Martino Genova, Poliambulanza Brescia, Cardarelli Napoli, Papa Giovanni XXIII Bergamo) in 1,551 postmenopausal EBC HR+ pts. The first analysis reports that 83% of EBC HR+ patients who started adjuvant HT were assessed for BH within 30 days compared to 43% in the 2019 national survey and 68% of pts started bisphosphonates/denosumab compared to 25% in the 2019 national survey.

Conclusions: Implementation of the P&P model has been shown to increase the rate of postmenopausal EBC HR+ pts on adjuvant HT assessed for BH and treated with bisphosphonate/denosumab to reduce the risk of bone fractures. A new project is ongoing to assess the rate of fractures in Italian pts after the approval of Note 79 by AIFA.

Background: Imlunestrant is an investigational, next-generation, oral SERD designed to deliver continuous ER target inhibition, including in *ESR1*-mutant BC. Imlunestrant monotherapy demonstrated favourable safety, pharmacokinetics, and preliminary efficacy in patients (pts) with heavily pre-treated ER+ advanced BC (Jhaveri ASCO 2022). We present final pharmacodynamic (PD) biomarker data from the preoperative EMBER-2 WOO study (NCT04647487), including the expanded data at the 200 mg dose level, evaluating imlunestrant in ER+, HER2- EBC.

Methods: Post-menopausal women with stage I—III operable ER+, HER2- untreated EBC ≥1 cm were enrolled to imlunestrant 200, 400 (RP2D), or 800 mg once daily for approximately two weeks up to the surgery date. Pre- and on-treatment tumor samples were compared for changes in PD biomarkers. Primary endpoint was change in ER expression by IHC. Secondary endpoints were change in progesterone receptor (PR) expression and Ki-67, safety, and tolerability.

Results: Seventy-five pts were evaluable for ER expression (200 mg: n = 22; 400 mg: n = 27; 800 mg: n = 26). Baseline characteristics were similar across cohorts, with a median age of 64 years, 69% invasive ductal carcinoma, 30% invasive lobular carcinoma, 1% other, 55% stage I, 40% stage II and 5% stage III. Among evaluable pts, relative reduction in PD biomarkers after a median of 16 days of treatment are presented in the table. There was no significant difference in PD biomarker modulation between imlunestrant doses or tumor histology. Imlunestrant was well tolerated..

Conclusions: Imlunestrant demonstrated evidence of consistent and robust target engagement across all evaluated doses and was well tolerated in an EBC population, supporting adjuvant development in the EMBER-4 study.

Clinical trial identification: NCT04647487.

Background: Abemaciclib is approved as adjuvant therapy for HR+, HER2-, high risk EBC based on clinically significant improvements in invasive disease-free survival (IDFS) and distant relapse-free survival (DRFS), which were maintained and deepened after the 2-year treatment period was completed. In monarchE, 44% of patients required dose reductions of abemaciclib to proactively manage adverse events. In abemaciclib MBC trials, similar rates of dose reductions did not compromise PFS (Rugo, 2021). Here we present the exploratory analyses to investigate the impact of dose reductions on efficacy in monarchE.

Methods: In monarchE, up to 2 abemaciclib dose reductions were permitted prior to discontinuation. Pts treated with abemaciclib were classified into 3 equal-sized subgroups according to their abemaciclib relative dose intensity (RDI), and IDFS rates were estimated within each subgroup. A time-dependent Cox proportional hazard (PH) model (Therneau, 2000) was also implemented to assess the impact of dose levels over time on IDFS.

Results: Among the 2791 pts treated with abemaciclib, 832 (30%) had one and 389 (14%) had two dose reductions. Patients $\geq$65 years old, or those with $\geq$4 pre-existing co-morbidities were more likely to have dose reductions. Across the 3 RDI groups ($\leq$66% vs 66%-93% vs $\geq$93%), 4-year IDFS rates were generally consistent (87.1% vs 86.4% vs 83.7% from the lowest RDI group to the highest). According to the time-dependent model, the effect of abemaciclib is similar when staying at the full 150mg dose compared to being dose reduced to either 100mg or 50mg (HR = 0.905; 95% CI = 0.727, 1.125).

Conclusions: Consistent with observations in the metastatic setting, the efficacy of adjuvant abemaciclib in monarchE was not compromised by dose reductions. Therefore, dose reductions should be considered as a safe and effective way to manage toxicity and retain patients on treatment, in order to maintain benefit from adjuvant abemaciclib in combination with endocrine therapy.

Background: Clinicopathological and molecular features of HR+/HER2- BC associated with response and survival following NACT or NET have been poorly characterized.

Methods: A total of 186 patients with early-stage HR+/HER2- BC treated with NACT (52.2%) and NET (47.8%) at the Hospital Clinic of Barcelona between 2014-2018 were evaluated. Associations with pathologic complete response (pCR), event-free survival (EFS) and overall survival (OS) were assessed with logistic and Cox regressions, where appropriate. Intrinsic subtypes (IS), risk of relapse (ROR) and selected genes' expression before and after neoadjuvant treatment (NAT) were assessed with a research-based PAM50. SAM analyses were carried out. Significance was set at $p \leq 0.05$ and false discovery rate (FDR)$\leq$5%.

Results: The pCR rates following NACT and NET were 18.6% and 3.4%, respectively. NACT (adjusted odds ratio [aOR]: 6.26, p=0.044) and non-Luminal IS (aOR: 8.89, p=0.021) were independently associated to pCR. Both NAT strategies reduced PgR and Ki67 levels significantly ($p<0.001$ all). After NAT, a significant ($p<0.001$) larger proportion of tumor samples were Luminal A/Normal-like (95.1% vs 55.3% at baseline) and ROR-low (78.8% vs. 22.9% at baseline). Both treatments induced the upregulation of selected immune genes and Basal-like-related genes/signature and downregulation of Luminal, proliferation and HER2-related genes/signatures (FDR<5% all). At a median follow-up of 64.0 months, 5-year EFS and OS were 90.4% and 95.0% with no significant difference based on NAT strategy (71.9% NET patients did not receive posterior CT). After adjusting for NAT cohort and significant factors at univariate analyses, including IS switch, only reduction of the proliferation signature remained significantly associated with better EFS (p=0.011) and OS (p=0.014). Similar results were observed with reduction of ROR for EFS (p=0.034), but not OS.

Conclusions: This study suggests that molecular downstaging induced by NACT or NET follows similar biological patterns and is associated with favorable survival outcomes, supporting molecular-driven neo-/adjuvant strategies, as tested in the ongoing RIBOLARIS phase II trial (NCT05296746).

Background: In HoR-positive/HER2-negative EBC pCR rates are low and ML algorithms could help to predict pCR using clinical and pathological characteristics.

Methods: Patients with EBC receiving NCT followed by surgery were included in the training/validation cohorts (TC/VC). pCR was defined as absence of residual invasive cancer on pathologic breast specimen and lymph nodes (ypT0/is ypN0). Eight ML models (c5.0, k-nearest neighbour, random forest [RF], neural network, support vector machine [linear/radial], boosted trees and boosted logistic regression) were trained and tuned. A stratified ten-fold cross-validation was used and models' performance was evaluated using the area under the receiver operation characteristics curve (AUC), sensitivity and specificity.

Results: 572 patients were included in the TC and 87 achieved pCR (15%, 95% CI 12-18%). Ten variables (menopausal status, age, histology, grade, clinical T/N, ER/PgR, Ki67 and HER2 [zero/low]) were included according to multivariate analysis and clinical relevance. The RF algorithm had the best performance: AUC 0.77, 95% CI 0.71-0.83; sensitivity 0.86 (95% CI 0.82-0.88) and specificity 0.56 (95% CI 0.46-0.66). Variables with the highest importance were Ki67, ER/PgR status, age and nodal status. 293 patients were included in the VC and 24 achieved pCR (8%, 95% CI 6-12%). The RF algorithm had an AUC of 0.71 (95% CI 0.61-0.81), sensitivity of 0.29 (95% CI 0.13-0.51) and specificity of 0.90 (95% CI 0.86-0.94). With a median follow-up of 53.3 and 57.7 months for DFS and OS, patients whose pCR was predicted by the model had longer DFS (HR 0.51, 95% CI 0.31-0.83, *p*=0.003) and OS (HR 0.48, 95% CI 0.29-0.79, p=0.001). A one percentage increase in the probability of predicted pCR was significantly associated with longer DFS (HR 0.992; 95% CI 0.986-0.999, p=0.02) and OS (HR 0.992, 95% CI 0.985-0.998, p=0.01).

Conclusions: The ML algorithm has the potential to predict pCR in HoR-positive/HER2-negative patients undergoing NCT, thus supporting clinicians to individualize treatment for EBC.

277P Fat body mass independently predicts incident vertebral fractures in breast cancer patients given adjuvant aromatase inhibitor therapy and denosumab

G. Schivardi[1], R. Pedersini[1], D. Cosentini[1], P. di Mauro[1], M. Zamparini[1], L. Rinaudo[2], N. Di Meo[3], A. Delbarba[4], C. Cappelli[4], M. Laganà[1], A. Alberti[1], M. Baronchelli[5], G. Guerci[1], L. Laini[1], E.L. Simoncini[1], D. Farina[3], G. Mazziotti[6], A. Berruti[1]

[1]Medical Oncology Department, ASST Spedali Civili di Brescia, University of Brescia, Brescia, Italy; [2]Technologic, Turin, Italy; [3]Radiology Unit, ASST Spedali Civili di Brescia, Brescia, Italy; [4]Endocrinology, ASST Spedali Civili di Brescia, Brescia, Italy; [5]Medical Oncology Department, University of Parma, Parma, Italy; [6]Endocrinology, Diabetology and Medical Andrology Unit, Metabolic Bone Diseases and Osteoporosis Section, IRCCS Humanitas Research Hospital Rozzano, Humanitas University, Pieve Emanuele, Italy

Background: Women with early breast cancer (EBC) receiving adjuvant aromatase inhibitors (AIs) are frequently given denosumab (Den) with the aim to both reducing fracture risk and preventing disease recurrence. However, a proportion of these patients still experience fragility fractures despite Den, and risk factors in women treated with upfront AIs and Den have never been explored.

Methods: Dual-X-ray absorptiometry (DXA) at baseline conditions and after 18 months was performed in 237 consecutive patients undergoing adjuvant therapy with AIs and Den (60 mg subcutaneously every 6 months), recruited at the Breast Unit of the ASST-Spedali Civili of Brescia. The following baseline parameters were evaluated to predict the risk of vertebral fracture (VF) as assessed by a morphometric approach on DXA images: age, body mass index (BMI), history of previous fractures, family history of fractures, smoking, alcohol consumption, FRAX score, DXA-derived bone mineral density (BMD), trabecular bone score (TBS), percentage fat body mass (% FBM), lean body mass (LBM), appendicular mass index (ALMI).

Results: Seventeen out of 237 (7%) reported incident VFs after 18 months of AIs therapy. At the univariate analysis, incident VFs were significantly associated with high FRAX score (Odd Ratio [OR]: 3.786, 95% Confidence interval [CI]: 1.039-13.790), previous VFs (OR: 3.217, 95% CI: 1.185-8.736), high %FBM (OR 5.174, 95% CI: 1.418-18.873, p=0.013), high android fat (OR 9.580, 95% CI: 1.174-78.209, p=0.035) and low ALMI/FBM ratio (OR 0.252, 95% CI: 0.078-0.818, p=0.022). Only high %FBM was independently associated to incident VFs at multivariate analysis.

Conclusions: FBM is an independent risk factor for VFs in EBC patients treated with adjuvant AIs and Den. A supervised physical activity aiming at avoiding obesity and potentiating LBM could synergize with Den in preventing AI-induced bone fragility.

278P Association between tamoxifen and endoxifen plasma levels and clotting proteins in patients with primary breast cancer

D. van Dorst[1], S.M. Buijs[1], M.J.H.A. Kruip[2], R.F.P. van den Akker[3], K.L. Cheung[3], R. Porrazzo[1], E. Oomen-de Hoop[1], A. Jager[1], S.L. Koolen[1], J. Versmissen[4], J.A.H. Danser[4], H.H. Versteeg[3], M.H.A. Bos[3], R.H. Mathijssen[1]

[1]Medical Oncology Department, Erasmus MC Cancer Institute, Rotterdam, Netherlands; [2]Department of Hematology, Erasmus MC - Erasmus University Rotterdam, Rotterdam, Netherlands; [3]Einthoven Laboratory for Vascular and Regenerative Medicine, LUMC-Leiden University Medical Center, Leiden, Netherlands; [4]Department of Internal Medicine, Erasmus MC - Erasmus University Rotterdam, Rotterdam, Netherlands

Background: Tamoxifen is effective for the adjuvant treatment of primary breast cancer, but increases the risk for venous thromboembolism. Tamoxifen decreases anticoagulant proteins, including antithrombin (AT), protein C (PC) and tissue factor pathway inhibitor, and increases thrombin generation (TG). However, the relation between levels of both tamoxifen and its active metabolite endoxifen and coagulation is unknown. To gain insight in the prothrombotic effects of tamoxifen and to guide safe dose-escalation, which may be performed in case of sub-therapeutic endoxifen levels, we studied the association between tamoxifen and endoxifen levels and various clotting proteins.

Methods: Tamoxifen and endoxifen levels were measured in 148 patients from the prospective TOTAM study (NL6918) after 3 months (m) and 6m of tamoxifen treatment. Plasma levels of the anticoagulants AT and PC, the procoagulant tissue factor (TF), and TG parameters were determined at both timepoints if samples were available (n=65-138 per analysis). Levels of clotting proteins and TG parameters were compared between: 1) quartiles of tamoxifen and endoxifen levels with ANOVA or Kruskall-Wallis with Dunnett's test, and 2) 3m and 6m of treatment in patients without dose adjustments with paired sample t-tests or Wilcoxon signed rank tests.

Results: After 3m of tamoxifen, levels of AT, PC, TF and TG parameters were not associated with tamoxifen nor endoxifen levels. At 6m, median TF levels were lower in patients in the 3rd (45 [range: 101] pg/mL), and 4th (50 [90] pg/mL) endoxifen quartiles compared to the 1st (lowest) quartile (70 [143] pg/mL) (adjusted *P* of 0.024 and 0.012, respectively), but no differences in anticoagulants or TG were observed. An increase in both median TF levels (3m: 46 [94], 6m: 54 [143] pg/mL, $P<0.001$) and TG parameters was observed at the 6m treatment period, while the AT and PC levels remained stable.

Conclusions: Our results indicate that higher tamoxifen and endoxifen levels are not associated with increased coagulation system activation, suggesting that both tamoxifen dose-escalation and high endoxifen levels do not have an additional prothrombotic effect. The time-dependent effect of tamoxifen on coagulation warrants further study.

Clinical trial identification: NL6918.

279P Early changes in bone turnover biomarkers during AI therapy are related to loss bone mineral density, data of the B-ABLE cohort

T. Martos Cardenas[1], N. Garcia-Giralt[2], I. Petit[3], M. Castro-Henriques Pinto-Machado[1], M. Martinez García[1], X. Monzonis Hernandez[4], J. Albanell Mestres[1], X. Nogués Solan[3], S. Servitja Tormo[1]

[1]Medical Oncology Deparment, Hospital del Mar - Parc de Salut Mar, Barcelona, Spain; [2]Internal Medicine, IMIM - Institut Hospital del Mar d'Investigacions Mediques, Barcelona, Spain; [3]Internal Medicine, Hospital del Mar - Parc de Salut Mar, Barcelona, Spain; [4]Bioinformatics, IMIM - Institut Hospital del Mar d'Investigacions Mediques, Barcelona, Spain

Background: Aromatase inhibitors (AI) are the preferred hormonal therapy in postmenopausal women with early breast cancer (eBC). Bone turnover markers (BTM) provide dynamic information about the accelerated bone remodeling in patients taken AI. Here we described early changes in BTM during the first year of AI therapy in patients included at B-ABLE cohort.

Methods: B-ABLE cohort includes 1071 postmenopausal women with eBC, candidates to receive AI. PTH, Vit D and BTMs including carboxy-terminal crosslinked telopeptide of type 1 collagen (CTX), amino-terminal crosslinked telopeptide of type 1 collagen (NTX), procollagen type 1 N-terminal propeptide (P1NP), bone-specific alkaline phosphatase (BAP) and osteocalcin (OC), were evaluated previous AI therapy, at 3 months, and then annually. Bone mineral density (BMD) was assessed by DXA (at lumbar spine (LS) and femoral neck (FN)) baseline and annually. Here we report data of early changes in BMTs the first year of AI and its relation with BMD at 12 months in 768 women receiving AI as single agent or switching from tamoxifen, no treated with antiresorptive agents.

Results: The median age was 60 years, BMI was 29.15 and 18% are current smokers. 30% were switching from tamoxifen and 54.3% received Chemotherapy. 62% have osteopenia, 0.5% osteoporosis, and 4% of patients had fragility fractures at baseline. Baseline BTM were CTX 0.44ng/ml, NTX 45.09ng/ml, P1NP 60.14ng/ml, OC 6.05ng/ml, BAP 13.44mcg/l. In patients with osteopenia, BTM were higher compared with patients with normal DXA ($p< 0.005$) at baseline and at 3 months. Early changes in FAO (p=0.001) and CTX (p=0.001) were correlated with higher risk of LS and FN BMD loss (Table).

Table: 279P Association of BMD loss at 12 months with bone remodelling markers at 3 months of AI treatment

Changes in BTMs at 3-mo	LS 12-mo OR (95% CI)	FN 12-mo OR (95% CI)
CTX	3.13 (1.94-5.04)	2.45 (1.56-3.83)
NTX	1.81 (0.93-3.60)	1.13 (0.58-2.12)
P1NP	1.90 (0.86-4.22)	1.16 (0.60-2-24)
OC	1.21 (0.77-1.92)	1.06 (0.68-1.66)
BAP	2.086 (1.43-2.49)	2.01 (1.43-2.81)

Conclusions: Early dynamic changes in CTX and BAP are related to bone loss at 12 month in LS and FN.

280P Adjuvant aromatase inhibitors in patients with PIK3CA mutation early breast cancer

K. Reinhardt[1], M. Vetter[2], S. Kaufhold[1], E. Kantelhardt[2], C. Thomssen[2]

[1]Department of Gynaecology, Martin Luther Universität Halle-Wittenberg, Halle (Saale), Germany; [2]Department of Gynaecology, UKH - Universitätsklinikum Halle (Saale), Halle (Saale), Germany

Background: Phosphatidylinositide-3-kinase (PI3K) regulates proliferation and apoptosis and; somatic *PIK3CA*-mutations may activate these processes. In a prospective cohort study of early breast cancer (eBC) patients, in case of somatic *PIK3CA*-mutation we observed resistance to aromatase inhibitor (AI) therapy *(Reinhardt K et al., Breast Cancer Res Treat 2022;196:483—493).* This study is aimed at validating these findings in a second cohort.

Methods: We studied a unicentre cohort of 262 patients with steroid hormone receptor-positive, HER2-negative eBC, who were planed to be treated with endocrine therapy only: aromatase inhibitor (AI, n=183) or Tamoxifen (TAM, n=69), AI and TAM (n=9), Fulvestrant (n=1) and tested the three most common somatic PIK3CA gene mutations (H1047R, E545K, E542K) by qPCR. The primary endpoint was recurrence-free survival (RFS), secondary endpoint overall survival (OS). Median follow up was 62 months.

Results: The *PIK3CA*-mutation rate was 42% (110 of 262). Overall, there was no difference considering RFS between patients with AI (n=183) and TAM (n=69) therapy (5 yrs-RFS 91.7% in both groups). Patients of the AI group harbouring a somatic PIK3CA mutation (n=75) had non-significantly more RFS related events compared to patients with PIK3CA wildtype (n=108): 5 yrs-RFS 89.5% (95% CI 82.1-97.0) versus 93.2% (95%CI 87.9 - 98.5), respectively (HR=1.2, 95%CI 0.461-2.961; n.s.). After 5 yrs, 91.2% (95% CI 84.5 — 97.9) of the patients with PIK3CA mutation were alive and 94.4% (95% CI 89.7 — 99.1) of patients without PIK3CA mutation, respectively (HR=1.3, 95% CI 0.453-3.447; n.s.). In the group of patients who were treated with TAM only (n=69), no interaction was observed between PIK3CA mutation and RFS or OS, respectively.

Conclusions: Although we observed a trend that AIs are less effective in patients with PIK3CA mutated tumours, formal validation is still lacking. Further data including prospective studies are required.

281P Cyclin-dependent kinase 4/6 inhibitors combined with endocrine therapy for hormonal receptor-positive, human epidermal growth factor receptor 2-negative early breast cancer: A meta-analysis of randomized clinical trials

V.F.C. Alves[1], F.C.A. Moraes[2], G.D.C. Gomes[3], G.D.O. Almeida[4], S. Carnevalli[5], J.N. Priantti[6], T.M. Madeira[7], M. Silveira Vilbert[8], C. Stecca[9]

[1]University of Sao Paulo Medical School, São Paulo, Brazil; [2]Medicine, Federal University of Pará, Belem, Brazil; [3]Medicine, Pontifical Catholic University of Minas Gerais, Belo Horizonte, Brazil; [4]Medicine, Federal University of Triângulo Mineiro, Uberaba, Brazil; [5]Medicine, Federal University of Santa Catarina, Florianópolis, Brazil; [6]Internal Medicine Department, Federal University of Amazonas, Manaus, Brazil; [7]Medicine, Federal University of Minas Gerais, Belo Horizonte, Brazil; [8]Department of Clinical Oncology, UHN - University Health Network - Princess Margaret Cancer Center, Toronto, ON, Canada; [9]Medicine, Center of Oncology of Parana, Curitiba, Brazil

Background: The use of cyclin-dependent kinase 4/6 (CDK 4/6) inhibitors combined with endocrine therapy (ET) has recently emerged in the early stages breast cancer (eBC) treatment landscape. The present analysis aims to clarify the efficacy and safety of this treatment for hormonal receptor-positive, human epidermal growth factor receptor 2-negative (HR+/HER-) patients in the early stages of breast cancer (eBC).

Methods: PubMed, Scopus, Web of Science, Cochrane, and the Central Register of Clinical Trials were systematically searched for studies using CDK4/6 inhibitors with ET in patients with HR+/HER- early breast cancer (I-IIIA stage). For the meta-analysis, statistical analysis was performed using RStudio v 4.4.2. Heterogeneity was examined with Cochran Q test and I^2 statistics and p-values inferior to 0.10 and I>25% were considered significant for heterogeneity. The p-value< 0.05 was considered statistically significant.

Results: This study included 9345 patients from six randomized clinical trials. Ductal (87%) and lobular (10%) were the most common, and 53% of women were postmenopausal. Lymph node status data revealed that 9% had N0 status, 72% had N1 status, and 19% had ≥ N2 status. In a pooled analysis, the invasive disease free survival (iDFS) was 82% (95% CI, 0.64-1.06), and the overall survival rates were consistent across the studies, with 12-month rates at 1.00 (95% CI 0.99-1.01), 24-month rates at 1.00 (95% CI 0.99-1.01), 36-month rates at 1.01 (95% CI 0.93-1.10), and 48-month rates at 1.04 (95% CI 0.91-1.19). The most common treatment-related adverse events (AE) included neutropenia (78.1%), leukopenia (51.6%), fatigue (37.6%), diarrhea (31.4%), anemia (30.5%), and arthralgia (29.3%). Any grade 3 adverse events were observed in 2.44 (95% CI 0.84-7.08) and grade 4 in 1.39 (95% CI 0.15-12.68).

Conclusions: This meta-analysis reinforces the antitumor activity of the combination of CDK4/6is with ET in patients with eBC, regardless of iDFS rate. Despite high rates of serious adverse events related to treatment, most were manageable.

282P Analysis of Prosigna in hormone receptor-positive early-stage breast cancer cohort after 8 years of experience at a single institution

D. Morchón Araujo[1], A. Olivares Hernandez[1], L. Figuero Pérez[1], J. Claros Ampuero[2], M. García Muñoz[3], J. Roldán-Ruiz[1], M.D.C. Garijo Martínez[1], E. Terán Brage[1], Á. López Gutiérrez[1], M. Sancho de Salas[4], A. Gómez Muñoz[4], R. Seijas Tamayo[5], R. Lozano Mejorada[1], R.A. Marcos Sánchez[1], E. Fonseca Sánchez[1], C.A. Rodríguez Sánchez[1]

[1]Medical Oncology, University Hospital of Salamanca, Salamanca, Spain; [2]Medical Oncologist, Hospital Universitario Severo Ochoa, Madrid, Spain; [3]Medical Oncology, University Hospital of Burgos, Burgos, Spain; [4]Pathology, University Hospital of Salamanca, Salamanca, Spain; [5]Oncology Department, Hospital of Avila, Avila, Spain

Background: Molecular signatures are recommended in HR+, HER2- early-stage breast cancer (EBC) to guide decisions for adjuvant treatment. Prosigna® is a standardized test based on the PAM50 gene signature with provides information on risk of recurrence and permits intrinsic subtype classification of tumor. The study aimed to evaluate the clinical impact of adopting Prosigna® assay after 8y.

Methods: A retrospective study of patients (pts) with ER+, HER2- EBC was carried out between 2015 and 2023 in a single center. Gene expression analysis of tumors was performed with PAM50/Prosigna® (NanoString Technologies, Seattle, WA, USA).

Results: 232 pts were included. All were node-negative. The median age was 55y (32-80) and 152 (65.5%) were postmenopausal. Risk of Recurrence (ROR) risk groups were as follows: low ROR: 97 (42%); intermediate ROR: 76 (33%); high ROR: 59 (25%). Intrinsic Subtype Reclassification: According to immunohistochemistry (IHC), 102 tumors (44%) were initially classified as luminal A and 130 (56%) as luminal B. After PAM50, 144 tumors (62%) were classified as luminal A, 86 (37%) as luminal B and 2 (0.01%) as HER2-E. The discordance rate for luminal B by IHC is noteworthy. 67 (52%) were reclassified as luminal A after PAM50. Impact on decision making: Prosigna® led to a treatment decision change in 64 pts (28%). Chemotherapy (CT) was added in 36 (27%) of the 132 pts (57%) initially assigned to hormonal therapy (HT). Of 100 pts (43%) initially assigned to HT-CT, 28 pts (28%) finally received HT alone. Follow-up: With a median follow-up of 48 months and a maximum follow-up of 90 months, no recurrence of the disease has been reported.

Conclusions: The use of gene expression platforms such as Prosigna ® directly impacts treatment decision making, allowing the selection the best adjuvant treatment adapted to the de risk of recurrence, without having registered any relapse so far in our HR+, HER2- EBC and node-negative patients. In addition, it seems that the intrinsic subtype determined by Prosigna® assay cannot be replaced by IHC parameters.

283P Patient profiles treated with extended adjuvant neratinib in the early access registry study: NEAR study

M. De Laurentiis[1], G. Hoste[2], X. González Farre[3], O. Romano[4], A. Cano Jimenez[5], F. Beghdad[6], O. Dialla[6], M. Zivanov[7], T. Silovski[8]

[1]Department of Breast and Thoracic Oncology, National Cancer Institute Pascale Foundation, Naples, Italy; [2]Department of Gynecology, UZ Leuven, Leuven, Belgium; [3]Department of Obstetrics and Gynecology, University General Hospital of Catalonia, Barcelona, Spain; [4]Department of Oncology, La Louvière Private Hospital, Lille, France; [5]Department of Oncology, Hospital of Jaen, Jaen, Spain; [6]Real World Evidence and Data, Pierre Fabre, Boulogne-Billancourt, France; [7]Medical Affairs, Pierre Fabre, Boulogne-Billancourt, France; [8]Department of Oncology, University Hospital Centre Zagreb, Zagreb, Croatia

Background: Neratinib is an oral pan-HER TKI approved in 2018 in Europe in adult patients with HR+ HER2+ early breast cancer (eBC) who completed adjuvant trastuzumab-based therapy. The approval is based on the phase III ExteNET trial that demonstrated clinically meaningful benefit for neratinib vs. placebo in this population, including significantly improved 5-year iDFS (Δ5.1%, HR 0.58, 95% CI 0.41-0.82). An Early Access Program (EAP) was initiated in Europe in 2017 and provided access to individual patients for extended adjuvant neratinib based upon the ExteNET protocol while neratinib was awaiting product approval and availability in multiple countries. Since ExteNET, the treatment landscape of HER2+ eBC has evolved and there is a need to document the clinical profile, the tolerability, and the effectiveness of patients treated with neratinib in a real-world setting.

Methods: This is a multicenter, retrospective, observational, longitudinal study in Croatia, France, Belgium, Spain and Italy. Eligible patients will be selected among those having received at least one dose of neratinib in the EAP, between 01/08/17 and 31/12/20. The aim of the study is to describe the characteristics of patients receiving neratinib and its use in the real world. Demography and clinical profiles of patients are presented.

Results: As of 30/01/23, 108 patients were included in the Full Analysis Set. Median age at neratinib initiation was 48.0 years and 37.4% of patients were premenopausal. 29.6% of patients had cT1 and 46.3% had cT2. Two-thirds of patients were N+ and three-quarters had stage II + III tumours. Overall, 85.2% of patients had HR+ eBC. 41.7% of patients had upfront surgery followed by adjuvant therapy while 58.3% received neoadjuvant therapy first; of them 19.0% achieved a pathological complete response. In the neoadjuvant setting, most patients received trastuzumab + pertuzumab (58.7%) and trastuzumab (31.7%), whereas in the adjuvant setting, anti-HER2 treatment mainly consisted of trastuzumab (79.6%).

Conclusions: Patients treated in this EAP reflected the profile of patients who were expected to receive extended adjuvant neratinib during the observational period, which included the use of more recent (neo)adjuvant treatments.

Clinical trial identification: NCT05599334.

Background: The prognostic marker uPA/PAI-1 is recommended by international guidelines for treatment decisions in node-negative breast cancer (BC). This study is aimed at validating the prognostic impact of uPA/PAI-1 by using a daily routine cohort and to consider the predictive impact with regard to chemotherapy in HR+ /HER2- breast cancer.

Methods: In a multicentre cohort study (PiA-study, Prognostic assessment in routine Application n=1,270, NCT 01592825), the concentrations of uPA and PAI-1 in fresh tumour tissue (n=813) were prospectively determined by ELISA (FEMTELLE®, Bio-Medica Diagnostics GmbH). The first objective was the association of uPA/PAI-1 with recurrence-free Interval (5 yrs RFI) and overall survival (5 yrs OS). As the second objective, we evaluated the impact of uPA/PAI-1 as a predictive factor for adjuvant chemotherapy in the intermediate risk group, which was defined as HR+, HER2-, G2, ≥35 yrs., 0-3 positive lymph nodes. Median follow-up was 60.3 months (1-129).

Results: After 5 years of observation, 96.7% (95% CI 94.5-98.9) of patients with low uPA/PAI-1 were without any RFI event compared to 87.2% (95% CI 84.1-90.3) with high uPA/PAI-1 (aHR 2.6, 95% CI 1.293-5.227, p=0.001). Also considering OS, a significant difference was detected; with low uPA/PAI-1, 93.9% (95% CI 91.0-96.8) were alive after 5 years (aHR 2.38, 95% CI 1.359-4.156) compared to 82.9% (95% CI 79.1-86.4) with high uPA/PAI-1. With regard to the intermediate risk group (n=378), even without chemotherapy, less than 1% of patients with low uPA/PAI-1 (n=120) had an RFI event. While patients with high uPA/PAI-1 had a significantly higher risk of disease-related events over the entire observation time (aHR 4.27, 95% CI 1.132-16.124). If patients were treated with adjuvant chemotherapy (n=181), uPA/PAI-1 had no further prognostic significance. Patients with high uPA/PAI-1 benefited significantly from adjuvant chemotherapy compared to patients without chemotherapy (aHR 0.21, 95% CI 0.076-0.600).

Conclusions: These real-world cohort data confirm that uPA/PAI-1 can routinely be used as an independent prognostic factor for decisions about adjuvant chemotherapy and underline the assumption that uPA/PAI-1 might be predictive for the effect of adjuvant chemotherapy.

Clinical trial identification: NCT01592825 (release date: 16.12.09).

285P Treatment patterns and clinical outcomes of germline BRCA mutation (gBRCAm)-associated breast cancer (BC): A matched, case-control study

S. Morganti[1], S.E. Kim[2], Q. Jin[2], J. Cha[3], J.E. Zeigler[4], A.B. Newman[5], J. Vincuilla[6], T. Parker[6], R. Buehler[4], E.A. Mittendorf[6], T.A. King[6], B. Bychkovsky[1], G. Curigliano[7], A.H. Partridge[1], N.U. Lin[1], J.E. Garber[4], N. Tayob[2], S.M. Tolaney[1], F. Lynce[1]

[1]Department of Medical Oncology, Dana Farber Cancer Institute, Boston, MA, USA; [2]Department of Data Science, Dana Farber Cancer Institute, Boston, MA, USA; [3]Department of Medicine, Harvard Medical School, Boston, MA, USA; [4]Center for Cancer Genetics and Prevention, Dana Farber Cancer Institute, Boston, MA, USA; [5]Department of Medicine, Brigham and Women's Hospital, Boston, MA, USA; [6]Department of Surgery, Brigham and Women's Hospital, Boston, MA, USA; [7]Early Drug Development for Innovative Therapies Division, IEO - Istituto Europeo di Oncologia, Milan, Italy

Background: Up to 10% of early BC occur in gBRCAm carriers. Whether gBRCAm-related and sporadic BC have different outcomes is controversial.

Methods: Consecutive patients (pts) who underwent surgery for BC at Dana-Farber Brigham Cancer Center between 1/2016 and 8/2021 and had known gBRCA status were included. gBRCAm cases were matched 1:3 with non-gBRCAm controls by age groups, stage, hormone receptor (HR) status and year of diagnosis. HER2-negative BC were excluded. Clinicopathologic features, treatments, and outcomes of gBRCAm carriers and non-gBRCAm controls were compared.

Results: We identified 189 gBRCAm (107 *BRCA1,* 82 *BRCA2*) carriers and 567 matched non-gBRCAm controls. Median age was 43 years (yrs) in carriers and 46 yrs in controls. Most pts had stage I (41.7%) or II (44.7%) BC; 55% of BC were HR+ (38 in *gBRCA1*m, 66 in *gBRCA2m;* 312 in non-gBRCAm). Compared to controls, gBRCAm carriers had higher tumor grade ($p<0.001$), higher recurrence score in HR+ (median 25 vs 19, $p<0.001$), were more likely to receive chemotherapy (CT) (81 vs 67.4%, $p<0.001$), including platinum-based regimens (17.6 vs 9.2%, $p=0.007$). 11 gBRCAm carriers and 3 controls received PARPi. At a median follow up of 42.3 months, invasive disease-free survival (iDFS) and relapse-free survival (RFS) did not differ between gBRCAm and controls after adjusting for age, grade, and CT administration (Table). In triple-negative BC (TNBC), risk of relapse was lower for gBRCAm vs controls ($p=0.025$).

Table: 285P

	N (%)	Events	3-yr IDFS	Adjusted hazard ratio [95% CI]	p-value
All	746 (100)	95	gBRCAm = 88.4% [83.3, 93.9] Non-gBRCAm = 88.9% [86.2, 91.7]	0.82 [0.46,1.44]	0.49
HR+ BC	411 (55)	47	gBRCAm = 88.4% [83.3, 93.9] Non-gBRCAm = 88.9% [86.2, 91.7]	1.44 [0.55, 3.81]	0.46
TNBC	335 (45)	48	gBRCAm = 91.8% [85.6, 98.5] Non-gBRCAm = 84.3% [79.7, 89.3]	0.53 [0.22, 1.31]	0.17
	N (%)	**Events**	**3-yr RFS**	**Adjusted hazard ratio [95% CI]**	**p-value**
All	748 (100)	83	gBRCA = 92.2% [87.8, 96.9] Non-gBRCA = 89.4% [86.8, 92.2]	0.57 [0.30, 1.08]	0.085
HR+ BC	412 (55)	40	gBRCA = 90.6% [84.1, 97.6] Non-gBRCA = 93.6% [90.7, 96.5]	1.14 [0.41, 3.21]	0.80
TNBC	336 (45)	43	gBRCA = 94.4% [89.1, 100.0] Non-gBRCA = 84.3% [79.7, 89.3]	0.25 [0.07, 0.84]	**0.025**

Conclusions: Pts with BRCA-associated BC have higher-risk pathologic features and are more often treated with CT compared to matched non-gBRCAm BC. After adjusting for treatment and clinicopathologic variables, short-term outcomes did not differ in gBRCAm carriers vs controls overall. However, in TNBC pts, risk of relapse was significantly lower among carriers than controls. Our results provide risk estimates for gBRCAm carriers that could inform the design of future clinical trials.

286P Prognostic role of HER2 expression in patients with ER-positive/HER2-negative breast cancer: Results from a population-based cancer registry study

A. Musolino[1], O. Serra[2], B. Pellegrino[1], C. Tommasi[1], D. Zanoni[2], F. Faccini[3], M. Michiara[2], P. Sgargi[2], G. Carrozzi[4], S. Ferretti[5], V. Grossi[6], A. Ravaioli[6], F. Zamagni[6], F. Falcini[6]

[1]Department of Medicine and Surgery, University of Parma; Gruppo Oncologico Italiano di Ricerca Clinica (GOIRC), Parma, Italy; [2]Medical Oncology and Breast Unit, Emilia-Romagna Cancer Registry, Parma Unit; University Hospital of Parma, Parma, Italy; [3]Public Health Department, AUSL Piacenza, Emilia-Romagna Cancer Registry, Piacenza Unit, Piacenza, Italy; [4]Public Health Department, Local Health Authority, Emilia-Romagna Cancer Registry, Modena Unit, Modena, Italy; [5]Department of Translational Medicine, Local Health Authority, Emilia-Romagna Cancer Registry, Ferrara Unit, Ferrara; University of Ferrara, Ferrara, Italy; [6]Clinical and Experimental Epidemiology and Cancer Registry, Emilia-Romagna Cancer Registry, Romagna Unit, IRCCS Istituto Romagnolo per lo Studio dei Tumori (IRST) "Dino Amadori", Meldola, Italy

Background: Estrogen Receptor (ER)-positive (+)/Human Epidermal Growth Factor Receptor 2 (HER2)-negative (-) breast cancers (BCs) express variable protein levels of HER2, which can influence prognosis.

Methods: This cohort study was conducted using data on all consecutive patients (pts) diagnosed with BC between 2005 and 2017, which were systematically and prospectively collected by the Emilia-Romagna Cancer Registry (Provinces of Piacenza, Parma, Modena, and Ferrara), Italy. The study included 13527 pts with ER+/HER2- BC. Tumors were classified by HER2 IHC score (0 [n=7155], 1+ [n=5186], or 2+ with negative FISH [n=1186]). Comparisons of clinicopathologic characteristics and disease outcome were performed.

Results: BCs with late-stage diagnosis, high histological grade, or high proliferative rate were more likely to be HER2 1+ or 2+/FISH- in comparison with earlier stage, low-grade, or low-proliferative tumors (lower bounds of 95% confidence intervals [CIs] for odds ratios [ORs] > 1). BCs with high expression of ER (≥ 80% [n=12383]) were more enriched with HER2 1+ (OR 1.39; 95%CI, 1.2-1.6) or 2+/FISH- tumors (OR 1.26; 95%CI, 1.0-1.6) than ER-low/moderate (1-79% [n=1144]) ones. The 5-year overall survival (OS) for HER2 1+ BCs was lower than that for HER2 0 or 2+/FISH- tumors ($P = 0.0018$). This finding was confirmed also after stratification by ER status (low/moderate and high expression; $P = 0.07$ and 0.007, respectively).

Conclusions: The worse prognostic impact of HER2 expression in pts with ER-positive/HER2-negative BCs seems to be restricted to HER2 1+ tumors. The better outcome observed in pts with HER2 2+/FISH- BCs may be related to the known FISH-negative (HER2-non-amplified) status of this subgroup. These findings may help identify optimal patient inclusion criteria for clinical trials with novel anti-HER2 therapies in ER-positive/HER2-negative disease.

287P Perturbation and stability of PAM50 subtyping in population-based primary invasive breast cancer

J. Staaf[1], S. Veerla[1], L. Hohmann[1], D.F. Nacer[1], J. Vallon-Christersson[2]

[1]*Laboratory Medicine, Lund University, Lund, Sweden;* [2]*Division of Oncology Department of Clinical Sciences, Lund University, Lund, Sweden*

Background: PAM50 gene expression subtypes represent a cornerstone in molecular classification of breast cancer and are included in risk prediction models to guide therapy. We aimed to illustrate the impact of included genes and biological processes on subtyping while considering a tumor's underlying clinical subgroup defined by ER, PR and HER2 status.

Methods: We used a population-representative and clinically annotated primary breast tumor cohort of 6233 samples profiled by RNA sequencing and applied a perturbation strategy of excluding co-expressed genes (gene sets) from the PAM50 centroids followed by nearest centroid classification.

Results: We demonstrate how PAM50 nearest centroid classification depends on biological processes present across, but also within, ER/PR/HER2 subgroups and PAM50 subtypes themselves. Our analysis highlights several key aspects of PAM50 classification. Firstly, we observed a tight connection between a tumor's nearest and second nearest PAM50 centroid. Additionally, we show that second-best subtype is associated with overall survival in ER-positive, HER2-negative, and node-negative disease. We also note that *ERBB2* has little impact on PAM50 classification in HER2-positive disease regardless of ER-status, that the Basal subtype is highly stable in contrast to the Normal subtype, and that the LumB subtype classification is mainly reliant on expression of proliferation-related genes and low expression of keratin-associated genes.

Conclusions: Improved consciousness of the commonly used PAM50 subtyping scheme will aid in our understanding and interpretation of breast tumors that have seemingly conflicting PAM50 classification when compared to clinical biomarkers. Our study adds further support in challenging the common misconception that PAM50 subtypes are distinct classes by illustrating that PAM50 subtypes in tumors represent a continuum that may have clinical implications.

288P Prognostic factors in nonmetastatic HER2 'low' & HER2 'negative' breast cancer: Single institute experience

A. Türkel[1], M. Dogan[1], E. Sertesen[1], C. Karacin[1], S.Ç. Irkkan[2], O. Ates[1]

[1]*Medical Oncology, Dr. Abdurrahman Yurtaslan Ankara Oncology Training and Research Hospital, Ankara, Turkey;* [2]*Pathology, Dr. Abdurrahman Yurtaslan Ankara Oncology Training and Research Hospital, Ankara, Turkey*

Background: Human epidermal growth factor-2 (HER2) low breast cancer is a novel entity that differs from HER2-negative ones. We evaluated prognostic factors in HER2 low & compared with HER2-negative breast cancer retrospectively.

Methods: Estrogen receptor (ER) +/ progesterone receptor (PR) +, HER2 low and HER2-negative patients without distant metastasis were included.

Results: 444 (HL n:209, HN n:235) patients were evaluated. Median follow-up was 47 months. Most (59%) were postmenopausal. 121 (27.3%) had immunohistochemistry (IHC) score 1, 88 (19.8%) had IHC score 2 (SISH -). Mean age was 54.5 vs 53.3 years. Stage 2 (35.8%) & grade 2 (49.3%) were most common. Median ER/PR/ki67 were 95/60/25% for HER2 low & HER2 negative. 375 patients had chemotherapy, most (86%) had adjuvant chemotherapy. 40 (9%) had relapse & most (n: 31, 77.5%) had distant relapse. HER2-negative patients tended to have higher relapse rate (11.5% vs 6.2%, p:0.053). 5 year-disease free survival (DFS) was shorter for patients with HER2 negative (83.4% vs 90.8%), positive lymph nodes ≥10 (63.2% vs 92.3%), ECE + (75.4% vs 91.5%), ki67≥20% (70.2% vs 83.9%) (p: 0.021, p:0.008, p:0.004, p:0.026) (Table). Stage was inversely correlated with DFS (p: 0.001). HER2 status [HR: 0.43 (95% CI: 0.20 −0.94), p=0.035] & ki67 [OR: 2.99 (95% CI: 1.21−7.36), p=0.017] were significant prognostic factors in multivariate analysis. Overall survival (OS) data was immature..

Conclusions: HER2 low breast cancer patients, especially with ki67 <20% had better DFS, Most patients had IHC score 1.

Table: 288P Survival according to clinical & pathological features

Background: Inhibitors of the Receptor Activator of NF*k*B (RANK) pathway, such as denosumab, have been shown to prevent breast cancer (BC) in preclinical models by reducing proliferation and tumor cell survival. Recent studies suggest that RANK pathway inhibition enhances the anti-tumor immune response. This study aimed to evaluate the antiproliferative, proapoptotic (primary endpoints), and immunomodulatory activity (exploratory endpoint) of denosumab in early BC.

Methods: D-BIOMARK study (NCT03691311) was a randomized window-of-opportunity trial designed to evaluate the biological effects of single-agent denosumab in early BC. Sixty patients with early HER2-negative BC were enrolled, 2:1 randomization to experimental (two doses of 120mg of denosumab separated by 7 days before surgery) or control (no treatment) group. Paired samples (core-biopsy and surgical specimen) were obtained from each patient for comparison of Ki67 (proliferation), Cleaved Caspase-3 (cell survival), and tumor infiltrating lymphocytes (TILS) according to international guidelines. Pre *vs*. post values were compared using a paired t-test.

Results: A total of 58 evaluable patients were analyzed, 10 with triple-negative breast cancer (TNBC), 27 premenopausal and 31 postmenopausal. Denosumab reduced free RANKL (sRANK) levels in patient's serum but did not reduce tumor cell survival or proliferation. Denosumab increased TILS in all patients, except TNBC (n=6) while differences in the control group did not reach statistical significance. When considering clinically significant increases in TILS (5% or 10%), no differences were found between both groups. No associations were found between basal sRANKL and an increase in TILS..

Conclusions: Denosumab did not affect tumor cell survival nor proliferation in early BC but may have an immunomodulatory effect that warrants further investigation.

Clinical trial identification: NCT03691311.

290P Metabolomic profiling and response to neoadjuvant therapy (NAT) in early breast cancer (EBC)

A. Gennari[1], E. Barberis[2], V. Martini[1], S. Gobbato[3], R. Alsati[3], R. Ben Ayed[3], V. Rossi[1], F. D'Avanzo[1], B. Ruffilli[3], B. Malagutti[3], I. Dodaro[1], E. Gallarotti[1], L. Galli[1], R. Boldorini[1], A. Gambaro[1], A. Rampi[1], C. Branni[3], M. Manfredi[3]

[1]Department of Translational Medicine, AOU Maggiore della Carità di Novara, Novara, Italy; [2]Translational Medicine, UPO - Università del Piemonte Orientale - DISIT, Novara, Italy; [3]Dipartimento di Medicina Traslazionale - DIMET, Università degli Studi del Piemonte Orientale - Amedeo Avogadro, Novara, Italy

Background: The presence of residual disease (RD) after NAT is correlated with a poor outcome in EBC patients. New strategies are required to early identify patients who will not achieve a pathological complete response (pCR). Metabolomics may represent an innovative technology to identify host-related factors correlated with treatment outcome. In this study, we evaluated the predictive ability of metabolomics combined with machine learning in EBC patients receiving NAT.

Methods: Untargeted metabolomic analysis was performed in EBC patients candidates for NAT at our institution. Plasma samples were collected at baseline, before start of treatment. Small molecules were extracted, derivatized and then analysed using bi-dimensional gas chromatography/mass spectrometer (GCxGC-MS). The metabolomic profiling was then evaluated according to response to therapy (pCR versus RD). A machine learning approach was implemented with Boruta features selection algorithm combined with genetical algorithm as classifier, on a training set of 69 samples and validated on the remaining 27.

Results: From 12/2020 to 05/2023, 109 EBC patients have been enrolled (26 ER+, 45 HER2+, 38 TN); surgery was performed in 96 patients so far, with an overall pCR of 51% (ER+ 19%, HER2+ 51%, TN 55%). 61 small molecules were expressed ($p<0.05$ and Fold Change FC >1.3) between patients in pCR or RD. By multivariate analysis patients with RD showed higher levels of unsaturated fatty acids, as eicosatrienoate (FC=6), 9-decenoic acid (FC=2.2) and 17-octadecynoic acid (FC=2.2) and lower levels of fatty acids, as hexadecenoic acid (FC >100), doconexent (FC=69.5), 9,11-conjugated linoleic acid (FC=5.2), circulating glucose (FC=71) and glucopyranose (FC=23). Pathway analysis revealed the involvement of amino and fatty acid metabolism. A prediction model, combining metabolomics and machine learning, was implemented on 35 metabolomic probes and correctly identified the type of response with an accuracy of 95%.

Conclusions: Our data indicate that host-related metabolomic signatures may identify patients with EBC failing to achieve a pCR after NAT. We identified several fatty acids, amino acids and small molecules that can be modulated through diet. Possible effects by BC subtype are being investigated.

291P Prognostic implications of HER2 gain in patients with HR+/ HER2- breast cancer (BC) and TNBC after neoadjuvant chemotherapy (NAC)

E. Ferraro[1], S. Chew Minmin[1], D. Nemirovsky[2], Y. Chen[2], A.V. Barrio[3], S. Modi[1], A. Seidman[1], H. Wen[4], E. Brogi[4], M. Robson[5], C. Dang[6]

[1]Breast Medicine Service, Memorial Sloan Kettering Cancer Center, New York, NY, USA; [2]Biostatistics, Memorial Sloan Kettering Cancer Center, New York, NY, USA; [3]Breast Surgery, Memorial Sloan Kettering Cancer Center, New York, NY, USA; [4]Pathology Department, Memorial Sloan Kettering Cancer Center, New York, NY, USA; [5]Medicine Dept, MSKCC - Memorial Sloan Kettering Cancer Center, New York, NY, USA; [6]Department of Breast Oncology, MSKCC - Memorial Sloan Kettering Westchester, West Harrison, IN, USA

Background: Residual disease (RD) after NAC is a well-established risk factor for recurrence in patients (pts) with triple-negative breast cancer (TNBC) or high-risk hormone receptor-positive (HR+)/ HER2-negative (-) BC. Biologic and prognostic significance of HER2 gain on RD after NAC are unknown. We sought to determine invasive disease-free survival (IDFS) in patients with HER2 gain in a cohort of consecutive patients with HER2(-) BC treated with NAC.

Methods: We identified pts with HER2(-) BC treated with NAC followed by surgery at our institution between 8/2019 and 12/2021. Pathologic complete response [pCR] (ypT0/is ypN0) rates and HER2 status pre- and post-NAC were assessed, the latter by 2018 ASCO/CAP guidelines. HER2-low was defined as IHC 1+ or IHC 2+, FISH non-amplified. IDFS was analyzed using the Kaplan-Meier method and differences assessed by log-rank test. Chi-square, Fisher's exact, Wilcoxon rank sum test, and logistic regression were used to evalute baseline features associated with HER2 gain. Any *p*-value less than 0.05 was deemed to be statistically significant.

Results: We included 528 HER2(-) pts [274 (52%) HR+/HER2- and 252 (48%) TNBC]. Overall, pCR was achieved in 40% of TNBC and 9% of HR+/HER2(-). The median follow-up was 17.5 months (14.5-21.3). Among 401 pts with RD, the rate of HER2 gain was 5% (20/401) (Table). HER2-low and HR+ status assessed on initial biopsy were independently associated with HER2 gain on the surgery sample with OR=3.05 (95% CI:1.07-10.9) and OR=4.09 (95%CI: 1.02-27.5), respectively, while high grade was not (OR=0.68; 0.24-1.78). After surgery, all but two pts with HER2 gain received anti-HER2 therapy. The 2-year IDFS rate was 100% in pts with HER2 gain and 85% (95%CI: 81-90%) in pts with HER2(-) RD (p=0.07).

Conclusions: HER2 gain after NAC was a rare event, more commonly occurring in pts with HR+/HER2(-) BC compared to TNBC, likely related to HER2 heterogeneity. Optimal adjuvant regimen remains to be established..

292P Unlocking the potential of circulating miRNAs in predicting response to neoadjuvant chemotherapy in breast cancer: A systematic review and meta-analysis

P. Tiberio[1], M. Gaudio[2], S. Belloni[3], C. Benvenuti[2], F. Jacobs[2], G. Saltalamacchia[2], A. Zambelli[2], A. Santoro[1], R. De Sanctis[1]

[1]Medical Oncology and Hematology Unit, IRCCS Humanitas Research Hospital, Rozzano, Italy; [2]Department of Biomedical Sciences, Humanitas University, Pieve Emanuele, Italy; [3]Educational and Research Unit, IRCCS Humanitas Research Hospital, Rozzano, Italy

Background: The potential role of circulating miRNAs as biomarkers for breast cancer (BC) has been widely reported. However, the large discrepancy between studies prevents the feasibility of implementing circulating miRNAs in routine clinical practice. In BC patients undergoing neoadjuvant chemotherapy (NAC), the ability to anticipate response could lead to improve prognosis by individualizing post-NAC approach. In this scenario, the present meta-analysis aims to quantify and clarify circulating miRNAs' predictive role for NAC response in BC patients.

Methods: We conducted a comprehensive literature search in 5 main medical databases until 16th February 2023, along with additional research sources. The systematic review and meta-analysis were performed in accordance with the Preferred Reporting Items for Systematic Reviews and Meta-Analyses and we applied the Cochrane recommended methodology for prognostic factor studies. We quantitatively pooled the effect sizes of each study by applying a random-effects model to consider within and between-study variances. Cochrane Q test (significance at 0.05) and I^2 value were used to assess between-study heterogeneity. The Prediction Model Risk Of Bias Assessment Tool evaluated studies' bias risk.

Results: The meta-analysis included 15 studies, with a total of 1521 early BC patients. Overall, our findings support the hypothesis that circulating miR-21-5p and miR-155-5p may act as predictive biomarkers. Pooled area under the curve values were 0.72 (95% confidence interval (CI) 0.59-0.86, $p < 0.05$) and 0.67 (95% CI 0.53-0.81, $p < 0.05$), respectively, thus indicating an acceptable predictive ability in anticipating NAC response.

Conclusions: To our knowledge, this is the first systematic review and meta-analysis that provides a quantitative synthesis of the predictive value of circulating miRNAs for NAC response in BC patients. However, due to the limited number of studies included in the meta-analyses and the high clinical and statistical heterogeneity, further studies are needed to confirm the predictive power of circulating miR-21-5p and miR-155-5p.

294P Prognostic significance and evolution of HER2 zero, HER2 low and HER2 positive in breast cancer after neoadjuvant treatment

T. Wei[1], D. Wang[2], Y. Peng[1]

[1]Department of VIP Medical, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China; [2]Department of Breast Surgery, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China

Background: With the development of anti-HER2 targeted antibody-drug conjugates, HER2 low has attracted a lot of attention in breast cancer (BC). It's significant to study the pathological response of HER2 zero, HER2 low and HER2 positive BC after neoadjuvant treatment and the HER2 status evolution.

Methods: A retrospective study was conducted at National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College. Data from patients who were diagnosed with BC between 2015 and 2021 at our center and who had received neoadjuvant treatment were collected. The pathological complete response (pCR) rate of HER2 zero, HER2 low, and HER2 positive was analyzed. And the analysis of HER2 status evolution were carried out.

Results: 1173 patients with BC who had received neoadjuvant treatment were collected. 11.85% of the patients (n=193) achieved pCR, and 88.15% of the patients (n=1034) were non-pCR. Among 526 patients with available baseline biopsy reports and matched pathological reports after neoadjuvant treatment, HER2 low BC was related to the lowest rate of pCR, followed by HER2 zero and HER2 positive BC (13.79% vs. 20.00% vs. 40.20%, respectively, p=0.000). Of the 526 patients, 381 were hormone-receptor-positive BC, and 145 were triple-negative breast cancer (TNBC) on baseline biopsy. In 381 patients with hormone-receptor-positive BC, HER2 low BC was also related to the lowest rate of pCR, followed by HER2 zero and HER2 positive BC as well (9.14% vs. 12.28% vs. 36.22%, respectively, p=0.000). A similar trend was also observed in TNBC without a statistically significant difference. On the converting of HER2 zero, HER2 low and HER2 positive before and after neoadjuvant treatment, HER2 zero has the highest discordance rate and 58.21% of HER2 zero on baseline biopsy converted into the other two types after neoadjuvant treatment. The conversion rates of HER2 low and HER2 positive on baseline biopsy were 28.10% and 14.43%, respectively.

Conclusions: Compared with HER2 zero and HER2 positive, HER2 low has the lowest pCR rate after neoadjuvant treatment. Besides, HER2 zero had the highest incidence of conversion to other HER2 statuses after neoadjuvant treatment.

Background: Currently, early breast cancer (eBC) is classified by using clinical and histopathological factors that are often considered insufficient for individualised therapy. This study is aimed at examining whether single gene mRNA expression of ESR1, PGR, ERBB2 and MKI67 can be used instead of histopathological analysis in high-risk eBC.

Methods: For this study, a sample of high-risk patients who were treated with neoadjuvant chemotherapy was selected from a prospective, multicentre cohort of 1,270 eBC patients (PiA, Prognostic Assessment in routine application, NCT 01592825). Histopathological data for ER, PgR, HER2 and Ki67 were taken from the routine results from pre-treatment core needle biopsies. Single gene mRNA expression analysis of ESR1, PGR, ERBB2 and MKI67 and intrinsic subtyping (PAM50) were generated by multiplex hybridisation method (nCounter, NanoString ®) using formalin fixed tumour material. Cut-off values were determined by ROC-analysis.

Results: A strong correlation for ESR1, PGR and ERBB2 with corresponding histopathological results (IHC/ISH) was demonstrated (Pearson's r= 0.701, r=0.716, and r= 0.669, respectively; all p<0.001). After dichotomisation positive predictive value was 98%, 92%, and 92%, resp. Overall percent agreement was 94.5%, 92.8% and 90.8%, resp. Cohen's Kappa showed high inter-reliability (κ=0.888, κ=0.856, κ=0.766 resp, all p<0.001). Odds ratio also indicates an association of single gene mRNA-expression with complementary histopathological and intrinsic subtypes (p<0.05). Single gene mRNA expression data of all four genes (including MKI67) was used to classify the tumours following the surrogate definitions by the St. Gallen International Expert Consensus and demonstrated concordance with histopathological groups and intrinsic subtypes.

Conclusions: Single gene mRNA expression analysis for ESR1, PGR, ERBB2 and MKI67 is feasible and, in our sample, the results show a strong correlation to the corresponding histopathological results. Single gene expression may be used as an alternative to standard histopathological analysis. In addition, also subtyping can be performed by using single gene data; however, the clinical reliability has still to be proven.

Background: Pathological complete response (pCR) after neoadjuvant chemotherapy (NAC) is known as a prognostic factor correlated with improved EFS and OS. Better prediction of pCR would allow better patient and treatment selection. We aim to reveal specific transcriptomic and metabolic signatures correlated with distinct responses to NAC based on patient diagnostic biopsies. We also compared metabolic profiles of *in vitro* models.

Methods: We performed bulk-RNA sequencing on 95 samples from diagnostic biopsies from all subtypes of early BC treated with NAC (NCT03314870 study). Early triple-negative BC cell lines (HCC38, HCC1143, HCC1937) and patient-derived tumor organoids were cultured for drug testing, RT-qPCR and metabolomics studies using Seahorse bioenergetic analyzer.

Results: Transcriptomic analyses showed a down-regulation of genes related to tumor cell metabolism such as genes involved in the glycolysis (e.g. *STC2,* FDR = 0.05) in non-responding patients (n=39). Gene set enrichment analysis (hallmark and KEGG pathway databases) showed a down-regulation of the glycolysis and the oxidative phosphorylation pathways in non-responding patients (adjusted p-value <0.05). In 2D cell cultures, the HCC1937 cell line showed resistance to paclitaxel and a higher glycolysis profile than the HCC38 and HCC1143 cells. Exposure to epirubicin or paclitaxel decreased the glycolysis in HCC38 and HCC1937 cell lines, while a decrease in the oxidative phosphorylation was observed in all 3 cell lines. A triple-negative organoid model (BCO17), initiated from a treatment naive tumor, showed resistance to epirubicin and paclitaxel. In BCO17, exposure to epirubicin or paclitaxel did not change the glycolysis or oxidative phosphorylation profile. Targeting glycolysis with 2-deoxy-2-glucose (2DG) in monotherapy showed 50% of cell mortality in a 2D and organoid models, while combination of 2DG with epirubicin and paclitaxel did not increase the cell mortality.

Conclusions: Glycolysis and oxidative phosphorylation are involved in non-response to NAC in early breast cancer. 2D and organoid models with distinct chemotherapy sensitivity showed different metabolic profiles that may be explored in drug development.

Background: The notch signalling pathway is considered to be an interesting prognostic and predictive marker in breast cancer as it is involved in proliferation, invasiveness and chemotherapy resistance.

Methods: From a prospective, multicenter cohort (Prognostic Assessment in Routine Application (PiA), 2009-2011, NCT01592825) of 1,270 breast cancer patients with a median follow-up of 60 months, the relative mRNA expression of NOTCH1 was determined in 414 tumour samples by qPCR. The primary objective was the evaluation of NOTCH1 mRNA expression and its association with patients and tumour characteristics. The secondary objectives were the associations with recurrence-free interval (RFI), overall survival (OS), and the predictive value of NOTCH1 mRNA expression with regard to adjuvant chemotherapy.

Results: Within our study, high NOTCH1 expression was detected in one-third of the tumours. We observed a significant prognostic impact of high NOTCH1 expression with regard to RFI (adjusted hazard ratio 2.1, 95% CI 1.077−4.118). Patients with high NOTCH1 expression and chemotherapy (n = 86) had a worse clinical outcome compared to those without chemotherapy with an adjusted 3.1 higher risk for disease-related events (RFI events, 95% CI 1.321−7.245, p = 0.009).

Conclusions: In summary, in our cohort for NOTCH1 we showed a prognostic and, particularly, a significant predictive impact. We observed that tumours with high NOTCH1 expression seem to be less sensitive to cytotoxic treatment. Therefore, we postulate, that downregulation of the Notch signalling pathway, e.g. with y-secretase inhibitors, may improve the efficacy of breast cancer therapy by restoring chemosensitivity.

298P Association of luminal-androgen receptor (LAR) subtype with low HER2 in triple-negative breast cancer

L. Min Ji, B. Seung Ho, S.E. Lee, Y. Kook, S. Moon, J. Kim, M.J. Kim, S.J. Bae, J. Jeong, S.G. Ahn

Department of Surgery, Gangnam Severance Hospital, Yonsei University College of Medicine, Seoul, Republic of Korea

Background: Low level of HER2+ breast cancer, a subset of HER-2 negative, accounts for about 50-60% of breast cancer. A recent publication highlighting the improved survival outcomes with trastuzumab deruxtecan in this group has raised the need to redefine low HER2+ breast cancer in the context of molecular characterization. In triple-negative breast cancer (TNBC), we compared molecular TNBC subtype, PAM50 subtypes, and clinical-pathological characteristics between the low HER2 and zero HER2 groups.

Methods: A study population included two cohorts with early TNBC. The adjuvant cohort consisted of 199 TNBC patients who underwent upfront surgery, while the neoadjuvant cohort comprised 124 TNBC patients treated with neoadjuvant chemotherapy (NAC). Transcriptome analysis was conducted in the adjuvant cohort to determine the TNBC molecular subtype and PAM50 types. Tumor-infiltrating lymphocyte (TIL) levels, PD-L1, and Ki67 expression were evaluated in both cohorts, along with recurrence-free survival (RFS) and event-free survival (EFS) investigations in each cohort.

Results: In 199 patients with transcriptome analysis, 66 (33.2%) had low HER2 disease, while 133 (66.8%) had zero HER2 tumors. The rates of luminal androgen receptor (LAR) and HER2-E subtypes were 13.1% (26/199) and 7.0% (14/199), respectively. Comparing the two groups, low HER2 tumors showed higher rates of LAR (22.7% vs. 8.5%, p=0.006) and HER2-E (15.2% vs. 3.3%, p=0.016), while other characteristics such as TIL, PD-L1, ROR-P score, and Ki67 did not differ between the two groups. In the neoadjuvant cohort, 31 (25.0%) had low HER2 disease while 93 (75.0%) had zero HER2 tumors, and there were no significant differences in TIL, PD-L1, and Ki67 expression between the two groups. Furthermore, low HER2 status did not significantly affect RFS and EFS in either cohort.

Conclusions: Low HER2 status in TNBC is distinctly associated with enriched LAR and HER2-E subtypes. However, other characteristics such as TIL, PD-L1, and Ki67 expression, as well as survival outcomes, were found to be similar between the two groups.

299P Single-cell transcriptomic analysis reveals specific luminal and T cell subpopulations associated with response to neoadjuvant therapy in early-stage breast cancer

X. Wang[1], D. Gacquer[1], S. Majjaj[1], M. Rediti[1], L. Craciun[2], D. Larsimont[2], F. Rothé[1], C. Sotiriou[1]

[1]Breast Cancer Translational Research Laboratory J-C. Heuson, Institut Jules Bordet, Hôpital Universitaire de Bruxelles (H.U.B), Brussels, Belgium; [2]Pathological Department, Institut Jules Bordet, Hôpital Universitaire de Bruxelles (H.U.B), Brussels, Belgium

Background: Neoadjuvant therapy (NAT) remains the standard of care for most early-stage breast cancer (BC) patients, especially in HER2+ and triple-negative (TNBC) subtypes. Patients who do not achieve pathological complete response (pCR) present an increased risk of disease recurrence. Here, we applied single cell RNA sequencing (SCS) to investigate tumor and immune landscape for the identification of predictive biomarkers of response to NAT.

Methods: Twenty-one BC patients treated with NAT were included in the study. Pretreatment biopsies, matched residual disease and adjacent normal tissue samples were prospectively collected for all patients. After tissue dissociation, single cell RNA profiles were investigated using the Chromium Next GEM Single Cell 5' kit (10X Genomics). After removing batch effect using Seurat integration, cell clusters were annotated based on the expression of specific marker genes. Epithelial luminal cells (KRT18+/KRT19+) were classified as malignant or non-malignant using copy number profiles computed by inferCNV. Wilcoxon rank sum test was used to compare cell proportions between pCR and non-pCR groups.

Results: pCR rates were 61.5% (8/13), 100% (4/4) and 25% (1/4) in TNBC, HER2+ and Luminal B patients respectively. A total of 21 TNBC, 6 HER2+ and 6 Luminal B samples were profiled with SCS. Malignant luminal epithelial cells were classified in luminal progenitor (LP) (KIT+/SLPI+/KRT5^{low}), luminal mature (LM) (KIT-/SLPI-/KRT5-) and luminal cycling cells (LC) (MKI67+/TOP2A+). Patients achieving pCR had a higher fraction of LC cells at baseline, considering all BC subtypes ($p<0.05$). Enrichment of LP cells at baseline was observed in TNBC patients achieving pCR ($p<0.05$). T cells reclustering further identified four CD4+ subtypes. Of note, lower proportions of FOXP3+ regulatory T cells and RORC+/CCR6+ Th17 cells at baseline were associated with a better response to NAT both in TNBC and HER2+ patients ($p<0.05$).

Conclusions: Our study showed substantial heterogeneity at the single cell level with specific cell types being associated with response to neoadjuvant chemotherapy, towards an improved BC care.

300P Correlation of PD-L1 protein and mRNA expression and their prognostic impact in triple-negative breast cancer

K. Schüler[1], M. Bauer[2], S. Kaufhold[1], E. Kantelhardt[3], C. Thomssen[4], M. Vetter[1]

[1]Department of Gynaecology, UKH - Universitätsklinikum Halle (Saale), Halle (Saale), Germany; [2]Institute of Pathology, Martin Luther University Halle-Wittenberg, Halle (Saale), Germany; [3]Institute of Epidemiology, Biometry and Informatics, Martin Luther University Halle-Wittenberg, Halle (Saale), Germany; [4]Department of Gynaecology, Martin Luther University Halle-Wittenberg, Halle (Saale), Germany

Background: PD-L1 expression is determined by immunohistochemical (IHC) analyses. PD-L1 positivity can differ depending on the used antibody. The aim of this study was to evaluate the correlation of IHC and mRNA PD-L1 expression and their associations to prognosis.

Methods: For this analysis, 85 TNBC samples from a prospective cohort of breast cancer patients (n=1,270, PiA Prognostic Assessment in routine application, NCT 01592825) were eligible. IHC was performed using CAL10 antibody (BioCare), ≥1% staining was considered PD-L1 positive for immune cell score (IC), tumour proportion score (TPS) and combined positive score (CPS). For analysis of mRNA expression, microarray analysis was performed (Affymetrix®, HG U133 Plus 2.0, probesets #1: 223824, #2: 227458, detecting different transcripts of the PD-L1 gene); maximum likelihood method was used for cut off determination. Correlations with IHC and TILs were tested using Spearman's rank correlation. Survival analysis included recurrence free interval (RFI) and overall survival (OS), considering only those patients who received chemotherapy (n=76). Median follow up was 73 months (20-127).

Results: In IHC analysis, half of the samples were classified PD-L1 positive for IC and CPS (50.6% and 49.4%) and only 23.5% considering TPS. In probeset #1, 63.5% were determined PD-L1 positive, no correlation to the IHC scores, TILs and probeset #2 was shown. In probeset #2 only 34.1% showed a PD-L1 positivity and had a strong correlation to the IHC scores and to TILs ($p<0.01$). PD-L1 positivity had no impact on survival when determined by IHC scores or probeset #2. In contrast, patients with high PD-L1 expression in probeset #1 had a more favourable 7-years RFI probability (84.6% vs 64.3%). Low PD-L1 expression showed higher risk for recurrence in univariate (2.68, 95%CI 1.089-7.532) and multivariate analysis (3.43, 95%CI 1.294-9.080, adjusted to nodal status). Considering OS only a trend was shown (HR 1.445, 95%CI 0.570-3.662).

Conclusions: In our cohort, the PD-L1 mRNA analysis detected additional PD-L1 positive tumours compared to IHC analysis. For validation of the prognostic impact and to examine the predictive value considering therapy with immune checkpoint inhibitors, further studies are warranted.

301P Epigenetic modifications of IL-17 gene in patients with early breast cancer and healthy controls

L. Radmilovic Varga[1], T. Marić[2], A. Katušić Bojanac[2], K. Horvatović[3], M. Popovic[4], A. Kulić[4], T. Silovski[5], M. Sirotkovic-Skerlev[6], M. Krizic[4], K. Bulić[7], H. Silovski[8], N. Dedic Plavetic[4]

[1]Oncology Department, General Hospital Varazdin, Varazdin, Croatia; [2]Department of Medical Biology, School of Medicine, University of Zagreb, Zagreb, Croatia; [3]School of Medicine, University of Zagreb, Zagreb, Croatia; [4]Department of Oncology, KBC - University Hospital Centre Zagreb, Zagreb, Croatia; [5]Medical Oncology Department, KBC - University Hospital Centre Zagreb, Zagreb, Croatia; [6]Department of Pathophysiology, School of Medicine, University of Zagreb, Zagreb, Croatia; [7]Department of Surgery, KBC - University Hospital Centre Zagreb, Zagreb, Croatia

Background: During malignant transformation, the composition and expression of cell surface molecules are changing allowing recognition by the host immune system. Interleukin 17 (IL-17) is an inflammatory mediator involved in all phases of the inflammatory process and tumour development and progression. The aim of this study was to determine the IL-17 gene methylation level and IL-17 serum concentration in patients with different surrogate subtypes of early breast cancer (eBC) and healthy controls (HCs).

Methods: Peripheral blood samples were obtained from a consecutive series of 130 female patients treated at the University Hospital Centre (UHC) Zagreb, Croatia, and 30 female HCs. The level of methylation of four CpG dinucleotide loci (CPG1, CPG2, CPG3, CPG4) in the promoter region of the IL-17 gene was measured by pyrosequencing with prior bisulfite conversion, while serum IL-17 concentrations were determined by enzyme-linked immunosorbent assay (ELISA). Blood samples, clinical and histopathological data were collected with prior UHC Zagreb 02/21 AG Institutional Review Board approval.

Results: According to the Mann-Whitney test, the HCs methylation level of the promotor region of the *IL-17* gene differed significantly from the BC patients ($p = 0.0011$), together with the methylation level of four individual CpG loci, also (p values; CPG1 0.0067; CPG2 0.0018; CPG3 CPG 0.0029; CPG4 0.0032, respectively). There was a statistically significant difference according to the Kruskal-Wallis test in CPG3 locus methylation among BC surrogate subtypes (p=**0.010**), whereas no difference in the methylation of the other three loci was observed. Preoperative IL-17 serum concentration was significantly higher in patients with HER-2 enriched and triple-negative eBC (Kruskal-Wallis test, p=**0.022**).

Conclusions: This study confirmed differences in epigenetic modification of *IL-17* gene in women with eBC compared to HCs. Differences in the IL-17 gene methylation and IL-17 serum concentration in patients with different subtypes of BC were observed. Further research is planned to define the impact of IL-17 on eBC outcome in this cohort.

302P Clinicopathological features and outcomes of pregnancy associated breast cancer: Case control study -single institution experience

N. Kordy[1], A. Haggag[1], S. Seddik[1], R. Eid[2], E. Shash[3]

[1]Biostatics, Epidemiology and Science Computing, Shefaa El Orman Oncology Hospital (SOH), Luxor, Egypt; [2]Biostatics, Epidemiology, National Cancer Institute - Cairo University, Cairo, Egypt; [3]Medical Oncology Department, National Cancer Institute - Cairo University, Cairo, Egypt

Background: Globally, breast cancer ranks among the primary contributors to the incidence and mortality rates of cancer. Pregnancy-Associated Breast Cancer (PABC) is an infrequent occurrence among young patients (≤45 years), characterized by diagnosis of breast cancer during pregnancy or within a year after delivery. In recent meta-analysis study, PABC patients showed higher mortality than control group. This retrospective case-control study aimed to assess the outcomes of PABC vs non-pregnancy-associated breast cancer (NPABC). The primary outcome measure was overall survival (OS), and secondary outcome measures included disease-free survival (DFS) and recurrence-free survival (RFS).

Methods: A retrospective case-control study was conducted at Shefa El Orman Hospital (SOH) from 2016 to 2021, on patients who met PABC criteria and were under follow-up for at least 3 years. Data collection was carried out using SOH Cancer Registry. 54 PABC patients cross matched with an equal number of control NPABC (≤45 years of age) with a 1:1 ratio. Statistical analysis was conducted through SPSS software. The Chi-square $\chi 2$ test was employed to conduct a comparative analysis of frequency distributions for categorical variables.

Results: Total of 54 PABC patients and equal number of control subjects. The median age of PABC cohort = 33 (IQR: 23-42), which did not differ significantly from NPABC (34, IQR: 22-42; p=0.650). PABC demonstrated a higher likelihood of presenting with metastasis at initial diagnosis compared to those NPABC (metastatic: 66.7% vs. 33.3%, p=0.018). PABC patients exhibited a noteworthy contrast in advanced stages during diagnosis, particularly in stage III and IV, in comparison to NPABC patients (61.1% vs 40.7%, p=0.021). Additionally, PABC patients showed an inferior median OS rate (48.9% vs 69.3%, p=0.085) compared to NPABC.

Conclusions: In conclusion, a significant difference exists between the OS and clinicopathological characteristics of PABC patients compared to NPABC. Furthermore, PABC patients exhibited an advanced stage of the disease upon presentation. Larger cohort studies are necessary to evaluate the treatment efficacy and to acquire molecular indicators that may impact the disease outcomes.

303P Differential prognostic role of PDGFRA alterations in breast cancer subtypes

P.J. Vlachostergios[1], N. Spathas[2], K. Thomopoulou[3], E. Lymperopoulos[4]

[1]*Medical Oncology, Weill Cornell Medicine, New York, USA & IASO Thessalias Hospital, Larissa, Greece;* [2]*4th Oncology Department, Metropolitan Hospital, Athens, Greece;* [3]*Department of Medical Oncology, Hygeia General Hospital, Athens, Greece;* [4]*Obstetrics and Gynecology, IASO General Hospital, Cholargos/Holargos, Greece*

Background: The platelet — derived growth factor (PDGF) signaling pathway and its main representative, PDGF receptor alpha is reportedly expressed in early breast cancer and has been associated with aggressive tumor features and worse outcomes. The aim of this study was to examine the prognostic relevance of *PDGFRA* molecular alterations across different breast cancer subtypes.

Methods: Patients with a diagnosis of non-metastatic, invasive breast carcinoma from The Cancer Genome Atlas (TCGA), including estrogen receptor (ER)-positive (n=594), ER-negative (n=174), human epidermal growth factor receptor 2 (HER2)-positive (n=120), and triple-negative (n=82) cohorts were interrogated for presence of somatic molecular alterations in *PDGFRA* gene. Kaplan Meier survival analysis was used to determine the associations between altered *PDGFRA* and disease-free survival (DFS).

Results: Sixty patients (10%) from the ER-positive cohort had altered *PDGFRA*, including 2 patients with gene amplification, 3 with missense mutations, 1 with homologous deletion and 55 with elevated mRNA expression. These patients had a longer DFS compared to those with unaltered PDGFRA (not reached vs 168 months, log-rank p=0.04). In the ER-negative cohort, 24 patients (14%) had tumors harboring *PDGFRA* alterations including 5 amplifications, 2 missense and 1 nonsense mutation, and high mRNA (n=16). There was a trend towards a shorter DFS in these patients (p=0.23). Within the HER2-positive cohort, 11 patients (9%) had somatic gene amplifications (n=1), missense mutation (n=1), and elevated mRNA (n=9). These patients experienced a significantly worse DFS (56 months vs not reached, p<0.001). Among TNBC patients, 10 (12%) were characterized by *PDGFRA* amplification (n=2), missense (n=2) and nonsense (n=1) mutations, and high mRNA (n=5). This group also featured a non-significant trend towards worse DFS (p=0.39).

Conclusions: *PDGFRA* molecular alterations in early breast cancer are mainly characterized by amplification and increased transcript levels. Their prognostic utility is variable depending on the hormone receptor- and HER2-status. An intriguing association with favorable prognosis in ER-positive cohort was found that merits further investigation.

304P Generalizability of 313-SNP PRS for breast cancer risk in non-European ancestries

H. Shang[1], Y. Ding[2], V. Venkateswaran[2], K. Boulier[3], B. Pasanuic[2], N. Kathuria-Prakash[4], P. Brown[1]

[1]*Internal Medicine, Ronald Reagan UCLA Medical Center, Los Angeles, CA, USA;* [2]*Computational Medicine, UCLA, Los Angeles, CA, USA;* [3]*Computational Medicine, Ronald Reagan UCLA Medical Center, Los Angeles, CA, USA;* [4]*Hematology/Oncology, Ronald Reagan UCLA Medical Center, Los Angeles, CA, USA*

Background: Polygenic risk scores (PRS), which summarize the combined effect of multiple common risk variants, have been associated with elevated breast cancer risk in patients who lack any identifiable monogenic risk factors. One of the most well-validated PRSs in breast cancer to date is PRS313, which was developed from a Northern European biobank (n = 33,673 cases and n = 33,381 controls). However, subsequent work has demonstrated an attenuated effect of PRS313 in African females, raising generalizability concerns. In this work, we further investigate the generalizability of the PRS313 for American women of European (EA), African (AFR), Asian (EAA), and Latinx (HL) ancestry within one institution, leveraging a singular EHR system, genotyping platform, and quality control process.

Methods: Participants were females drawn from the UCLA ATLAS Biobank (N=18,627) from 2018-2023. SNPs were genotyped on a genome-wide array and imputed to the TOPmed reference panel. Breast cancer cases and controls were identified using ICD9 and ICD10 coding. We previously identified 5 Genetically Inferred Ancestries (GIA) based on Principal Component Analysis (PCA) and k-means clustering including African Americans (AA), Hispanic Latino Americans (HLA), East Asian Americans (EAA), European Americans (EA). Breast cancer subtypes were identified based on prescription patterns.

Results: We found that the PRS313 achieved overlapping AUCs in females of Lantix (AUC, 0.68; 95% CI, 0.65-0.71) and European ancestry (AUC, 0.70; 95% CI, 0.69-0.71) with lower AUCs for the AFR and EAA populations (AFR: AUC, 0.61; 95% CI, 0.56-0.65; EAA: AUC, 0.64; 95% CI, 0.60-0.680).

Conclusions: In summary, we found that PRS313 was significantly associated with breast cancer in American females of Hispanic and East Asian ancestry but with attenuated accuracy in women of African descent. Our results are consistent with prior studies on PRS313 and further highlight the need for ethnically diverse cohorts in developing and implementing polygenic risk scores.

305P Prognostic implications of HER2 changes after neoadjuvant chemotherapy in patients with HER2-zero and HER2-low breast cancer

S. Kang[1], S.H. Lee[2], H.J. Lee[3], H. Jeong[4], J-H. Jeong[2], J.E. Kim[2], J-H. Ahn[2], K.H. Jung[2], H.H. Kim[5], S. Lee[6], J. Lee[6], S-B. Kim[2]

[1]*Hemato-Oncology, Chungnam National University Hospital, Daejeon, Republic of Korea;* [2]*Department of Oncology, Asan Medical Center - University of Ulsan College of Medicine, Seoul, Republic of Korea;* [3]*Pathology, Asan Medical Center - University of Ulsan College of Medicine, Seoul, Republic of Korea;* [4]*Internal Medicine Department, Asan Medical Center - University of Ulsan College of Medicine, Seoul, Republic of Korea;* [5]*Department of Radiology, Asan Medical Center - University of Ulsan, Seoul, Republic of Korea;* [6]*Surgery, Asan Medical Center - University of Ulsan, Seoul, Republic of Korea*

Background: Transition of HER2 status after neoadjuvant chemotherapy (NAC) has frequently been reported previously; however, few study has focused on HER2-low breast cancer. Here, we evaluated the HER2 transition proportion among HER2-zero and HER2-low breast cancer cases post-NAC and the impact of clinical outcome after our initial report on pathologic complete response, long term outcomes and recurrence pattern in between two groups after neoadjuvant chemotherapy (S Kang, European Journal of Cancer, 2022).

Methods: We retrospectively reviewed HER2-zero and HER2-low breast cancer patients who underwent NAC and surgical resection during 2014—2018 at Asan Medical Center. We included 1288 patients who had paired pre- and post-therapeutic HER2 status results. HER2-zero was defined as immunohistochemistry (IHC)0, and HER2-low was defined as IHC1+ or IHC2+, with in situ hybridization-negativity.

Results: Of patients who were HER2-zero pre-NAC(n=650), 68% and 29% of patients were HER2-zero and HER2-low, respectively, post-NAC. Among patients who were HER2-low pre-NAC(n=638), 32% of patients showed HER2 changes, and 59% of patients had a constant HER2-low status post-NAC. Patients with constant HER2-low or transitions from HER2-low to zero had a higher proportion of hormone-receptor [HR] positivity (84% and 79%) than those with changes from HER2-zero to low (77%) or with constant HER2-zero (56%), respectively. Multivariable logistic regression analysis revealed that patients with HR positivity had a higher probability of gaining HER2-low expression than those with HR negativity (Odds ratio 2.48). No significant differences were observed in terms of overall survival and disease-free survival between patients with and without HER2-changes according to hormone receptor status, except in the post-therapeutic HER2-low HR-negative subset.

Conclusions: Temporal heterogeneity of HER2-low expression is observed in substantial portions of post-NAC breast cancer patients. Clinical outcomes show no significant associations, except in the post-therapeutic HER2-low, HR-negative subset. Prognostic implications of HER2 transition in HER2-low breast cancer require further investigation.

306P Multiplexed immunofluorescence (mIF) to select patients with HER2+ breast cancer (BC) having an excellent outcome without chemotherapy (chemo): A substudy of the PERNETTA trial (SAKK22/10-UCBG-BOOG)

K. Zaman[1], S. Tissot[1], F. Benedetti[1], D. Dietrich[2], D. Tarussio[1], J. Huober[3], H. Bonnefoi[4], P. Weder[5], E. Boven[6], S. Rusakiewicz[7], L.E. Kandalaft[1]

[1]Department of Oncology, Lausanne University Hospital CHUV, Lausanne, Switzerland; [2]Oncology, SAKK - Swiss Group for Clinical Cancer Research, Bern, Switzerland; [3]Oncology, Cantonal Hospital St. Gallen, St. Gallen, Switzerland; [4]Medical Oncology Department, Institute Bergonié - Centre Régional de Lutte Contre le Cancer (CLCC), Bordeaux, France; [5]Oncology, Tumor- und BrustZentrum Ostschweiz, St.Gallen, Switzerland; [6]Oncology, Amsterdam UMC - Vrije University Medical Centre (VUmc), Amsterdam, Netherlands; [7]Oncology Department /CTE, Ludwig Cancer Center of the University of Lausanne - CHUV, Lausanne, Switzerland

Background: PERNETTA trial randomized 210 HER2+ BC patients (pts) to 1st-line trasutuzmab-pertuzumab (T-P) alone or combined with chemo. In the final analysis (median follow-up 63 months), pts with chemo had longer progression free survival (PFS), but similar overall survival (OS) at 2 years. In this ancillary study, we aimed to identify immune biomarkers predicting for long PFS in pts with the chemo-free anti-HER2 strategy.

Methods: Six good and 6 poor responders were selected in each study arm, based on their PFS (total 24 pts); 77 proteins were assessed using GeoMx digital spatial profiling technology in these 24 samples, in the Immune Landscape Laboratory of the Ludwig Institute in Lausanne. Proteins discriminating good versus poor responders were selected to construct a panel of 7 proteins, which was then tested by mIF in the 142 available pts' samples. After high-definition scanning, the tissue images were analyzed by IFQuant software and the results correlated with pts' PFS and OS by stratification cox regression.

Results: CD8, GrzB, BCL2, CD44, MET, DAPI, and CK were selected for the final panel. In the chemo-free arm, pts with low expression of CD8-GrzB in stroma or CD8-MET in tumor had similar PFS as pts receiving chemo (p=0.8 and 0.4) and significantly better than the pts with high expressions (p=0.03 and 0.05). Pts without chemo and with low expression of CD8-MET in tumor showed a better OS than the pts with high expression (p=0.02) and even better than the pts having received chemo (p=0.04). In addition, different combined expressions of these biomarkers in stroma and in tumor were able also to discriminate pts with good versus poor outcome in arm A, arm B or whole study population.

Conclusions: Immunity plays a significant role in the efficacy of anti-HER2 treatments. mIF allowing to assess simultaneously several biomarkers presence, intensity and location seems to permit selecting pts with HER2+ advanced stage BC having an excellent outcome in terms of PFS and OS without chemo in 1st line. If validated these biomarkers may contribute to treatment de-escalation and quality of life improvement.

307P Identifying new biological subgroups of triple-negative breast cancer using next-generation integrative clustering pipeline

X. Zhu[1], J. Bayani[2], M. Dewan[1], H. Tovey[1], L. Kilburn[1], K. Taylor[3], J. Banerji[1], C. Toms[1], A. Sadanandam[4], P.J. Barrett-Lee[5], J. Bliss[1], D.A. Cameron[6], J.M.S. Bartlett[7], M.C.U. Cheang[1]

[1]Clinical Trial and Statistics Unit, The Institute of Cancer Research, Sutton, UK; [2]Diagnostic Development, Ontario Institute for Cancer Research, Toronto, ON, Canada; [3]Edinburgh Cancer Research Centre, Cancer Research UK Edinburgh Centre, Edinburgh, UK; [4]Department of Molecular Pathology, The Institute of Cancer Research, London, UK; [5]Velindre Cancer Centre, Velindre NHS University Trust - NHS Wales, Cardiff, UK; [6]Institute of Genetics and Cancer, University of Edinburgh, Edinburgh, UK; [7]Diagnostic Development, University of Edinburgh, Edinburgh, UK

Background: Early triple-negative breast cancer (eTNBC) is molecularly heterogenous, with differential prognosis. We aimed to identify new biological subgroups (B-grp) of eTNBC via an integrative clustering pipeline (ICP) and evaluate the clinical value of these B-grp in a large randomised clinical trial.

Methods: TACT2 was a phase 3, randomised trial testing adjuvant accelerated versus standard Epirubicin in early breast cancer. From TACT2, 551 eTNBC tumours were stratified into training (n=367) and testing (n=184) by treatment arm. Expressions of 758 genes (GE) and Triple-Negative Subtypes (TNS; Burstein CCR 2015) of tumour were profiled by nCounter@ Breast Cancer 360TM. Immunohistochemistry expressions (IHC) of HER2, EGFR and CK5/6 were assessed. Clinicopathological features (ClinPath) included age, nodal status, tumour size and grade. The ICP included random forest (RF) and 9 unique clustering methods with hypergeometric test to reconcile clustering results to a final output. Survival endpoint was time to recurrence (TTR) for multivariable cox regression (mCox), of which the goodness-of-fit was assessed by chi-square, brier score and integrated calibration index.

Results: The ICP returned 4 B-grp using GE, IHC and ClinPath of the training set. GE was the main factor of clustering, summarising B-grp into immune-enriched (IM), Luminal-AR (LAR), mesenchymal like (MES) and basal like (BL). IM and LAR contained mainly TNS-BLIA and TNS-LAR, respectively. Both MES and BL comprised TNS-BLIA, TNS-BLIS and TNS-MES. The RF was trained using GE as unimodal single-sample predictor to assign the B-grp on the testing set. Adding B-grp to ClinPath yielded more accurate 5-year TTR prediction for test samples when compared to TNS (Table).

Table: 307P Comparing the goodness-of-fit of three mCox models using chi-square, brier score and integrated calibration index

	ClinPath	ClinPath + TNS	ClinPath + B-grp
Chi-square	19.27	**59.98**	32.29
Chi-square (against the ClinPath model)	-	**40.71** ($p < 0.0001$)	16.02 ($p = 0.001$)
Brier score	0.1477	0.1544	**0.1425**
Integrated calibration index	0.021	0.064	**0.019**

Brier score is the mean square difference between the true classes (0 = no recurrence, 1 = recurrence) and the predicted probabilities at given time point. Integrated calibration index is the weighted absolute difference between the calibration curve and the diagonal line of best fit.

Conclusions: We identified 4 eTNBC B-grp based on distinct biology which provided more accurate 5-year TTR prediction in addition to ClinPath than TNS. The association of the B-grp with survival for other treatments could be further evaluated.

Clinical trial identification: NCT00301925.

308P Regression-based deep-learning predicts breast cancer recurrence risk score from pathology slides

O.S.M. El Nahhas[1], C.M.L. Loeffler[1], A. Marra[2], Z. Carrero[1], F. Pareja[2], H. Wen[2], B. Weigelt[2], P. Selenica[2], S. Chandarlapaty[3], J.S. Reis-Filho[2], J.N. Kather[1]

[1]Clinical AI, EKFZ - Else Kröner Fresenius Zentrum für Digitale Gesundheit, Dresden, Germany; [2]Department of Pathology and Laboratory Medicine, MSKCC - Memorial Sloan Kettering Cancer Center, New York, NY, USA; [3]Department of Medicine and Human Oncology and Pathogenesis Program, MSKCC - Memorial Sloan Kettering Cancer Center, New York, NY, USA

Background: Breast cancer (BC) treatment decisions can be challenging, particularly in patients with early-stage hormone receptor-positive/HER2-negative (HR+/HER2-) tumors. Prognostic assays, such as the 21-gene recurrence score assay (Oncotype DX), are used to determine individual patient risk of recurrence and guide decision on whether to administer adjuvant chemotherapy or not. However, these tests are costly and time-intensive to perform. Deep-Learning (DL) can predict molecular biomarkers from routine hematoxylin and eosin (H&E) pathology slides, potentially serving as an inexpensive and accessible pre-screening tool. We aim to use DL for the outcome prediction of the Oncotype DX test.

Methods: We trained a DL-based regression model in a weakly-supervised manner to detect Oncotype DX risk score directly from routine H&E-stained pathology slides in a large (n=5,303) cohort of early-stage HR+/HER2- BCs from Memorial Sloan Kettering (MSK). We then externally validated the model onto The Cancer Genome Atlas (TCGA) BC cohort for which Oncotype DX scores were available (n=100). The model was evaluated using the Pearson's correlation coefficient r. Moreover, the recurrence score was divided into low ($<$11) and intermediate/high ($\geq$11) risk groups, enabling evaluation via the area under the receiver operating characteristic curve (AUROC).

Results: The model yielded a significant r of 0.59 ($p<0.0001$) on the test set of the training cohort of MSK BCs and 0.58 ($p<0.0001$) on the external cohort of TCGA BCs. When binarizing the predictions into intermediate/high and low recurrence risk groups, we found that the model was particularly accurate for identifying patients with intermediate/high risk scores, reaching an AUROC of 0.87 ($\pm$ 0.04) and 0.79 ($\pm$ 0.03) in the MSK and TCGA cohort, respectively.

Conclusions: We developed a DL-model that can accurately predict Oncotype DX score from routine pathology slides, offering a cost-effective and time-efficient pre-screening tool for identifying a high-risk subgroup HR+/HER2- early BCs and to democratize the access to complex but clinically useful biomarkers. This approach could support informed treatment decisions by accurately determining recurrence risk, ultimately improving patient outcomes.

Background: Data support the role of immune infiltrate in breast cancer (BC) prognosis and therapy prediction. The aim of this study was to characterize the immune landscape in early BC at a multiplex and spatial resolution using machine learning (ML)-based algorithms and investigate its potential prognostic value.

Methods: Tissue microarrays (TMA) were constructed from pretreatment samples from patients enrolled in the EORTC 10994/BIG 1-00 neoadjuvant randomized phase III trial (taxane/anthracycline vs FEC). An automated algorithm for digital TIL (dTIL) quantification was applied on H&E stained TMA. Multiplex fluorescent immunohistochemistry (mfIHC) was performed for an immune antibody panel and cell phenotyping/localization was applied with a ML-based software. *TP53* mutational status was available for a subset of patients. Logistic and Cox regression models investigated the association of immune-related metrics with pathological complete response (pCR) and progression-free survival (PFS), respectively.

Results: Median follow-up was 11.4 years. 587 patients had dTIL and 478 had mfIHC data. Among the dTIL variables, easTIL [sum of TIL area (mm^2)/stroma area (mm^2)] were higher in the triple-negative subtype and an independent predictor of pCR (ORadj= 1.59, 95% CI 1.00 — 2.54, p=0.05) in the whole cohort. No significant association with PFS was noted. However, a significant interaction was observed between esTIL (TIL/stromal cells) and *TP53* mutational status (p= 0.028); higher esTIL abundance was prognostic for worse PFS only in patients with *TP53* wild-type tumors. CD8+ T-cells were the most abundant cell subset in both tumor and stroma compartments. Expression of total CD4+ (ORadj= 1.79, 95% CI 1.07 — 2.97, p=0.026) and intra-tumoral CD8+ T-cells (ORadj= 1.83, 95% CI 1.05 — 3.20, p=0.033) was independently associated with improved pCR.

Conclusions: Our data indicate that ML-based models could be used for studying the immune infiltrate in BC. Abundance of dTIL and spatial distribution of immune markers contain prognostic information, which might depend on *TP53* mutational status. Further validation is warranted.

Clinical trial identification: NCT00017095.

Background: Plasma-only ctDNA detection is a strategy to identify molecular residual disease (MRD) in early breast cancer (EBC). MRD-positivity in the absence of clinical/radiographic disease may have prognostic implications and enable intervention prior to clinical recurrence.

Methods: Plasma samples from baseline, perioperative, adjuvant and follow-up timepoints were collected in patients with estrogen receptor positive/HER2-negative (ER+) and triple-negative (TN) breast cancer treated with neoadjuvant chemotherapy (2015 onward). Samples were analyzed using the Guardant Reveal pan-tumor assay on the INFINITY™ platform. Clinical/pathologic characteristics and recurrence outcomes were collected. ctDNA/MRD-positivity was defined as a methylation score > 0.

Results: 270 timepoints (median 3 per patient, range: 1-9) were analyzed from 83 patients with ER+ (n=38) and TN (n=45) EBC; 95% (256/270) produced successful results. Baseline positivity rate was 67.5% (54/80) in all patients (66.7% in ER+, 68.2% in TN). Nine patients had a mutation called at baseline (7 *PIK3CA*; 1 of *TP53*, *FGFR1*, *BRAF*, *GATA3*, or *NOTCH2*). Larger tumor size (p=0.014) and nodal involvement (p=0.011) were associated with baseline test positivity. 17/83 (20.5%) patients have had a clinical recurrence (13 distant, 4 local). 14/17 (82.3%) patients with recurrence had a positive test at baseline (2 negative, 1 fail) and baseline methylation scores were higher in patients with recurrence (p=0.0032). Seven of 8 patients with recurrence had a positive sample collected at or prior to clinical recurrence with lead time of up to 5.1 months. Four patients with no documented recurrence had a positive test at their last follow up [range: 4.7-19.1 months from last test] with methylation scores lower than those of patients with recurrence (p=0.012). Any ctDNA positivity in follow up after surgery was strongly associated with a risk of recurrence (HR = 7.02, 95%CI: 1.82-27.2, p=0.001).

Conclusions: This longitudinal evaluation of a plasma-only methylation based ctDNA assay demonstrates ctDNA detection and dynamic changes in a large EBC cohort. Potential prognostic and predictive applications warrant further evaluation.

311P Multinational survey study assessing genetic testing and counselling among patients (pts) with breast cancer (MAGENTA): Results on the genetic counselling experience

R. Kaur[1], S.L. Powell[2], M. Artigas[3], I. Borovova[4], P. Gadiya[5], A. Hsu[6], L. Kidd[7], D. Rosenfeld[8], M.M. Saeed[9], E. Scarelli[10], M. Wahib[11]

[1]Consultant, Breast Cancer Welfare Association Malaysia, Selangor, Malaysia; [2]Pink Hope, Narrabeen, NSW, Australia; [3]Private individual, Argentina, Buenos Aires, Argentina; [4]Russian Association of Oncology Patients, "ZDRAVSTVUY!", Moscow, Russian Federation; [5]Nag Foundation, N Main Rd, Koregaon Park, Pune, India; [6]Patient author, Taiwan, Taipei City, Taiwan; [7]Victorian Department of Education, Beaconsfield Primary School, Beaconsfield, VIC, Australia; [8]Private individual, Mexico, Mexico City, Mexico; [9]Private individual, Egypt, Cairo, Egypt; [10]Oncoguia Institute, Sao Paulo, Brazil; [11]Medical Affairs, AstraZeneca Egypt, Cairo, Egypt

Background: Despite genetic testing (GT) and counselling (GC) being key in breast cancer (BC) risk assessment, GC uptake rates are low even among pts undergoing GT. A global survey was conducted among pts with BC to identify the gaps in the GC experience and to propose strategies to fill them.

Methods: A steering committee comprising of pts and pt advocates co-developed a 38-question survey, which was offered to pts in Argentina, Australia, Brazil, Egypt, India, Malaysia, Mexico, Russia and Taiwan in local languages, through social media. The questions pathway was dependent on response to prior questions. Chi-square test was used to assess significance between responses, if applicable.

Results: The final analysis set (FAS) included responses from 1176 respondents with a > 90% completion rate of survey questions. In the FAS, 737 (63%) respondents reported having undergone GT. Most respondents in the FAS (768/1061; 71%) rated their awareness level of GT/GC (before BC diagnosis) as between 'very low' to 'moderate'. Among pts undergoing GT, 616 respondents responded to the question enquiring on the resources available to them to guide their GT experience, beyond their oncologist. These were the genetic counsellor (295/616; 48%), pt support groups (232/616; 38%) and websites (217/616; 35%). Among the 439 respondents who did not undergo GT, 174 (40%) were offered GT by their doctor but did not take it. The table shows the level of understanding of GC reimbursement eligibility among the respondents.

Table: 311P

Question	Population	No. of respondents	Response [n (%)]		
			Yes	No	I don't know
Did you receive any GC?*	Tested	737	327 (44)	266 (36)	86 (12)
	Not tested	439	31 (7)	277 (63)	46 (11)
Should you qualify, is the cost of GC for breast cancer reimbursed in your country?	FAS	1176	302 (26)	174 (15)	372 (32)
	Tested	737	325 (44)	129 (18)	283 (38)
	Not tested	439	82 (19)	120 (27)	237 (54)

*Statistically significant difference (p<0.00001) between tested and not tested pts

Conclusions: Most pts with BC are not offered GC, which significantly correlates with GT uptake. Since poor awareness of GC is a critical gap, improving GC services and pt education through pt advocates and online tools may increase GT rates, offering a more impactful GT experience for pts and their families.

312P Prediction model of breast cancer patient's neoadjuvant treatment outcome using breast cancer organoids cultured from core needle biopsies

D.W. Lee[1], G.Y. Kim[2], K.H. Park[2], B.J. Chae[3], J.E. Lee[3], S.W. Kim[3], S.Y. Jang[3], J.Y. Choi[3], J.M. Ryu[3], S.K. Lee[3], J.H. Yu[3], S.J. Nam[3], B. Ku[4]

[1]Biomedical Engineering, Gachon University - Global Campus, Seongnam, Republic of Korea; [2]Precision Medicine Research Institute, MBD Co., Ltd, Suwon, Republic of Korea; [3]Division of Breast Surgery, Department of Surgery, Samsung Medical Center (SMC)-Sungkyunkwan University School of Medicine, Seoul, Republic of Korea; [4]MBD Co., Ltd, Suwon, Republic of Korea

Background: The incidence of breast cancer is steadily increasing, and many patients receive adjuvant chemotherapy before or after surgery. In particular, neoadjuvant drug therapy is commonly used to suppress microinvasive before surgery. In this study, the patient-derived organoids (PDOs) from breast cancer patient's biopsies were used for drug sensitivity test. To predict patient's neoadjuvant treatment outcome, we propose a new drug sensitivity evaluation method based on multi-factors such as Area Under Curve (AUC) of dose response curve, organoid growth rate.

Methods: Patient cells were obtained from core needle biopsy before surgery and mechanically dissociated before being mixed with extracellular matrix (ECM) to generate PDOs. Anti-cancer drug sensitivity testing was performed on these PDOs using a pillar-based organoid system, which involved single or combination treatments with anti-cancer drug with 384 plate-based high throughput screening. Area Under Curve (AUC) values of the dose-response curves (DRC) and organoid growth rate were calculated by pillar-based organoid system.

Results: The proposed multi-factor prediction model was verified by comparing drug sensitivity test with patient's neoadjuvant outcome. We performed drug sensitivity test of 79 breast cancer patients. So far, 13 patients have finally been evaluated for neoadjuvant treatment results. Multi-factor prediction model (***C***ancer ***O***rganoid-based ***D***iagnosis ***R***eactivity ***P***rediction, CODRP) shows 83 % sensitivity and 85 % specificity while conventional prediction model using only AUC shows 50 % sensitivity and 71 % specificity.

Conclusions: Therefore, Multi-factor prediction model (CODRP) may provide useful supplementary diagnostic information for individual breast cancer patients by selecting optimal anticancer drug candidates for patient treatment.

Background: Breast cancer is a heterogeneous disease with regard to diagnosis, therapy and survival. Complementary to the histopathological classifications of the tumours, molecular biological tests specify individualised therapy recommendations. Our aim was to classify tumours into intrinsic subtypes and to analyse the association of grouping with disease progression.

Methods: Intrinsic subtypes were determined from 1,070 tumours by mRNA expression profiling (PAM50 algorithm) from fresh tumour tissue or FFPE tissue in a prospective, multicenter cohort study (n=1,270; NCT 01592825). mRNA expression evaluation was performed either by nCounter®NanoString or GenChip™ HG U133 Plus 2.0 or BioMark™ Fluidigm. Endpoints were recurrence free interval (RFI) and overall survival (OS). Median follow-up time was 60.3 months. Survival analyses were done by Kaplan-Meier method and Cox model adjusting for age, nodal status, tumour size, and tumour differentiation.

Results: The PAM50 analysis resulted in 44.9% in Luminal A (n=480), 23.9% Luminal B (n=256), 14.4% HER2-enriched (n=154), and 16.8% in Basal-like (n=180). In the total cohort, 89.9% (95% CI 87.9-91.9) of patients were free of RFI event and 87.5% (95% CI 85.3-89.7) were alive at 5 years of observation. Of patients with a Luminal A tumour, 93% were free of RFI event (95% CI 88.1-97.9). The remaining patients had a substantially higher risk of RFI events: Luminal B, HR=3.3 (95% CI 1.78-6.01); HER2-enriched, HR=3.8 (95% CI 2.01-7.21); Basal-like, HR=4.7 (95% CI 2.53-8.7). In the Cox model, only tumour size (HR=2.5) and nodal status (HR=2.2) had a significant additional prognostic impact. Also with regard to OS, PAM50 subtypes, tumour size, and nodal status were the only significant prognostic factors.

Conclusions: Even after guideline-based therapy, the intrinsic subtypes still have prognostic significance. Nearly half the patients can be identified as Luminal A with an excellent course of disease, whilst patients with Luminal B, HER2-enriched, Basal-like still have a substatial risk of recurrence, requiring further improvement of therapy concepts.

Clinical trial identification: NCT01592825 (release date: 16.12.09).

314P Concordance of somatic variants between circulating tumor DNA and tissue in patients with breast cancer

K. Shin, M-S. Park, E.H. Cho, H. Park, H-Y. Woo, M-J. Kwon

Laboratory Medicine, Kangbuk Samsung Hospital, Sungkyunkwan University School of Medicine, Seoul, Republic of Korea

Background: Analysis of circulating tumor DNA (ctDNA) is a noninvasive method for detecting somatic variants. However, the sensitivity of ctDNA is limited by the dilution of ctDNA with cell-free DNA from non-cancer cells. In this study, we evaluated the concordance of somatic variants between ctDNA and tissue in patients with breast cancer to assess the clinical usefulness of ctDNA testing.

Methods: Paired plasma and tissue samples at the diagnosis were collected from 29 patients with breast cancer. Next-generation sequencing targeting 49 genes was performed on both plasma and tissue samples and the concordance between plasma and tissue was evaluated.

Results: A total of 140 variants were detected in paired tissue and plasma samples of 29 patients. Among them, 66.4% (93/140) of variants were detected only in tissue, 14.3% (20/140) of variants were detected only in plasma, and 19.3% (27/140) of variants were detected in both samples. The median variant allele frequency of concordant and discordant variants in ctDNA was 1.5% and 0.6%, respectively. Actionable variants were detected in four genes: *BRCA1*, *BRCA2*, *ERBB2*, and *PIK3CA*. For 29 patients, the overall concordance rate for detecting actionable variants was 65.5% (19/29), with individual gene concordance rates of 96.6% (28/29) for *BRCA1*, 93.1% (27/29) for *BRCA2*, 79.3% (23/29) for *ERBB2*, and 79.3% (23/29) for *PIK3CA*. The overall sensitivity and specificity were 41.2% and 100%, respectively.

Conclusions: ctDNA testing showed a high concordance and specificity in detecting actionable variants. It can be used as a complementary test to tissue biopsy for selecting appropriate therapeutic agents.

315P Multinational survey study assessing genetic testing and counselling among patients (pts) with breast cancer (MAGENTA): Results on perceptions on testing

S.L. Powell[1], M. Artigas[2], I. Borovova[3], P. Gadiya[4], A. Hsu[5], R. Kaur[6], L. Kidd[7], D. Rosenfeld[8], M.M. Saeed[9], E. Scarelli[10], M. Wahib[11]

[1]Pink Hope, Narrabeen, NSW, Australia; [2]Private individual, Argentina, Buenos Aires, Argentina; [3]Russian Association of Oncology Patients, "ZDRAVSTVUY!", Moscow, Russian Federation; [4]Nag Foundation, N Main Rd, Koregaon Park, Pune, India; [5]Private individual, Taiwan, Taipei City, Taiwan; [6]Consultant, Breast Cancer Welfare Association Malaysia, Selangor, Malaysia; [7]Victorian Department of Education, Beaconsfield Primary School, Beaconsfield, VIC, Australia; [8]Patient author, Mexico, Mexico City, Mexico; [9]Private individual, Egypt, Cairo, Egypt; [10]Oncoguia Institute, Sao Paulo, Brazil; [11]Medical Affairs, AstraZeneca Egypt, Cairo, Egypt

Background: Genetic testing (GT) is vital in the risk assessment of breast cancer (BC) and along with genetic counselling (GC), may inform treatment decisions. However, fewer than one-third of patients (pts) with BC undergo GT. A multinational survey was conducted for a deeper understanding of the barriers in the uptake of GT and GC. Results from this survey, focusing on awareness and pts' perceptions towards GT and GC have been reported here.

Methods: A steering committee comprising of pts and pt advocates co-developed a 38-question online survey, which was launched in local languages for pts in Argentina, Australia, Brazil, Egypt, India, Malaysia, Mexico, Russia and Taiwan, through different social media platforms. The questions pathway was determined based on response to certain questions on GT & GC uptake. Percentage responses to a response option was calculated against the number of respondents for that question.

Results: The final analysis set (FAS) included responses from 1176 participants with more than 90% completion rate of survey questions. Median age among respondents in the FAS was 42 years (IQR: 35, 49) at the time of BC diagnosis. Among survey respondents, 63% (737/1176) had undergone GT, and 37% (439/1176) did not undergo GT. The table lists select questions on some aspects of the GT experience as well as perceptions of testing. .

Conclusions: There are critical gaps in the awareness of GT among pts and the public, along with gaps in perceived value and access to GT, with notable variance between the tested and the non-tested populations. Strategic action is needed to overcome the barriers to GT and to improve the pt experience.

Background: Breast cancer that is estrogen receptor positive (ER+) and human epidermal growth factor receptor 2 negative (HER2-) can be further stratified into intrinsic molecular subtypes by employing PAM50-based gene expression profiling. Despite its association with poor outcome, the HER2-enriched (HER2E) subtype currently holds no implications for clinical treatment decisions due to a lack of insight into its distinguishing features. Therefore, we aimed to evaluate the response of patients to conventionally administered therapies and identify molecular features to inform therapy optimization.

Methods: Two primary breast cancer cohorts provided clinical, transcriptomic, and genomic data on ER+/HER2- cases: SCAN-B 4413 (HER2E: 89, Luminal A (LumA): 3049, Luminal B (LumB): 1349) and METABRIC 1227 (HER2E: 58, LumA: 601, LumB: 340), including whole genome sequencing data for 32 HER2E cases. Focal points were analyses based on overall survival and invasive disease-free survival (IDFS),

Table: 315P

Question	Response		No. of respondents/Total no. of respondents to the question (%)	
How would you rate the awareness levels of GT/GC of yourself, before diagnosis?	Moderate to very low		758/1061 (71)	
Should all pts diagnosed with BC undergo GT first before starting treatment?	Yes	Underwent GT Did not undergo GT	603/849 (71)	460/625 (74) 143/224 (64)
How willing would you be to have your children and other family members undergo GT?	Very willing	Underwent GT Did not undergo GT	371/1176 (32)	322/737 (44) 49/439 (11)
What was your main reason for not undergoing GT?	I was not offered GT		282/394 (72)	
What are the main barriers to GT for you and your family? (Top 2)	Cost Lack of understanding		210/425 (49) 163/425 (38)	

differential gene expression, pathway enrichment, mutational frequencies and signatures, and copy number alterations.

Results: Clinicopathological analyses highlighted HER2E breast cancer to be a small subgroup associated with worse prognoses than other luminal PAM50 subtypes, regardless of whether patients were treated with endocrine therapy (E) or both endocrine and chemotherapy (EC), independent of tumor size, grade, age, and lymph node status (IDFS; E: HR 4.0, CI95 2.0-7.8; EC: HR 2.8; CI95 1.16-6.9; LumA as reference). Furthermore, HER2E tumors were larger and higher graded than LumA tumors. Next to highly proliferative characteristics akin to LumB, HER2E tumors were distinguished by their low *ESR1* expression, high *FGFR4* expression, high immune response, and high frequency of *TP53* mutations.

Conclusions: The HER2E subtype within ER+/HER2- disease is a small but clinically relevant patient subgroup that is not constituted by misclassified cases and is less ER dependent than other luminal subtypes. It does not represent a distinct biological entity, but it is nevertheless associated with potentially targetable molecular features, for instance in form of a high immune response and high *FGFR4* expression.

317P Awareness of genomic testing among patients with breast cancer in Europe

A. Cardone[1], D. Bell[2], C.B. Biurrun[3], F. Cardoso[4], L.D. Csaba[5], L. Guéroult-Accolas[6], M.P. Lux[7], A. Ramírez Piris[8], I. Rubio[9], R. Simcock[10], R. D'Antona Fidanzia[11]

[1]Patient Advocacy, Cancer Patients Europe, Brussels, Belgium; [2]Treatment, Medicines, Genomics, Macmillan Cancer Support, London, UK; [3]Cancer Patient Advocacy, Federación Española de Cáncer de Mama, Santander, Spain; [4]Breast Unit, Champalimaud Clinical Centre, Lisbon, Portugal; [5]Sociology and Social Work, Babes-Bolyai University, Cluj-Napoca, Romania; [6]Patient Networks, Patients en Réseau, Paris, France; [7]Frauen- und Kinderklinik St. Louise, Klinik für Gynäkologie und Geburtshilfe, Paderborn, Germany; [8]Patient Advocacy, Exact Sciences, Zurich, Switzerland; [9]Mammary Pathology, Clinica Universidad de Navarra, Madrid, Spain; [10]Cancer Centre, University Hospitals Sussex, Brighton, UK; [11]Cancer Patient Advocacy, Europa Donna, Milan, Italy

Background: Genomic testing, involving expression profiling of tumour tissue removed from patients with breast cancer, is a powerful tool to help choose the most appropriate treatment for individual patients. The objective of this study was to evaluate awareness of genomic cancer testing in five European countries (France, Germany, Italy, Spain, and the United Kingdom), with a focus on women with breast cancer.

Methods: The survey was initiated by Cancer Patients Europe (CPE) as part of its my Cancer my Concern (myC) initiative and was developed with a panel of oncologists and patient association representatives. Participants were recruited by e-mail and through a social media campaign. They responded to a 42-question internet survey (Survey Monkey) which took ∼10 minutes to complete..

Results: Of 1,383 participants completing the survey, 566 women with HR+ and HER2- breast cancer who were eligible for genomic testing were analysed. 245 (43.3%) were aged 50-59 years and 381 (67.3%) had received higher education. 238 participants (42.1%) had heard about genomic testing; only 122 (21.6%) were told that they were eligible for it and 104 (18.4%) were told the reasons for the test. The majority (N = 479; 84.6%) considered that they did not have sufficient information to make a decision about genomic testing and only 139 (24.6%) actually decided to take a test. Overall, 234 (41.3%) would have liked to have received more information on treatment options, and 246 (43.5%) more information on additional testing. 464 participants (82.0%) sought more information on their disease. The principal sources of information on breast cancer management were healthcare professionals (N = 363; 64.1%), internet (N = 351; 62.0%), and patient associations (N = 117; 20.7%). For the majority (N = 398; 70.3%), the healthcare professional did not provide advice on where to find more information.

Conclusions: This study demonstrates that awareness of and access to genomic testing for breast cancer in Europe is sub-optimal. Healthcare professionals need to improve communication with patients regarding genomic testing and involve them in shared decision-making. Patient associations should also act as a portal for providing information on genomic testing.

318P Evaluation of novel diagnostic kits using the semi-dry dot-blot method combined for detecting metastases in sentinel lymph nodes of patients with breast cancer: A multi-center prospective study

R. Otsubo[1], M. Matsumoto[1], E. Inamasu[1], A. Tanaka[1], S. Kuba[2], M. Morita[2], F. Kaseida[3], S. Maeda[4], M. Nakashima[5], H. Ikari[6], S. Ohno[7], H. Takei[8], S. Eguchi[2], T. Nagayasu[1]

[1]Surgical Oncology, Nagasaki University Hospital, Nagasaki, Japan; [2]Surgery, Nagasaki University Hospital, Nagasaki, Japan; [3]Laboratory Medicine, Nagasaki University Hospital, Nagasaki, Japan; [4]Breast and Endocrine Surgery, National Hospital Organization Nagasaki Medical Center, Omura, Japan; [5]Tumor and Diagnostic Pathology, Nagasaki University Atomic Bomb Disease Institute, Nagasaki, Japan; [6]Surgery, Sasebo Chuo Hospital, Sasebo, Japan; [7]Breast Oncology Center, The Cancer Institute Hospital of JFCR, Koto-ku, Japan; [8]Breast Surgery, Nippon Medical School Main Hospital, Tokyo, Japan

Background: The semi-dry dot-blot (SDB) method, a diagnostic procedure for detecting lymph node (LN) metastases using anti-cytokeratin (CK) antibody, is based on the theory that epithelial components such as CK are not found in normal LNs. Thus, metastases are diagnosed on basis of the presence of CK in lavage fluid of sectioned LNs. We prospectively evaluated novel SDB kits that use a newly developed anti-CK19 antibody and an automatic reader for diagnosing sentinel LN metastases in patients with breast cancer as a multi-center study.

Methods: We obtained 924 sentinel LNs dissected between January 2021 and December 2021 at six institutes in Japan. We excluded patients with neoadjuvant chemotherapy and neoadjuvant endocrine therapy. These LNs were sliced at 2-mm intervals and washed with PBS. Cells suspended in the lavage fluid of sliced LNs were centrifuged and lysed to extract protein. The extracted protein was applied to the SDB kit to diagnose LN metastasis using an automatic reader that evaluates absorbance. Washed LNs were blindly examined using intraoperative and permanent histological examination. Diagnoses based on SDB kit were compared with diagnoses made by permanent histological examination of the LNs. Primary endpoints were sensitivity, specificity, and overall agreement of the SDB kit for distinguishing macrometastases from non-macrometastases.

Results: Ninety-four of the 924 LNs were assessed as macrometastases, 40 as micrometastases and 790 as negative by histological examination. With a borderline CK19 absorbance of 11.9 milli-absorbance for detecting macrometastases with 0.989 Area Under the Curve, the sensitivity, specificity, and overall agreement of the SDB kit were 94.7%, 98.3%, and 97.9%, respectively. Furthermore, the kits and the automatic reader yielded diagnoses in approximately 20 min at a cost of less than 30 EUR for the SDB kit and less than 3,000 EUR for the automatic reader.

Conclusions: The kits with an automatic reader used in our study were accurate, quick, and cost-effective in diagnosing LN metastases without loss of LN tissue, and were especially useful for detecting distinguish macrometastases.

319P The impact of low HER2 expression on clinical significances and outcomes in patients with HER2-negative early breast cancer

Y. Koi[1], W. Tajiri[1], J. Kawasaki[1], S. Akiyoshi[1], C. Koga[1], Y. Nakamura[1], K. Taguchi[2], E. Tokunaga[1]

[1]Breast Oncology, National Hospital Organization Kyushu Cancer Center, Fukuoka, Japan; [2]Department of Pathology, National Kyushu Cancer Center, Fukuoka, Japan

Background: HER2-low, defined by immunohistochemically (IHC) 1+ or 2+ with negative in situ hybridization (ISH), has recently attracted attention as a novel classification in determining treatment strategies in HER2-negative metastatic breast cancer (BC). However, clinical significance of this new subcategory in early-stage BC and testing methodologies of HER2-low remain unclear.

Methods: We retrospectively reviewed the clinical data of 1,359 patients with HER2-negative BC at stage I-III between January 2008 and December 2017 in our institute. They were classified into HER2-low (n=455) and HER2-0 (n=904) subgroups according to IHC assay or gene amplification on ISH. We compared the difference in clinicopathological characteristics, recurrence-free survival (RFS), and overall survival (OS) between these subgroups. Since three different immunostaining kits (HercepTest; Dako (i), Bond III stainer (Leica Biosystems) (ii), Ventana ultra View PATHWAY HER2/neu (4B5) (iii)) were used in defining HER2 expression depending on period, we also evaluated the frequency of HER2 expression level by immunostaining kits.

Results: The median age was 57 (range 24—87) and the median follow-up period was 77 months (range 1.1—175.6). The number of patients at clinical stage I, II, and III was 790, 462, and 107, respectively. The HER2-low subgroup tended to have lower histological grade ($p < 0.01$) and higher frequency of hormone receptor positivity ($p < 0.01$) compared to the HER2-0 subgroup. There were no statistically significant

differences in RFS (p = 0.95) or OS (p = 0.87) between two subgroups. Intriguingly, there were significant differences in the percentages of HER2-low and HER2-0, depending on the immunostaining kits (42.2% vs 57.8% (i), 84.5% vs 15.5% (ii), 87.9% vs 12.1% (iii)).

Conclusions: In this study, there was no prognostic difference based on HER2 expression status in HER2-negative early-stage BC, but there was a frequency difference in determining HER2-low and HER2-0 depending on the immunostaining kits. While there are many assays for HER2 evaluation approved in the practice, an appropriate companion diagnosis for HER2-low seems to be critical to select patients who may benefit from newer treatment such as Trastuzumab Deruxtecan.

320P Clinical and pathological characteristics of breast cancers switching from early luminal-like to metastatic triple-negative phenotype

M. Ivanova[1], A. Marra[2], S. Morganti[3], K. Venetis[1], E. Sajjadi[4], L. Ascione[2], B. Taurelli Salimbeni[2], P. Zagami[2], P.P.M. Berton Giachetti[2], G. Curigliano[2], N. Fusco[1], C. Criscitiello[2]

[1]Division of Pathology, IEO - Istituto Europeo di Oncologia IRCCS, Milan, Italy; [2]Division of New Drugs and Early Drug Developement, IEO - Istituto Europeo di Oncologia IRCCS, Milan, Italy; [3]Breast Oncology Center, Dana Farber Cancer Institute, Boston, MA, USA; [4]Oncology and Hematology-Oncology Department, UNIMI - Università degli Studi di Milano Statale, Milan, Italy

Background: Loss of hormone receptors (HR) at breast cancer (BC) metastatic relapse has been reported. Few data are available on the clinicopathologic features associated with HR loss and its prognostic impact.

Methods: We retrospectively identified a cohort of 51 patients (pts) with primary HR+/HER2- BC and triple-negative (TN) metastasis (LUM-TN) along with two control cohorts of paired HR+/HER2- and TN on both primary and metastatic samples (LUM-LUM, n=50; TN-TN, n=49). Clinical features and outcomes were retrieved from medical charts. HR and HER2 status were independently reviewed by two pathologists on all archival samples. Estrogen receptor (ER) expression between 1% and 10% was considered as ER-low. Cox-proportional hazard models were used to assess the impact of variables on distant metastasis-free survival (DMFS) and overall survival (OS).

Results: The three cohorts had no difference in median age, menopausal status nor stage at diagnosis. Pts in LUM-TN cohort had a higher frequency of invasive lobular (20% vs 10% vs 2%, p=.03), primary ER-low BCs (22% vs 0% vs 0%, p<.001) and locoregional relapse (18% vs 0% vs 2%, p<.001) than pts in the LUM-LUM and TN-TN cohorts. Metastatic samples from pts in LUM-TN and LUM-LUM cohorts were more frequently HER2-low than those in TN-TN cohort (57% vs 66% vs 24%, p<.001). At univariate analysis, pts with LUM-TN switch had a longer DMFS compared to the TN-TN (median DMFS 62 vs 18 months; HR 3.35, 95%CI 2.2-5.1, p<.001), but similar to the LUM-LUM cohort (median DMFS 62 vs 64 months; HR 0.95, 95%CI 0.6-1.41, p<.8). The DMFS difference was not significant after adjusting for other variables, including grade and ER-low status. Median OS was significantly lower for pts in LUM-TN (median OS 93 vs 139 months; HR 2.3, 95%CI 1.3-4.1, p<0.004) and TN-TN cohorts (median OS 47 vs 139 months; HR 3.4, 95%CI 1.1-10.7, p<0.03) when compared to the LUM-LUM cohort, independently from other clinicopathologic features.

Conclusions: HR loss at metastatic relapse is frequent in lobular and ER-low primary BCs. Pts with HR loss have similar DMFS compared to pts with maintained HR expression, but apparently reduced OS. Further investigation on biological mechanisms underpinning the LUM-TN phenotype switch is ongoing.

321P Non-BRCA variants in hereditary breast and ovarian cancer patients in the northern Mexico population

D. Aguilar[1], M.D.L. Garza Rodriguez[2], D.C. Pérez-Ibave[2], C.M. Villarreal Garza[3], O. Vidal-Gutierrez[2], C.H. Burciaga Flores[2]

[1]Breast Cancer Center, Hospital Zambrano Hellion TecSalud, San Pedro Garza Garcia, Mexico; [2]Oncology Service, CUCC - Centro Universitario Contra el Cáncer - Universidad Autónoma de Nuevo León (UANL), Monterrey, Mexico; [3]Breast Cancer Center, Hospital Zambrano Hellion, Tecnologico de Monterrey, San Pedro Garza Garcia, Tlalpan. D.F., Mexico

Background: Hereditary cancer syndromes explain 5-10% of all cancer cases. Germline pathogenic variants in BRCA1 and BRCA2 genes (BRCA) are present in 2-3% of all breast cancer (BC), and 15% of all ovarian cancer (OC) cases. BRCA1 and BRCA2 pathogenic variants (PV) represent 25-28% of BC and 40% of OC patients with a positive familial history. BRCAs are the most studied genes for the prevalence, family history, preventive surgeries, and target treatment options in both BC and OC. There are other genes, important in the diagnosis, pathogenesis, and treatment options of the patients: TP53, PALB2, CHEK2, among others. This study aims to identify the prevalence of non-BRCA genes related to the development of hereditary breast and ovarian cancer syndrome in patients of Northeast Mexico.

Methods: This is a multicenter study that recruited patients from two reference oncology centers in Nuevo Leon, Mexico: the CECIL (The CUCC Early Cancer Detection Clinic) Hereditary Cancer Registry and Hereditary Cancer Program from Tec Salud. From March of 2016 to March of 2023, a total of 872 patients meeting NCCN criteria were evaluated by Medical Geneticists from both centers and were tested with NGS multigene cancer panels.

Results: A total of 665 (76.26%) patients with a clinical diagnosis of HBOC (Hereditary Breast Hereditary Cancer Syndrome) were included. We found 310 (46.6%) patients had at least one variant, 180 (58%) with at least one pathogenic variant, and 130 (41%) with a VUS (a variant of uncertain significance). BRCA1 was found in 79 (43.8%) and BRCA2 in 32 (17.7%) of all PV. Non-BRCA PV were found in 69 (38.3%) patients: 4 ATM, 2 BLM, 3 BRIP1, 22 CHEK2, 4 CDKN2A, 5 MUTYH, 10 PALB2, 4 RAD51C, 2 SDHA, 2 TP53, 2 WRN, CDH1, CDK4, DICER, MSH3, NBN, PTEN, RAD50, USH2A one of each. Is remarkable that 19 of the 22 patients with CHEK2 and 5 of the 10 patients with PALB2 had the recurrent PV c.707T>C and c.2167_2168del, respectively.

Conclusions: Non-BRCA PV in Northern Mexico correspond to one-third of the BC and OC cases, including HRD (homologous recombination deficiency) genes. HDR patient carriers are potential targets of iPARP therapies. This project reinforces the fact that multigene panels should be employed to ensure a complete diagnosis in hereditary cancer patients.

322P Clinicopathological characteristics and genomic profiling of pure mucinous breast cancer

S. Wang[1], Q. Lu[2], H. Zhou[1], P. Sun[3], K. Shao[4], K. Lee[5], F. Xu[1], W. Xia[1], K. Jiang[1]

[1]Medical Oncology, Sun Yat-sen University Cancer Center, Guangzhou, China; [2]Department of Radiology, Sun Yat-sen University Cancer Center, Guangzhou, China; [3]Pathology, Sun Yat-sen University Cancer Center, Guangzhou, China; [4]Joint institute of Medicine, BGI-Shenzhen - Headquarters, Shenzhen, China; [5]Department of Ultrasound, First Affiliated Hospital of Sun Yat-Sen University, Guangzhou, China

Background: Pure mucinous breast cancer (PMC) is a rarely seen histological type with favorable prognosis. Nevertheless, cases with recurrence have been reported and diagnosed in clinical practice. The recurrent patterns and mechanisms of PMC are unknown. Thus, in this study, we aim to discover the prognostic factors of PMC and reveal the genomic profiling of PMC with positive lymph nodes.

Methods: A total of 166 cases diagnosed as PMC were included. We compared the clinicopathologic characteristics across different groups using Mann-Whitney U test or chi square test according to variables. 21-gene assay was done in 10 patients with recurrence and 20 TNM staging-matched patients. Whole-exon sequencing was done in 12 PMC primary tumor and 4 positive lymph nodes. We compared the genomic alterations between two groups in single nucleotide polymorphism, copy number variation and enriched pathways.

Results: The median age at diagnosis was 45 years old in total 166 patients. After median follow-up of 84 months, 21/166 patients developed recurrence with/without distant metastasis. The significant different factors between patients with recurrence and without recurrence were tumor size, lymph node status and TNM staging. 21-gene recurrence scores were not statistically significant between two groups. Whole-exon sequencing showed that lymph node-positive(LNP) PMC primary tumors were more recurrently with mutations of ADCY10 (3/6) and SHANK3 (3/6), while lymph node-negative(LNN) PMC did not harbor these genes. Moreover, LNP group

prevalently harbored gains of 15q23, 17q23.2, 20p11.21 and loss of 21p11.2, while LNN group did not harbored any of these copy number variations. In terms of pathway enrichment, LNP group was involved in several pathways but LNN group was not enriched in any pathways.

Conclusions: Overall prognosis is good in PMC. TNM staging is an important prognostic factor of PMC. PMC with positive lymph node more recurrently harbored gains of 15q23,17q23.2, 20p11.21 and loss of 21p11.2. More researches, especially integration of multi-omics studies, are needed in revealing the underlying mechanism of lymph node metastasis in PMC.

323P Macrophage population analysis of the breast cancer microenvironment within the context of seroma formation after mastectomy (SerMa pilot study)

F. Schneider[1], M. Köpke[1], C. Kuhn[1], M. Wild[2], M. Schneider[1], C. Dannecker[1], L.C. Hinske[3], U. Jeschke[1], N. Ditsch[1]

[1]Department of Obstetrics and Gynecology, Universitätsklinikum Augsburg, Augsburg, Germany; [2]Department of Obstetrics and Gynecology, Data Management and Clinical Decision Support, Universitätsklinikum Augsburg, Augsburg, Germany; [3]Data Management and Clinical Decision Support, Universitätsklinikum Augsburg, Augsburg, Germany

Background: The primary goal of the SerMa pilot study was to identify possible immunological/inflammatory factors related to seroma formation after mastectomy and first diagnosis of breast cancer. CD68 is a common marker for tumor-associated monocytes and macrophages in general. CD163 is used to detect M2-polarized macrophages. Both are known to have an influence on defense reactions and wound healing due to their immunomodulatory effect. Thus, the aim of this evaluation was to evaluate whether a correlation can be shown within the context of postoperative seroma formation.

Methods: From 100 patients meeting the criteria of the study, tumor tissue of 80 patients was available for evaluation. Immunohistochemical antibody staining against CD68 and CD163 was performed, and two groups were compared: Patients with and without seroma formation. The number of macrophages in the tumor microenvironment was manually quantified at three sites representative of each specimen in the entire field of view at a magnification of 40x lens. The mean value of the three areas was used for further analysis.

Results: For CD68, the range of the mean value was from 0 to 354 macrophages. The number of CD68-positive macrophages was significantly increased (p=0.036) in patients with seroma development (mean=45.31) compared to those without (mean=34.31). For CD163, the range extends from 0 to 309 macrophages. Again, the number of CD163-positive macrophages was significantly increased (p=0.027) in patients with postoperative seroma formation (mean=45.57) compared to patients without (mean=33.99).

Conclusions: These data demonstrate a significant correlation of CD68 and CD163 positive macrophages in the tumor microenvironment and seroma formation in the breast after mastectomy. This study was the first to investigate these possible relationships. As highly associated with immunological processes, the significant higher detection of CD68 and CD163 within the population of "Seroma developers" supports our study group's previously published results on the identification of immunological markers in seroma fluid and thus the hypothesized relationship of seroma formation based on immunological/inflammatory processes.

324P Nodal underestimation rate in early-stage ER+/HER2- breast cancer patients with limited positive sentinel lymph nodes in the era of precise medicine: A real-world multicenter analysis from 40 institutions in China

Y. Zong[1], Y. Lu[2], Y. Tong[2], X. Fei[3], Y. Zhu[4], Z. Wang[2], X. Zhang[2], Y. Zhu[2], J. Huang[2], J. Hong[2], S. Zhu[2], W. Gao[2], X. Chen[2], O. Huang[2], J. He[2], W. Chen[2], Y. Li[2], K. Shen[2], J. Wu[2]

[1]Department of Internal Medicine, Wayne State University, Detroit, MI, USA; [2]Comprehensive Breast Health Center, Ruijin Hospital - Shanghai Jiao Tong University School of Medicine, Shanghai, China; [3]Department of Pathology, Ruijin Hospital - Shanghai Jiao Tong University School of Medicine, Shanghai, China; [4]Department of Ultrasonographic, Ruijin Hospital - Shanghai Jiao Tong University School of Medicine, Shanghai, China

Background: Emerging data show more estrogen receptor-positive/ human epidermal growth factor receptor 2-negative (ER+/HER2-) early breast cancer patients with 1-3 positive sentinel lymph nodes (SLNs) omitted axillary lymph node dissection (ALND) but received adjuvant radiation therapy, which led to equivalent locoregional and distant disease control. In this study, we aimed to evaluate whether sentinel lymph node biopsy (SLNB) only can provide accurate lymph node staging to select candidates for multigene assay testing and adjuvant CDK4/6 inhibitor treatment in ER+/HER2- breast cancer patients with 1-3 positive SLNs.

Methods: Consecutive patients with cT1-3N0, ER+/HER2- disease, and 1-3 positive SLNs were retrospectively included from the multicenter Shanghai Jiao Tong University-Breast Cancer Database. The nodal underestimation rate (NUR) was calculated in patients receiving SLNB+ALND in the overall population and in potential candidates for multigene assays and CDK4/6 inhibitors according to the RxPONDER, MINDACT, and monarchE trials.

Results: Among the 3672 patients included, 24.1% received SLNB only. The overall NUR was 9.5%. For those who met the inclusion criteria for the RxPONDER, MINDACT, and monarchE trials, positive non-SLNs were found in 3.0%, 3.5%, and 3.7% of the patients, respectively. The low NUR was not influenced by breast surgery modality. Additional ALND upon SLNB brought no survival benefit for eligible patients of these trials (RFI P=0.090; OS P=0.772).

Conclusions: ALND can be safely omitted in cT1-3N0, ER+/HER2- breast cancer patients with 1-3 positive SLNs when selecting candidates for multigene assays testing and adjuvant CDK4/6 inhibitor treatment.

325P Impact of breast tumour location on axillary nodal involvement, chemotherapy use, and survival

Y. Xu, J. Cao, L. Barbera

Oncology, Tom Baker Cancer Centre, Calgary, AB, Canada

Background: Axillary level I-II node (ALN) status is used to stratify breast cancer risk and inform systemic therapy decisions. We sought to investigate the association of breast tumour location with ALN involvement, use of chemotherapy, and breast cancer-specific survival (BCSS).

Methods: Patients diagnosed with stage T1-2 M0 breast cancer from 2004 to 2019 were identified from the SEER 17 registries database. Tumour locations were classified as outer quadrant, inner quadrant, or central. Covariates were age, race, median household income, year of diagnosis, tumour size, histology, grade, and ER/PR/HER2 status. Propensity score weighting with Bayesian additive regression trees was used to balance covariates between tumour locations. Doubly robust estimation was then performed with multivariable logistic and Cox regressions to assess the association of tumour location with binary outcomes and BCSS, respectively.

Results: A total of 453,387 patients with a median follow-up of 70 months were eligible for analysis, of whom 293,070 (65%) had outer quadrant tumours, 127,237 (28%) had inner quadrant tumours, and 33,560 (7%) had central tumours. After propensity score weighting, the rates of ALN metastases for outer quadrant, inner quadrant, and central tumours were 28.2%, 20.2%, and 32.6%, respectively. Chemotherapy was given to 38.0%, 36.5%, and 38.8% of patients. Ten-year BCSS were 91.6%, 91.0%, and 90.5%. Compared to outer quadrant tumours, inner quadrant tumours had lower odds of ALN metastases (OR 0.62; 95% CI 0.61-0.63; P<0.001) and central tumours had higher odds (OR 1.30; 95% CI 1.26-1.33; P<0.001). Similarly, inner quadrant tumours had lower odds of receiving chemotherapy (OR 0.90; 95% CI 0.88-0.91; P<0.001) while central tumours had higher odds (OR 1.07; 95% CI 1.04-1.10; P<0.001). BCSS was worse in both inner quadrant (HR 1.07; 95% CI 1.04-1.10; P<0.001) and central (HR 1.10; 95% CI 1.04-1.15; P<0.001) tumours.

Conclusions: The risk of ALN metastases from breast cancer varies with tumour location. Inner quadrant tumours have worse BCSS than outer quadrant tumours despite a lower risk of ALN metastases. Reliance on ALN staging without consideration

of tumour location may lead to treatment decisions that are inconsistent with breast cancer risk.

326P Sentinel lymph node mapping in breast cancer: Evaluating the dual-tracer method with indocyanine green and radioisotope

A. Kwong[1], B.H.H. Cheung[2], V.C.M. Man[2]

[1]Surgery Department, The University of Hong Kong - Li Ka Shing Faculty of Medicine, Hong Kong, China; [2]Surgery, HKU - The University of Hong Kong, Hong Kong, China

Background: Indocyanine green (ICG) has the potential to improve sentinel lymph node (SLN) mapping. This current cohort study was designed to assess the value of ICG using a new ICG handheld system with radioisotope (RI) in patients with early breast cancer undergoing SLN biopsy.

Methods: A prospective self-controlled trial compared the detection efficacies of ICG and RI was conducted. Concordance (ICG and RI-positive cases divided by RI-positive cases) and reverse concordance (ICG and RI-positive cases divided by ICG-positive cases) were documented and adverse event were also assessed.

Results: Of 69 patients (median age 56.7 (range 33-85), median BMI 22.6 (range 17.0 − 44.5)) enrolled between 2019 and 2021, 71 SLN biopsies were performed. Sixty-one (85.9%) underwent upfront surgery, while ten (14.1%) were given neoadjuvant treatment. Thirty-four breast-conserving surgeries (BCS) (47.9%), 33 mastectomies (46.5%) and four cryotherapies (5.6%) were performed. No adverse event nor skin staining were reported. The SLN identification rate was 87.3% (62/71) for ICG and 95.8% (68/71) for RI (p=0.13). Dual tracer method resulted in 97.2% successful identification, significantly superior to ICG alone (p=0.04, OR 5.0, CI 1.0-24.1) and and was in line with the reported rate of 96.7% (94.3-99.1)[1] by blue dye and RI. Concordance and reverse concordance rates were 89.7% and 98.4%, respectively. A median of 2 lymph nodes was detected by both ICG (range 0 − 6) and IR (range 0 − 5) with no statistical difference (p=0.60). Of 10 cases with 13 metastatic nodes confirmed by histology, both ICG and RI achieved 100% concordance rates. Breast conserving treatments had a higher ICG failure rate compared to mastectomy (21.1% vs 3.0%, p=0.05, OR 8.5, CI 1.0-72.4). In addition, among three cases with prior surgery, two failed ICG SLN identification. Meanwhile, age, BMI, tumour location, multifocality, neoadjuvant treatment, and ICG volume showed no significant correlation with ICG detection rate.

Conclusions: The combined use of ICG and RI ensures adequate SLN identification without problems known with the use of blue dye, such as skin staining and anaphylaxis. A higher failure rate was noted in patients with breast-conserving treatments for ICG tracing.

327P Defining ≥10% radioisotope-hot stained nodes as sentinel lymph nodes by "blue dye + radioisotope" dual-tracer method for sentinel lymph node biopsy leads to the overdetection and excessive excision

Y. Jiao, Q. Lv

Breast Surgery Department, West China School of Medicine/West China Hospital of Sichuan University, Chengdu, China

Background: Sentinel lymph node biopsy (SLNB) has been widely used to assess axillary staging. In clinical practice, it is crucial to define sentinel lymph node (SLN) and determine whether the detected nodes are SLNs during the process of SLNB. It is important to consider whether currently existing consensus on SLNB method which is dual-tracer technique may lead to the excessive and unnecessary removal of negative nodes. In addition, no uniform measurable and objective index has been established to define intra-operation palpable nodes, the excision of which may increase the random detection of SLN. The purpose of this study was to optimize the specific method of SLNB.

Methods: To propose an optimal cut-off value for "radioisotope+bule dye" dual-tracer method, the detailed information of (BC) patients who had no clinical node involvement and underwent SLNB from November 2010 to February 2021 was prospectively collected in the breast surgery department of West China Hospital. We analyzed the site and size, radioactivity, the status of blue dye and the pathological results of each node detected of each patients.

Results: A total of 4985 lymph nodes from 1595 BC patients were identified. Only 11.57% (577/4985) SLNs were defined as pathologically positive, resulting in 88.43% (4408/4985) negative nodes removed excessively. By gradually increasing the threshold of radioisotope count in comparison to the hottest SLN, we found that when elevating the cut-off value from 10% to approximately 60%, 17.3% of lymph nodes were spared removal, among which only 0.88% were missed positive SLNs. Raising the optimal cutoff value of radioisotopes to 60% and exempting palpable nodes at the same time could reduce the number of nodes detected by 30.81% with only 1.75% missed positive SLNs. Additionally, multivariate analysis in our study showed that larger tumor size and higher clinical N stage was significantly positively associated with SLN metastasis.

Conclusions: Raising the optimal cut-off value of radioisotope to 60% and exempting palpable nodes may be considered as a potential alternative method to avoid removing excessive negative nodes in SLNB.

328P Frequency of radiotherapy-induced malignancies in Li-Fraumeni syndrome patients with early breast cancer and influence of the radiotherapy technique

V. Petry[1], R. Colombo Bonadio[1], K. Moutinho[2], L. Senna[1], L. Testa[1], M.C. Fragoso[3], M.D.P. Estevez Diz[1]

[1]Clinical Oncology, ICESP - Instituto do Cancer do Estado de Sao Paulo, Sao Paulo, Brazil; [2]Radiation Oncology, ICESP - Instituto do Cancer do Estado de Sao Paulo, Sao Paulo, Brazil; [3]Endocrinology, ICESP - Instituto do Cancer do Estado de Sao Paulo, Sao Paulo, Brazil

Background: Breast cancer (BC) is the most common malignancy in female patients (pts) with Li-Fraumeni Syndrome (LFS). These pts are at increased risk of other malignancies, including radiotherapy-induced malignancies (RIM) that are those occurring in a previously irradiated field. We aimed to evaluate the frequency of RIM and other oncologic outcomes of LFS pts with eBC.

Methods: We evaluated pts with a germline pathogenic/likely pathogenic variant of TP53 (LFS) diagnosed with eBC and followed by the Hereditary Cancer Team of a single cancer center between Dec/99 and Apr/23. The primary endpoint was the frequency of RIM among pts treated with adjuvant RT.

Results: Forty-nine pts were evaluated. Median age was 39 years (range 21 - 62); 79% were ER-positive; 35% HER2-positive; 35% stage I and 27% stage II; and 71% had TP53 R337H variant. Most pts (87%) were unaware of the LFS at the time of BC treatment. Regarding treatment, 62% underwent a mastectomy, 66% (neo)adjuvant chemotherapy, and 62% RT. The use of RT was more common after conservative surgery as expected (87% vs 46% with mastectomy, P=0.010). Oncologic outcomes are summarized in the table. Among 30 pts treated with RT, 4 (13.8%) developed RIM in the irradiated field (3 soft tissue malignancies and 1 BC). The occurrence of RIM was not influenced by RT dose ($\leq$ 40.8 or $>$ 40.8), but was influenced by the type of RT. RIM was observed in 100% with 2D RT (n=2/2), 100% (n=1/1) with volumetric modulated arc therapy (VMAT), 6% (n=1/16) with 3D RT, and 0% with intensity-modulated RT (n=0/1) (P=0.007).

Table: 328P

	Radiotherapy (n=30)	No radiotherapy (n=18)	P
Local recurrence	2 (6.7%)	1 (5.6%)	1.000
Distant recurrence	5 (16.7%)	1 (5.6%)	0.388
Contralateral BC	5 (16.7%)	2 (11.1%)	0.696
Second neoplasia	15 (50%)	5 (27.8%)	0.226
RIM	4 (13.8%)	-	-

Conclusions: Our study confirms an alarming rate of RIM after adjuvant RT, highlighting the need for a careful risk-benefit evaluation for the indication of RT, which should be preferentially avoided if possible. Despite the small numbers in each subgroup, the risk of RIM seemed to be influenced by the RT technique, with higher rates with 2D RT and VMAT. Early TP53 testing is crucial to guide the BC treatment plan.

329P Pulmonary function and lung fibrosis up to 12 years after breast cancer radiotherapy

J. Karlsen[1], T. Tandstad[2], S. Steinshamn[3], Ø. Salvesen[4], N. Parlikar[4], S. Lundgren[4], R.J. Reidunsdatter[3]

[1]Cancer Clinic St Olavs Hospital, Trondheim, NTNU - Norwegian University of Science and Technology, Trondheim, Norway; [2]Cancer Clinic St Olavs Hospital, Trondheim, St. Olavs Hospital, Trondheim, Norway; [3]Department of Circulation and Medical Imaging, NTNU - Norwegian University of Science and Technology, Trondheim, Norway; [4]Faculty of Medicine and Health Sciences, NTNU - Norwegian University of Science and Technology, Trondheim, Norway

Background: Breast cancer (BC) radiotherapy (RT) may induce lung damage ranging from radiological changes only to respiratory failure. The evidence of long-term radiation fibrosis (RF) and its impact on lung function and patients reported dyspnea is scarce. The aim of the present study was to evaluate lung function from before RT to up to 12 years after treatment and identify predictors for long-term RF and reduced lung function.

Methods: BC patients (n=250) referred to postoperative RT (2 Gy x 25) were enrolled in a prospective cohort study from February 2007 to October 2008. All assessments were conducted through clinical controls before RT (baseline), at 3, 6 and 12 months and at long-term follow- up ranging from 7-12 years after RT. Lung function was assessed by the pulmonary function tests (PFT) Vital capacity (VC), Forced Expiratory volume in 1second (FEV1), Forced Vital Capacity (FVC) and diffusion capacity for carbon monoxide (DLCO). RF was diagnosed by High Resolution Computer Tomography scans and graded in accordance with the CTCAE version 3.0 criteria. Patient reported dyspnea was assessed by the EORTC QLQ-C30.

Results: VC, FVC, FEV1 and DLCO declined at 3 months after RT and remained low at long-term follow-up except for DLCO which increased up to 12 years after RT. VC, FEV1, and FVC changes from baseline differed between patients treated with chemotherapy and those not treated with chemotherapy. FEV1 changes from baseline differed between locoregional and local radiated patients. A decline in VC, FEV1, and FVC 3 months after RT predicted a decline in PFT up to 12 years (p=0.020, p=0.004, and p=0.020, respectively). At long-term follow-up age was the only patient and treatment-related factor associated with RF (p=0.021). RF was observed in 144 patients (91%), of which 129 (81%) had fibrosis Grade 1 and 15 (9%) had fibrosis Grade 2. 61 (35%) patients reported dyspnea, mainly grade 1.

Conclusions: Pulmonary function deteriorated in the first year and up to 12 years after BC RT. An early decline in VC, FVC and FEV1 predicted further decline at long-term follow-up. RT. Chemotherapy and locoregional RT predicted a decrease in PFT in the first year and for up to 12 years after RT. Older age was associated with RF at long-term follow-up. Few patients reported severe dyspnea.

330P Effect of radiotherapy in deep inspiration in patients with left breast cancer: Does the size of the target area affect the dose for the most crucial organs at risk?

Z. Locsei[1], B. Nagy[2], T. Brunner[3], L. Mangel[4]

[1]Universitätsklinik für Strahlentherapie-Radioonkologie, Graz, Hungary; [2]Radiotherapy, PTE-AOK - Pecs University Medical School - Institute of Oncotherapy, Pécs, Hungary; [3]Radiation Oncology, Graz Medical University, Graz, Austria; [4]Institute of Oncotherapy, PTE-AOK - Pecs University Medical School - Institute of Oncotherapy, Pécs, Hungary

Background: After radiotherapy (RT) to the left breast, the long-term risk of developing various cardiovascular diseases may increase. In our study, we present how deep inspiration treatment changes the doses of organs at risk (OAR), especially the heart. Furthermore, we examined if there is a relationship between the size of the irradiated target area and the dose on the heart.

Methods: From May 2016 to August 2020, 503 patients with left-sided breast cancer underwent RT at our institute. Since May 2018, we have treated our patients in deep breathing (DIBH) using the "voluntary breath-hold" technique. We compared the D_{mean} and D_{max} values for the most critical OAR (left lung, heart, left ventricle, LAD-left anterior descending artery) based on the two treatment methodologies. Subsequently, both groups were then further subdivided into whether the treatment was given by standard fractionation or hypofractionation and created 3-3 groups based on the size of the target area (PTV).

Results: In patients treated with normal fractionation in DIBH vs. without, the doses of the OARs were the following: lung D_{mean}: 9.3 Gy vs. 9.96 Gy (p=0.029), left ventricle D_{mean}: 3.52 Gy vs. 7.56 Gy (p=2.69E-27), heart D_{mean}: 2.78 vs. 5.31 (p=1.11E-24), LAD D_{mean} 12.17 vs. 25.91 Gy (p=4.63E-24) respectively. In the hypofractionated group with vs. without DIBH the values were lung D_{mean}: 7.43 Gy vs. 8.08 Gy (p=0.17), left ventricle D_{mean}: 3.48 Gy vs 6.4 Gy (p=2.64E-10), heart D_{mean}: 2.64 vs 4.62 (p=2.96E-08), LAD D_{mean} 11.46 vs 18.35 Gy (p=3.37E-06) respectively. In the standard fractionated group, the average doses for each structure decreased mostly in women with large breast sizes after DIBH treatment. Generally, as the breast size increases, the values of the left ventricle, heart, and LAD increase, whilst the values of the lungs decrease. Although, a significant difference could only be detected in a few categories.

Conclusions: DIBH RT of the left breast significantly reduces radiation exposure to crucial OAR than free-breathing radiation therapy. At the same time, the coverage of the target area does not change, and our results suggest that this benefit is most pronounced in patients with large breast sizes.

331P miR-21 and miR-34a as biomarkers of radiotherapy skin adverse events in ductal carcinoma in situ

T. Marinko[1], A. Cvetkoska[2], S. Redenšek Trampuž[3], V. Dolžan[3], K. Goričar[3]

[1]Radiotherapy Department, Institute of Oncology Ljubljana, Ljubljana, Slovenia; [2]Faculty of Medicine, University of Ljubljana, Ljubljana, Slovenia; [3]Pharmacogenetics Laboratory, Institute of Biochemistry and Molecular Genetics, Faculty of Medicine, Ljubljana, Slovenia

Background: Ductal carcinoma *in situ* (DCIS) is a non-invasive type of breast cancer treated with surgery and adjuvant radiotherapy (RT). RT improves local disease control, but also causes adverse effects. Molecular factors could contribute to interindividual variability in the incidence of skin adverse events after RT. Radiation exposure can affect expression of miRNAs, small non-coding RNAs involved in post-transcriptional regulation of gene expression. Our aim was to evaluate whether miR-21 and miR-34a expression changes after RT and if miRNA expression is associated with skin adverse events of RT in patients with DCIS.

Methods: Our prospective study included 119 patients with DCIS treated with adjuvant RT. Skin adverse events were assessed using Common Terminology Criteria for Adverse Events (CTCAE) v.5 immediately after RT and six months after RT. MiRNA was isolated from plasma before and after RT and quantitative PCR was used to determine miR-21 and miR-34a expression. Non-parametric tests and logistic regression were used in statistical analysis.

Results: Immediately after RT, 5.7% patients had grade 2 skin adverse events, while 26.1% patients experienced grade 2 adverse events after six months. More skin adverse events after six months were observed in smokers (p=0.036). After RT, the expression of miR-21 (p=0.001) and miR-34a (p<0.001) was significantly increased. Patients with a greater increase in miR-34a expression after RT were more likely to have a higher grade of skin adverse events immediately after RT, even after adjustment for clinical parameters (OR_{adj}=1.13; 95% CI_{adj}=1.02-1.26; p_{adj}=0.026). Similarly, greater increase in miR-34a expression was associated with more adverse events six months after RT, but the association was only significant adjustment for clinical parameters (OR_{adj}=1.13; 95% CI_{adj}=1.01-1.27; p_{adj}=0.035). Expression of miR-21 was not associated with skin adverse events.

Conclusions: Our results suggest that miR-21 and miR-34a expression increases after RT and miR-34a expression might serve as a biomarker of RT skin adverse events. Research grants: ARRS J3-1753, ARRS J3-2527, P1-0170 and P3-0321.

332P Early prediction of residual cancer burden to neoadjuvant chemotherapy in breast cancer by longitudinal MRI-based multitask learning: A multicenter cohort study

W. Li[1], Y. Huang[2], T. Zhu[2], K. Wang[2]

[1]Breast Cancer, The First People's Hospital of Foshan, Foshan, China; [2]Breast Cancer, Guangdong Provincial People's Hospital, Guangzhou, China

Background: Neoadjuvant chemotherapy (NAC) has been a standard treatment for locally advanced breast cancer (BC). However, the high heterogeneity of BC results in various tumor response. Therefore, there is a growing need for early assessment of tumor response, particularly for insensitive BC, to guide personalized treatment. We

aim to develop a longitudinal radiomics multitask model to accurately predict RCB score in the early stage of NAC for breast cancer.

Methods: A total of 1048 patients with breast cancer receiving NAC across four institutions were retrospectively enrolled. We collected longitudinal MRI sequences at the pre-NAC and mid-NAC timepoints, and extracted 21804 radiomics features per patient. We used a multitask learning strategy to predict RCB score (RCB 0-I, II and III). The Mann-Whitney U-test, Spearman analysis, the least absolute shrinkage and selection operator regression and Boruta method were used to perform feature selection. We developed various base machine learning models, followed by an ensemble stacking method to integrate the base model outputs. The multitask learning model was subsequently verified in three independent external validation cohorts.

Results: Of the total patients, 442 (42.18%) reached RCB 0-I, 462 (44.08%) reached RCB II and 144 (13.74%) reached RCB III. 17 and 19 significant features were selected for two independent tasks. For identifying RCB 0-I and RCB II-III, the multitask model reached an area under the curve (AUC) of 0.932 in primary cohort, and AUCs of 0.890, 0.919 and 0.911 in the external validation cohorts. It also identified RCB II and RCB III with an AUC of 0.916 in primary cohort, and AUCs of 0.870, 0.899 and 0.871 in external validation cohorts.

Conclusions: The longitudinal radiomics multitask learning model is a noninvasive tool to predict RCB score for breast cancer, and help clinical decision-making in the early stage of NAC.

Background: Early metabolic change on FDG PET/CT was predictive of response to neoadjuvant trastuzumab/pertuzumab (HP) in TBCRC026, with high negative predictive value (NPV) suggesting a lack of decline in SULmax at cycle 1 day 15 (C1D15) best predicts those who will not achieve pathological complete response (pCR) with HP alone. We hypothesized that a composite biomarker incorporating both PET and HER2 tissue-based biomarkers could improve biomarker performance in this setting.

Methods: Patients with stage II-III ER-negative/HER2-positive breast cancer received neoadjuvant HP. PET/CT was performed at baseline and C1D15. Promising imaging biomarkers included $\geq$40% SULmax decline between baseline and C1D15, and C1D15 SULmax $\leq$3 (n=83 evaluable). Baseline tissue-based biomarkers included HER2-enriched intrinsic subtype (72%, 46/64 available; Nanostring [NS] BC360), log2 tumor HER2 protein abundance (median 13.5, range 7.1-15.9; NS GeoMxTM DSP), HER2 3+ (83%, 64/77; immunohistochemistry central review). Logistic regressions were used to construct prediction models for pCR with the composite HER2/PET biomarker. Overall discriminatory power of the predictive model was evaluated using the C statistic. Sensitivity and specificity were evaluated at the optimal cut-off point determined by maximizing Youden's index in the receiver operating characteristic (ROC) analysis.

Results: Factors most predictive for response (pCR 22%, PMID 33999652) in single predictor models included D15 SULmax (OR 0.43; p=0.007, c=0.77), % reduction in SULmax (OR 1.03, p=0.006, c=0.72) and tumor HER2 protein abundance (OR 1.75; p=0.01, c=0.76). The composite of D15 SULmax and % reduction in SULmax combined with their interaction term, had improved probability (c=0.89 from c=0.78), with high sensitivity (100%) and NPV (100%). The addition of tumor HER2 protein did not further improve prediction power (c=0.90).

Conclusions: The composite HER2/PET biomarker had high prediction power for pCR, however was not superior to the prediction power of PET/CT alone. These data suggest clinical trials informed by early FDG PET/CT biomarkers warrant further evaluation to personalize breast cancer care.

Clinical trial identification: NCT01937117.

334P The contribution of nurses in early detection of breast cancer in Cameroon

N. Calvin[1], M. Florence[1], J.F. Domgue[2], T. Gracious[1], K. Mireille[1], N. Marious[1], C. Claudette[1], D. Bonghaseh[3], N. Kathleen[1], S. Manga[1]

[1]Women's Health Program, Cameroon Baptist Convention Health Services, Bamenda, Cameroon; [2]Epidemiology, The University of Texas M. D. Anderson Cancer Center, Houston, TX, USA; [3]Georgetown Global Health, Georgetown University, Yaounde, Cameroon

Background: Compared to global figures, breast cancer mortality to incidence ratio is worst in Sub Saharan Africa where about 80% of patients present with locally advanced and metastatic disease at diagnosis. In Cameroon, breast cancer is the commonest cancer with 4,170 cases recorded each year constituting 20.1% of all cancers diagnosed. Late disease presentation is attributed to poor awareness, absence of organized early detection programs, and inadequate facilities for accurate and timely diagnosis and treatment. Our objective was to investigate the role that nurses involved in cervical cancer screening/prevention can play in early detection of breast cancer in Cameroon.

Methods: The nurses involved in cervical cancer screening/prevention in a large faith-based healthcare organization called the Cameroon Baptist Convention Health Services (CBCHS) were trained to do clinical breast exams (CBE) for women aged 21 years and over, and also trained on breast tissue collection for pathology processing and examination. Clients with abnormal breast findings were provided Fine Needle Aspirations (FNA), TruCut biopsies or referred for ultrasound and/or mammography depending on the clinical presentation.

Results: Between January 2020 and December 2022, a total of 16,038 women age range (14-99) years were provided CBE with a mean and median age of 40.4 and 39, respectively. Among these, 750 (4.7%) had abnormal findings. Among those with

abnormal findings, 397(52.9%) had breast masses for which 213 (53.7%) had TruCut biopsies and FNA and the others were either referred or had previously established diagnosis. From the 213 Tru-Cut biopsies and FNA's done, 76 (35.7%) showed a pathology diagnosis of invasive breast cancer while the others showed: acute mastitis 3 (2.9%), fibroadenoma 25 (11.7%), benign mass 83 (39.0%), non-diagnostic 12 (5.6%) and other diagnosis 19 (8.9%).

Conclusions: Nurses can play a key role in early detection of breast cancer if they are trained, and this can greatly reduce the number of women seen with late stage disease and also reduce mortality rates.

335P Real-world data: Correlation of radiological and pathologic complete response after neoadjuvant treatment of breast cancer

K. Cular, D. Gudelj, L. Toula, M. Krizic, M. Soce, N. Dedic Plavetic, M. Popovic, T. Silovski

Department of Oncology, KBC - University Hospital Centre Zagreb, Zagreb, Croatia

Background: Neoadjuvant chemotherapy (NAC) of newly diagnosed breast cancer is used to improve resectability, reduce the extent of breast and axillary surgery and improve overall survival. Accurate assessment of locoregional response to NAC is important for surgical planning. Radiological method of choice is post-treatment breast magnetic resonance imaging (MRI), which determines the rate of response according to RECIST criteria. The primary indicator of outcome of NAC is pathologic complete response (pCR). This study aimed to compare radiologic and pathologic complete response rates after neoadjuvant treatment of early breast cancer.

Methods: A retrospective study of 259 breast cancer cases who received NAC between 01.01.2020 and 31.12.2021 at University Hospital Centre Zagreb was conducted with prior Ethics Committee approval. Radiological and pathohistological characteristics of the tumor at the time of diagnosis and after neoadjuvant treatment were analyzed using the Hospital information system (BIS). Furthermore, post-neoadjuvant therapy MRI findings were correlated with the postoperative pathohistological findings. Sensitivity, specificity, accuracy, and positive predictive value of radiologic complete response (rCR) as a predictor of pCR were calculated.

Results: Complete data was available for 94.98% (246/259) of patients. In 62 (25.20%) patients, rCR was recorded, radiologic partial response (rPR) in 150 (60.98%), stable disease in 22 (8.94%), and progressive disease in 9 patients. In 78 (31.71%) patients pCR was achieved, 46 (58.97%) were also classified as rCR, while 32 (41.03%) of those showed a radiological stable disease or rPR. Out of the 62 patients with rCR, 16 (25.81%) did not achieve pCR. The sensitivity and specificity of rCR were 90.48% and 58.97%, respectively, while positive predictive value was 82.61%. The overall accuracy of breast MRI in predicting pCR was 80.49%.

Conclusions: Although the sensitivity of breast MRI in predicting pCR was high, the specificity was low with only moderate overall accuracy. Low specificity can lead to an incorrect choice of breast surgery, therefore a better method of evaluation is necessary.

336P Dual-mode near-infrared multispectral imaging system equipped with deep learning models improves the identification of cancer foci in breast cancer specimens

Y. Liu[1], L. Zhang[1], J. Liao[2], M. Zhang[1], Y. Liu[1], D. Han[1], Z. Jia[1], S. Niu[1], H. Bu[3], J. Yao[2]

[1]Department of Pathology, The Fourth Hospital of Hebei Medical University, Shijiazhuang, China; [2]AI Lab, Tencent, Shenzhen, China; [3]Department of Pathology, West China Hospital, Sichuan University, Chengdu, China

Background: For surgically resected breast cancer samples, it is challenging to perform specimen sampling by visual inspection, especially when the tumor bed shrinks after neoadjuvant therapy in breast cancer.

Methods: We developed a dual-mode near-infrared multispectral imaging system (DNMIS) to obtain richer sample tissue information by acquiring reflection and transmission images covering visible to NIR-II spectrum range (400—1700 nm). Additionally, artificial intelligence (AI) was used to segment the rich multispectral data. 80 breast cancer samples were collected to verify the advantage of DNMIS in assisting pathologists to identify tumor beds.

Results: DNMIS demonstrated better tissue contrast and eliminated the interference of surgical inks on the breast tissue surface, helping pathologists find the tumor area which is easy to be overlooked with visual inspection. Statistically, AI-powered DNMIS provided a higher tumor sensitivity (95.9% vs visual inspection 88.4% and X-rays 92.8%), especially for breast samples after neoadjuvant therapy (90.3% vs visual inspection 68.6% and X-rays 81.8%).

Conclusions: We infer that DNMIS can improve the breast tumor specimen sampling work by helping pathologists avoid missing out tumor foci.

337P Comparison of fused diffusion-weighted imaging using unenhanced MRI and abbreviated post-contrast-enhanced MRI in patients with breast cancer

K. Lee

Diagnostic Radiology, Pusan National University Yangsan Hospital, Yangsan, Republic of Korea

Background: To determine the percentage of breast cancers detectable by fused diffusion-weighted imaging (DWI) using unenhanced magnetic resonance imaging (MRI) and abbreviated post-contrast-enhanced MRI.

Methods: Between October 2016 and October 2017, 194 consecutive women (mean age, 54.2 years; age range, 28-82 years) with newly diagnosed unilateral breast cancer who underwent preoperative 3.0 T breast MRI with DWI were evaluated. Both fused DWI and abbreviated MRI images were independently reviewed by two radiologists for the detection of index cancer (which showed the most suspicious findings in both breasts), location, lesion conspicuity, lesion type, and lesion size. Moreover, the relationship between cancer detection and histopathological results of surgical specimens were evaluated.

Results: Index cancer detection rates were comparable between fused DWI and abbreviated MRI (radiologist 1: 174/194 [89.7%] vs. 184/194 [94.8%], respectively, $P = 0.057$; radiologist 2: 174/194 [89.7%] vs. 183/194 [94.3%], respectively, $P = 0.092$). In both radiologists, abbreviated MRI showed a significantly higher lesion conspicuity than fused DWI (radiologist 1: 9.37 ± 2.24 vs. 8.78 ± 3.03, $P < 0.001$; radiologist 2: 9.16 ± 2.32 vs. 8.39 ± 2.93, $P < 0.001$). The κ value for the interobserver agreement of index cancer detection was 0.67 on fused DWI and 0.85 on abbreviated MRI. For lesion conspicuity, the intraclass correlation coefficients were 0.72 and 0.82 on fused DWI and abbreviated MRI, respectively. Among the histopathological factors, tumor invasiveness was associated with cancer detection on both fused DWI ($P = 0.011$) and abbreviated MRI ($P = 0.004$, radiologist 1), lymphovascular invasion was associated with cancer detection on abbreviated MRI ($P = 0.032$, radiologist 1), and necrosis was associated with cancer detection on fused DWI ($P = 0.031$, radiologist 2).

Conclusions: Index cancer detection was comparable between fused DWI and abbreviated MRI, although abbreviated MRI showed a significantly better lesion conspicuity.

338P Breast cancer follow-up: A population-based cohort study

S. Di Cosimo[1], R. Miceli[2], S. Ljevar[2], G. Tinè[2], P. Baili[3], V. Cappelletti[1], G. Apolone[3]

[1]Advanced Diagnostics, Fondazione IRCCS - Istituto Nazionale dei Tumori, Milan, Italy; [2]Clinical Epidemiology and Trial Organization, Fondazione IRCCS - Istituto Nazionale dei Tumori, Milan, Italy; [3]Scientific Directorate, Fondazione IRCCS - Istituto Nazionale dei Tumori, Milan, Italy

Background: Breast cancer (BC) survivorship guidelines recommend follow-up (F/U) with a schedule of physician visits and annual mammography. However, literature reflects an increasing reliance on advanced imaging. Our goal was to analyze BC F/U practice with its roots and effects at a population level.

Methods: We included women ≥18 years with early BC undergoing surgery between 2012-2014. We accessed the data warehouse of Lombardy Region in Italy. After calculating the annual frequency of each imaging *per* patient, we included the derived covariates in unsupervised clustering to set three statistically different groups with increasing F/U intensity, ie minimal, moderate and maximal. We used the Kaplan-Meier method for overall survival (OS) estimates and the Cox model for multivariable analysis.

Results: Overall 28,775 women entered the study, median age was 61 years (IQR 49-72), median time since diagnosis 87.6 months (IQR 77.7-97.9), 69.7% had breast-

conservative surgery. Of the 862,955 exams prescribed in the 5 years after surgery, 12.8% were mammograms. Ultrasound (64.7%) was the most common non recommended imaging, followed by computed tomography (11.7%), magnetic resonance (6.2%), and bone scan (4.6%). Intensive F/U was more likely after triple negative (30.1%) and HER2 positive (27.8%) than luminal-like BC (13.1%). Surveillance intensity decreased over time, resulting in 56% of BC survivors having minimal F/U from the third year after surgery onwords. At a 12 month landmark analysis, OS was 80.8%, 87.4% and 66.2% in women having minimal, medium, and maximal intensive F/U. The survival benefit of medium intensive F/U was significant in luminal-like; whereas, the negative effect of maximal intensive F/U extended to all subtypes and was independent of age, surgery, adjuvant and radiotherapy (HR 2.16, 1.99-2.36).

Conclusions: Use of non recommended imaging is common after BC surgery and increases with increasing risk of relapse. Due to the retrospective nature of our study, survival findings are only hypotheses generating. While intensive F/U possibly included women with poor prognostic factors not accounted for by the adjustment, medium intensive F/U might have allowed for timely/curative intervention of recurrent BC. Data overall offers an opportunity to discuss current F/U strategies.

339P An online mindfulness-based stress-reduction (MBSR) intervention for breast cancer (BC) survivors: A randomized trial

M.G. Salazar-Alejo[1], A.S. Ferrigno[2], J. Gutiérrez-Ornelas[3], F. Mesa-Chavez[1], A. Platas[4], H.C. Verduzco-Aguirre[5], C.M. Villarreal Garza[1]

[1]Breast Cancer Center, Hospital Zambrano Hellion TecSalud, San Pedro Garza Garcia, Mexico; [2]Department of Medicine, Yale University, New Haven, CT, USA; [3]Mindfulness Training, Centro Mindfulness Monterrey, San Pedro Garza García, Mexico; [4]Clinical Research, Médicos e Investigadores en la Lucha contra el Cáncer de Mama, Mexico City, Mexico; [5]Departamento de Hemato-Oncologia, Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Mexico City, Mexico

Background: Recent literature has proposed MBSR as an intervention that can decrease symptom burden in oncologic patients. However, there is paucity of data on the effect of online-delivered interventions despite the potential of this modality to improve access and adherence to treatment. The aim of this study was to study the effects of an online MBSR intervention on BC survivors.

Methods: Women aged $\geq$18 years, diagnosed with stage 0-III BC at least 1 year prior to inclusion and not undergoing active treatment were invited to participate. Those with mild anxiety were randomized to an online MBSR intervention or waitlist (WL). The MBSR intervention consisted of 8 weekly sessions of meditation guided by a certified instructor. Measured outcomes included anxiety (GAD-7), depression (PHQ-9), worry about disease recurrence (CWS), fatigue (FACIT-F), insomnia (ISI), and vasomotor symptoms (MENQOL). Assessments were done at baseline, 2 months, 5 months, and 8 months.

Results: A total of 97 patients with a median age of 45 years (IQR: 40-51) and a median of 24 months (IQR: 15-36) after diagnosis were included. 66 were randomized to MBSR and 31 to WL. Most participants were married (54%), had public health insurance (49%), and were diagnosed with stage III (33%) or II (32%) BC. Linear mixed models controlling for health insurance, education, and stage showed that MSBR led to significant reductions in anxiety (GAD-7 -3.76, $p<0.01$), depression (PHQ-9 -4.17 points, $p<0.01$), cancer worry (CWS -2.59 points, $p<0.05$), fatigue (FACIT-F -4.15 points, $p<0.05$), and insomnia (ISI -4.10 points, $p<0.01$) at the 8 months follow-up, but not vasomotor symptoms (MENQOL score +0.51 points, $p=0.42$). Adjusted mean scores are shown in the Table.

Table: 339P

Questionnaire	Group	Baseline	8 months
GAD-7	MSBR	10.3	5.6
	WL	11.1	9.4
PHQ-9	MSBR	11.3	6.1
	WL	12.8	10.3
FACIT-F	MSBR	13.7	8.5
	WL	14.9	12.7
CWS	MSBR	14.4	11.0
	WL	14.0	13.6
ISI	MSBR	13.9	8.2
	WL	13.1	12.3
MENQOL	MSBR	4.4	3.1
	WL	3.9	2.6

Conclusions: An online MBSR intervention demonstrated a statistically significant and persistent reduction in anxiety and depression symptoms in BC survivors. This modality offers BC patients better access to interventions with the potential to improve their quality of life.

340P Novel application of spatial analyses to investigate environmental factors and hormone receptor-positive breast cancer

A. Thomas[1], A. Zorn[2], K.M. Conway[2], A. Rhoads[2], J.J. Oleson[2], J. Pakish-Darby[3], C.F. Lynch[2], P.A. Romitti[2]

[1]Internal Medicine, Wake Forest University School of Medicine, Winston-Salem, NC, USA; [2]Epidemiolgy, Biostatistics, Toxicology Department, S416 CPHB, The University of Iowa - College of Public Health, Iowa City, IA, USA; [3]Obstertrics and Gynecology, Wake Forest University School of Medicine, Winston-Salem, NC, USA

Background: Incidence of hormone receptor-positive (HR+) breast cancer (BC) is increasing. With environmental factors associated with HR+ tumors, we used spatial analysis to identify regions with excess HR+ BC.

Methods: Surveillance data for 38,944 women with a primary diagnosis of BC with reported HR status during 2000-18 and no prior cancers were obtained from the Iowa Cancer Registry. HR+ tumors were defined as those that were estrogen receptor-positive or progesterone receptor-positive. Spatial patterns in HR+ BC/1,000 women and as a proportion of all women with BC with known HR status were examined by county (n=99) for premenopausal aged (15-49 years; n=7,935) and post-menopausal aged ($\geq$50 years; n=31,009) women; proportions were analyzed using logistic regression with spatial correlation via intrinsic conditional auto-regressive models at the county level and general additive models (GAMs) at the residence level (premenopausal, n=7,930; postmenopausal, n=30,988).

Results: HR status was classified for 38,944 women (premenopausal: 6,188 HR+, 1,747 HR-; postmenopausal: 26,190 HR+, 4,819 HR-). Across all counties, rates of HR+ BC ranged from 4.9-17.1/1,000 premenopausal women, representing 57.6-96.8% of BC cases among these women and a state average of 78.0%. Respective values were 29.3-61.1/1,000 postmenopausal women, 75.6-92.6%, and 84.5%. The top 21 counties with the highest estimated proportions of HR+ BC after spatial smoothing within each age group represented 25.3% of all premenopausal women and 21.2% of all postmenopausal women in Iowa. Twelve (57.1%) of these counties overlapped between age groups; two counties were elevated above the respective state averages for both age groups, with 95% probability. GAMs indicated similar areas of increased probability of HR+ BC.

Conclusions: Findings suggest some spatial overlap in proportions of incident HR+ BC between pre- and postmenopausal women. This overlap may indicate shared environmental risk factors for HR+ BC between age groups in these regions. Our analytical approach provides a model that can be applied across broader geographic regions. Future analyses will explore temporal differences in these incident cancers.

Background: Preclinical evidence using mouse model suggests that thermal/cold stress increases tumor growth by modulating the tumor microenvironment; however, the clinical relevance of temperature on BC outcomes is unknown. Studies show that residing in cold regions is associated with higher incidence of BC. We aim to study the impact of environmental temperature on the pathological complete response (pCR) and survival of early-stage BC patients (pts).

Methods: A multi-institutional study was conducted within the Oncology Research Information Exchange Network. We analyzed the clinical and genomic data for early-stage BC pts from 12 centers in the United States from different environment zones (5 warm (W) and 7 cold (C)) (based on average annual regional temperature obtained from National Centers for Environmental Information). Cox regression was used to measure the association of climate and overall/relapse-free survival (OS/RFS) after adjusting for confounders.

Results: Out of the 1,304 early-stage BC pts, 271 pts received neoadjuvant chemotherapy (NAC) (186 W, 85 C). Higher clinical T- and N-stages were observed in pts from W compared to C regions ($p<0.001$). Pts residing in C regions had more comorbidities (57.6% vs 48%, $p<0.001$). Pts in W regions had higher pCR, though not statistically significant (8% vs 2.5%, $p= 0.1$). The OS (univariate (UV) HR= 0.48, 95% CI 0.27-0.64, $p <0.001$; multivariate (MV) aHR= 0.56, 95% CI 0.32 - 0.96, $p= 0.03$) and RFS (UV HR= 0.51, 95% CI 0.38 - 0.68, $p<0.001$; MV aHR= 0.52, 95% CI 0.36 - 0.75, $p= 0.0005$) were higher in pts from W compared to C regions (Table). The OS (aHR= 0.35, $p= 0.02$) and RFS (aHR= 0.49, $p= 0.02$) of pts who received NACT were also higher in W regions.

Table: 341P

Regions (n)	5-yr OS (95% CI)	Median OS (months) (95% CI)	5-yr RFS (95% CI)	Median RFS (95% CI)	p-value
Cold (782)	83 (76-86) %	157.7 (116.6-NR)	69 (62-76) %	108.4 (88.9-147.8)	<0.001
Warm (522)	95 (92-97) %	214.7 (205.3-NR)	83 (79-87) %	250.4 (129.9-250.4)	

Conclusions: Early-stage BC pts living in cold have worse OS and RFS compared to warm regions. Larger studies are warranted to validate these interesting findings and further research focusing on therapeutic strategies to abrogate this outcome disparity by temperature is needed.

342P Fertility preservation in young breast cancer patients: Patient's knowledge and perception

Z. Naimi, A. Riahi, M. Bohli, R. Ben Amor, A. Hamdoun, R. Haddad, G. Bouguerra, L. Kochbati

Department of Radiation Oncology, Abderrahmen Mami Hospital, Ariana, Tunisia

Background: This study aimed to assess breast cancer (BC) patients' knowledge and perception of fertility risks and preservation, and to determine factors that impact fertility preservation(FP) patient decision making.

Methods: We performed a cross-sectional study including 70 BC patients $\leq$ 45 year-old. Patients were surveyed using a 29 item questionnaire assessing their personal experience and knowledge about fertility risks and FP treatments. A knowledge score (0-12) was calculated with 1 point awarded for each correct answer. Statistical associations between socio-demographic characteristics, personal experience and knowledge score were analyzed.

Results: Mean age was 34 year-old. Thirty-seven patients had a college degree and 80% were married. Previous pregnancy/live birth were reported in 77%/72% of patients. Twenty-seven percent of patients had prior contact with infertility. Fifty-five patients were informed about infertility risks related to BC treatment. Only 62.8% of patients received information about FP treatments. Thirty-five patients were referred to FP consultation of whom 12 patients received FP treatments. Embryos/oocytes freezing were the main used options. The main reasons for skipping FP treatments were lack of pregnancy desire (38.6%) and insufficient provided information (30%). "Complexity of FP procedure" and "fear of delaying cancer treatment" were reported in 8.6% and 4.3% of cases respectively. Mean knowledge score was 6(3 -11). Forty-six percent of patients believed that "FP treatment is related to an increased risk of cancer recurrence". Only 61.4% of patients were aware that "freezed eggs remain available in the future whenever the patient is ready to use them". Most of the patients (81.4%) were aware that having a spouse was not a prerequisite for FP treatment. Knowledge about FP treatments availability and costs was poor with more than half of patients overestimating costs and assuming the lack of FP treatment options. Only 60% of patients were aware of an operational legal framework for FP in Tunisia.

Conclusions: This study showed that FP baseline knowledge in BC patients is generally poor. Patient's access to clear and concise fertility information is the key for effective interventions for fertility preservation.

343P Modulation of the immune system (ImS) during moderate physical activity (mPA) in breast cancer (BC) patients (pts) treated with neoadjuvant chemotherapy (NACT)

O. Garrone[1], A. Abbona[2], M. Paccagnella[2], F. Ruatta[1], P. Vanella[3], G. Tomasello[1], F. Barbin[1], M.G. Rossino[1], N. Croce[3], M.C. Merlano[4]

[1]Medical Oncology, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy; [2]Medical Oncology, Fondazione ARCO - Cuneo, Cuneo, Italy; [3]Medical Oncology, Azienda Ospedaliera S. Croce e Carle Cuneo, Cuneo, Italy; [4]Medical Oncology, Candiolo Cancer Institute FPO - IRCCS, Candiolo, Italy

Background: The link between mPA and ImS is known. We studied the effect of mPA on a panel of circulating cytokines (Cy) during NACT in BC pts.

Methods: Pts underwent epirubicin and cyclophosphamide, followed by weekly paclitaxel $\pm$ trastuzumab. Blood samples were collected in pts underwent mPA (TR, Nordic or fit walking, 3 workouts/week, 1 hour each in the 10-12 weeks before surgery) and in pts who declined mPA (UN) at T0, at day 1 of week 6 of paclitaxel (T1, starting point of mPA) and before surgery (T2). 22 Cy: IL1b, IL2, IL4, IL5, IL6, IL7, IL8, IL10, IL12, IL13, IL15, IL17a, IL18, IL21, CCL2, CCL4, CXCL10, CCL22, IFNγ, TGFβ, TNFα, VEGF were measured by Simple Plex Ella™. Differences between the median Cy values were analyzed with Mann-Whitney U test. Comparisons between time points within the same group were analyzed with Wilcoxon signed-rank test. ROC analysis was performed to highlight relevant variables for TR and UN. PCA and PERMANOVA evaluated the impact of mPA on Cy at T1 and T2.

Results: 91 pts have been accrued. 88 pts have been analysed, 68 TR and 20 UN. At T0 IL4 was higher ($p < 0.01$) in UN pts. At T1 IL4 and IL17 were higher ($p < 0.01$) in UN. At T2 higher values ($p < 0.01$) of IL4, IL7, IL17, VEGF in UN. Higher IL21 ($p < 0.01$) in TR. Longitudinal analysis (LA) between T0 and T1 in TR and UN showed increase of INF-γ, IL5, IL15, CCL2, CXCL10, IL17α. UN pts showed also increase of IL6. TR pts showed increase of IL7, IL18 and decrease of IL4, IL13, CCL22. LA between T1 and T2 showed increase of IL21, CCL22, TNFα and decrease of IL6, IL8, IL15 TGFβ in TR pts. UN showed increase of CXCL10 and decrease of IFNγ, IL6, IL8, CCL2, TGFβ. PCA discriminated TR from UN pts at T2 ($p=0.045$ PERMANOVA analysis).

Conclusions: TR and UN pts were similar at T0. LA between T0-T1 showed that CT induced prominent changes in TR suggesting a more plastic ImS. LA between T1-T2 showed significant changes of Cy only in TR supporting a role of mPA in the modulation of the ImS. Overall, CT induced weak changes in UN and more consistent changes in TR pts, suggesting a more efficient ImS and a possible additional effect derived from mPA in TR. PCA at T2 supports these hypotheses showing a significant grouping of TR clearly separate from UN.

344P Epidemiological analysis and overall survival of female breast cancer in a developing middle eastern country over 18 years

M. Abunasser[1], A. Alhajahjeh[2], Z. Abdulelah[3], A. Abdulelah[4], A. Ghazzawi[4], D. Murshedi[4], H. Abdel-Razeq[5]

[1]Medical Oncology, KHCC - King Hussein Cancer Center, Amman, Jordan; [2]Internal Medicine, IAU - The University of Jordan, Amman, Jordan; [3]Internal Medicine, St. Bartholomew's Hospital - Barts Health NHS Trust, London, United Kingdom; [4]Internal Medicine, KHCC - King Hussein Cancer Center, Amman, Jordan; [5]Lung Cancer, Genitourinary Cancers, Breast Cancer, KHCC - King Hussein Cancer Center, Amman, Jordan

Background: Breast cancer imposes a significant regional and global health burden not only due to being the most prevalent malignancy in females in the Middle East and worldwide, but due to the associated substantial morbidity and mortality. Therefore, the determination of the epidemiological features of breast cancer in the Middle East is of prominent interest given the significant resultant burden associated with breast cancer as it enables for the efficient introduction of effective interventions.

Methods: Data on 20,046 female patients of different nationalities and residing in Jordan diagnosed with breast cancer during the period of 2000-2018 were obtained from the Jordan Cancer Registry. Consequently, comprehensive statistical analysis was performed to establish the epidemiological characteristics of breast cancer in Jordan, including the overall survival and crude incidence.

Results: A total of 20,046 female patients with a mean age of 51.5 ± 12.5 years old were included in the analysis. Only 6.54% of the enrolled patients were smokers at the time of diagnosis. Breast cancer was more commonly affecting the left breast, 46.9% of the patients, than the right breast, 43.5% of the patients, whereas 1.18% of the patients had breast cancer bilaterally. The upper outer quadrant of the breast was the most commonly reported site of tumour location. Moderately differentiated carcinoma was the most commonly encountered grade in 31.4% of the patients, whereas 28.9% had poorly differentiated carcinoma. Regional spread to the lymph nodes was observed in 19.0% of the sample and 13.1% of the patients had distant metastasis, while localized breast cancer was noted in 16.6% of the patients. A statistically significant increase in the crude incidence of breast cancer in females has been observed in Jordan over the 18 years period with a crude incidence estimated effect of 0.46 (P-value<0.001). The overall survival rate was determined to be 95.8%, 83.2%, and 62.8% at 1-year, 3-year, and 5-year interval, respectively.

Conclusions: Breast cancer in Jordan imposes a significant burden due to the significant increase in the crude incidence over the 18-year period, and thus mandating vigorous and vigilant screening and preventative measures.

345P The effect of early post-operative exercise on shoulder function in breast cancer patients: A randomised controlled trial

J. Min[1], J. Ryu[2], S. Yeon[2], S. Park[3], J.Y. Kim[3], S.I. Kim[3], J.W. Kang[4], S. Jun[4], R. Park[5], Y.J. Lee[5], T.H. Lee[4], E. Kim[2], C. Oh[4], K. Chiho[5], D-H. Park[2], J. Jeon[2]

[1]Convergence Medicine, Yonsei University College of Medicine - Wonju Severance Christian Hospital, Wonju, Republic of Korea; [2]Sports Industry Studies, Yonsei University, Seoul, Republic of Korea; [3]Division of Breast Surgery, Department of Surgery, Severance Hospital - Yonsei University College of Medicine, Seoul, Republic of Korea; [4]Sports Medicine, Yonsei University, Seoul, Republic of Korea; [5]Sports Industry, Yonsei University, Seoul, Republic of Korea

Background: Breast cancer surgery can impair shoulder function, and the effects of rehabilitation exercise during early recovery remain uncertain. This study aims to assess the effectiveness of tailored exercise intervention on shoulder function recovery at one and six months post-surgery.

Methods: A total of 122 breast cancer patients (Stage 0-3) scheduled for surgery were evaluated, and 58 patients (mean age 50.2±6.6 years) were randomly assigned to an exercise or usual care group (1:1). The exercise group underwent five tailored exercise education sessions, starting one day before hospital discharge and continuing for four weeks after surgery. Participants received exercise diaries, online links, and QR codes for home-based workouts. The primary outcome measured the proportion of participants achieving 90% of their pre-surgery shoulder ROM and strength at one and six months post-surgery. Secondary measures included DASH and SPADI scores, physical activity levels, and body composition.

Results: Out of 58 participants, 56 (96.6%) completed the trial, with a 96.6% exercise compliance rate one month after surgery. In the exercise group, 92.9% and 96.2% achieved pre-surgery shoulder strength levels at one and six months post-surgery, respectively, compared to 3.7% and 32.1% in the control group. The exercise group also exhibited significantly lower shoulder pain and disability scores (SPADI) at one and six months after surgery, as well as higher physical activity levels at six months.

Table: 345P Change in shoulder strength among postoperative breast cancer patients

	Affected arm		
	EPET (n=25)	Usual Care (n=26)	*p*
Sum of strength (lb)			
T0	44.1±10.2	47.5±11.1	0.36
T1	23.2±10.3***	23.8±9.4***	0.80
T2	40.4±11.9	28.5±11.9***	**0.001**
T3	45.9±14.7	32.0±11.2***	**<0.001**
T4	51.3±14.0	32.0±9.2***	**<0.001**
T5	61.0±17.1***	38.3±8.4***	**<0.001**

Mean±SD, *P*=represented the results of independent T-test (the p-value adjusted for Bonferroni method (0.05/6=0.0083), *=represented paired t-test [**p<0.01 vs. baseline, ***p<0.001 vs. baseline (p-value adjusted for Bonferroni method)] Abbreviation: early postoperative exercise therapy; EPET

Conclusions: Early implementation of tailored exercise during rehabilitation significantly improved shoulder function beyond pre-surgery levels. This study provides essential insights into the efficacy and safety of early rehabilitation exercises for breast cancer patients during the post-surgery recovery phase.

Clinical trial identification: The Institutional Ethics Review Board of Severance Hospital and WHO International Clinical Trials Registry Platform (ICTRP; KCT0006997) approved the trial.

346P Quality of life (QoL) and toxicity in patients (pts) with hormone receptor-positive, HER2-negative early breast cancer (HR+, HER2− eBC) treated with adjuvant (adj) endocrine therapy (ET) in the CANcer TOxicities (CANTO) study

A. Bertaut[1], T. Badovinac Crnjevic[2], A-L. Martin[3], C. Gaudin[4], L. Chen[5]

[1]Methodology and Biostatistics Unit, Centre Georges François Leclerc Cancer Center, Dijon, France; [2]Clinical Science Oncology, F. Hoffmann-La Roche AG - Switzerland, Basel, Switzerland; [3]Health Data and Partnership Department, Unicancer, Paris, France; [4]CANcer TOxicity (CANTO), Unicancer, Paris, France; [5]Product Development-Data Science- RWD Enabling Platform, Genentech, Inc., South San Francisco, CA, USA

Background: ET is the mainstay treatment (tx) for HR+ eBC but they have persistent side effects that negatively affect QoL, leading to early tx discontinuation and compromising outcomes. We describe the incidence of ET toxicity and its QoL impact in CANTO.

Methods: CANTO (NCT01993498) is a prospective, longitudinal cohort study enrolling pts with invasive (cT0-cT3, cN0-3, no metastases) BC from 26 French cancer centres. Pts with HR+, HER2− eBC treated with adj ET were followed for the first 3 years (yrs) after eBC diagnosis. Pt demographics, clinical data, adherence, symptoms and QoL were collected. Questionnaires were administered at baseline (BL), 3−6 months (mo; M0) after primary surgery, chemotherapy or radiotherapy completion (whichever came last), and 12 mo, 36 mo and 60 mo after M0. Descriptive analyses were conducted for frequency of symptoms and mean/median QoL questionnaires summary scores.

Results: Of the 5564 pts who met the inclusion criteria (median age: 57 yrs), 63% were post-menopausal and 52% had stage I eBC at diagnosis. The table shows QoL and toxicity data. Global and functioning QoL remained high at BL and during tx. BC-specific symptoms persisted during tx. Pain was the most prevalent toxicity in the first 3 yrs; prevalence of muscular and joint pain increased over time. Mean intensity of global, muscular and joint pain all remained high over the course of ET (median intensity: ∼6 [0−10 scale]). ET adherence was 81−93% over time; in the first 3 yrs, 23% switched ET and 7% discontinued adj ET; toxicity was the main reason cited.

Table: 346P

	BL	M0	12 mo	36 mo

Toxicity, %				
Global and back pain	-	71	74	72
Muscular and back	-	32	36	38
Joint and back	-	59	68	70

Conclusions: While global and functional QoL remained high in the first 3 yrs after eBC diagnosis, BC-specific symptoms slightly increased/persisted during ET. This study confirmed long-term toxicity of ET, particularly pain. Better management of symptoms and supportive interventional strategies are needed to further improve QoL in eBC.

Clinical trial identification: NCT01993498, first posted November 25, 2013.

348P Long-term opioid use following treatment of localized breast cancer: A real-world analysis

A. Shai[1], E. Granot-Hershkovitz[2], S. Amar-Farkash[2], K. Rosenberg-Katz[2], D. Aran[3]

[1]Breast Cancer Unit, RAMBAM Health Care Campus, Haifa, Israel; [2]Data Science and Research Department, Carelon Digital Platforms Israel, Tel Aviv, Israel; [3]Faculty of Biology, Technion - Israel Institute of Technology, Haifa, Israel

Background: Chemotherapy for early breast cancer (BC) increases the risk of chronic opioid use. Factors associated with new opioid use after (neo)adjuvant chemotherapy for BC are poorly understood.

Methods: We analyzed Elevance Health administrative claims and Cancer Care Quality Program data between 2017-2022. BC patients who underwent surgery and (neo)adjuvant chemotherapy were included. Patients that had claims for either opioids or for medications used to treat neuropathic pain before BC diagnosis were excluded. Long-term use was defined as opioid drug claims lasting at least 3 months within 1 year of follow-up. We explored factors associated with this outcome via logistic regressions, with additional stratification to adjuvant/neoadjuvant groups.

Results: Among 3,353 BC patients, 156 (4.56%) were prescribed long-term opioids during the first year following chemotherapy. Young age, advanced stage, mastectomy (vs. lumpectomy), and higher comorbidity score were associated with long-term opioid usage (Table). Of patients aged $\leq$ 45 (N=442), 8.6% had long-term opioid claims, while patients aged 65-75 (N=653), 2.45% had such claims. When analyzing specific comorbidities, significant associations with opioid use were found for chronic obstructive pulmonary disease (COPD), liver disease, and peptic ulcer in patients treated with neoadjuvant chemotherapy. Rheumatic disease and congestive heart failure were associated with opiod use in patients treated with adjuvant chemotherapy.

Table: 348P Factors associated with long term opioid use

	OR	Confidence interval	p value
Age	0.66	0.55-0.78	1.40E-06*
Lymph node +	1.51	1.02-2.24	4.13E-02
Social determinant index	1.07	0.91-1.26	4.17E-01
Charlson's comorbidity	1.4	1.21-1.64	1.29E-05*
Stage II (ref stage I)	2.16	1.33-3.52	1.93E-03*
Stage III (ref stage I)	1.35	0.72-2.54	3.52E-01
Mastectomy (ref lumpectomy)	2.41	1.52-3.81	1.77E-04*
Mastectomy and lumpctomy (ref lumpectomy)	5.72	3.33-9.8	2.34E-10*
Radiotherapy	0.64	0.43-0.96	2.87E-02*
Hormonal	0.71	0.5-1	5.27E-02
Anti HER2	0.91	0.63-1.31	6.09E-01
Immunotherapy	2.29	0.75-6.97	1.45E-01
Taxans	1.09	0.59-1.99	7.87E-01

Conclusions: This study offers valuable real-world insights into the prevalence and potential risk factors for chronic opioid use during the first year following chemotherapy for BC. Young age, mastectomy and higher comorbidity index were associated with chronic opiod use in this cohort.

349P The influence of diabetes on taxane-induced neurotoxicity and quality of life in breast cancer patients

E. Cimbro[1], M. Dessi[1], P. Ziranu[1], C. Madeddu[1], F. Atzori[1], E. Lai[1], A. Pretta[1], S. Mariani[1], C. Donisi[1], D. Spanu[1], M. Pozzari[1], S. Murgia[1], C. Codipietro[1], E. Palmas[1], G. Sanna[1], F. Semonella[1], S. Sardo[2], G. Finco[2], M. Scartozzi[1]

[1]Medical Oncology Department, University Hospital of Cagliari, Monserrato, Italy; [2]Anesthesiology Department, University of Cagliari, Monserrato, Italy

Background: Peripheral neuropathy is one of the long-term complications of diabetes. In breast cancer diabetic patients, this condition can worsen neurotoxic symptoms induced by taxane-based therapy administration. Chemotherapy induced peripheral neuropathy (CIPN) and its influence on patient's quality of life (QoL) is evaluated through certified questionnaires (NCI-CTC, EORTC QLQ-CIPN20, FACT-TAXANE).

Methods: Data from stage I-III breast cancer patients treated with taxane-based therapy between 2018 and 2022 were retrospectively analyzed at the Medical Oncology of the University Hospital of Cagliari. 300 patients, median age 57 years (32-85), followed a schedule of PCT 80mg/m2 $\pm$ 30 weekly per maximum 12 administrations; 43 patients had diabetes (14,3%). Peripheral neuropathy was evaluated by the NCI-CTC scale at every drug administration. QLQ-CIPN20 and FACT-TAXANE questionnaires were collected at baseline, at 4 and 12 weeks of treatment. Kruskal-Wallis test was used to assess relation between neurotoxicity grade and QoL; ANOVA for repeated measures was used to test differences at different timing. Student's T-test was used to analyze differences in diabetic and non-diabetic population.

Results: Neurotoxicity influenced QoL, in both populations, at cycle IV ($p<0.001$) and cycle XII ($p=0.008$). Patients with grade 0, 1 and 2 neurotoxicity reported a QLQ-CIPN20 median score of 32, 34 and 43 at cycle IV respectively, and a median value of 27, 33 and 34 at cycle XII respectively. ANOVA test showed a significant worsening of QLQ-CIPN20 and FACT-TAXANE scores at 4 and 12 weeks vs. baseline ($p<0.001$ for both). Values of QLQ-CIPN20 remained significantly higher in comparison to baseline also at 3 ($p<0.001$), 6 ($p<0.001$) and 12 months ($p<0.001$) follow up. In diabetic population, scores were significantly higher ($p<0.05$) in all neurotoxicity questionnaires, but no difference in QoL was highlighted by FACT-TAXANE, compared to non diabetic patients.

Conclusions: The use of QLQ-CIPN20 and FACT-TAXANE questionnaires identified neurotoxicity onset and its correlation to QoL, yet at an initial phase of treatment. Diabetic patients presented more severe neurotoxicity, without influencing overall QoL.

350P Quality of life data on sexual relations in early breast cancer patients

M.L. Garrido, B.I. Tavara, L. Lopez, S. Pérez, M. Vázquez, M. Lopez Flores, C. Castañón, S. Abella Alvarez, A. López

Medical Oncology Department, Complejo Asistencial Universitario de León, León, Spain

Background: The diagnosis and treatment of breast cancer involves changes in personal, family, social, professional and sexual relationships. In this study we assessed sexual satisfaction in patients with early breast cancer using the validated SEXSAT-Q scale.

Methods: We used the SEXSAT-Q quality of life questionnaire in 60 patients diagnosed with early breast cancer at our centre. Six dimensions were studied: 1. Loss of sexual desire. 2. Alteration of body image. 3. Psychological coping. 4. Discomfort during sexual intercourse. 5. Satisfaction during sexual intercourse. 6. Satisfaction with breast reconstruction. Data were collected in Medical Oncology Department during March 2023.

Results: A sample of 60 patients was selected, aged 26-72 years old, with a median age of 52 years, who had undergone breast cancer surgery, 73.33% by conservative surgery. 20% were premenopausal, 10% were perimenopausal and 70% were menopausal. 35% were being treated with chemotherapy, 56.67% with hormonoterapy and 8.33% with anti-HER2. 78.33% had a stable partner and did not use contraception. 30% of patients were quite or very sad and depressed since starting treatment. 50% of patients believe that the treatment has worsened their body image. 75% reported that during treatment their sexual relations were not satisfactory. 61.67% believe that their sexual desire has decreased and 45% admit having more problems reaching orgasm since diagnosis.

Conclusions: Women with curable breast cancer it is important to know the impact of diagnosis and treatment on the sexual sphere. The SEXSAT-Q questionnaire is a validated scale capable of measuring the sexual satisfaction of our patients.

351TiP EORTC BCG 1984 — NOBLE: Noeoadjuvant olaparib and durvalumab for patients with BRCA-associated triple-negative breast cancer

E. Buhrer[1], E. Xenophontos[1], A.-S. Hamy-Petit[2], J. Casas[1], C. Callens[3], A. Lanzi[4], T. Meyskens[5], C. Poncet[6], E.G.C. Brain[2]

[1]Medical Department, EORTC AISBL/IVZW - European Organisation for Research and Treatment of Cancer, Brussels, Belgium; [2]Medical Oncology Department, Hopital René Huguenin - Institut Curie, Saint-Cloud, France; [3]Genetics Department, Institut Curie, Paris, France; [4]Breast Cancer Medico-Scientific Program, Institut Curie, Paris, France; [5]Medical Oncology Department, AZ Klina, Brasschaat, Belgium; [6]Statistical Department, EORTC AISBL/IVZW - European Organisation for Research and Treatment of Cancer, Brussels, Belgium

Background: The standard of care for patients with early triple-negative breast cancer (TNBC) is neoadjuvant chemotherapy followed by surgery. Recently, immune checkpoints inhibitors (ICI) added to neoadjuvant chemotherapy have shown efficacy. Among TNBC, BRCA mutations and other homologous recombination deficiency (HRD) signals are relatively frequent. As opposed to other types of breast cancer, HRD TNBC show a high neoantigen load, a large number of tumour infiltrating lymphocytes (TILs), and a high PD-L1 expression. In BRCA/HRD breast cancer, PARP inhibitors (PARPi) exhibit a distinct anticancer activity. In addition, they show immunomodulatory effects by promoting PD-L1 expression and DNA damage, increasing neoantigen load. Chemotherapy-free regimens combining PARPi and ICI result in promising synergistic activity as shown in the metastatic setting, supporting investigation in the neoadjuvant setting.

Trial design: NOBLE is an EORTC phase 2, randomized, multicentre, open label, clinical trial. It includes a minimax Simon's two-stage design with an early feasibility step. Eligible patients must have early TNBC harbouring a tumoral (t)BRCA1/2 mutation, or another HRD signal based on methylation. Following central screening for tumoral BRCA/HRD (Institute Curie, 455 patients), 152 patients will be randomized between olaparib vs olaparib and durvalumab for 4 cycles of neoadjuvant treatment. Thereafter, patients will undergo surgery. All patients will be followed-up to 2 years (y) after surgery. The trial will be conducted in 3 steps (screening/randomization): Step 1 — Feasibility (60/20): to assess the central testing failure rate, the turn-around time for central testing and the prevalence of tBRCA/HRD; Step 2 (193/64) — Futility; and Step 3 (202/152) — Expansion of recruitment. The primary endpoint is the rate of pathologic complete response at the time of surgery, defined as ypT0/is ypN0. Secondary endpoints are response based on RECIST v1.1, surgery rate, 2-y event-free-survival, 2-y overall survival, safety, and quality of life. The study is expected to be activated in early autumn 2023 and the primary endpoint will be available approximately 5 years after the screening of the first patient.

Clinical trial identification: EudraCT 2022-003594-33. NCT05209529.

352TiP Neoadjuvant chemo-immunotherapy plus/minus fasting-like approach in stage II-III triple-negative breast cancer patients: The phase II randomized BREAKFAST-2 trial

C. Vernieri[1], F. Ligorio[1], M.V. Dieci[2], M. Lambertini[3], C. De Angelis[4], M. Iorfida[5], A. Botticelli[6], C. Strina[7], A. Vingiani[8], L. Provenzano[1], G.V. Bianchi[1], S. Folli[9], D. Generali[7], A. Zambelli[10], S. de Placido[4], L. Del Mastro[3], V. Guarneri[2], G. Capri[1], G. Pruneri[8], F.G.M. De Braud[1]

[1]Medical Oncology and Hematology Department, Fondazione IRCCS - Istituto Nazionale dei Tumori, Milan, Italy; [2]Department of Surgery, Oncology and Gastroenterology, University of Padova, Padua, Italy; [3]Department of Medical Oncology, IRCCS AOU San Martino - IST-Istituto Nazionale per la Ricerca sul Cancro, Genoa, Italy; [4]Department of Clinical Medicine and Surgery, Azienda Ospedaliera Universitaria Federico II, Naples, Italy; [5]Division of Medical Senology, IEO - European Institute of Oncology, Milan, Italy; [6]Department of Radiological, Oncological and Pathological Science, Sapienza University of Rome, Rome, Italy; [7]Multidisciplinary Unit of Breast Pathology and Translational Research, ASST Cremona, Cremona, Italy; [8]Department of Advanced Diagnostics, Fondazione IRCCS - Istituto Nazionale dei Tumori, Milan, Italy; [9]Breast Unit, Fondazione IRCCS - Istituto Nazionale dei Tumori, Milan, Italy; [10]Department of Biomedical Sciences, Humanitas University, Milan, Italy

Background: Despite remarkable improvements in early-stage Triple-Negative Breast Cancer (TNBC) treatment with neoadjuvant chemoimmunotherapy (CT-IO), a considerable proportion of TNBC patients (pts) still experience tumor relapse after surgery. Preclinical studies indicate that TNBC is exquisitely sensitive to fasting-like approaches (FLAs), and we have recently shown that cyclic FLA boosts systemic and intratumor immunity in cancer patients. We hypothesize that combining FLA with preoperative CT-IO can increase pathologic complete response (pCR) rates in pts with stage II-III TNBC.

Trial design: BREAKFAST-2 (NCT05763992) is an open-label, multicentric, randomized, phase 2 trial aimed at investigating the antitumor activity of experimental FLA in combination with standard preoperative CT-IO in pts with treatment-naïve, localized (T1c and N1-2, or T2-4 and N0-2) TNBC. Pts will be randomized in a 1:1 ratio to: a) control arm (standard CT-IO), consisting of 12 administrations of weekly paclitaxel + carboplatin concomitant with 4 triweekly cycles of Pembrolizumab, followed by 4 triweekly cycles of doxorubicin/epirubicin + cyclophosphamide + Pembrolizumab every three weeks; b) experimental arm, consisting of CT-IO + 5-day FLA every three weeks, up to 8 FLA cycles. Then pts will undergo surgery. Key eligibility criteria are: age of 18-75 years, ECOG PS 0-1, BMI > 19 kg/m^2, absence of malnutrition, diabetes, uncontrolled autoimmune disorders, or severe comorbidities. The primary study endpoint is pCR. Hypothesizing that the experimental treatment is able to increase the pCR rate from 65% (historical data with CT-IO alone) to 85%, and assuming an α error of 5% and a power of 85%, a total of 145 patients will be enrolled. Secondary endpoints include: safety and tolerability, compliance, Event-Free Survival (EFS) and Overall Survival (OS). We will combine plasma metabolomics and bulk/single cell RNA-seq analyses to explore the impact of the experimental treatment on systemic and intratumor immunometabolic pathways, as well as to assess the association between immunometabolic changes and clinical outcomes. The trial has started to enroll pts on May 2nd, 2023.

Clinical trial identification: NCT05763992.

353TiP Phase III study to evaluate the efficacy and safety of GLSI-100 (GP2 + GM-CSF) in breast cancer patients with residual disease or high-risk PCR after both neo-adjuvant and postoperative adjuvant anti-HER2 therapy, Flamingo-01

S. Patel[1], J. Thompson[1], M. Patel[1], F.J. Daugherty[1], M. Rimawi[2]

[1]Clinical and Regulatory, Greenwich LifeSciences, Inc., Stafford, TX, USA; [2]Hematology and Oncology, Baylor College of Medicine, Houston, TX, USA

Background: GP2 is a biologic nine amino acid peptide of the HER2/*neu* protein delivered in combination with Granulocyte-Macrophage Colony Stimulating Factor (GM-CSF) that stimulates an immune response targeting HER2/neu expressing cancers, the combination known as GLSI-100. In a prospective, randomized, single-blinded, placebo-controlled, multicenter phase IIb study, no recurrences were observed in the HER2+ population after 5 years of follow-up, if the patient was treated with GLSI-100, survived, and was followed for more than 6 months ($p = 0.0338$). Immunotherapy elicited a potent response measured by skin tests and immunological assays. Of the 146 patients that have been treated with GLSI-100 over 4 clinical trials, GLSI-100 was well-tolerated and no serious adverse events observed were considered related to the immunotherapy.

Trial design: This phase III trial is a prospective, randomized, double-blinded, multi-center study. After 1 year of trastuzumab-based therapy, 6 intradermal injections of GLSI-100 or placebo will be administered over the first 6 months and 5 subsequent boosters will be administered over the next 2.5 years. The participant duration of the trial will be 3 years treatment plus 1 additional year follow-up. Approximately 498 patients will be enrolled. To detect a hazard ratio of 0.3 in invasive breast cancer free survival (IBCFS), 28 events will be required. An interim analysis for superiority and futility will be conducted when at least 14 events have occurred. This sample size provides 80% power if the annual rate of events in placebo patients is 2.4% or greater. Up to 100 non-HLA-A*02 subjects will be enrolled in an open-label arm. The patient population is defined by these key eligibility criteria: 1) HER2/neu positive and HLA-A*02 and 2) Residual disease or High risk pCR (Stage III at presentation) post neo-adjuvant therapy. The trial objectives are to: 1) Determine if GP2 therapy increases IBCFS, 2) Assess the safety profile of GP2, and 3) Monitor immunologic responses to treatment and assess relationship to efficacy and safety. The study has been initiated in the US with plans to open in Europe.

Clinical trial identification: NCT05232916.

Background: Definitive locoregional (surgery ± radiotherapy) and standard adjuvant ET (± chemotherapy or cyclin-dependent kinase 4/6 inhibitor [CDK4/6i]) can achieve cure in many patients (pts) with ER+/HER2− early BC. Nevertheless, a significant proportion of pts with stage I—III disease will experience recurrence to metastatic, incurable disease (5- and 10-year cumulative incidences of recurrence of 8.3% and 14.0%, respectively). There is evidence that incorporating a more effective endocrine therapy after 2 years of standard adjuvant ET can result in clinical benefit for high-risk individuals. Camizestrant is a next-generation oral selective ER degrader and pure ER antagonist. In SERENA-2, camizestrant 75 mg and 150 mg significantly prolonged progression-free survival vs fulvestrant in postmenopausal women with ER+/HER2− advanced BC with disease recurrence or progression after ET. The CAMBRIA-1 study (NCT05774951) is evaluating the potential of extended adjuvant therapy with camizestrant to improve outcomes in pts with ER+/HER2− early BC with an intermediate or high risk of recurrence after definitive locoregional therapy and standard adjuvant ET.

Trial design: This phase 3 randomised, open-label study is enrolling women (pre- or postmenopausal) and men with ER+/HER2− (IHC 0/1+/2+/ISH−) early BC who have completed definitive locoregional therapy and standard adjuvant ET (± CDK4/6i) for ≥2 and ≤5 years (+ 3 months) without disease recurrence. Pts must be considered at intermediate or high risk of recurrence based on clinical, biological and genomic factors. Pts are randomised (1:1) to continue standard ET of the investigator's choice (tamoxifen or aromatase inhibitor ± LHRH agonist) or camizestrant ± LHRH agonist for up to 60 months. The primary endpoint is invasive BC-free survival (STEEP 2.0 criteria). Secondary endpoints include invasive disease-free survival and distant relapse-free survival (STEEP 2.0 criteria), overall survival, safety, and health-related quality of life. Approximately 4300 pts will be randomised; enrollment is ongoing.

Clinical trial identification: NCT05774951.

Background: The I-SPY2 Trial is a randomized phase II platform trial testing novel neoadjuvant therapies. Serial MRI and pathology are used to evaluate response. New agents (+/- taxane) are tested in a 12 week (wk) treatment block, followed by Adriamycin/Cytoxan (AC). We sought to determine whether MRI functional tumor volume (FTV)-based predictive models, in conjunction with breast core biopsy, could identify early responders who had reached pCR and thus proceed to surgery without receiving AC, sparing them additional toxicity. The "predicted Residual Cancer Burden" (preRCB) models were developed using retrospective I-SPY data and prospectively tested in I-SPY2.

Methods: Eligible patients (pts) were required to be on preRCB-designated treatment arms and consented to participate in the optional preRCB process. PreRCB included breast MRI at baseline, wk 3 and wk 12 of the initial I-SPY2 treatment block and a clinical core biopsy of the tumor bed at 12-weeks. Pts who met combined preRCB criteria (predicted probability of pCR above threshold in a subtype specific FTV model and no invasive tumor on breast biopsy) were eligible to proceed to surgery without AC after return of results (ROR) and consultation with their clinician.

Results: From 1/20-6/22, 172 pts underwent preRCB and completed surgery. 51/172 (30%) met combined MRI/biopsy preRCB criteria and 40/51 proceeded to surgery without AC (Table). 96% (49/51) pts who met preRCB criteria had RCB0/1 vs. 48% (57/120) of pts who did not meet criteria (OR 27 [6.5-235]; Fisher's exact test p=1.04E-10). Overall, preRCB led to a 24% reduction in AC use without significant difference in RCB0/1 rate between those with and without AC (p=1).

Conclusions: Implementation of preRCB in I-SPY2 identified patients with pCR prior to AC. High uptake of early surgery recommendations led to reduced use of AC while maintaining optimal outcome. I-SPY 2.2 is testing next-generation models to enable further optimization.

Table: 355P

PreRCB met (n=51)				PreRCB not met (n=120)			
No AC 40/51 (78%)		Received AC 11/51 (22%)		No AC 22/120 (18%)		Received AC 98/120 (82%)	
RCB 0/1	RCB 2/3	RCB 0/1	RCB 2/3	RCB 0/1	RCB 2/3	RCB 0/1	RCB 2/3
38 (95%)	2 (5%)	11 (100%)	0 (0%)	12 (55%)	10 (45%)	45 (46%)	53 (54%)

D. Anderson Cancer Center, Houston, TX, USA

Background: Residual Cancer Burden (RCB) after neoadjuvant chemotherapy (NAC) has been validated to predict event-free survival (EFS) across breast cancer subtypes but its prognostic ability has not been specifically studied for invasive lobular carcinoma (ILC).

Methods: We studied patient-level data (histologic subtype, RCB, and EFS) from a previously published pooled cohort from 12 institutions in the US and Europe. ILC was defined by local institutional protocols. Characteristics in pure ILC vs. non-ILC were compared using t-test or chi-squared test. Associations between continuous RCB index and EFS were assessed in both groups with mixed effect Cox models and multivariable analyses. Recursive partitioning was used in an exploratory model to stratify prognosis by individual clinicopathologic variables and the components of RCB.

Results: Of 5161 patients, the diagnosis was ILC in 216 (4.2%) and non-ILC in 4945. ILC cases were older, had lower grade, higher tumor (T) category, and more hormone receptor (HR) positive HER2 -negative subtype (73.6% vs 36.4%) (all p-values <0.05). Pathologic complete response (pCR/RCB 0) was achieved in 10.6% of ILCs and 33.4% of non-ILC (2.5% and 11.8% respectively among HR+HER2- cases, $p<0.0005$). Increased RCB index was significantly associated with worse EFS in both ILC and non-ILC ($p<0.05$) and remained prognostic when adjusted for age, grade, T category, baseline nodal status, and receptor subtype. While continuous RCB index had a linear relationship with probability of EFS event (log scale) in non-ILC, this relationship was non-linear in ILC cases; for ILC, prognosis was similar for RCB index ≤ 1.9, with increasing risk for RCB index >1.9. Recursive partitioning demonstrated residual tumor cellularity as most prognostic in ILC, followed by number of positive nodes and tumor dimensions.

Conclusions: While pCR rate after NAC is low in ILC, RCB retains prognostic value, with residual cellularity providing the most information. RCB index values ≤ 1.9 had similar prognosis to pCR. These results underscore the utility of RCB for evaluating NAC response in those with ILC for clinical management and as an endpoint for clinical trials.

357P Prediction of pathologic response to neoadjuvant chemotherapy (NAC) using diffuse optical breast scanner (DOB-Scan) in patients with locally advanced breast cancer (LABC)

P.T. Nguyen[1], S. Momtahen[2], M. Momtahen[2], P. Atwal[3], W.W. Yap[4], B. Bradshaw[5], A. Chinnadurai[6], H.M. Abusin[1], A. Gurjal[1], S. Gilmour[1], M.A. Shaikh[1], R. Ramaseshan[2], F. Golnaraghi[2], J. Ko[1]

[1]Medical Oncology Dept., BC Cancer - Abbotsford, Abbotsford, BC, Canada; [2]Mechatronics, Simon Fraser University, Surrey, BC, Canada; [3]Physics, BC Cancer - Abbotsford, Abbotsford, BC, Canada; [4]Diagnostic Imaging, Surrey Memorial Hospital, Surrey, BC, Canada; [5]Anatomic Pathology, ARHCC - Abbotsford Regional Hospital and Cancer Centre, Abbotsford, Canada; [6]Medicine, University of Western Ontario, London, ON, Canada

Background: No modality exists to accurately predict pathologic response to chemotherapy prior to surgery in patients with LABC receiving NAC. The objective of this study is to use the novel DOB-scan to evaluate the pathologic response of breast cancer to NAC before surgery.

Methods: The study aims to enroll 90 patients and recruitment is ongoing. An eligible patient had a diagnosis of LABC and was recommended NAC followed by resection. DOB-Scan used near-infrared light to examine healthy and breast cancer tissue prior to NAC, at clinic visit prior to each WNAC cycle, and after NAC was completed. Palpated tumour size was measured at the same time; ultrasound (US) was performed prior to NAC start, halfway, and after final NAC. After surgery, the specimens were reviewed by reference pathologist and assigned the pathologic Residual Cancer Burden (pRCB) class (Symmans et al. JCO 2007 ; Yau et al. SABCS 2019). We calculated the optical RCB (oRCB) class by determining the minimum reflectance that correlated with maximum absorption on DOB-Scan after the last NAC prior to surgery. Correlation between pRCB and oRCB was modelled to fit a linear regression.

Results: 60 patients have been enrolled; data from 30 patients who completed NAC and surgery were included in this interim analysis. Median age was 58 (range 29-72); all but 1 had ductal carcinoma; 22 had axillary lymph node(s) involved. Median longest diameter of the primary tumour on US was 2.3 cm (range 0.7-18). Final size by palpation or US indicated response to NAC, but did not correlate with pRCB. The oRCB clustered linearly with pRCB (pRCB $=$ 4.4 x oRCB), with a sensitivity of 97% and a specificity of 100%. Artificial-intelligence rendered noise reduction of oRCB increased the sensitivity to nearly 100%.

Conclusions: Early results suggest that the oRCB can predict final pathologic response more accurately than palpation or US during NAC. Lower oRCB indicated better response to NAC, with the ability to predict pRCB and pathologic complete response prior to resection. DOB-Scan can be used as a point-of-care hand-held instrument to assess tumour response and assist with treatment decisions in patients receiving NAC.

358P Major adverse cardiovascular event outcomes of adjuvant taxane + anthracycline versus taxane-based chemotherapy in older adults with triple-negative breast cancer: A SEER-Medicare study

S.C. Roy[1], S. Lakritz[2], A. Schreiber[2], E. Molina[3], C. Bradley[4], L. Kondapalli[5], J.R. Diamond[6]

[1]Internal Medicine, University of Colorado Denver - Anschutz Medical Campus, Aurora, CO, USA; [2]Division of Medical Oncology, University of Colorado Denver - Anschutz Medical Campus, Aurora, CO, USA; [3]Population Health Shared Resource, UCHealth Cancer Care - Anschutz Medical Campus - University of Colorado Cancer Center, Aurora, CO, USA; [4]Department of Health Systems, Management, and Policy, University of Colorado Denver - Anschutz Medical Campus, Aurora, CO, USA; [5]Department of Cardiology, University of Colorado Denver - Anschutz Medical Campus, Aurora, CO, USA; [6]Medical Oncology Dept., UCHealth Cancer Care - Anschutz Medical Campus - University of Colorado Cancer Center, Aurora, CO, USA

Background: Triple-negative breast cancer (TNBC) is regarded as relatively more aggressive compared to other subtypes of breast cancer with characteristic metastatic patterns and poor prognosis. The standard of care for TNBC has historically been anthracycline and taxane-based chemotherapy (ATAX). Despite its effectiveness, anthracyclines carry a small but important risk of cardiotoxicity, which is a concern in older women. The purpose of this study was to evaluate major adverse cardiovascular events in older women with TNBC.

Methods: Using the Surveillance, Epidemiology, and End Results (SEER)-Medicare database, we identified 2,215 women with TNBC diagnosed at age $>$ 65 between 2010-2015. We compared patient and clinical characteristics according to adjuvant chemotherapy regimen (ATAX versus TAX). Logistic regression was performed to estimate the odds ratios (OR) and 95% confidence intervals (CIs), Kaplan Meier survival curves were generated to estimate three-year overall survival (OS) and cancer specific survival (CSS). Cox proportional hazards models were used to analyze OS and CSS while controlling for patient and tumor characteristics. MACE was defined as acute myocardial infarction, heart failure, potentially fatal arrhythmia, and cerebral vascular incidence. Few patients experienced a cardiac death and therefore this was excluded in the analysis.

Results: Of the 2,215 patients in our cohort, a majority of patients 1334 (60.26%) received TAX compared to ATAX 881 (39.78%). Patients who received ATAX were not more likely to experience cardiac outcomes such as acute myocardial infarction (OR 1.10, 95% CI [0.66, 1.82], p=0.724), heart failure (OR 0.73, 95% CI [0.52, 1.05], p=0.09), CVA (OR 0.76, 95% CI [0.45, 1.29], p=0.31), or potentially fatal arrhythmia (OR 0.66, 95% CI [0.29, 1.50], p=0.32) when controlling for traditional risk factors. Among patients who experienced a cardiac outcome, there was no difference in OS or CSS in patients who received TAX vs ATAX (HR 1.18, 95% CI [0.46-2.98], p=0.74 and HR 1.39, 95% CI [0.38 $-$ 5.11] p=0.62).

Conclusions: Among older women with TNBC, receipt of adjuvant chemotherapy with ATAX was not associated with increased risk of adverse cardiac outcomes. For those who experienced a cardiac event, there was no difference in survival amongst those who received TAX compared to ATAX.

359P Unveiling the factors influencing exercise engagement in breast cancer patients: Insights from the early recovery phase

S. Yeon[1], J. Min[2], J.Y. Kim[3], S.I. Kim[3], T.H. Lee[4], D-H. Park[1], R. Park[5], J.W. Kang[4], Y.J. Lee[6], C. Oh[4], E. Kim[1], S. Jun[4], K. Chiho[6], J. Jeon[1]

[1]Sport Industry Studies, Yonsei University, Seoul, Republic of Korea; [2]Convergence Medicine, Yonsei University College of Medicine - Wonju Severance Christian Hospital, Wonju, Republic of Korea; [3]Division of Breast Surgery, Department of Surgery, Yonsei University College of Medicine, Seoul, Republic of Korea; [4]Sports Medicine, Yonsei University, Seoul, Republic of Korea; [5]Sports Industry, Yonsei University, Seoul, Republic of Korea; [6]Department of Sports Industry, Yonsei University, Seoul, Republic of Korea

Background: Although engaging in exercise after breast cancer surgery (BCS) has been shown to facilitate faster recovery, factors influencing exercise participation during the early recovery phase remain unclear in breast cancer patients. Therefore, this study aimed to explore the perceptions, attitudes, and barriers to exercise in breast cancer patients immediately after surgery and up to 4 weeks post-surgery.

Methods: A descriptive qualitative research method was employed to investigate this topic. A purposive sample of 33 breast cancer patients was selected, and each participant was interviewed three times over a one-month period after surgery.

Results: We found physical constraints and psychological resistance were identified as barriers to exercise. Postoperative physical symptoms (pain, range of motion, lack of fitness, and seroma) and surgical drains were identified as physical constraints. Participants also faced psychological resistance such as concerns about side effects, lack of willpower, and fear of pain. Furthermore, a lack of trustworthy information regarding the timing of exercise initiation and proper types of exercise after surgery was identified as a psychological resistance.

Conclusions: The identified barriers, both physical and psychological, should be taken into consideration when developing strategies to motivate and support patients in engaging in exercise. The identified barriers, both physical and psychological, should be taken into consideration when developing strategies to motivate and support patients in engaging in exercise.

Clinical trial identification: This study involves human participants and was approved by the Institutional Review Board of Severance Hospital (IRB No. 4-2018-1094).

360P Neoadjuvant inetetamab combined with pertuzumab, paclitaxel and carboplatin for locally advanced HER2-positive breast cancer: Primary analysis of a phase II study

Y. Chai[1], M. Jiang[1], J. Liu[1], M. He[1], X. Wang[2], Y. Wang[2], X. Yang[2], J. Wang[2], B. Xu[3], Q. Li[4]

[1]Medical Oncology Dept., Chinese Academy of Medical Sciences and Peking Union Medical College - National Cancer Center, Cancer Hospital, Beijing, China; [2]Surgical Oncology, Chinese Academy of Medical Sciences and Peking Union Medical College - National Cancer Center, Cancer Hospital, Beijing, China; [3]Medical Oncology, Chinese Academy of Medical Sciences and Peking Union Medical College - National Cancer Center, Cancer Hospital, Beijing, China; [4]Oncology, Chinese Academy of Medical Sciences and Peking Union Medical College - National Cancer Center, Cancer Hospital, Beijing, China

Background: Inetetamab is a neotype HER2-targeted monoclonal antibody with amino acids modified Fc segment which optimizes the antibody-dependent cellular cytotoxicity effect. However, robust evidence evaluating the combination of inetetamab combined with pertuzumab, paclitaxel and carboplatin (TCbIP) for neoadjuvant therapy is still lacking. This study aimed to evaluate the efficacy and safety of TCbIP as a neoadjuvant therapy for patients with locally advanced (LA) HER2-positive breast cancer.

Methods: This phase II trial included female patients with histologically confirmed stage IIA to IIIC HER2-positive primary invasive breast cancer. Eligible patients received TCbIP treatment every three weeks for a maximum of six cycles followed by surgery. The primary endpoint was pathologic complete response (pCR, ypT0/is ypN0) rate. Key secondary endpoints included near pCR (npCR, residual breast disease $<$1cm) rate, objective response rate (ORR) and safety.

Results: From November 2021 to May 2023, 28 patients were enrolled in the trial. One patient received one cycle of the study treatment and was lost to follow-up without surgery, and four patients received one cycle of the study treatment and were still in treatment, leaving 23 patients in the ITT population. Among these 23 patients (82.6% in stage III), 16 patients completed the study treatment and surgery (PP population) and six patients were still undergoing neoadjuvant treatment. The ORR was 91.3% (21/23) in the ITT population and 93.8% (15/16) in the PP population. Among the 16 patients in the PP population, 10 patients (62.5%) achieved pCR. A total of 14 patients (87.5%) achieved npCR. For patients with hormone receptor (HR) negative and positive tumors, the pCR rates were 88.9% (8/9) and 28.6% (2/7), respectively. The most common grade 3 adverse event was neutropenia (25.0%). No significant reduction in the left ventricular ejection fraction was observed in any patient.

Conclusions: Neoadjuvant therapy with TCbIP has shown promising efficacy and manageable toxicity in patients with HER2-positive LA breast cancer.

Table: 359P Themes, codes, and categories from the interviews

Categories	%(n)	Codes	%(n)	Theme	%(n)
Physical constraints	100% (33)	Postoperative physical symptoms	100% (33)	Pain at the surgery site	87.9% (29)
				Limited range of motion	66.6% (22)
				Lack of fitness	33.3% (11)
				Seroma	12.2% (4)
		Operation derived condition	45.4% (15)	Drain	45.5% (15)
Psychological resistance	48.5% (16)	Perception and attitude	54.5% (18)	Concerns about side effects	42.4% (13)
				Lack of willpower	15.2% (5)
				Fear of pain	15.2% (5)
		Concerns due to lack of trustworthy exercise information	54.5% (18)	Concerns regarding the exercise timing being inappropriate	42.4% (14)
				Discouragement from others	18.2% (6)

361P A phase II study of fulvestrant combined with chemotherapy in the neoadjuvant treatment of HR+/HER2- locally advanced breast cancer

J. Wu, Q. Shao, X. Pan, W. Zhou, Y. Wang, N. Zhang, X. Zhou, W. Li, F. Xu, X. Zeng

Department of Breast Center, Chongqing University Cancer Hospital, Chongqing, China

Background: HR+/HER2- breast cancer are less sensitive to neoadjuvant chemotherapy (NCT), with a low objective response rate (ORR) of approximately 65% and a much lower pathological complete response (pCR) rate ranging from 5% to 10%. This phase 2 study aims to evaluate the efficacy and safety of adding fulvestrant to NCT in patients (pts) with HR+/HER2- breast cancer, and to investigate the predictive value of ^{18}F-FES PET/CT for effectiveness.

Methods: In this single-arm phase 2 study, eligible pts were female with histologically confirmed HR+/HER2- locally advanced breast cancer (IIB-IIIC). Pts received fulvestrant (500 mg, on days 0, 14, 28, then every 28 days thereafter, every 4 weeks for six cycles) plus AC-T regimen, followed by surgery. Premenopausal women received a concomitant GnRH analogue. Pts underwent ^{18}F-FES PET/CT examination at baseline. The primary endpoint was ORR. Secondary endpoints include tpCR (ypT0/is ypN0), overall survival (OS), and safety.

Results: From Dec 2020 to Sep 2022, 36 pts were enrolled. The median age was 53 years (range, 35-67), 78% were ECOG PS 1, 69% were postmenopausal, 92% were nodal involved, and 83% had stage III. After neoadjuvant therapy, the ORR and DCR were 86.1% (95% CI, 70.5%-95.3%) and 100% (95% CI, 90.3%-100.0%), respectively. All pts completed surgery, with a tpCR rate 8.3% (3/36; 95% CI, 1.8%-22.5%). 29 (80.6%; 95% CI, 64.0%-91.8%) pts had pathological tumor response [Miller-Payne (MP) grade $\geq$3]. Grade $\geq$3 treatment-emergent adverse events (TEAEs) occurred in 22% (8/36). The most common TEAEs were neutropenia (13.9%) and leukopenia (8.3%). Among the 36 pts, 24 completed ^{18}F-FES PET/CT scan at baseline. The average SUV_{max} in primary breast lesions was 4.17 (range 1.00-12.80). The SUV_{max} was significantly associated with MP grade (R=0.82, p=8.4e-07). The SUV_{max} of the primary tumor from pts with MP grade 2/3 was significantly lower than those in pts with MP grade 4/5 (p=2.33e-05).

Conclusions: The addition of fulvestrant to NCT showed manageable toxicity and promising antitumor activity for pts with HR+/HER2- locally advanced breast cancer. The SUV_{max} of ^{18}F-FES PET/CT was positively correlated with patient efficacy.

362P CYBERNEO trial: Update of results at 14 years of follow-up

S. Ben Dhia[1], R. Schiappa[2], J. Gal[3], J-M. Ferrero[4], P. Bahadoran[5], C. Chapellier[6], P-Y. Bondiau[1]

[1]Radiation Oncology, Centre Antoine Lacassagne, Nice, France; [2]Epidemiology, Biostatistics and Data, Centre Antoine Lacassagne, Nice, France; [3]Biostatistics Unit, Centre Antoine Lacassagne, Nice, France; [4]Medical Oncology, Centre Antoine Lacassagne, Nice, France; [5]Dermatology, CHU Nice - Hopital Pasteur, Nice, France; [6]Radiology, Centre Antoine Lacassagne, Nice, France

Background: The purpose of the phase I "CYBERNEO" trial was to define the efficacy of the CyberKnife®(CK) for locally advanced (stage III) breast tumors combined to a neo-adjuvant treatment with chemotherapy for patients for whom a conservative surgery could not be considered at the onset. Neoadjuvant chemotherapy (NAC) consisted of 6 cycles: 3 cycles of docetaxel and 3 cycles of 5-fluorouracil-epirubicin-cyclophosphamide (FEC). CK was performed during the second cycle of chemotherapy. Breast surgery was performed six to eight weeks later and conventional breast irradiation without boost, afterwards. The main objective was to define the maximum tolerated dose of hypofractionated radiotherapy concurrent with NAC.We present an updated survival data for patients included in this trial and we evaluate the late toxicities of this combination.

Methods: We updated the survival data of 25 patients treated for a stage III breast cancer between 2007 and 2009 at the Antoine Lacassagne Center in Nice and included in the CYBERNEO trial by recording late toxicities and esthetic results.

Results: With a median follow-up of 12 years, 95% CI [10-14], 19 patients (76%) were in remission, 1 patient had a controlled axillary lymph node relapse (4%) band 5 patients (20%) died due to metastatic progression within a median of 5 years after treatment (min: 1, max: 9). Nine patients (36%) had a complete histological response (pCR). The highest percentage of pCR was in the group of patients treated in the 4th stage (28.5 Gy in 4 fractions). Overall survival at 14 years was 71%, 95% CI [53%-94%]. Two patients developed chronic radiation toxicity during follow-up with a fibrosis (8%), of which one was in the 4th stage and one in the 5th stage (31.5 Gy). Three patients (12%) had a change of prosthesis after treatment which for one patient was 24 months after the end of support.

Conclusions: The updated results of the CYBERNEO trial with 14 years of follow-up confirm the satisfactory results in terms of local control with an excellent long-term safety profile.

Pereira Lima-Jr[2], D.V. Tenazoa Wong[2]

[1]Oncologia Clinica, HHJ - Hospital Haroldo Juacaba - Instituto Do Cancer do Ceara (ICC), Fortaleza, Brazil; [2]Department of Physiology and Pharmacology, Center for Drug Research and Development (NPDM), Federal University of Ceará, Fortaleza, Brazil; [4]Pesquisa Clinica, HHJ - Hospital Haroldo Juacaba - Instituto Do Cancer do Ceara (ICC), Fortaleza, Brazil; [5]Biologia Molecular, HHJ - Hospital Haroldo Juacaba - Instituto Do Cancer do Ceara (ICC), Fortaleza, Brazil; [6]Patologia, HHJ - Hospital Haroldo Juacaba - Instituto Do Cancer do Ceara (ICC), Fortaleza, Brazil

Background: Metabolic syndrome (MetS) has been identified as a factor related to a worse prognosis in breast cancer. However, the association between adipocytokines and IL-18bp serum levels, MetS, and breast cancer is not demonstrated.

Methods: We prospectively evaluated 151 women with breast cancer eligible for neoadjuvant chemotherapy (NAC). We studied adipocytokines (resistin and leptin) and IL-18bp serum levels and their association with MetS, patients' clinical and laboratory data, and clinical and pathological responses after NAC. Data analysis used the Fisher/Chi-Square and Mann-Whitney Tests (SPSS v20.0, $p<0.05$). Study approval number 5.332.237.

Results: 134 subjects (95.7%) achieved clinical objective response (complete + partial). Among the 151 patients evaluated, 82 (54.3%) had MetS, with HDL-C <50 mg/dl being the most frequent criterion (n=72, 87,8%). Age>45 years, postmenopausal status, obesity, NAC dose reduction, and delay in performing surgery were more associated with the MetS group ($p<0.01$). MetS breast cancer patients with high resistin levels presented with positive lymph nodes (97%), >=88 cm waist circumference (94%), and invasive breast carcinoma of no special type (100%) versus the group with low levels of resistin ($p<0.05$). Additionally, high IL-18bp levels were associated with non-luminal A breast cancers (94%) versus 73% of patients with IL-18bp low levels ($p<0.05$). Leptin was elevated in patients with hyperglycemia and hypertriglyceridemia, while IL18-bp levels increased in subjects with HDL-C < 50md/dl ($p<0.05$). The higher frequency of objective response was associated with no need for dose reduction and low serum IL-18bp concentration ($p<0.05$).

Conclusions: High adipocytokines and IL-18bp serum levels are associated with lower objective response rates after neoadjuvant treatment in breast cancer patients with metabolic syndrome.

365P Effectiveness and safety of human type 5 recombinant adenovirus (H101) in malignant tumor with malignant pleural effusion and ascites: A multicenter, observational, real-world study

B. Wang[1], C. Zhong[1], Z. Liao[2], H. Wang[3], X. Cai[4], Y. Zhang[2], J. Wang[5], T. Wang[6], H. Yao[7]

[1]Department of Oncology, No. 960 Hospital of PLA, Jinan, China; [2]Department of Medical Oncology, Shaanxi Provincial Cancer Hospital, Xi'an, China; [3]Department of Oncology, The Second Hospital of Tianjin Medical University, Tianjin, China; [4]Department of General Internal Medicine, Sun Yat-Sen University Cancer Center, Guangzhou, China; [5]Department of Oncology, The First Affiliated Hospital of Shandong First Medical University/ Shandong Provincial Qianfoshan Hospital, Jinan, China; [6]Hepatobiliary Pancreatic Center, Beijing Tsinghua Chang Gung Hospital, Beijing, China; [7]Department of Medical Affairs, Guangdong Techpool Bio-pharma Co., Ltd, Guangzhou, China

Background: Human type 5 recombinant adenovirus (H101) has shown promising efficacy in malignant serous effusion (MSE), but evidence is limited. The purpose of this study was to analyze the effectiveness and safety of H101 in Chinese patients

with malignant pleural effusion and ascites (MPE/MA) in the real world, so as to guide clinical use of H101.

Methods: This multicenter, observational, real-world study recruited patients with MPE or MA caused by malignant tumor receiving H101-containing treatment between January 2020 and June 2022 across 5 hospitals. Effectiveness was evaluated by overall remission rate (ORR), and safety was evaluated based on adverse events (AEs). Subgroup analysis was performed on patients grouped according to tumor type, the volume of MPE and MA, and dosage of H101.

Results: A total of 653 eligible patients were enrolled in this study, among whom 467 received H101 monotherapy and 176 received H101 combined with chemotherapy. In H101 monotherapy group, the decrease of MPE or MA was achieved in 282 (60.4 %) patients, 176 (37.7%) patients showed no change in volume of MPE or MA, and 9 (1.9%) patients showed an increase, yielding an ORR of 60.4% (282/467). The ORR for the combination therapy group was 60.2% (106/176), with 106 cases of PR, 69 cases of NC and 1 case of PD. Subgroup analyses based on tumor type, volume of MPE and MA, and dosage of H101 all showed high ORR, approximately 60%. The main AEs associated with H101-containing regimens were fever, nausea and vomiting. No serious AEs occurred in both groups.

Conclusions: Encouraging clinical benefits and manageable toxicity of H101 against MPE and MA were observed in the real-world clinical setting, indicating that the H101-containing regimen is reliable, safe, and feasible, providing a novel and effective option for the treatment of this disease.

366P Artificial intelligence (AI)-powered assessment of complete and intense human epidermal growth factor receptor 2 (HER2)-positive tumor cell proportion in breast cancer: Predicting fluorescence in situ hybridization (FISH) positivity and response to HER2-targeted therapy

M. Jung[1], S-W. Kim[2], S.G. Song[3], S.K. Baek[4], S.I. Cho[5], S. Shin[5], S. Kim[5], H. Song[5], S. Park[5], S. Pereira[5], D. Yoo[5]

[1]Department of Pathology, Yonsei University College of Medicine, Seoul, Republic of Korea; [2]Department of Pathology, Kyung Hee University College of Medicine, Seoul, Republic of Korea; [3]Department of Pathology, Seoul National University College of Medicine, Seoul, Republic of Korea; [4]Department of Internal Medicine, Kyung Hee University College of Medicine, Seoul, Republic of Korea; [5]Oncology, Lunit Inc., Seoul, Republic of Korea

Background: The level of expression of HER2 is important in predicting response to HER2-targeted therapies. HER2 expression level is classified in groups (3+ positive, 2+ equivocal, and 1+ or 0 negative) or quantified as an H-score based on the proportion of tumor cell intensity (complete and intense [strong positive], weak to moderate complete [moderate positive], incomplete and faint/barely perceptible [weak positive]). If the case is classified as 2+ equivocal, an additional test such as Fluorescence In Situ Hybridization (FISH) test is performed to confirm the positivity. In this study, we aim to figure out that the complete and intense HER2-positive tumor cell proportion can predict both FISH positivity and response to HER2-targeted therapy, compared to the H-score.

Methods: Lunit SCOPE HER2, an AI-powered HER2 analyzer that identifies and quantifies HER2 IHC according to staining intensity of tumor cells, was used to evaluate the HER2 status of breast cancer cases (n=205) from Kyung Hee University Hospital. They consisted of 41 3+, 163 2+, and 1 1+, as interpreted by pathologists. Of these, 171 had FISH results, and 44 received HER2-targeted therapy as neoadjuvant (n=25) or as palliative (n=19). The proportion of strong positive tumor cells or the H-score by the AI-powered HER2 analyzer was assessed to predict clinical outcomes.

Results: Among all cases, FISH positivity was 20.5%, pathologic complete response (pCR) after neoadjuvant therapy was 40.0%, and complete/partial response during palliative therapy was 68.4%. The proportion of strong positive tumor cells was a better predictor of FISH positivity and response compared to H-score (Area under the curve: 0.784 vs. 0.688 for FISH, and 0.872 vs. 0.859 for response). Prediction of pCR was equivalent for both (0.773). The DeLong test showed a significant difference in the prediction of FISH positivity (p=0.023).

Conclusions: This study showed that AI analysis of breast cancer HER2 expression, specifically the proportion of strong positive tumor cells, can predict FISH and therapy response better than the H-score.

367P Sentinel lymph node biopsy (SLNB) in patients with locally advanced breast cancer (LABC): Descriptive, inferential and survival analysis

J.M. Espejo Niño

Medicina Nuclear, Hospital Universitario Cruces, Barakaldo, Spain

Background: The objective was to perform a descriptive, inferential and overall survival analysis of patients with LABC who underwent SLNB.

Methods: Retrospective study(January/12-December/22) in patients with LABC selected for SLNB with: initial clinical and radiological tumor and lymph node staging(TNM-AJCC-7&8-Edition), histological types, prognostic tumor markers, with evaluation of the response(radiological & pathological) of the tumor and lymph nodes after neoadjuvant chemotherapy(NACT). We performed a descriptive, inferential and survival analysis.

Results: 141patients with LABC met inclusion criteria: 128(91%)Infiltrating Ductal Carcinoma, 7(5%)Infiltrating Lobular Carcinoma, 2(1%) Infiltrating Ductal Carcinoma in-situ, and 1case(1% each) of: tubular, medullary, mucinous and colloid carcinoma. The TNM staging before NACT was: T1:14(9.9%)patients; T2:95(67.4%); T3:27(19.2%) and T4:5(3.5%). 89(63.1%)patients were cN(+) and 52(36.9%) were cN(0). Intrinsic subtypes were: Luminal-A 10(7.1%) patients, Luminal-B 26(18.4%); Luminal-B-Her2 34(22%); Her2 31(28.4%) and 40(24.1%)Triple negative. Histological grades (HG) were: grade I 5(3.5%)patients, grade II 53(37.6%), and grade III 83(58.9%). We obtained 46(32.6%)SLNB(+), 85(60.3%)SLNB(-) and in 10(7.1%)there was no migration (NM). We performed 93 lymphadenectomies(LDN): 44 SLNB(+); 39 SLNB(-) and 10-NM. We obtained 29LDN(+):19SLNB(+), 6NM and 4SLNB(-). We obtained 64LDN(-): 25SLNB(+), 4NM and 35SLNB(-). 8-patients died: 3LDN(+): 2SLNB(+) and 1NM; 4-LDN(-): 2SLNB(+) and 2SLNB(-); and 1 SLNB(-) without LDN. 46-patients(51.7%) went from cN(+) to pN0. In the inferential analysis we found a statistically significant correlation between the SLNB result and the intrinsic subtype ($p<0.001$), with Luminal-B-Her2 subtypes and triple negative patients as those with the most SLNB(-) results. Detection rate(DR) was 95.3%. False negative rate (FNR) was 8%, considering SLNB(+) as a true positive. The survival time for patients with SLNB(+) was 111 months, for SLNB(-) it was 127 months ($\pm$2.4) and for patients with NM it was 95 months.

Conclusions: Our DR was 95%, FNR was 8%, mortality was 5%, and overall survival with SLNB(-) was 127 months.

368P Impact of PET-CT-determined sarcopenia on survival and pathological complete response in breast cancer patients with neoadjuvant chemotherapy

G. Tahtaci[1], B. Yildiz[2], U. Aydos[3]

[1]Medical Oncology Department, Gazi University - Faculty of Medicine, Ankara, Turkey; [2]Internal Medicine, Gazi University - Faculty of Medicine, Ankara, Turkey; [3]Nuclear Medicine, Gazi University - Faculty of Medicine, Ankara, Turkey

Background: Neoadjuvant chemotherapy (NACT) is a frequently used treatment method in breast cancer. Achieving pathological complete response (pCR) is one of the surrogate marker for long-term survival. Sarcopenia is considered a poor prognostic factor in breast cancer. The association between pCR and sarcopenia has not been fully elucidated in neoadjuvant setting in breast cancer. It was aimed to evaluate the effect of sarcopenia on pCR and overall survival (OS) in breast cancer patients with NACT.

Methods: Patients with NACT between 2014 and 2021 were included in the study. SMI (skeletal muscle index), VFA (visceral fat tissue area), sarcopenic obesity (VFA/SMI) were determined at the level of the third lumbar vertebra on PET-CT images before and after NACT. Patients were categorized according to pCR. The relationship between pCR and clinicopathological features and PET-CT parameters were evaluated by logistic regression analysis. Kaplan-Meier method was used for survival analysis.

Results: The medical records of 56 patients who received NACT were reviewed and twenty-three patients who met the inclusion criteria were included in the study. They were classified as sarcopenic according to the previously determined cutoff value for sarcopenia (SMI: 38.9 cm2/m2). Sarcopenia was present in 50% of patients. Post-NACT sarcopeni was found in 20% of the patients. The rate of post -NACT sarcopenic obesity was %27.3. pCR was achieved in 28.3% of patients. Sarcopenia was not associated with clinicopathologic features, pCR and OS. There was no association between clinicopathologic factors and pCR. Recurrence, post treatment high VFA, and post treatment sarcopenic obesity were significantly associated with survival. In multivariate analysis post treatment high VFA level was significantly associated with increased mortality (HR: 3.278 CI: 95% (1.143-9.401), p= 0.027).

Conclusions: Dynamic follow-up for sarcopenic obesity and visceral adipose tissue increase may improve the survival in breast cancer with NACT. Further prospective studies will be elucidated the relationship between breast cancer and sarcopenia.

369P The impact of germline BRCA mutations in locally advanced, triple-negative breast cancer (TNBC) treated with platinum-based neoadjuvant chemotherapy

H. Goldvaser[1], I. Kuchuk[2], R. Yerushalmi[3], A. Goldshtein[4], O. Rotem[3], A. Lotan[5], A.A. Gabizon[1], R. Mutai[3]

[1]Oncology Department, Shaare Zedek Medical Center, Jerusalem, Israel; [2]Oncology, Meir Medical Center, Kfar Saba, Israel; [3]Oncology Dept., Rabin Medical Center Davidoff Cancer Centre, Beilinson Campus, Petah Tikva, Israel; [4]Faculty of Medicine, The Hebrew University of Jerusalem, Jerusalem, Israel; [5]Plastic Surgery, Shaare Zedek Medical Center, Jerusalem, Israel

Background: Whether germline BRCA (gBRCA) mutation affects prognosis and whether it has implications on treatment decision in the neoadjuvant setting is unclear.

Methods: Two centers retrospective cohort study comprising all women with early-stage TNBC who completed genetic testing and were treated with neoadjuvant chemotherapy with dose-dense chemotherapy containing carboplatin, between 10.2014 and 3.2020. Clinico-pathological features and data on dose reduction and delays were collected. Data on outcomes including pathological complete response (pCR), overall-survival (OS) and disease-free survival (DFS) were also calculated. Differences of these variables by gBRCA status were investigated.

Results: Sixty-four 64 women were included in the final analysis, of which 31 had pathogenic gBRCA mutation and 33 were gBRCA wild-type. Clinico-pathological characteristics and dose density and intensity were similar between both groups. Among gBRCA mutated patients, 23/31 (74%) achieved pCR, compared to 17/33 (51%) in the non-mutated, p=0.035. At a median follow-up of 30 months, gBRCA mutated women had significantly favorable OS (HR=8.64, 95% CI 1.08-69.21, p=0.042) and a trend for a favorable DFS (HR=7.4, 95% CI 0.91-60.27; p=0.062). The favorable OS for gBRCA mutated women remained significant in multivariate analysis (p=0.029) and was noted regardless to pathological response (p=0.01).

Conclusions: Compared to non-mutated, gBRCA mutated women with locally advanced TNBC treated with neoadjuvant chemotherapy containing carboplatin had a higher pCR rate and better outcome. Whether gBRCA mutation has a role in deescalating treatment in this population, should be further investigated.

370P LYMPHA surgery to reduce lymphedema following axillary node clearance: A new study at a London plastics centre

D. Hobday, L. Ioannidi, M. Kanapathy, S. Hamilton, A. Mosahebi, N. Naderi

Plastic Surgery Dept., Royal Free London NHS Foundation Trust, London, UK

Background: LYMPHA is a relatively new surgical technique that dramatically reduces the incidence of lymphedema following axillary node clearance in breast cancer patients. The technique identifies dominant lymph vessels draining the arm with the aid of dye and, following clearance of the axillary nodes, anastomosing lymphatic vessels to a branch of the axillary vein to enable free drainage of lymphatic fluid. Not currently widely available to breast cancer patients in the UK, this simple surgical procedure carried out at the time of axillary node clearance has been shown to reduce the incidence of lymphedema from 25% to 4%. We report on the establishment of a LYMPHA service at a major London Plastics Centre and first 2 years of its outcomes.

Methods: Suitable patients were referred to plastics by the breast surgery team and seen preoperatively to discuss LYMPHA. Upon agreeing to the procedure, pre-operative measurements of arm volume and arm bioimpedance were completed as well as screening questionnaires on symptoms of lymphedema. Subsequent to the procedure the two measurements and the questionnaires were repeated at 1, 3, 6, 12 and 24 month intervals.

Results: Of 16 patients that have undergone the LYMPHA procedure 0 have experienced signs or symptoms of lymphedema to date. One patient suffered temporary swelling of the arm 1-month post-op which subsequently resolved. No patients have suffered any complications relating to LYMPHA. 1 patient withdrew due to metastatic disease recurrence. The patients enrolled have been followed up for between 3-23 months with a current mean follow up time of 12.61 months.

Conclusions: Our findings thus far support current evidence that LYMPHA surgery is both safe and effective in reducing the incidence of lymphedema. This pilot study is currently being developed into an RCT which will add to the evidence base of this relatively niche area of plastic surgery.

371P Adherence to standardized and structured electronic symptom reporting (ePRO) via mobile app in HER2-positive breast cancer treated with HER2 biosimilar trastuzumab

A. Trojan[1], M.K. Kiessling[1], M.S. Aapro[2], A. Eniu[3]

[1]Breast Oncology, Brustzentrum Zürichsee, Horgen, Switzerland; [2]Cancer Center, Clinique de Genolier, Genolier, Switzerland; [3]Department Service Interdisciplinaire de Cancerologie, HRC - Hopital Riviera-Chablais - Site de Rennaz, Rennaz, Switzerland

Background: The treatment of HER2+ breast cancer (BC) patients with Herceptin® was the standard for more than a decade. Development of trastuzumab biosimilars has prompted the demonstration of clinical equivalency to the reference biosimilar and safety. So far, adherence to dynamic standardized and structured real-world assessment of wellbeing and symptoms, via ePROs in patients treated with the HER2 biosimilar Ogivri® has not been reported. We assess the adherence of ePROs using the medidux app (previously: consilium care) and perform a comparative analysis of ePROs obtained from HER2+ BC patients in two studies where Herceptin® was administered (NCT02004496, NCT03578731).

Methods: In this 6 week observational study, patients were treated with trastuzumab (Ogivri®) +/- Pertuzumab, +/- Chemotherapy +/- anti-hormones. Patients used the medidux™ app to record well-being, symptoms (according to CTCAE), EQ-5D-5L, trail maker test and vital parameters and intake of medication in a standardized manner. Patients also received a pop-up reminder in case of missing data entries after 3 days. Previously obtained ePROs from 38 patients treated with Herceptin® similar therapeutic settings were used for comparative analysis.

Results: From 53 female patients included in this trial so far, there was only one drop out. About 60% of patients continued to use the app after the observational 6 weeks period. Close to 10`000 symptom entries were recorded with an average of $>$ 2 symptoms/day. Of the more than 90 individual symptoms, the most common reported were fatigue, taste disorder, diarrhea, nausea, dry mucosa, joint discomfort, tingling, headache and appetite loss. Results available from $>$70% of all data sets suggests that patients symptoms were reported in a similar incidence and score as from the comparative analysis of Herceptin®. Adherence to the app use and electronic recording of symptoms was continued in average for another 3 months after the end of observation without clear correlation to age or symptom severity.

Conclusions: The majority of patients continued the ePRO app use after end of study participation. Only 1 drop out (from 53 pats) was noted in this propsective observational study.

Clinical trial identification: SNCTP000004711.

D. Hinduja National Hospital and Medical Research Centre, Mumbai, Maharashtra, India; [13]Medical Oncology Department, Sir Ganga Ram Hospital, New Delhi, India; [14]Medical Affairs, AstraZeneca India, Bangalore, India; [15]Medical Affairs Department, AstraZeneca India, Bangalore, India; [16]Medical Oncology Department, Tata Memorial Centre - Homi Bhabha National Institute, Mumbai, India

Background: Germline mutations in breast cancer susceptibility genes 1 or 2 (gBRCA1/2mut) increase predisposition to breast cancer. Previous Indian breast cancer studies suggest gBRCAmut prevalence of 18.6-36.2%, but data are either single-centre or in patients selected by family history, histopathological subtype or age.

Methods: This was a prospective,cross-sectional,multicentre, study conducted in 14 institutions across India among patients with newly diagnosed stage I to IV breast cancer who had not yet completed 1st- line treatment and were not enriched for gBRCAmut. Based on previous Indian data, a sample size of 313 was estimated to be adequate. Germline BRCA 1/2 testing was performed in a single central laboratory in blood sample-derived DNA by next-generation sequencing (NGS), with reflex multiplex ligation probe amplification (MLPA) in patients who were -ve on NGS or were detected with Variant of Unknown Significance (VUS).

Results: Between June 2022 and Feb 2023, 304 patients were recruited in the study with a median age of 46 (22-83) years.The prevalence of pathogenic or likely pathogenic (P/LP) gBRCA 1/2 mutation was 27 (8.8%, 95%CI 6.18-12.61%) in the full study population. P/LP gBRCAmut prevalence in patients with ER/PR+/HER2 negative, HER2 positive and TNBC were 10/123 (8.13%, 95% CI 4.48-14.32), 2/80 (2.5%, 95% CI 0.69-8.66), and 15/102 (14.8%, 95% CI 9.12-22.85) respectively; in patients $\leq$ 50 years and $>$50 years were 20/194 (10.31%, 95% CI 6.77-15.39) and 7/110 (6.37%, 95% CI 3.12-12.56) respectively; in patients with and without relevant family history were 10/35 (28.57%, 95% CI 16.33-45.05) and 17/269 (6.32%, 95% CI 2.57-7.63), respectively; and in patients with stage I-III and stage IV disease were 22/235 (9.36%, 95% CI 6.26-13.77) and 5/68 (7.35%, 95% CI 3.18-16.09), respectively. The majority of P/LP gBRCAmut were in BRCA1 (16/304, 5.26%, 95%CI 3.04-8.4%), of whom 12/16 (75.0%) patients had TNBC, while 11/304 (3.62%) patients had gBRCA2mut of whom 7/11 (63.63%) had ER/PR+/HER2 -negative disease and 4/11 (36.37%) were TNBC.

Conclusions: Less than 10% of unselected newly diagnosed Indian breast cancer patients have P/LP gBRCA mutations. Younger age, TNBC subtype and positive family history enrich for such mutations.

373P Impact of comorbidities on real-world (rw) clinical outcomes of patients (pts) with hormone receptor-positive/human epidermal growth factor 2-negative (HR+/HER2-) advanced breast cancer (ABC) treated with palbociclib and enrolled in POLARIS

D. Tripathy[1], J.L. Blum[2], M.S. Karuturi[1], S. McCune[3], S. Kurian[4], M.M. Moezi[5], D.M. Anderson[6], Y. Wang[7], M.Z. Montelongo[8], Z. Zhang[9], E. Gauthier[10], G. Rocque[11]

[1]Department of Breast Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX, USA; [2]Department of Oncology, Baylor-Sammons Cancer Center, Texas Oncology, US Oncology, Dallas, TX, USA; [3]William S. Gibbons Cancer Research Institute, Northwest Georgia Oncology Centers Wellstar, Marietta, GA, USA; [4]Hematology/Oncology, West Virginia University Cancer Institute, Morgantown, VA, USA; [5]Medical Oncology, Cancer Specialists of North Florida, Fleming Island, FL, USA; [6]Oncology & Hematology, Health Partners Institute, Saint Paul, MN, USA; [7]Oncology Medical Group, Pfizer Inc, New York, NY, USA; [8]Biostatistics and Medical Writing, ICON Commercialisation and Outcomes, ICON plc, Blue Bell, PA, USA; [9]Oncology Clinical Statistics, Pfizer Inc, San Diego, CA, USA; [10]Global Medical Affairs, Pfizer Inc, San Francisco, CA, USA; [11]Division of Hematology/Oncology, Department of Medicine, University of Alabama at Birmingham, Birmingham, AL, USA

Background: Palbociclib is used to treat HR+/HER2− ABC with an aromatase inhibitor as first line of therapy (1LOT) or with fulvestrant in pts whose disease progressed on endocrine therapy. Limited information exists on comorbidities' impact on rw clinical outcomes in these pts.

Methods: POLARIS is a prospective observational study of pts with HR+/HER2− ABC receiving palbociclib in clinical practice in the US and Canada. Rw progression-free survival (rwPFS) and overall survival (OS) for pts with clinically relevant comorbidities and by Charlson Comorbidity Index (CCI) score were descriptively summarized.

Results: 1250 pts were enrolled (median age 64 y; 99% female; 27% de novo metastatic diagnosis; 32% bone-only; 40% visceral metastases). Of these, 908 (73%) received palbociclib as 1LOT and 342 (27%) as $\geq$ 2LOT. Pts had a median (range) of 2 (0−9) comorbidities; 5% had 0, 56% had 1−2, 32% had 3−4, and 7% had >4. Median OS (months; 95% CI) for pts with CCI scores of 0, 1−2, and 3+ were 48.8 (37.3−NE), NR (43.0−NE), and 34.3 (29.1−44.1) in 1LOT and 39.5 (30.6−50.5), 35.2 (26.5−41.6), and 31.6 (20.9−45.2) in $\geq$ 2LOT, respectively. Median rwPFS for CCI scores and certain comorbidities are shown (Table).

Conclusions: Pts with HR+/HER2− ABC receiving palbociclib and CCI scores 0 and 1−2 had similar rwPFS and OS regardless of LOT. Pts with CCI score 3+ had shorter rwPFS and OS in the 1LOT, and similar rwPFS but shorter OS in the $\geq$ 2LOT than pts with score 0−2. Pts with cardiac disorders in the 1LOT and blood and lymphatic disorders in the $\geq$ 2LOT had shorter rwPFS, while other subgroups achieved generally comparable clinical outcomes. Understanding potential impact of comorbidities on clinical outcome in the rw is important for treatment decision-making. Larger rw studies may be needed to further assess the true impact of these comorbidities.

Table: 373P rwPFS in pts with HR+/HER2− ABC by comorbidities and LOT

Subgroups	1LOT (n=908)		≥ 2LOT (n=342)	
	n (%)	Median rwPFS, months (95% CI)	n (%)	Median rwPFS, months (95% CI)
CCI score				
0	276 (30)	20.3 (17.1−24.8)	101 (30)	13.9 (7.4−19.7)
1−2	493 (54)	24.7 (20.2−29.5)	189 (55)	13.1 (9.0−17.5)
3+	139 (15)	16.8 (12.4−21.9)	52 (15)	13.2 (8.0−24.0)
Comorbidities				
Vascular	496 (55)	23.7 (19.5−28.1)	183 (54)	13.1 (8.7−17.2)
Psychiatric	240 (26)	19.6 (15.2−27.2)	92 (27)	13.2 (9.4−24.0)
Metabolic and nutritional	173 (19)	19.6 (14.8−24.0)	55 (16)	14.9 (6.7−23.7)
Blood and lymphatic system	147 (16)	16.8 (12.2−20.8)	83 (24)	8.6 (4.8−11.7)
Cardiac	32 (4)	12.5 (8.5−34.1)	12 (4)	11.6 (2.9−42.8)

Clinical trial identification: NCT03280303.

Background: Patient-reported outcomes (PROs) are a valuable component to understand treatment tolerability and toxicity. We have implemented an electronic system for monitoring PROs and quality of life (QOL) for patients enrolled in the I-SPY2 trial, a phase II trial evaluating the effect of novel neoadjuvant therapies for breast cancer. We associated patient demographic factors with symptoms, decline in physical function (PF), and tolerability to treatment.

Methods: Study population for this analysis includes 259 enrolled patients receiving combinations of experimental immunotherapy and chemotherapy. Patients completed PRO-CTCAE/PROMIS/FACT surveys reflecting symptom severity, symptom frequency, tolerability of drug, and physical function at baseline through follow up (12 months). CTCAE 5.0 was collected weekly at these timepoints to assess adverse events (AE). Odds ratio and regularized multi-variate regression was used to evaluate early symptoms predictive of a clinically significant decline in PF from baseline to post-treatment follow-up.

Results: Of 259 patients, 160 (58%) were White, 13 (5%) were Asian, 26 (10%) were African American (AA), and 25 (9.3%) were Hispanic. 25% of all patients had a clinically significant decline in PF between baseline and pre-surgery/follow-up. Symptom predictors of decline included high frequency of diarrhea and severity of joint pain. African American (AA) patients had higher severity of joint pain than White patients (OR = 14.9, $P < 0.05$). Within the first 12 weeks of treatment, AA patients and non-white (NW) patients were more likely to report severe vomiting than White patients (OR =13.22 and 12.72, $P < 0.05$ and $P < 0.03$ respectively). Overall, patients that reported lower tolerance to therapy had higher grade of AE. While patients with low-grade adverse events were less bothered by their side effects at follow-up, higher grade adverse events such as hypothyroidism impacted distress levels by more than double.

Conclusions: Among I-SPY2 participants, when higher grade of symptoms is persistent through follow up, it impacts physical function and tolerability even after end of therapy. Our study can allow physicians to be more diligent in active and post treatment monitoring.

Clinical trial identification: NCT01042379.

Legal entity responsible for the study: I-SPY2 Trial Investigators.

Funding: Research reported in this manuscript was supported by the National Cancer Institute of the National Institutes of Health under award number P01CA210961. The authors wish to acknowledge the generous support of the study sponsors, Quantum Leap Healthcare Collaborative (QLHC, 2013 to present) and the Foundation for the National Institutes of Health (2010 to 2012). The authors sincerely appreciate the ongoing support for the I-SPY2 Trial from the Safeway Foundation , the William K. Bowes, Jr. Foundation, Give Breast Cancer the Boot, QLHC and the Breast Cancer Research Foundation.

Background: Immune checkpoint inhibitors have improved outcomes for patients with various cancer types, yet most experience disease progression. Growing evidence supports that myeloid cells, such as macrophages, play a major role in inhibiting tumor progression. Macrophage and cancer cell interaction can be inhibited by the SIRPα-CD47 pathway. Blocking this pathway may restore antitumor immune functions of macrophages and reduce tumor growth. DS-1103a, a recombinant humanized IgG4 anti-SIRPα antibody, blocks this pathway by binding to the major human variants of SIRPα. T-DXd, an antibody-drug conjugate consisting of an anti-HER2 antibody and topoisomerase I inhibitor payload, is approved for various cancers. In nonclinical studies, DS-1103a enhanced the trastuzumab-induced antibody-dependent cellular phagocytosis, suggesting a potential benefit of the combination. This study will assess the preliminary safety and efficacy of DS-1103a + T-DXd in advanced solid tumors.

Trial design: This phase 1, global, multicenter, first-in-human, 2-part, dose-escalation, and dose-expansion study (NCT05765851) plans to enroll up to 78 patients. Part 1 (dose-escalation [based on BOIN design]) will enroll patients with pathologically documented HER2-expressing (IHC1+ or greater) or HER2-mutated (activating mutation) advanced solid tumors not amenable to standard of care. Part 2 (dose-expansion) will enroll patients with HER2-low (IHC2+/ISH- or IHC1+ [ISH- or untested]) breast cancer who received 1-2 prior lines of chemotherapy in the recurrent or metastatic setting. DS-1103a monotherapy will be administered for Cycle 1 of Part 1, DS-1103a + T-DXd for all other 21-day cycles and during Part 2. The evaluation period for dose limiting toxicity will be before Cycle 3 in Part 1. Primary endpoints include the safety and tolerability of the combination in both parts, determining the recommended dose of DS-1103a in combination for expansion in Part 1, and assessing the objective response rate in Part 2. Secondary endpoints include the antitumor activity of DS-1103a + T-DXd, pharmacokinetic profile of DS-1103a, and incidence of antidrug antibodies against DS-1103a.

Clinical trial identification: NCT05765851.

Background: DESTINY-Breast04 (NCT03734029) assessed T-DXd vs TPC in pts with HER2-low mBC (immunohistochemistry [IHC] 1+ or IHC 2+/in situ hybridization−). At primary data cutoff (DCO; January 11, 2022), median overall survival (mOS) for the full analysis set (FAS = hormone receptor-positive [HR+] and hormone receptor-negative [HR−]) was 23.4 months (mo) for T-DXd vs 16.8 mo for TPC (hazard ratio, 0.64; $P = 0.001$), with 18.4 mo median follow-up (F/U). Here, we report results from a preplanned further F/U (DCO, March 1, 2023).

Methods: Pts were randomly assigned 2:1 to T-DXd or TPC. At the updated DCO, analyses of OS (HR+ and FAS), progression-free survival (PFS) by investigator (HR+ and FAS), and safety were conducted.

Results: At DCO, median F/U was 32 mo. Median treatment duration was 8.2 mo (range, 0.2-39.1 mo) for T-DXd and 3.5 mo (range, 0.3-19.7 mo) for TPC. Efficacy results are shown in the table. Grade ≥3 treatment-emergent adverse events (TEAEs) were lower in T-DXd vs TPC (54.4% vs 67.4%). The most common TEAEs were gastrointestinal or hematological in nature; all-grade nausea (T-DXd: 76.0%; TPC: 30.2%) and vomiting (T-DXd: 40.7%; TPC: 13.4%) were most common for T-DXd and decreased neutrophil count (T-DXd: 22.1%; TPC: 36.0%) was most common for TPC. Exposure-adjusted incidence rates for any-grade TEAEs were 1.2 and 2.6 for the T-DXd vs TPC arm, respectively. No new adjudicated drug-related interstitial lung disease/pneumonitis events were reported with longer F/U (primary DCO: 45 pts [12.1%] for T-DXd; 1 pt [0.6%] for TPC).

Conclusions: Results from the 32-mo median F/U for DESTINY-Breast04 confirms the sustained clinically meaningful improvement for T-DXd vs TPC previously demonstrated in HER2-low mBC, regardless of HR status. Similar to the primary analysis, the overall safety profile was generally manageable with longer duration of treatment exposure.

Clinical trial identification: NCT03734029.

Background: T-DXd is approved for treatment of pts with HER2+ unresectable or mBC who have received ≥1 prior anti-HER2-based regimens. We report exploratory pooled efficacy and safety data of T-DXd vs comparator (comp) in pts from DB-01, DB-02, and DB-03 with treated/stable (treated) and untreated/active (untreated; from DB-02/-03) BMs at baseline, as defined by the US FDA (FDA 2020).

Methods: DB-01/-02 enrolled pts who were resistant/refractory to trastuzumab emtansine (T-DM1); DB-03 included pts previously treated with trastuzumab and taxane. T-DXd data and ad hoc exploratory intracranial analyses were pooled from DB-01/-02/-03. Comp data, physician's choice chemotherapy and T-DM1, were pooled from DB-02 and -03, respectively. Endpoints were intracranial (IC) objective response rate (ORR; complete [CR] or partial response [PR] in brain) per blinded independent central review (BICR) by RECIST, IC duration of response (DoR), central nervous system-progression-free survival (CNS-PFS) by BICR, and safety.

Results: Of the 148 pts with BMs at baseline who received T-DXd, 104 (70.3%) had treated and 44 (29.7%) had untreated BMs. Pts had a median of 3 (range, 1.0-14.0) prior regimens in the metastatic setting. Median treatment duration was 12.7 mo (range, 0.7-45.1) with T-DXd and 5.6 mo (range, 0.1-43.0) with comp. Efficacy data are in the Table. Any-grade drug-related treatment-emergent adverse events (TEAEs), drug-related grade ≥3 TEAEs, and serious drug-related AEs were observed in 94.5%, 43.2%, and 13.0% of pts with T-DXd, vs 94.0%, 36.1%, and 7.2% with comp, respectively.

Conclusions: T-DXd exhibited robust IC responses in pts with treated and, notably, untreated BMs vs comp. Although pt numbers were small and not statistically tested, numerically longer median IC-DoR and CNS-PFS were observed in pts with untreated BMs with T-DXd. Safety was acceptable and generally manageable with T-DXd.

Clinical trial identification: NCT03248492; NCT03523585; NCT03529110.

378O Persistence under abemaciclib and endocrine treatment (ABA+ET) in patients with advanced breast cancer (aBC): First results of the randomized IMPACT trial comparing patient coaching with the MASCC oral agent teaching tool (MOATT) versus local routine patient coaching (LC)

M.K. Welslau[1], P. Fasching[2], L. Mueller[3], E. Belleville[4], L. Rieger[5], M-O. Zahn[6], B. Lex[7], L. Häberle[8], H. Tesch[1]

[1]Oncology Department, Klinikum Aschaffenburg, Aschaffenburg, Germany; [2]Department of Gynecology and Obstetrics, Universitätsklinikum Erlangen, Erlangen, Germany; [3]Leer, Onkologie Untere Ems - Leer Papenburg Emden, Leer, Germany; [4]Womens Health Department, ClinSol, Wuerzburg, Germany; [5]Gynaecologic Oncology Department, Praxis Dr. Vehling-Kaiser, Landshut, Germany; [6]Oncology and Haematology Department, MVZ Onkologische Kooperation Harz, Goslar, Germany; [7]Department of Gynecology and Obstetrics, Department of Gynecology and Obstetrics, Kulmbach, Germany; [8]Frauenklinik, Universitätsklinik Erlangen, Erlangen, Germany

Background: Recent studies showed the positive impact of supportive care programs on patients. Possible benefits include the prevention of incorrect medication intake, a decrease of treatment-related symptoms and the reduction of hospitalization due to adverse events. MOATT is a standardized patient coaching program which might be suitable to improve the therapy management of BC patients with oral treatments. Aim of this study was to investigate the impact of MOATT on persistence and therapy management under ABA+ET.

Methods: IMPACT (NCT04030728) was a prospective randomized, controlled trial in patients with hormone receptor positive, HER2-negative aBC treated with ABA+ET. Patients were randomized to LC vs. MOATT. Primary endpoint was the persistence rate after 24 weeks of treatment. Further endpoints included compliance rate, the number of dose reduction and dose interruptions.

Results: A total of 211 patients were randomized between 06/20 and 02/22. Persistence probability after 24 weeks was 0.71 (95%CI 0.63-0.81) with LC and 0.82 (95%CI: 0.74-0.90) with MOATT (hazard ratio: 0.59 (95%CI: 0.32-1.07; $p_{log\text{-}rank} = 0.078$). Disease progression or death were the main reasons for therapy discontinuation in 14 cases in the LC arm and in 10 cases in the MOATT arm. A decision for a permanent discontinuation of ABA in the first 24 weeks was seen in 14 patients (14.1%) in the LC arm and 8 Patients (7.8%) in the MOATT arm. Dose reductions were planned in 24.5% of patients with LC and in 17.2% of patients in the MOATT arm. Therapy interruptions were planned in 14.9% of LC-patients and 10.1% in the MOATT arm.

Conclusions: The risk of therapy discontinuation within the first 24 weeks of treatment is clinically relevant. Coaching with MOATT reduced the probability for permanent therapy discontinuations by about 40% during the first 6 months of therapy. Standardized patient coaching improved therapy management of oral cancer therapies like abemaciclib. Patient coaching might be very useful to improve therapy management also in the adjuvant breast cancer setting.

Clinical trial identification: NCT04030728 and July 24, 2019.

Background: B7-H4, a transmembrane glycoprotein in the B7 superfamily, has limited expression in normal tissues but is highly expressed in various cancers. HS-20089 is a novel B7-H4 directed antibody-drug conjugate (ADC) with a drug to antibody ratio of 6. We conducted a first-in-human phase I trial to evaluate the dose-limiting toxicity (DLT), safety, tolerability, pharmacokinetics, and efficacy of HS-20089 in patients (pts) with advanced solid tumors refractory to standard therapy.

Methods: Eligible pts were enrolled in sequentially escalating dose cohorts (0.7 to 7.2 mg/kg) of HS-20089 administered intravenously every 3 weeks. The accelerated titration combined with Bayesian optimal interval (BOIN) was used as the dose escalation schedule in this phase I dose escalation trial.

Results: As of Apr. 11th, 2023, 44 pts with advanced solid tumors (41 breast cancers, 2 ovarian cancers, and 1 endometrial cancer) received HS-20089 treatment. Three DLTs were observed in 2 pts (both in 7.2 mg/kg). The most common treatment-emergent adverse events ($\geq$20%) were leukopenia, neutropenia, nausea, anemia, thrombocytopenia, vomiting, fatigue, increased alanine aminotransferase, anorexia, increased aspartate aminotransferase and hyponatremia. No interstitial lung disease and infusion reaction were reported. Of 33 response-evaluable pts, 8 partial responses (PRs) were observed in pts treated with HS-20089 (response rate: 24.2%), including 3 confirmed PRs and 5 PRs awaiting confirmation. The disease control rate was 63.6%. In the subset of 16 triple-negative breast cancer (TNBC) pts, 6 PRs were observed (response rate: 37.5%), including 2 confirmed PRs and 4 PRs awaiting confirmation. At potential target therapeutic dose (4.8 and 5.8 mg/kg), 5 PRs of 12 pts were observed (response rate: 41.7%) in TNBC. The patient achieving PR with the longest treatment duration of 403 days remains on treatment in 0.7 mg/kg cohort.

Conclusions: Based on data from the ongoing study, HS-20089 was well tolerated and showed antitumor activities in advanced solid tumors, with encouraging clinical efficacy in TNBC.

Clinical trial identification: NCT05263479.

Background: BEGONIA (NCT03742102) is an ongoing 2-part, open-label platform study in 1L a/mTNBC, evaluating D, an anti—PD-L1 antibody, plus novel therapies, including Dato-DXd, an antibody-drug conjugate made of a anti-TROP2 antibody covalently linked via a cleavable linker to a topoisomerase I inhibitor payload. Early data from BEGONIA Arm 7, Dato-DXd + D, showed promising responses. Updated results, including response duration (DoR), are reported.

Methods: Patients (pts) with unresectable a/mTNBC eligible for 1L treatment were enrolled, regardless of PD-L1/TROP2 expression, and received Dato-DXd 6 mg/kg IV + D 1120 mg IV Q3W until progression or unacceptable toxicity. PD-L1, assessed by the VENTANA PD-L1 (SP263) Assay, was high if ≥10% of the tumor area was populated by PD-L1—expressing tumor or immune cells. Primary endpoints were safety and tolerability. Secondary endpoints included investigator-assessed ORR, PFS (RECIST v1.1), and DoR.

Results: As of 2 Feb 2023, 62 pts received Dato-DXd + D (29 ongoing). Median follow-up was 11.7 (range 2—20) months (mos). At baseline, median pt age was 53 years; 60% had visceral metastases; 87% had PD-L1—low expression. Confirmed ORR was 79% (95% CI, 67—88); 6 (10%) pts had complete and 43 (69%) had partial responses. Response to treatment was irrespective of PD-L1 expression level. Median DoR was 15.5 mos (95% CI, 9.9—not calculable [NC]). Median PFS was 13.8 mos (95% CI, 11—NC). Nausea and stomatitis were the most common adverse events (AEs; 40 [65%] each). Any Grade (G) 3/4 AEs occurred in 35 (57%) pts and serious AEs in 14 (23%). Low rates of anemia (9 [15%]), diarrhea (8 [13%]), and neutropenia (3 [5%]) occurred. Adjudicated treatment-related interstitial lung disease/pneumonitis occurred in 3 (5%) pts (2 G2; 1 G1). No deaths due to treatment-related AEs occurred. 10 (16%) pts discontinued any study drug due to AEs. No new safety signals were reported.

Conclusions: Dato-DXd combined with D continues to demonstrate manageable safety and compelling high, durable response rates in 1L a/mTNBC. Further investigation is warranted. Translational data analysis is ongoing. Funding: AstraZeneca/ Daiichi Sankyo.

Clinical trial identification: NCT03742102; November 15, 2018.

Background: TROP2 is commonly overexpressed in HR+/HER2- mBC and associated with poor prognosis. SKB264 is a novel anti-TROP2 ADC developed using sulfonyl pyrimidine-CL2A-carbonate linker to conjugate its payload, a belotecan-derivative topoisomerase I inhibitor, to achieve an average Drug-to-antibody Ratio (DAR) of 7.4. This is the first report of results from a phase II cohort in patients (pts) with HR+/ HER2- mBC.

Methods: Pts with HR+/HER2- (including HER2-low and HER2-zero) mBC received SKB264 at a dose of 5 mg/kg Q2W until progression or unacceptable toxicity. Eligibility included progression on endocrine-based therapy and at least one prior chemotherapy for mBC. Tumor assessment was performed every 8 weeks per RECIST v1.1 assessed by investigator.

Results: As of data cut-off (April 12, 2023), 41 pts (median age 50 yrs [34-66], 61% ECOG PS 1) were enrolled. Median follow-up was 8.2 months (mo). Treatment-related adverse events (TRAEs) of ≥ Grade 3 were reported in 48.8% (20/41) of pts. The most common ≥ Grade 3 TRAEs (≥ 5%) were neutrophil count decreased (36.6%), white blood cell count decreased (22%), anemia (14.6%), platelet count decreased (9.8%) and GGT increase (7.3%). TRAEs led to dose reduction in 17.1% (7/41) of pts. No neuropathy or drug-related ILD/pneumonitis was reported. No TRAEs led to treatment discontinuation or death. Of 38 pts evaluable for response assessment, 47% of pts had primary endocrine resistance; 79% of pts had received ≥2 prior chemotherapy for metastatic disease, and prior treatments included taxane (100%), and CDK 4/6 inhibitors (65.8%). The ORR was 36.8% (14/38, 12 confirmed PR and 2 unconfirmed PR) and DCR was 89.5%, median DoR was 7.4 mo (range, 4.2 to 14.9+), 6-mo DoR rate was 80%. Median PFS was 11.1 mo (95% Cl: 5.4, 13.1), and 6-mo PFS rate was 61.2%.

Conclusions: SKB264 at 5 mg/kg demonstrates a manageable safety profile and promising antitumor activity in pts with pre-treated HR+/HER2- mBC. Two phase 3 studies are currently planned in HR+/HER2- mBC, one in China for pts after at least one chemo for mBC and a second global for pts previously untreated with chemo for mBC, both comparing SKB264 vs investigator selected chemo.

Clinical trial identification: NCT04152499.

Background: OP-1250 is a small molecule CERAN/SERD with antitumor activity in breast cancer (BC) xenograft models, including *ESR1*/*PIK3CA* mutations and brain metastasis. OP-1250 was administered at 30—300 mg daily (qd) in the dose-escalation part of a phase 1 study. Maximum tolerated dose was not reached and no dose-limiting toxicities occurred. OP-1250 at 60 mg and 120 mg was assessed in the dose-expansion part. Based on safety, pharmacokinetics, and preliminary antitumor activity, 120 mg qd was selected as the recommended phase 2 dose. Here we present the phase 1/2 study data (phase 2 is ongoing).

Methods: Pts with measurable and nonmeasurable disease were included. Eligible women (any menopausal status) and men had received $\leq$4 lines of endocrine therapy (ET) and $\leq$1 line of chemotherapy for metastatic disease. Pts with stable brain metastasis had to have $\geq$1 prior line of ET and $\leq$3 prior lines of chemotherapy (both for metastatic disease). Tumor assessment (RECIST v1.1) occurred every 8 weeks (NCT04505826).

Results: By March 17, 2023, of 86 pts on OP-1250 (120 mg), 66% had $\geq$2 prior lines of ET, 30% prior chemotherapy, 67% prior fulvestrant, and 98% prior cyclin-dependent kinase 4/6 inhibitors (CDK4/6i); 45% (34/75) of pts with available baseline ctDNA had *ESR1* mutations. The most common ($\geq$15% of pts) all-grade treatment-emergent adverse events (AEs) were nausea, vomiting, neutropenia, fatigue, headache, constipation, and diarrhea. The most common grade 3/4 treatment-related AEs were neutropenia (9%), nausea (3%), and vomiting (3%). Neutropenia was reversible; 3 pts with grade 4 neutropenia were rechallenged at a lower dose without recurrence. There were 4 partial responses (3 confirmed) with a clinical benefit rate of 40% (23/57). In pts with an *ESR1* mutation, CBR was 50% (11/22). D[NZ1] [NZ2] ata continue to mature and updated data will be presented.

Conclusions: OP-1250 (120 mg qd) was well tolerated with promising efficacy in heavily pretreated pts, including pts progressing on fulvestrant and CDK4/6i. A phase 3 monotherapy study in metastatic BC (second/third line) is planned in 2023.

Clinical trial identification: NCT04505826.

Background: Imlunestrant is an investigational, next-generation, oral SERD designed to deliver continuous ER target inhibition, including in *ESR1*-mutant BC. In the first-in-human phase 1a/b EMBER study, imlunestrant demonstrated favorable safety, pharmacokinetics (PK), and clinical benefit rate when administered as monotherapy (Jhaveri ASCO 2022) or with abemaciclib (Jhaveri SABCS 2022). We present the first clinical data of imlunestrant with everolimus or alpelisib and updated imlunestrant monotherapy data from the EMBER study (NCT04188548).

Methods: Patients (pts) received imlunestrant alone as part of the phase 1a (escalation) or 1b (expansion), or with everolimus or alpelisib in 1b. Key phase 1b eligibility

included ER+, HER2- aBC, prior endocrine therapy (ET) sensitivity, ≤2 prior therapies, and a *PIK3CA* mutation (alpelisib arm only). Assignment to phase 1b treatment arms was made by investigators. Men and premenopausal women received GnRH agonist. Key endpoints included RP2D, safety, PK, ORR (complete response [CR] plus partial response [PR]) and CBR (CR or PR, or stable disease ≥24 weeks) per RECIST v1.1.

Results: As of 6 Oct 2022, 114 pts received imlunestrant monotherapy, 42 pts received imlunestrant + everolimus, and 21 pts received imlunestrant + alpelisib. Baseline characteristics were similar across combination cohorts; 46% pts had visceral disease and 46% had an *ESR1* mutation at baseline. Median number of prior aBC therapies in combination cohorts was: 1 (range 1-2); including prior ET (100%), CDK4/6i (100%), fulvestrant (35%) and chemo (17%). No cardiac or ocular toxicity was seen. Safety and preliminary efficacy are presented (Table).

Table: 383MO Safety and preliminary efficacy

Endpoint	Imlunestrant monotherapy (n=114)	Imlunestrant + everolimus (n=42)	Imlunestrant + alpelisib (n=21)
All-grade treatment emergent AEs (TEAEs) - %	Nausea — 40 Fatigue — 32 Diarrhea — 31	Diarrhea — 55 Fatigue — 45 AST increase — 38	Diarrhea — 86 Rash — 67 Hyperglycaemia - 62
Grade ≥3 treatment related AEs (TRAEs) - %	5 Fatigue — 2 Neutropenia — 2	19 Hypertriglyceridemia — 5 AST increase — 5	62 Rash — 43 Hyperglycemia - 10
Dose reductions due to TRAEs - %			
Imlunestrant alone	2	0	0
Everolimus/alpelisib alone	N/A	12	24
Both	N/A	2	14
Discontinuations due to TRAEs - %			
Imlunestrant alone	0	0	0
Everolimus/ alpelisib alone	N/A	2	29
Both	N/A	0	0
ORR (%)	7/75 (9)	6/28 (21)	6/12 (50)
CBR (%)	48/114 (42)	26/42 (62)	13/21 (62)

AEs = adverse events.

Conclusions: Imlunestrant alone or in combination with everolimus or alpelisib demonstrated robust efficacy in pts with pre-treated ER+, HER-2 aBC. Toxicities were consistent with the known safety profile of both alpelisib and everolimus.

Clinical trial identification: NCT04188548.

384MO Final overall survival analysis for fulvestrant vs anastrozole in endocrine therapy (ET)-naïve, hormone receptor-positive (HR+) advanced breast cancer (FALCON)

J. Robertson[1], Z. Shao[2], S. Noguchi[3], S. Singh[4], S. Subramaniam[5], M.J. Ellis[6]

[1]Medicine Department, University of Nottingham, School of Medicine, Nottingham, UK; [2]Breast Surgery Dept., University Shanghai Cancer Center, Shanghai, China; [3]Breast Surgery, Hyogo Prefectural Nishinomiya Hospital, Nishinomiya, Japan; [4]AstraZeneca Netherlands, Zoetermeer, Netherlands; [5]AstraZeneca India, Bangalore, India; [6]Oncology R&D, AstraZeneca Pharmaceuticals LP, Gaithersburg, MD, USA

Background: The phase 3 international, randomised, double-blind FALCON trial (NCT01602380) met its primary endpoint showing a statistically significant improvement in progression-free survival (PFS) with fulvestrant vs anastrozole as a first-line treatment for HR+ advanced breast cancer (BC). PFS improvement was confined to non-visceral disease (HR=0.59 [95% CI 0.42—0.84]) vs visceral disease (HR=0.99 [95% CI 0.74—1.33]). At the primary analysis, interim overall survival (OS) data were immature (31%). Here we report the prespecified final analysis of OS.

Methods: Postmenopausal women with ET-naïve, HR+/HER2— locally advanced or metastatic BC were randomised 1:1 to fulvestrant (500 mg, Days 0, 14 and 28, then monthly thereafter) or anastrozole (1 mg, daily). Secondary endpoints of OS, safety, and quality of life (QoL) are reported. The final OS analysis was triggered at a threshold of 65% maturity and ≥8 years since the last patient was enrolled, with an available 1-sided alpha of 0.01845.

Results: In the overall population (462 patients; 68% maturity; cut-off 11 July 2022), median OS was 44.8 months with fulvestrant vs 42.7 months with anastrozole (HR=0.97 [95% CI 0.77—1.21]; p=0.7579). Median OS across prespecified subgroups was consistent with the overall population. In patients with non-visceral disease, a 15% reduction in the risk of death was observed with fulvestrant vs anastrozole, although statistical significance was not reached (Table). No meaningful differences were seen in QoL. No new safety signals emerged.

Table: 384MO Median OS for visceral and non-visceral disease [DCO 11 July 2022]

	Median OS, months		HR (95% CI)
	Fulvestrant	Anastrozole	
Non-visceral disease	n=95 65.2	n=113 47.8	0.85 (0.60−1.20)
Visceral disease	n=135 37.2	n=119 40.7	1.06 (0.80−1.42)

CI, confidence interval; DCO, data cut-off; HR, hazard ratio; OS, overall survival.

Conclusions: At the final analysis of FALCON, no significant difference in OS was seen between fulvestrant and anastrozole in ET-naïve postmenopausal women with HR+/HER2− locally advanced or metastatic BC. The positive trend observed in OS for fulvestrant in non-visceral disease compared with visceral disease is consistent with the primary analysis.

Clinical trial identification: NCT01602380.

Background: DP303c is a HER2-targeting ADC with a cleavable linker-MMAE payload. Pre-clinical study demonstrated similar to or better antitumor activity than T-DM1 in xenograft models. Here we present the safety and efficacy of DP303c in patients (pts) with HER2-positive pre-treated advanced solid tumors.

Methods: Adult pts with HER2-positive advanced solid tumors who were not eligible to receive standard of care (SoC) or had no SoC, or failed SoC were recruited. This phase I study consisted of dose escalation with a modified 3+3 design at DP303c 0.5, 1.0, 2.0, 3.0 and 4.0 mg/kg, and then dose expansion at 3.0 mg/kg, intravenously administered every 3 weeks. The primary endpoints were safety and RP2D.

Results: As of 28 Feb 2023, 94 pts were enrolled in dose escalation (22 pts) and dose expansion (72 pts). The median follow-up was 11.98 months (mo). Median age was 51.5 yrs (range: 28-73). Tumor types were breast cancer (BC, 68 pts), colorectal cancer (10 pts), gastric cancer (9 pts) and others (7 pts). ECOG PS was 0 in 15 pts (16.0%), and 1 in 79 pts (84.0%). All 94 pts received $\geq$ 1 prior line of systemic therapy. 65 pts (95.6%) with BC received $\geq$ 2 prior lines of systemic therapy. One dose limiting toxicity [Grade (G) 3 eye pain] was observed in 4.0 mg/kg with 3.0 mg/kg selected as expansion dose. Treatment-related adverse events (TRAEs) of any grade occurred in all 94 pts, in which 34 (36.2%) were G $\geq$ 3. The most common G $\geq$ 3 TRAEs were vison blurred (16.0%), xerophthalmia (6.4%), and neuropathy peripheral (3.2%). No treatment-related death occurred. Among 91 efficacy evaluable pts, ORR and DCR were 42.9% (95%CI: 32.5-53.7) and 68.1% (95%CI: 57.5-77.5). The median PFS and DoR were 4.44 mo (95%CI: 3.35-6.44) and 10.97 mo (95%CI: 3.98-NA) for all 94 pts. The minimal effective dose was 1.0 mg/kg in BC. Among 66 efficacy evaluable pts with BC, ORR and DCR were 51.5% (95%CI: 38.9-64.0) and 77.3% (95%CI: 65.3-86.7). The median PFS and DoR were 6.44 mo (95%CI: 4.14-8.51) and 10.97 mo (95%CI: 3.98-NA) for all 68 pts with BC.

Conclusions: DP303c demonstrated promising anti-tumor activity with acceptable safety in pts with pre-treated advanced solid tumors, especially BC. The pivotal phase II study in pts with BC is ongoing.

Clinical trial identification: NCT04146610.

Background: Trastuzumab duocarmazine (T-Duo, SYD985) is a HER2-targeting antibody-drug conjugate comprised of trastuzumab bound to the DNA alkylating agent duocarmazine with a drug-antibody ratio of 2.4 to 2.8. TULIP is a randomized, international, multicenter, phase 3 study in patients with pre-treated HER2-positive metastatic breast cancer (MBC). The initial analysis of the primary endpoint progression free survival (PFS) showed a clinically meaningful and statistically significant difference in favor of T-Duo versus physician's choice (PC) (Saura *et al.*, ESMO 2021). At that time, preliminary overall survival (OS) data were reported. Final OS and updated secondary outcomes are reported here.

Methods: The TULIP trial randomly assigned patients with HER2-positive locally advanced or MBC with $\geq$2 previous HER2-targeting MBC regimens or pretreated with T-DM1, in a 2:1 ratio between T-Duo (1.2 mg/kg q3w) and PC. PC could be either trastuzumab combined with capecitabine or vinorelbine or eribulin or lapatinib plus capecitabine. The primary endpoint was PFS by blinded, independent, central review. Key secondary endpoints are PFS by investigator, OS, overall response rate, QoL, duration of response and safety.

Results: A total of 291 patients were randomized to the T-Duo group and 146 to the PC group. At the data cut off, the median follow-up of the T-Duo and PC groups were 35.6 months and 32.0 months, respectively. Median OS was 21.0 months in the T-Duo group and 19.5 months in the PC group. The hazard ratio was 0.87 (95% CI 0.68, 1.12) p=0.236. The 1-year survival estimate was 70% in the T-Duo group and 68% in the PC group. The primary endpoint PFS (7.0 vs 4.9 months, HR 0.63, p=0.002) and other secondary efficacy outcomes did not change in this analysis compared to the initial analysis. No new safety findings were observed with longer follow-up.

Conclusions: T-Duo showed a meaningful and statistically significant improvement in PFS in patients with pre-treated HER2-positive MBC. The final OS results confirm a trend towards a numerically prolonged OS (statistically non-significant) in the T-Duo group compared with PC group. Safety was aligned with the primary analysis, with no new signals identified.

Clinical trial identification: NCT03262935, Eudract 2017-001994-18.

Background: The SOLTI-1903 HOPE study aims to assess the feasibility of a molecular screening program promoting active participation of patients with Advanced Breast Cancer (ABC) in the management of their disease to better characterize the genomic landscape of ABC and to facilitate pt access to matched-targeted therapies in Spain.

Methods: HOPE (NCT04497285) is a patient-centric study where pts diagnosed with ABC lead their inclusion, participation, and follow-up through a digital tool (DT). They report clinical information and provide archival tumor samples to be analyzed by FoundationOne CDx. At progression disease, patients undergo a liquid biopsy with the Guardant360 panel. Clinical and genomic information is discussed by a Molecular Advisory Board (MAB) that issues a report explaining the alterations and enumerating potentially useful targeted treatments. Then, participants record disease evolution in the DT for 2y. The primary objective is to assess the real-world clinical practice of integrating molecular profiling into the Standard of Care management of pts with ABC.

Results: Between Oct 2020 and Feb 2022, 604 patients were included in the study, and the median age was 51 ys (range 27-82y). The most common reported IHC subtype was ER+/HER2- (74%), followed by HER2+ (14%) and triple negative (12%). 512 tumor samples were received from 423 patients, and DNA-seq results with positive results were obtained in 298 (58%) cases. Common alterations were PIK3CA mut (34%), CCND1 amp (27%), and TP53 mut (26%). Blood extractions were obtained from 378 patients, and ctDNA detection was observed in 303 (80%) cases. Frequently mutated genes were PIK3CA (38%), TP53 (38%), and ESR1 (29%). As of April 2023, the MAB reviewed 306 cases, observing at least one ESCAT I-III alteration in 75% of cases. Of these, only 15% were already known before HOPE. After a mean follow-up of 1.3ys, 20% of ABC cases discussed received a targeted treatment.

Conclusions: Patient-centric molecular screening programs implemented on a nationwide level are viable, have the potential to impact treatment decisions in a subgroup of patients and seems more efficient to bring patients to receive treatments targeted to the identified alterations.

Clinical trial identification: NCT04497285.

Background: The DESTINY-Breast04 trial (NCT03734029) demonstrated significantly improved progression-free survival (PFS) and overall survival (OS) in pts with HER2-low mBC treated with T-DXd vs TPC. Consistent efficacy was also demonstrated in pts with BMs at baseline with T-DXd vs TPC. In this exploratory analysis, we provide additional intracranial (IC) efficacy data in pts with BMs at baseline.

Methods: Pts with centrally confirmed HER2-low (immunohistochemistry [IHC] 1+ or IHC 2+/in situ hybridization−) mBC who were previously treated with 1 or 2 lines of chemotherapy were randomized (2:1) to T-DXd or TPC. Pts with investigator-assessed clinically stable and treated BMs at baseline were eligible, and exploratory analyses of IC clinical activity were completed. Analysis was based on central review of brain MRI or CT scans. Endpoints included IC objective response rate (ORR) by blinded independent central review (BICR), best overall response, clinical benefit rate, disease control rate, and IC PFS by BICR.

Results: Of 35 pts with BICR-assessed BMs at baseline, 24 pts received T-DXd and 11 received TPC. Like the full dataset, most pts with BMs at baseline had hormone receptor-positive tumors (T-DXd, 75.0%; TPC, 72.7%). Of those pts who received $\geq$1 dose of trial drug, median treatment duration was 6.6 mo (mo; range, 0.3-24.3 mo) for T-DXd (n = 24) and 1.4 mo (range, 0.4-17.4 mo) for TPC (n = 9); 20.8% and 11.1% of these pts remained on T-DXd and TPC for >12 mo, respectively. IC response data are shown in the table. Median IC PFS by BICR for T-DXd was 9.7 mo (95% CI, 4.4-15.1 mo) vs not evaluable for TPC, due to small pt numbers.

Table: 388P Summary of intracranial responses

	T-DXd n = 24	TPC n = 11
Intracranial confirmed ORR (CR + PR), n (%) [95% CI][a]	6 (25.0) [9.8-46.7]	0 [0-28.5]
Best overall intracranial response, n (%)		
CR	4 (16.7)	0
PR	2 (8.3)	0
SD	12 (50.0)	7 (63.6)
PD	0	1 (9.1)
NE	1 (4.2)	0
Missing[b]	5 (20.8)	3 (27.3)
Clinical benefit rate (CR + PR + (>6 mo) SD), n (%) [95% CI][a]	14 (58.3) [36.6-77.9]	2 (18.2) [2.3-51.8]
Disease control rate (CR + PR + SD), n (%) [95% CI][a]	18 (75.0) [53.3-90.2]	7 (63.6) [30.8-89.1]

CR, complete response; NE, not evaluable; PD, progressive disease; PR, partial response; SD, stable disease. [a]Based on Clopper-Pearson method for single proportion. [b]Imaging not performed/available.

Conclusions: In this exploratory analysis, IC responses favored T-DXd over TPC in pts with clinically stable and treated baseline BMs. While only a small number of pts were included here, the IC efficacy data suggest a clinical benefit of T-DXd over TPC.

Clinical trial identification: NCT03734029.

389P Efficacy and safety analyses by prior lines of chemotherapy from the phase III TROPiCS-02 study of sacituzumab govitecan (SG) vs treatment of physician's choice (TPC) in patients (pts) with HR+/HER2- metastatic breast cancer (mBC)

J. Cortés[1], F. Marmé[2], P. Schmid[3], H.S. Rugo[4], S.M. Tolaney[5], W. Verret[6], T. Valdez[7], Y. Huo[8], A. Bardia[9]

[1]Department of Medicine, Oncology Department, International Breast Cancer Center (IBCC), Madrid, Spain; [2]Department of Obstetrics and Gynaecology, Universitaetsklinikum Mannheim - Medizinische Fakultaet, Mannheim, Germany; [3]Medical Oncology, Barts Health NHS Trust, London, UK; [4]Department of Medicine, University of California San Francisco Helen Diller Family Comprehensive Cancer Center, San Francisco, CA, USA; [5]Department of Medical Oncology, Dana Farber Cancer Institute, Harvard Medical School, Boston, MA, USA; [6]Department of Clinical Development, Gilead Sciences, Inc., Foster City, CA, USA; [7]Department of Patient Safety, Gilead Sciences, Inc., Foster City, CA, USA; [8]Department of Biostastistics, Gilead Sciences, Inc., Foster City, CA, USA; [9]Medical Oncology, Massachusetts General Hospital Cancer Center, Harvard Medical School, Boston, MA, USA

Background: SG is a Trop-2–directed antibody-drug conjugate approved for pretreated HR+/HER2- (IHC 0, 1+, or 2+/ISH-) mBC in the US. In the TROPiCS-02 study, SG treatment showed statistically significant improvement in progression-free survival (PFS; hazard ratio [HR] 0.66; 95% confidence interval [CI] 0.53-0.83) and overall survival (OS; HR 0.79; 95% CI 0.65-0.96) vs TPC with manageable safety in pts with pretreated HR+/HER2- mBC (Rugo et al. ESMO 2022). Outcomes worsen with multiple prior lines of chemotherapy (LoT). We present a post-hoc analysis of outcomes with SG vs TPC by prior LoT from TROPiCS-02.

Methods: Pts with HR+/HER2- mBC and $\geq$ 1 endocrine therapy, taxane, and CDK4/6 inhibitor, and 2 to 4 prior LoT for mBC, were randomized to SG (10 mg/kg IV Days 1 and 8, Q3W) or TPC. The primary endpoint was PFS; secondary endpoints included OS, objective response rate (ORR), clinical benefit rate (CBR), and safety. This analysis included pts with 2 vs $\geq$ 3 prior LoT in the metastatic setting.

Results: 543 pts were randomized to SG (n = 272; 113 (42%) had 2 prior LoT, 159 (58%) had $\geq$ 3) and TPC (n = 271; 120 (44%) had 2 prior LoT, 151 (56%) had $\geq$ 3). Baseline characteristics were similar in pts with 2 and $\geq$ 3 prior LoT and across treatments. Median PFS and OS were improved with SG vs TPC irrespective of prior LoT, with HR of 0.61 and 0.82 in pts with 2 prior LoT and 0.72 and 0.78 in pts with $\geq$ 3 prior LoT, respectively (Table). CBR was improved with SG vs TPC in pts with 2 and $\geq$ 3 prior LoT, ORR was improved in pts with 2 prior LoT, and the safety profile was similar in both subgroups (Table).

Table: 389P

Efficacy, ITT	2 Prior LoT		≥3 Prior LoT	
	SG (n=113)	TPC (n=113)	SG (n=159)	TPC (n=158)
Median PFS[a,b] (95% CI), mo	5.7 (4.2-8.5)	4.1 (2.8-5.6)	5.3 (4.0-6.9)	4.0 (2.9-4.4)
HR (95% CI)	0.61 (0.44-0.84)		0.72 (0.54-0.97)	
Median OS[c] (95% CI), mo	15.3 (12.7-19.8)	12.4 (10.4-14.9)	13.9 (12.3-15.5)	10.3 (8.7-12.4)
HR (95% CI)	0.82 (0.60-1.12)		0.78 (0.61-1.01)	
ORR[a,c](95% CI), %	30 (22-39)	16 (10-24)	14 (9-21)	13 (8-19)
CBR[a,c](95% CI), %	41 (32-50)	25 (17-34)	29 (22-37)	20 (14-27)
Safety, all treated, n (%)	**SG (n=112)**	**TPC (n=109)**	**SG (n=156)**	**TPC (n=140)**
Any grade TEAEs[c]	112 (100)	106 (97)	156 (100)	133 (95)
Grade 3/4	79 (71)	58 (53)	113 (72)	92 (66)

[a]Per independent central review. [b]Data cutoff: Jan 3, 2022; [c]Jul 1, 2022.

Conclusions: Regardless of number of prior LoT, SG demonstrated improved efficacy vs TPC in pts with HR+/HER2- mBC, with manageable safety across subgroups. Findings are consistent with the ITT population, demonstrating the potential for pts to benefit from SG in earlier LoT. Table

Clinical trial identification: NCT03901339.

Background: Vepdegestrant (ARV-471), an oral PROTAC ER degrader, was well tolerated and had clinical activity in heavily pretreated patients (pts) with ER+/HER2- advanced breast cancer in the phase 1 dose escalation (data cutoff: Sep 30, 2021) and phase 2 expansion cohort portions of a phase 1/2 study (NCT04072952). We present updated phase 1 dose escalation data after an additional 13 months of follow-up.

Methods: Eligible pts had ER+/HER2- advanced breast cancer, ≥1 prior cyclin-dependent kinase (CDK)4/6 inhibitor, and ≥2 prior endocrine therapies. Primary endpoints were safety, tolerability, and recommended phase 2 dose.

Results: As of Nov 1, 2022, 83 pts (median age: 64 y [range: 36–80]; 99% female) received vepdegestrant (30–700 mg total daily dose). Pts had a median of 4 prior regimens (range: 0–10; 100% prior CDK4/6 inhibitors, 81% prior fulvestrant, and 82% prior chemotherapy [60% in metastatic setting]). There were no dose-limiting toxicities. Treatment-related adverse events were mostly grade 1/2 (Table). Clinical benefit rate (rate of confirmed complete or partial response [PR] or stable disease ≥24 wks) for evaluable pts (n=76) was 37% (95% CI: 26–49). Of 64 pts with baseline measurable disease, 6 had a confirmed and 4 an unconfirmed PR. At data cutoff, 27 pts had treatment for ≥24 wks (7 for ≥48 wks) with 10 pts ongoing. Pharmacokinetics (PK) showed dose-dependent exposure for 30–500 mg daily doses. Substantial on-treatment reductions in mutant *ESR1* circulating tumor DNA levels were observed.

Table: 390P TRAEs reported in ≥10% of pts overall

	30–700 mg total daily dose (n=83)		
	Any grade	Grade 1/2	Grade 3[a]
Any TRAE, n (%)	58 (70)	53 (64)	5 (6)[b]
Nausea	20 (24)	19 (23)	1 (1)
Fatigue	20 (24)	20 (24)	0
Arthralgia	11 (13)	11 (13)	0
Constipation	11 (13)	11 (13)	0
Hot flush	10 (12)	10 (12)	0

[a]No grade ≥4 TRAEs occurred in any pts [b]Other grade 3 TRAEs not listed were headache (n=1), increased aspartate aminotransferase (n=1), increased amylase (n=1), increased lipase (n=1), QT prolongation (n=1), and venous embolism (n=1); pts may have experienced more than one TRAE TRAE=treatment-related adverse event

Conclusions: Vepdegestrant continued to be well tolerated across all doses and showed clinical activity in heavily pretreated pts with ER+/HER2- advanced breast cancer; PK was dose-dependent up to 500 mg daily. Data support further development of vepdegestrant; the ongoing phase 3 VERITAC-2 study (NCT05654623) is evaluating vepdegestrant 200 mg once daily vs fulvestrant.

Clinical trial identification: NCT04072952.

391P Detrimental effect on overall survival of CDK4/6 inhibitor dose reduction if immortal time bias is considered

A. Bjerrum[1], A.F. Henriksen[1], A.S. Knop[1], T. Berg[1], I.E.V. Tuxen[2], U.N. Lassen[1], T.S. Petersen[3]

[1]Department of Oncology, Rigshospitalet, Copenhagen, Denmark; [2]Department of Oncology, Nordsjællands Hospital, Hillerød, Denmark; [3]Department of Clinical Pharmacology, Bispebjerg Hospital, Copenhagen, Denmark

Background: Since 2017, the combination of CDK4/6 inhibitors and endocrine therapy has been the standard first-line treatment for patients diagnosed with hormone-positive/HER2-negative metastatic breast cancer (mBC) in Denmark. Previous analyses, based on randomized phase III studies, have shown that the clinical benefit

remains after CDK4/6i dose reduction, but analyses may have been susceptible to immortal time bias.

Methods: This real-world cohort study is based on electronic health records from 695 patients from the capitol region of Denmark who initiated first-line treatment for mBC with CDK4/6i between May 2017 and October 2022. We used landmark Kaplan-Meier estimates and Cox regression to examine the association of dose reduction with treatment duration and overall survival. Patients were categorized based on dose reduction from the recommended dose prior to the landmark, defined at 3 months after initiation of treatment. Hazard ratios were adjusted for CDK4/6i agent, age, comorbidity, BMI, LDH > ULN, ECOG performance status and visceral metastases.

Results: A total of 530 patients were eligible for inclusion in the landmark analysis and 198 (37%) were categorized into the dose reduction group. Patients with dose reduction were significantly older and more had received prior endocrine therapy. Dose reduction was significantly associated with overall survival and shorter treatment duration, 39.6 vs 55.6 months (95%CI: 35.5-NE vs 49.9-NE) and 19.6 vs. 30.3 months, respectively. Adjusted hazard ratio for death was 1.49 for patients with dose reduction (95% CI: 1.01-2.22).

Table: 391P

Characteristic	Dose reduction, N = 198[1]	Full dose, N = 332[1]	p-value
CDK4/6i			0.14
Abemaciclib	48 (24%)	99 (30%)	
Palbociclib	104 (53%)	145 (44%)	
Ribociclib	46 (23%)	88 (27%)	
Age	72 (63, 78)	67 (58, 75)	<0.001
Primary metastatic	51 (26%)	102 (31%)	0.2
Prior endocrine treatment	144 (73%)	199 (60%)	0.003
Charlson Comorbidity Index[2]			0.3
0	145 (73%)	256 (77%)	
1	31 (16%)	52 (16%)	
2+	22 (11%)	24 (7%)	
Visceral metastasis[3]	41 (55%)	41 (55%)	>0.9
ECOG Performance Status[3]			0.2
0	30 (50%)	45 (66%)	
1	25 (42%)	20 (29%)	
2	5 (8.3%)	3 (4.4%)	
Unknown	15	7	

[1]n (%); Median (IQR). [2]Modified to exclude solid tumors. [3]Manual review of a random sample of 75 patients in each group.

Conclusions: Dose reduction of CDK4/6i within the first 3 months was associated with significantly higher mortality and shorter treatment duration. These findings contrast previous analyses that have shown no effect of dose reduction on treatment efficacy. Consideration of immortal time bias in this study may be a decisive reason for the disparate findings.

Background: This study aims to determine the prognostic impact of body mass index (BMI) in patients with hormone receptor-positive/human epidermal growth factor receptor 2-negative (HR+/HER2-) advanced breast cancer (ABC).

Methods: All patients (≥18 years) diagnosed with HR+/HER2- ABC who received first-line endocrine therapy with or without a cyclin-dependent kinase (CDK) 4/6 inhibitor between 2007 and 2020 in the Netherlands were identified from the Southeast Netherlands Advanced Breast Cancer Registry (SONABRE). Patients with a recorded BMI at diagnosis were classified as underweight (BMI: <18.5 kg/m^2), normal weight (18.5-24.9 kg/m^2), overweight (25-29.9 kg/m^2), or obese (≥30 kg/m^2). Progression-free survival (PFS) and overall survival (OS) were compared between BMI classes using multivariable Cox regression analyses.

Results: This study included 35 (2.4%) underweight, 580 (39.8%) normal weight, 479 overweight (32.9%), and 362 (24.9%) obese patients. The presence of bone-only metastases increased with a higher BMI, whereas the presence of visceral metastases decreased (p for trend = <0.001). When compared with other BMI classes, underweight patients had a worse WHO performance status (p = <0.001) and were more frequently diagnosed with *de novo* metastatic disease (p = 0.001). Median follow-up time was 60.9 months (interquartile range (IQR): 37.5-96.0). When compared with normal weight patients, no differences in PFS were observed in underweight (hazard ratio (HR)=1.05; 95% confidence interval (CI): 0.73-1.51), overweight (HR=0.90; 95% CI: 0.79-1.03), or obese patients (HR=0.88 (95% CI: 0.76-1.02). However, the OS of underweight patients (HR=1.45; 95% CI: 0.97-2.15) tended to be worse, whereas the OS of overweight (HR=0.99; 95% CI: 0.85-1.16) and obese patients (HR=1.04; 95% CI: 0.88-1.24) was similar to the OS of normal weight patients.

Conclusions: In this cohort of 1,456 patients with HR+/HER2- ABC, overweight and obesity were prevalent, while underweight was uncommon. When compared with normal weight patients, overweight and obese patients did not experience a decrease in either PFS or OS. Interestingly, however, underweight seemed to be an adverse prognostic factor for OS.

393P Real-world (RW) use patterns, effectiveness, and tolerability of sacituzumab govitecan (SG) for second-line (2L) and later treatment of metastatic triple-negative breast cancer (mTNBC)

K. Kalinsky[1], L. Spring[2], C. Yam[3], I. Ntalla[4], B. Stwalley[5], N. Sjekloca[6], C. Lai[7], A. Kaushiva[8], A.J. Taylor[9], R. Nanda[10]

[1]Hematology & Medical Oncology, Winship Cancer Institute, Emory University, Atlanta, GA, USA; [2]Hematology/Oncology, Massachusetts General Hospital Cancer Center and Harvard Medical School, Boston, MA, USA; [3]Department of Breast Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX, USA; [4]Real World Evidence, Gilead Sciences Europe Ltd, Stockley Park, UK; [5]US Medical Affairs, Gilead Sciences, Inc., Foster City, CA, USA; [6]Global Medical Affairs, Oncology, Gilead Sciences Europe Ltd, Stockley Park, UK; [7]Clinical Development, Gilead Sciences, Inc., Foster City, CA, USA; [8]Real World Data & Evidence, ConcertAI, Cambridge, MA, USA; [9]Real World Evidence, Gilead Sciences Europe Ltd, Stockley Park, Middlesex, UK; [10]Department of Medicine, Section of Hematology/Oncology, The University of Chicago Medicine, Chicago, IL, USA

Background: SG is a Trop-2-directed antibody-drug conjugate approved in multiple countries for patients (pts) with mTNBC after ≥ 2 prior systemic therapies (≥ 1 for metastatic disease). In the ASCENT study (NCT02574455) in pts with mTNBC, SG had superior efficacy vs single-agent chemotherapy and a manageable safety profile (Bardia et al. *NEJM* 2021). This study describes RW SG dosing and clinical outcomes in pts with mTNBC treated with SG in 2L and later in the US.

Methods: This retrospective cohort study used de-identified US electronic health records in the ConcertAI database of pts (≥ 18 y) with mTNBC treated with SG in 2L and later from April 2020 to May 2022 to allow for a 3-month minimum data accrual. Clinical outcomes (RW overall survival [rwOS], time to next treatment or death [TTNTD], and RW progression-free survival [rwPFS]) from start of SG (index date) were estimated by Kaplan-Meier methods.

Results: 230 female pts (median age 60 y, 26% Black, 17% ECOG performance status ≥ 2, 66% treated in community settings) were included in the analysis. Median follow-up was 7.2 months (IQR 3.9-11.1). SG RW outcomes for all pts and by SG line (2L and 3L+) are in the Table. Clinical outcomes were similar for all pts and stratified analyses (by race, concomitant G-CSF use, treatment-free interval duration). Of 134 pts (58%) who had G-CSF during SG treatment, 99 (74%) previously received G-CSF. Median time from SG start to G-CSF use was 8.5 days (IQR 8-29). SG was discontinued due to toxicity in 17 pts (7%).

Table: 393P

	2L mTNBC SG n = 77	3L mTNBC SG n = 153	2L+ mTNBC SG N = 230
Median rwOS (95% CI), months*†	13.9 (9.8-NE)	8.4 (7.4-10.3)	10.0 (8.3-11.1)
rwOS rate (95% CI), %			
12-month	51 (37-64)	35 (26-44)	40 (33-48)
24-month	32 (13-54)	20 (11-29)	23 (15-32)
Median TTNTD (95% CI), months†	4.8 (3.2-6.9)	4.4 (3.8-5.5)	4.6 (3.9-5.3)
Median rwPFS (95% CI), months†	4.9 (2.9-6.0)	3.5 (2.7-4.2)	3.8 (3.1-4.3)

IQR, interquartile range; NE, not estimable.
*Kalinsky et al. ASCO 2023 abstr e18879. †Measured from index date.

Conclusions: This RW analysis included patients with mTNBC treated with SG in 2L and later line settings since approval of SG in the US. SG showed survival benefit in this broad patient population. Follow-up duration was short for some pts in this analysis. As data will continue to mature over time, they will provide more insight into RW effectiveness of SG.

Background: Abemaciclib, ribociclib and palbociclib are CDK4/6 inhibitors (CDKi) that have shown benefit in combination with endocrine therapy (ET) for estrogen receptor-positive (HR+) metastatic breast cancer (mBC). We aimed to compare the effectiveness of CDKi in mBC using twang propensity weight.

Methods: We performed a retrospective study using data from patients (pts) with HR+/HER2- mBC treated with abemaciclib, ribociclib or palbociclib plus ET in endocrine sensitive and resistant setting between July 2014 and March 2022 in 24 hospitals in Italy with at least 1 year of follow up. We used multinomial propensity weight from the twang package to balance baseline characteristics across treatment groups. We estimated the hazard ratios (HR) for progression-free survival (PFS), overall survival (OS). We also compared the grade 3-4 toxicities between the three drugs.

Results: We included 1184 patients (abemaciclib n=158, ribociclib n=326, palbociclib n=700). After twang propensity weight, the treatment groups were well balanced. In the endocrine-sensitive setting PFS was not significantly different between abemaciclib and ribociclib, while palbociclib was associated with shorter PFS compared both to ribociclib (HR 1.41, 95% CI 1.21-1.66, $p<0.001$) and abemaciclib (HR 1.33, 1.12-1.58, $p=0.001$). OS in the palbociclib group was also shorter compared to abemaciclib (HR 1.75, 95% CI 1.35-2.28, $p<0.001$) and ribociclib (HR1.29, 95% CI 1.05-1.58, $p=0.014$). In the endocrine-resistant setting abemaciclib showed a longer PFS compared to ribociclib (HR 0.53, 95% CI 0.44-0.64, $p<0.001$) and albociclib (HR 0.55, 95% CI 0.46-0.66, $p<0.001$) while no difference was observed between ribociclib and albociclib. OS was not significantly different between the three CDKi. Abemaciclib was associated with higher rates of grade 3-4 diarrhea and thromboembolism, palbociclib with anemia and neutropenia, and ribociclib with liver toxicity ($P<0.001$).

Conclusions: Our study showed that abemaciclib, ribociclib in the endocrine-sensitive setting have different efficaciesin terms of PFS and OS compared to palbociclib. In the endocrine'resistant setting abemaciclib showed a better PFS compared to other agents. This evidence coupled with different toxicity profiles that may guide treatment selection.

Hoffmann-La Roche Ltd, Mississauga, ON, Canada; [10]Biomarker Scientist in Translational Medicine, Oncology Biomarker Development, Genentech, Inc., South San Francisco, CA, USA; [11]Product Development Safety, Clinical Safety Community, Genentech, Inc., South San Francisco, CA, USA; [12]Clinical Pharmacology, Genentech, Inc., South San Francisco, CA, USA; [13]Product Development Oncology., Genentech, Inc., South San Francisco, CA, USA; [14]Clinical Pharmacology Department, Genentech, Inc., South San Francisco, CA, USA; [15]Medical Oncology, Breast Cancer, Hospital Clínico Universitario, Valencia, Spain

Background: Many pts with ER+ BC experience disease relapse during/after adjuvant endocrine therapy (ET) or develop resistance due to *ESR1* mutations. G is a highly potent non-steroidal oral (PO) selective ER antagonist and degrader; IPAT is a potent, PO, AKT inhibitor. We present a 16-week IA of G vs. G + IPAT in MORPHEUS BC (NCT04802759).

Methods: Pts with disease progression on 1–2 lines of ET (including a cyclin-dependent kinase 4/6 inhibitor [CDK4/6i]) for LA/mBC were randomised 1:6 to G (30 mg PO daily [QD]) or G + IPAT (400 mg PO QD; Days 1–21 per 28-day cycle) until disease progression/unacceptable toxicity. Primary endpoints were safety and objective response rate (ORR); other endpoints included progression-free survival, overall survival, clinical benefit rate (CBR), disease control rate, duration of response and pharmacokinetics. Genetic alterations were defined using baseline circulating tumour DNA.

Results: As of 17 May 2022, eight and 24 pts (23 evaluable) were enrolled in the G and G + IPAT arms, respectively; 50% (n = 4)/75% (n = 18) received one prior line and 38% (n = 3)/25% (n = 6) received two prior tx lines for LA/mBC. In the overall population the ORR was 0%/17% (n = 4) and stable disease (SD) was 63% (n = 5)/52% (n = 12) in the G and G + IPAT arms, respectively. In pts with AKT signalling alterations (G = 3; G + IPAT = 10), ORR was 0%/30% (n = 3) and SD was 67% (n = 2)/70% (n = 7). Updated data will be presented including longer follow-up and CBR.

Table: 395P

Safety data are % of pts	G	G + IPAT
Tx-related adverse events (TRAEs) Grade 3–4	63% 0	96% 35%
AE/TRAE leading to tx discontinuation	0	9%
AEs leading to dose modification/interruption	13%	52%
Fatal AEs	0	0
Most common TRAEs (≥ 20% incidence rate)	Fatigue; insomnia	Diarrhoea; nausea; constipation; rash; vomiting

Conclusions: Encouraging activity was seen with G + IPAT in pts with disease progression on 1–2 lines of ET (including a CDK4/6i), especially in pts with AKT signalling alterations. G + IPAT was well tolerated, with no unexpected safety signals.

Clinical trial identification: NCT04802759; 17 March 2021.

396P Real-world treatment and survival outcomes in previously untreated patients with metastatic triple-negative breast cancer (mTNBC) in the United States (US)

K. Punie[1], A. Kurian[2], I. Ntalla[3], D.H. Huynh[4], N. Sadetsky[5], A. Estrin[6], E. Dabrowski[6], N. Sjekloca[7], C. Lai[8], S.A. Hurvitz[9]

[1]Medical Oncology, GZA Hospital Sint-Augustinus, Wilrijk, Belgium; [2]Department of Medicine and of Epidemiology & Population Health, Division of Oncology, Stanford University, Stanford Cancer Genetics Program, Palo Alto, CA, USA; [3]Pharmacovigilance & Epidemiology, Gilead Sciences, Uxbridge, UK; [4]Clinical Development Oncology, Gilead Sciences, Inc., Foster City, CA, USA; [5]RWE Oncology, Gilead Sciences Inc., Foster City, CA, USA; [6]Science/Delivery, Aetion Inc., New York, NY, USA; [7]Medical Affairs, Gilead Sciences Ltd, Uxbridge, UK; [8]Clinical Research, Gilead Sciences, Inc., Foster City, CA, USA; [9]Department of Medicine, Division of Hematology/Oncology, David Geffen School of Medicine, University of California, Los Angeles, CA, USA

Background: mTNBC is a clinically aggressive disease associated with poor prognosis with a median overall survival (OS) after metastasis of 15.5 mo. Despite improved survival from recent first-line (1L) therapy (Cortes et al. NEJM. 2022), most patients have disease progression. This study aims to describe the unmet need in previously untreated patients with mTNBC in the US.

Methods: This retrospective observational analysis used Flatiron Health de-identified electronic health record data. Pts (aged ≥ 18 years) with mTNBC (defined by American Society of Clinical Oncology/College of American Pathologists guidelines: HER2 IHC0, 1, or 2/ISH-negative; ER/PR negative) who initiated 1L treatment (tx) from January 2011 to May 2022 were included. Pts receiving HER2-targeted or hormone tx, or a clinical trial drug were excluded. Real-world (rw)OS and time to next tx or death (TTNTD) were calculated using Kaplan-Meier method.

Results: The study included 1764 pts (Table). Median time from diagnosis to 1L tx was 0.85 mo. Most pts received CT mono- (46.9%) or combination (36.7%) therapy (Table). Of the 1764 pts, 907 (51%) initiated second (2)L tx (33% had died) and 453 (26%) initiated 3L tx (35% had died). Median rwOS (95% CI) was 11.2 mo (10.7-12.0) with a 1- and 2-year survival rate (95% CI) of 47.5% (45.1-49.9) and 23.9% (21.7-26.1),

respectively. Median TTNTD (95% CI) for 1Ltx was 4.3 mo (4.1-4.5). Stratified analyses by year of mBC diagnosis, tx type, and other factors will be presented.

Table: 396P

Characteristic	Patient population N = 1764
Median age, (IQR), years	60 (51, 70)
Sex, female, %	99.7
Race, % White Black	57..4 20.8
Eastern Cooperative Oncology Group performance status ≥ 2, %	12.4
De novo mBC, %	30.2
1L treatment, % CT monotherapy Capecitabine Taxanes Other CT monotherapy	46.9 18.4 16.9 11.6
CT combination Carboplatin/gemcitabine Cyclophosphamide/doxorubicin Other CT combination PD-(L)1 inhibitor-based regimen	36.7 9.8 8.6 18.3 14.6
Poly (ADP-ribose) polymerase inhibitor- based regimen	0.85

Conclusions: In this rw study, most pts received CT as 1L therapy. Clinical outcomes were poor, and many pts did not receive tx after 1L due to high attrition rates between lines of therapy. These data confirm the unmet need for more efficacious tx options for pts with mTNBC in the 1L setting.

397P Efficacy and safety of the recombinant humanized anti-HER2 monoclonal antibody-MMAE conjugate RC48-ADC in patients with HER2-positive or HER2-low expressing, locally advanced or metastatic breast cancer: A single-arm phase II study

F. Qu, W. Li, Y. Yi

Oncology Department, Jiangsu Province Hospital - The First Affiliated Hospital with Nanjing Medical University, Nanjing, China

Background: Current treatment options for HER2-positive (IHC 3+, or IHC 2+/FISH+) metastatic breast cancer (MBC) at third-line and above have shown limited clinical benefit. There is no recommended HER2-targeting treatment for HER2-low expressing (IHC 2+/FISH-, or IHC 1+) population. Here, we report the efficacy and safety of RC48-ADC in patients with MBC.

Methods: Patients with HER2-positive or HER2-low expressing MBC were eligible and received RC48 2.5 mg/kg every two weeks alone or combined with drugs with different anti-tumor mechanisms, such as immune checkpoint inhibitors (ICIs), tyrosine kinase inhibitors (TKIs) and antiangiogenic compounds. The primary endpoint was the objective response rate (ORR). Secondary endpoints included progression-free survival (PFS), overall survival (OS), disease control rate (DCR) and safety.

Results: 76 female MBC patients were enrolled and treated with RC48. 58 patients (76.3%) were HER2-positive and 18 patients (23.7%) were HER2-low expressing. At baseline, 35 patients (46.0%) had liver metastases, 27 patients (35.5%) had brain metastases, and 67 patients (88.1%) had received ≥3 prior chemotherapy regimens. In the overall population, the ORR was 31.6%. The median PFS was 5.7 months. The DCR was 57.9%. In the HER2-positive subgroup, the ORR and mPFS were 34.5% and 6.3 months. In the HER2-low expressing subgroup, the ORR and mPFS were 22.2% and 3.6 months. In addition, the mPFS in the dual drug combination-treated group was longer than that in the single drug treatment group, with mPFS of 7.1 months and 4.6 months, respectively. The most frequently reported adverse events were increased AST (62.4%), increased ALT (61.9%), decreased white blood cell count (42.4%), and fatigue (30.4%), most were grade 1-2 in severity.

Conclusions: RC48-ADC showed consistent efficacy in HER2-positive and HER2-low expressing subgroups. No new safety signals were observed. Coadministration with ICIs, TKIs and antiangiogenic compounds demonstrated substantially enhanced efficacy and could be a future direction of ADC.

398P A phase Ib/II study of IN10018/FAKi in combination with pegylated liposomal doxorubicin (PLD) and toripalimab in metastatic triple-negative breast cancer (TNBC): IN10018-010

X. Hu[1], Q. Ouyang[2], M. yan[3], C. Wenyan[4], S. Cang[5], Y. Huang[6], C. Tian[2], Z. Tao[1], S. Xie[7], Y. Zhu[7], Z. Wang[7]

[1]Department of Breast and Urologic Medical Oncology, Fudan University Shanghai Cancer Center, Shanghai, China; [2]Breast Internal Medicine Department, Hunan Cancer Hospital, Changsha, China; [3]Breast Department, Henan Cancer Hospital, Zhengzhou, China; [4]Department of Breast Oncology, Nanchang People's Hospital, Nanchang, China; [5]Department of Oncology, Henan Province People's Hospital, Zhengzhou, China; [6]Department of Gynecology and Oncology, Hubei Cancer Hospital, Wuhan, China; [7]Clinical R&D Department, InxMed (Shanghai) Co., Ltd, Shanghai, China

Background: IN10018 is a highly potent and selective oral inhibitor of focal adhesion kinase (FAK). Preclinical data showed that IN10018 in combination with PLD had synergistic antitumor effect and can further enhance immunotherapeutic effect in TNBC animal model. This study was to evaluate the safety and antitumor activity of IN10018 combined with PLD +/- anti-PD-1 antibody, Toripalimab in metastatic TNBC.

Methods: All enrolled metastatic TNBCs who had failed in 1-2 lines of systemic therapy were assigned to either doublet group: IN10018+PLD or triplet group: IN10018+PLD+Toripalimab. Phase Ib-dose finding part was to identify the recommended phase II dose (RP2D) of triplet combination. Phase II-dose expansion part was to evaluate the primary endpoint of objective response rate (ORR) and secondary endpoints of disease control rate (DCR), duration of response (DOR), progression-free survival (PFS), overall survival (OS) and safety.

Results: At data cutoff of April 28, 2023, 12 pts received IN10018+PLD and 14 pts received IN10018+PLD+Toripalimab. Median follow-up duration was 7.2 mo (range: 4.9-9.7) in doublet group and 6.0 mo (range: 2.0-10.5) in triplet group. The RP2D was determined as IN10018 100mg qd + PLD 40mg/m^2 q4w + Toripalimab 3 mg/kg q2w. In doublet group, ORR by investigators was 16.7% (95% CI, 2.1-48.4); DCR was 50% (95% CI, 21.1-78.9); median PFS was 3.65 mo (95% CI, 1.77-NA); and median OS was 7.52 mo (95% CI, 5.59-NA). In triplet group, ORR by investigators was 14.3% (95% CI, 3.8-42.8); DCR was 78.6% (95% CI, 49.2-95.3); median PFS was 9.26 mo (95% CI, 3.02-NA); and median OS was not reached. No drug-related death was observed. In doublet group, TEAEs grade ≥3 occurred in 58.3% pts with TEAEs in ≥2 pts being WBC and

neutrophil count decreased; SAE occurred in 2 pts with 1 related to treatment. In triplet group, TEAEs grade ≥3 occurred in 64.3% pts with TEAEs in ≥2 pts being anemia, WBC and neutrophil count decreased; SAE occurred in 5 pts with 4 related to treatment.

Conclusions: The combination of IN10018 with PLD and Toripalimab showed promising antitumor activity in metastatic TNBC. The combination safety profile was comparable to each single agent with no additional safety signal.

Clinical trial identification: NCT05830539.

399P Results from a first-in-human phase Ia/b study of LX-039, an oral selective estrogen receptor (ER) degrader (SERD), in postmenopausal patients with ER+, HER2- advanced breast cancer (ABC)

W. Shen[1], X. Hu[2], J. Zhang[1], J. Cao[2], H. Yao[3], X. Wang[4], Y. Chen[5], Y. Du[1], Z. Tao[1], L. Wang[1], C. Hu[6], C. Li[7]

[1]Phase I Clinical Trial Center, Fudan University Shanghai Cancer Center, Shanghai, China; [2]Department of Medical Oncology, Fudan University Shanghai Cancer Center, Shanghai, China; [3]Phase I Clinical Trial Center, Sun Yat-Sen University, Guangzhou, China; [4]Department of Medical Oncology, Zhejiang Cancer Hospital - Cancer Research Institute, Hangzhou, China; [5]Breast Surgery, The Second Affiliated Hospital Zhejiang University School of Medicine, HangZhou, China; [6]Medical Oncology Department, Anhui Provincial Cancer Hospital, Hefei, China; [7]Medical Oncology Department, Xinxiang Central Hospital, Xinxiang, China

Background: LX-039 is an oral SERD that blocks ER signaling pathway through receptor antagonism and degradation. LX-039 demonstrated robust antitumor efficacy and good PK profile in preclinical studies.

Methods: This was a multi-center, open-label, first in human, dose escalation and expansion phase I study to evaluate the safety, efficacy and PK/PD profiles of LX-039 monotherapy in postmenopausal patients(pts) with histologically confirmed ER+, HER2- ABC, who had failed ≥1 line endocrine therapy and ≤2 line chemotherapy. The initial dose was 50 mg, sequentially escalated from 100 mg to 1200 mg via traditional "3+3" design. LX-039 was administrated once daily in 28-day cycles until unacceptable toxicity, progression, or withdrawal of consent. ^{18}FES PET/CT scan was undergone on baseline and day 28 after treatment. Primary endpoint was MTD, secondary endpoints included safety, efficacy, and PK/PD.

Results: 44 pts (median age 56.5, ECOG = 1: 88.6%, visceral metastasis: 77.3%) were enrolled. All pts received prior endocrine therapy (range: 1-7 lines, 56.8% fulvestrant) and/or CDK4.6i(40.9%), chemotherapy(54.5%) in the advanced setting. Two pts experienced DLTs: G3 hepatic function abnormal in 1000 mg cohort (1/6) and G4 ALT increased in 1200 mg cohort (1/1), so MTD was not reached. TRAEs were mostly grade 1-2 and experienced by ≥20% of pts were diarrhea (81.8%, G3 15.9%), ALT increased (56.8%, ≥G3 15.9%); AST increased (47.7%, G3 4.5%), fatigue (38.6%), decreased appetite (29.5%), vomiting (29.5%), nausea (27.3%), weight decreased (22.7%). Dose-dependent plasma exposure was seen with an estimated half-life of approximately 7 h. In 29 pts with measurable lesions who received 600 mg or higher doses, 4 pts (13.8%) achieved partial response, with median DOR of 7.4 months. Median PFS in the ITT population was 5.5months (95% CI: 3.5, 5.9). CBR at 24 weeks was 40.0% and DCR was 70.3%. ^{18}FES-PET scan (n = 13) showed that all patients experienced SUV_{max} decrease from baseline with a median reduction of > 70 %.

Conclusions: LX-039 was well tolerated with preliminary anti-tumor activity in ER+, HER2- ABC. RP2D was determined at 600 mg QD and a phase II trial is being planned.

Clinical trial identification: NCT04097756.

Background: Palbociclib, Ribociclib and Abemaciclib, in combination with endocrine therapy (ET), are considered the first-line treatment for hormone-responsive (HR+) disease. Breast cancer frequently metastasizes to the bone with the possible occurrence of skeletal related events (SRE, pathological fractures, hypercalcemia, radiotherapy, spinal cord compression, and orthopaedic surgery).Clinical trials have demonstrated the efficacy of these combination of treatments, but there are limited data on their effect on bone endpoints: time to SRE and skeletal Progression Free Survival (PFS).

Methods: We conducted a retrospective analysis using data from patients (pts) treated with these CDK 4/6 inhibitors (CDKIs) and ET as first- or second-line therapy between July 2014 and March 2023 in 24 hospitals in Italy. Pts had bone metastases at the treatment start. We calculated the propensity weight for each patient based on baseline characteristics using the twang package to reduce selection and confounding bias in observational analyses for the evaluation of time to SRE and Skeletal PFS.

Results: We enrolled 1139 pts (Abemaciclib n=154, Ribociclib = 316, Palbocilib= 668), 562 (49.4%) treated with Denosumab, 235 (20.7%) with zoledronic acid and 341 (30%) did not receive any anti-resorptive therapy. The radiation to the bone was the most frequent SRE that occurred in the 20% of pts. After the twang propensity weight the time to SRE (95% CI) was longer in the Acid zoledronic group than denosumab (P= 0.024). The time to SRE was longer between pts treated with zoledronic acid compared to those who did not receive any bone-targeted agent (P= 0.017). Skeletal PFS (95% CI) was longer in pts treated with zoledronic acid than to Denosumab (39 [35—39] versus 27 [25-32] months, P < 0.001) and then who don't receive therapy (39 [35—39] versus 30 [28-32] months, P < 0.001). There was no significant differences in skeletal PFS between denosumab and none therapy.

Conclusions: Our study suggests that the use of zoledronic acid may lead to a longer time to SRE and skeletal PFS compared to denosumab or no anti-resorptive therapy. These findings can be important for the management of bone metastases in pts with HR+ metastatic breast cancer. Further prospective studies are needed to confirm these results.

401P Utidelone in combination with etoposide and bevacizumab in HER2-negative breast cancer with brain metastasis (UTOBIA-BM): A prospective, single-arm, phase II trial

Y. Shi[1], P. Wang[2], Y. Zhu[1], X. Wang[1], S. Li[1], B. Zhang[3], Z. Yuan[4], J. You[4], B. Zhang[4], Y. Zheng[5]

[1]Medical Oncology Department of Breast Cancer, TMUCIH - Tianjin Medical University Cancer Institute and Hospital, Tianjin, China; [2]Department of Neurosurgery, TMUCIH - Tianjin Medical University Cancer Institute and Hospital, Tianjin, China; [3]Breast Cancer Department I, TMUCIH - Tianjin Medical University Cancer Institute and Hospital, Tianjin, China; [4]Department of Radiation Oncology, TMUCIH - Tianjin Medical University Cancer Institute and Hospital, Tianjin, China; [5]National Clinical Trial Management Office, TMUCIH - Tianjin Medical University Cancer Institute and Hospital, Tianjin, China

Background: Utidelone, a genetically engineered epothilone analogue, has been proved to be efficacious for advanced breast cancer. However, the effect of utidelone for breast cancer patients(pts) with brain metastasis has not been reported. This trial

was to assess the efficacy and safety of utidelone in combination with etoposide and bevacizumab in HER2-negative breast cancer pts with brain metastasis.

Methods: HER2-negative breast cancer pts with brain metastasis were enrolled and Simon's two-stage optimal trial design was used for this trial (NCT05781633). If more than 3 out of 13 pts show central nervous system (CNS) response, 30 more pts would be further enrolled. Utidelone (30mg/m^2, iv, d1-5), and etoposide (100mg/m^2, iv, d1-3) concurrently with bevacizumab (10mg/kg iv, d1) every 21 days for 6 cycles, with utidelone and bevacizumab maintenance until disease progression or unacceptable toxicity. The primary endpoint was CNS—objective response rate (ORR). Secondary endpoints include CNS-clinical benefit response (CBR), CNS-progression-free survival (PFS), ORR, PFS, CBR, overall survival (OS), and safety.

Results: 17 female pts with a median age of 48 years (range 34-67) were enrolled from August 11, 2022 to March 22, 2023. 11 patients are evaluable for response with median cycles of 6 (2-8) , all of whom are still under treatment. CNS-ORR, CNS-CBR, ORR, CBR were 73% (8/11), 82% (9/11), 27% (3/11) and 55% (6/11), respectively, including a pt with PR for 8 cycles. PFS and OS have not been reached due to a short follow-up time. Therefore, the trial has met the criteria to enter the second stage. The major adverse event (AE) was peripheral neuropathy (PN), primarily classified as sensory. Grade 3 PN was seen in 9% (1/11) of the total patients. Most of the treatment-related AEs were grade 1 or 2 and were considered manageable and reversible. 1 pt experienced utidelone-related dose adjustment. No treatment-related death occurred.

Conclusions: Utidelone in combination with etoposide and bevacizumab has shown anti-tumor activity and manageable toxicity in breast cancer pts with brain metastasis, and a randomized control trial is warrantied.

402P First-line ribociclib (RIB) + endocrine therapy (ET) vs combination chemotherapy (combo CT) in aggressive HR+/HER2− advanced breast cancer (ABC): A subgroup analysis of patients (pts) with or without visceral crisis from the phase II RIGHT choice study

Blochin, Ministry of Healthcare of Russian Federation, Moscow, Russian Federation; [10]Oncology, Independent Patient Advocate, Amman, Jordan; [11]Oncology, Novartis Pharma AG, Basel, Switzerland; [12]Oncology, Novartis Pharmaceuticals Corporation, East Hanover, NJ, USA; [13]Clinical Development & Analytics, Novartis Pharmaceuticals Corporation, East Hanover, NJ, USA; [14]Department of Oncology, NTUH - National Taiwan University Hospital, Taipei City, Taiwan

Background: RIGHT Choice showed a statistically significant median progression-free survival (mPFS) benefit of ≈1 yr with first-line RIB + ET vs combo CT (HR, 0.54; P=.0007) in pts with aggressive HR+/HER2− ABC. As visceral crisis indicates need for a more rapidly efficacious treatment (tx), a subgroup analysis by visceral crisis status was performed.

Methods: Pre/perimenopausal pts (N=222) with no prior systemic therapy for aggressive HR+/HER2− ABC were randomized 1:1 to RIB + letrozole/anastrozole + goserelin or physician's choice of combo CT. Visceral crisis assessment was based on physician's judgment, following ABC 3 guidelines available at the time.

Results: Overall, 116 (RIB + ET, n=61; CT, n=55) and 106 (RIB + ET, n=51; CT, n=55) pts presented with or without visceral crisis, respectively. In pts with visceral crisis, a mPFS of 12.9 mo was seen with RIB + ET vs 11.2 mo with combo CT (HR, 0.87). While in these pts the overall response rate (ORR) numerically favored RIB + ET, the time to treatment failure (TTF) and clinical benefit rate (CBR) were similar in both tx arms (Table). In pts with no visceral crisis, a mPFS benefit was seen with RIB + ET vs combo CT (24.0 vs 12.7 mo; HR, 0.34); also, TTF and CBR favored RIB + ET over combo CT. RIB + ET was associated with lower rates of symptomatic adverse events than combo CT in both groups. These interim results are based on the 12 Apr 2022 data cutoff; final results will be shown at ESMO 2023.

Conclusions: This analysis shows similar PFS and TTF outcomes but greater ORR with RIB + ET vs combo CT in pts with physician-assessed visceral crisis. Clinically meaningful tx benefit with RIB + ET over combo CT was seen in pts with aggressive disease not classified as visceral crisis. These findings support RIB + ET over combo CT in pts with aggressive ABC even in the presence of visceral crisis.

Clinical trial identification: NCT03839823.

403P Breast cancer specific survival (BCSS) in HR+/HER2- metastatic breast cancer (mBC) from 2010 to 2019

A.M. Brufsky[1], M. Kwan[2], R. Sandin[3], S. Karanth[4], A. Cha-Silva[5], D. Makari[6], S. Stergiopoulos[5], R. Goyal[7]

[1]Division of Hematology/Oncology, Comprehensive Breast Cancer Center, University of Pittsburgh Medical Center, Pittsburgh, PA, USA; [2]Division of Research, Kaiser Permanente, Oakland, CA, USA; [3]Outcomes Research, oncology, Pfizer - Sweden, Sollentuna, Sweden; [4]Health Economics, RTI Health Solutions - Headquarters, Research Triangle Park, NC, USA; [5]Global Access and Value, Pfizer Inc, New York, NY, USA; [6]Medical Affairs Dept., Pfizer, Cambridge, MA, USA; [7]Health Economics, RTI Health Solutions, Research Triangle Park, NC, USA

Background: Treatment advances, e.g., CDK 4/6 inhibitors (CDK 4/6is) have become standard of care over time in HR+/HER2- mBC in the US since the first approval in 2015. However, whether survival has improved in this patient population post 2015 has not been studied.

Methods: This retrospective study used Surveillance, Epidemiology, and End Results (SEER) registry data to assess BCSS in HR+/HER2- mBC patients from 2010-2019. Kaplan-Meier and Cox Proportional Hazards (CPH) models were used to compare BCSS in two patient cohorts: those diagnosed before (2010-2013 with follow-up [FUP] to 2014), and after (2015-2018 with FUP to 2019) guideline recommendations for CDK 4/6i use.

Results: A total of 11,467 women with de novo HR+/HER2- mBC with a mean age at diagnosis of 62.3 years were included. Unadjusted median BCSS was 39 months for patients diagnosed post 2015 (95% CI: 38-42) and 35 months for patients diagnosed pre 2015 (95% CI: 33-37). After adjusting for age, race & ethnicity, SEER geographic region and site, household income, and marital status, patients diagnosed post 2015 had a 10% reduced risk of BC specific death compared with patients diagnosed pre 2015 (hazard ratio [HR]: 0.90, p<0.01, Table).

Table: 403P Multivariable Analysis of Predictors of BCSS (CPH)*

Variable	HR	95% CI

Significant at **p<0.05 and ***p<0.01
Ref: Referent

Conclusions: Using the largest US population-based longitudinal dataset, we observed improvements in BCSS post 2015 in patients with HR+/HER2- mBC. While the limitations of the current analysis prevent attribution to specific treatments, advances such as the introduction of CDK 4/6is in HR+/HER2- mBC may have contributed to population-level improvement in BCSS over time. This is consistent with other RWE studies that have shown an association between CDK4/6i treatment and improved survival.

Background: Birociclib is a selective inhibitor of cyclin-dependent kinase (CDK) 4 and 6. This phase II study (NCT04539496) was to evaluate the efficacy and safety of birociclib as single-agent in patients with refractory HR+/HER2- metastatic breast cancer (MBC).

Methods: The patients with $HR^+/HER2^-$ MBC who had progressed after prior endocrine therapy and 1-2 prior chemotherapy regimens in the metastatic setting were eligible. Birociclib 480 mg was administered orally on a continuous schedule twice daily until disease progression or unacceptable toxicity. The primary endpoint was objective response rate (ORR) assessed by Independent Reivew Committee (IRC) per RECIST v1.1. Other endpoints included investigator-assessed ORR,duration of response (DoR), progression-free survival (PFS), overall survival (OS) and safety,etc.

Results: 131 patients were enrolled from 29 hospitals in China between 10/2020 and 08/2021. As of Nov 30, 2022, the median duration of follow-up was 19.0 months. Median duration of treatment was 6 months. The majority (84.7%) patients had visceral metastasis, 60.3% of patients had ≥3 metastatic organs. In the metastatic setting, patients had received a median of 3 prior systemic therapies including a median of 1 chemotherapy regimen and 2 endocrine therapy regimens. The main results are shown in the table.

Table: 404P Responses according to RECIST v1.1

BOR n(%)	IRC-assessed N=131	Investigator-assessed N=131
CR	0	1 (0.8)
PR	38 (29.0)	29 (22.1)
ORR (%)[95% CI]	29.0 [21.4, 37.6]	22.9 [16.0, 31.1]
DCR (%)[95% CI]	73.3 [64.8, 80.6]	66.4 [57.6, 74.4]
CBR (%)[95% CI]	42.0 [33.4, 50.9]	39.7 [31.3, 48.6]
mDoR (m) [95% CI]	14.8 [9.5, 16.7]	13.1 [9.4, 14.8]
mPFS (m) [95% CI]	11.0 [7.3,12.9]	8.3 [5.5, 9.3]
mOS (m) [95% CI]	24.3 [24.3, -]	
24m OS rate	62.9%	

The most common treatment-emergent adverse events (TEAEs) were gastrointestinal and hematological toxicity, common to CDK4/6 inhibitors. Most of these AEs were grade 1-2, and manageable with supportive treatments.

Conclusions: In patients with refractory HR+/HER2- MBC who have previously received chemotherapy and endocrine therapy, continuous dosing of single-agent birociclib exhibited promising and sustaining clinical activity with manageable toxicities, thus it provides an alternative orally single-agent therapy.

Clinical trial identification: NCT04539496.

Background: E7389-LF is a liposomal formulation of eribulin being tested as 1L chemotherapy in pts with advanced HER2− BC. In an open-label phase 1 study of E7389-LF, a dose-escalation part determined a recommended regimen of 2.0 mg/m^2 once every 3 weeks (Q3W). Here, we present efficacy and safety data from the dose-expansion part in Japanese pts with confirmed metastatic HER2− BC who had not received prior chemotherapy for locally advanced/metastatic disease.

Methods: E7389-LF was administered at 2.0 mg/m^2 Q3W until disease progression, development of unacceptable toxicity, or withdrawal of consent. Efficacy endpoints included objective response rate (ORR), progression-free survival (PFS), and overall survival (OS). Tumors were assessed by investigators per RECIST v1.1. Additionally, a subanalysis was conducted in pts with luminal BC (hormone receptor-positive [HR+]) and in pts with triple-negative BC (TNBC) who were programmed-death ligand 1-negative (PD-L1−). Adverse events (AEs) were monitored and recorded, and serum biomarkers were explored.

Results: At the data cutoff date (October 26, 2022), of 26 pts who received E7389-LF, 10 (38.5%) had ongoing treatment; 16 pts discontinued due to either disease progression (13 [50%]), AEs (2 [7.7%]), or pt choice (1 [3.8%]). Median age was 59 y (range 35−77); 19 pts (73.1%) had ECOG-PS 0; 22 pts (84.6%) were HR+; 4 pts (15.4%) had TNBC and were PD-L1−. ORR was 30.8% overall (HR+: 27.3%; TNBC and PD-L1−: 50%). Median PFS was 8.1 months (95% CI 4.4−11.1). Median OS was not reached (95% CI not estimable). Treatment-emergent AEs (TEAEs) led to dose reduction in 15 pts and drug discontinuation in 2 pts. TEAEs of grade ≥3 occurred in 25 pts (96.2%), most commonly (>40%) neutropenia (n=20, 76.9%) and leukopenia (n=11, 42.3%). Of 7 pts given prophylactic pegylated granulocyte-colony stimulating factor (peg-GCSF), 0 developed febrile neutropenia (FN). Of the 19 pts without peg-GCSF, 2 (10.5%) had FN. Changes in vasculature- and IFNγ-related serum markers were noted.

Conclusions: E7389-LF showed promising efficacy and a manageable toxicity profile and should be explored as a 1L treatment option for pts with advanced HER2− BC.

Clinical trial identification: NCT03207672.

Background: Nadunolimab (Nad; CAN04) is an ADCC-enhanced IgG1 antibody targeting IL-1 Receptor Accessory Protein (IL1RAP) expressed on tumor and stroma cells. Nad blocks downstream IL-1 signaling, including both IL-1α/β signaling. Nad has shown promising clinical activity in PDAC and NSCLC studies. Among breast cancer subtypes, TNBC has the highest IL1RAP expression. TRIFOUR is a phase 1b/randomized phase 2 trial to evaluate NadGC in mTNBC patients (pts). Preliminary safety and efficacy from the phase 1b dose-escalation are presented. Analysis of immunological biomarkers are ongoing.

Methods: Standard 3+3 dose-escalation design was used for phase 1b. mTNBC pts received NadGC on days 1 and 8, in cycles of 3 weeks. Two dose levels (DLs) of Nad (DL1=1 mg/kg; DL2=2.5 mg/kg) were evaluated with standard G (1000 mg/m2) and C (area under the curve 2 mg/mL/min). Nad DL2 was considered the target dose and further dose escalation was not planned.

Results: Phase 1b recruitment is completed with 15 stage IV female pts. Median age was 50 years (32-69), six pts (40%) were pre-/perimenopausal, 14 pts (93%) had visceral disease. BRCA1/2 was known in 47% and was wild type in all. All pts but one received prior (neo)adjuvant therapy; four pts had received platinum. 33% received NadGC as first-line for mTNBC. Overall, 13 patients were evaluable for the DLT period (3 DL1, 10 DL2). Two patients had DLT, both in DL2: one Grade (Gr) 3 febrile neutropenia and one delay >1 week in C2D1 due to Gr3 neutropenia. Gr3/4 AEs in >one pt were neutropenia 47%, thrombocytopenia 33%, anemia 20% and febrile neutropenia 13%. All were considered related by the investigator. At data cut-off, seven pts were still on treatment. Efficacy analysis was available in 12 pts with 1 CR and 5 PR; overall response rate 50% (95% CI: 21-79%).

Conclusions: Nadunolimab at 2.5 mg/kg plus standard G and C is well tolerated and shows promising antitumor activity. Neutropenia is the most frequent toxicity but does not limit treatment. The randomized phase 2 part is currently enrolling with the 2.5 mg/kg dose.

Nadunolimab at 2.5 mg/kg plus standard G and C is well tolerated and shows promising antitumor activity. Neutropenia is the most frequent toxicity but does not limit treatment. The randomized phase 2 part is currently enrolling with the 2.5 mg/kg dose.

Clinical trial identification: NCT05181462.

Background: CDK4/6 inhibitors plus endocrine therapy (ET) are the first-line (1L) standard for patients (pts) with HR+/HER2- advanced breast cancer (ABC). Data from clinical trials have shown high efficacy and good tolerability. Real World Studies are important to support these data and close potential knowledge gaps.

Methods: The prospective, non-interventional PERFORM study is going to enroll 1,900 pts from 320 sites across Germany and Austria to gain further insights on effectiveness, tolerability, patient-reported outcomes (PRO) and longitudinal treatment patterns after 1L treatment with palbociclib + ET. In this second interim analysis (IA 2), response rates and dose modifications in the total population and in age-related subgroups (≥75 years vs <75 years) were investigated.

Results: Between 10/2020 and 09/2022, 938 pts were enrolled and 624 pts had a follow-up of >6 months and were evaluable for analysis. The median age was 68 years (range 33-89), 39% of pts had *de novo* ABC and 11% ECOG ≥2, at inclusion. 30% of patients were ≥75 years of age. Of these, 22% had an ECOG performance status of ≥2 at inclusion compared to 7% of pts <75 years. The rate of *de novo* ABC was higher in pts ≥75 years (44%) than pts <75 years (36%), whereas the number and

distribution of metastases was comparable. Progression-free survival (PFS) rate at 12 months was 71.7%; overall response rate (ORR) and clinical benefit rate (CBR) were 33.2% and 57.4%, respectively. Notably PFS, ORR and CBR were consistent across age groups. Dose modifications were performed in 74.1% of pts ≥75 years vs 61.5% of pts <75 years, respectively; >70% of pts in both subgroups are still on study treatment. Treatment discontinuation rates were comparable in both age groups (28.6% ≥75 years vs 27.3% <75 years), but (serious) adverse event as reason for treatment discontinuation was more frequent in pts ≥75 years (9.2% vs 3.0%).

Conclusions: The IA 2 of PERFORM shows comparable results regarding PFS, ORR and CBR of 1L treatment with palbociclib + ET in pts ≥ and <75 years, even though pts ≥75 years required dose modifications more frequently. These findings are in line with the data of clinical trials and support use of palbociclib based treatment independent of age.

408P Proxalutamide plus endocrine therapy as a combination therapy in women with HR+/HER2-/AR+ metastatic breast cancer: A phase I study

H. Li[1], H. Jiang[1], G. Song[1], R. Ran[1], J. Wang[1], X. Wang[2], J. Huang[2], J. Feng[3], L. Zhang[3], A. Zang[4], H. Yang[4], Y. Pan[5], X. He[6], M. Donng[6], Y. Tong[7], Z. Wang[8], Z. Shao[8]

[1]Department of Breast Oncology, Peking University Cancer Hospital and Institute, Beijing, China; [2]Department of Medical Oncology, Zhejiang Cancer Hospital - Cancer Research Institute, Hangzhou, China; [3]Department of Medical Oncology, Jiangsu Cancer Hospital, Nanjing, China; [4]Department of Medical Oncology, Affiliated Hospital of Hebei University, Hebei, China; [5]Department of Medical Oncology, Anhui Provincial Hospital, Hefei, Anhui, China; [6]Department of Clinical Research, Suzhou Kintor Pharmaceuticals Inc., Suzhou, China; [7]Suzhou Kintor Pharmaceuticals Inc., Suzhou, China; [8]Department of Breast Oncology, Fudan University Shanghai Cancer Center, Shanghai, China

Background: This phase I clinical study aimed to assess the safety, efficacy and pharmacokinetic (PK) characteristics of proxalutamide, in combination with Endocrine therapies (ETs), in hormone-receptor (HR)+/human epidermal growth factor receptor 2 (HER2-)/AR+ metastatic breast cancer (mBC).

Methods: In part 1 of the study, patients who progressed on multiple lines of therapy (≥1) were enrolled. Monotherapies were initiated including letrozole (2.5 mg/day on days 1-14) for cohort A, exemestane (25 mg/day on days 1-14) for cohort B, and fulvestrant (intramuscularly 500 mg once on days 1, 15 and 28) for cohort C, followed by proxalutamide 200 mg QD and ETs for in a 28-day cycle. In part 2 of the study, patients who either progressed on or were not tolerant to the first-line therapy were enrolled to receive proxalutamide 200 mg QD plus fulvestrant [cohort D] at a dose of 500 mg once on days 1 and 15 and day 1 of each cycle thereafter. The primary endpoint is safety and tolerability. PK and antitumor activity were also assessed.

Results: Between June 18, 2019 and Sep 5, 2022, 37 (17 in part 1 and 20 in part 2) patients received the combination therapy. No DLTs or drug-related SAEs were reported. The commonly reported Grade ≥3 TEAEs were neutrophil count decreased (3/37, 8.1%), hypokalemia (3/37, 8.1%) and bone marrow suppression (3/37, 8.1%). 6 (15.8%) patients on proxalutamide plus fulvestrant achieved a partial response and 13 (34.2%) patients had stable disease, with an overall disease control rate of 50.0% (95% CI, 33.4%—66.6%; 38.9% in part 1 and 60.0% in part 2). The overall median PFS was 6.4 months (95% CI, 2.7-19.3) for cohort C and 11.0 months (95%CI: 5.5-NA) for cohort D. PK profiles indicated rapid absorption of proxalutamide following a single dose. After multiple doses, proxalutamide and its major metabolite reached steady-state serum concentration levels at day 29 and exhibited a tendency for drug accumulation.

Conclusions: This study suggested a good antitumor activity and safety profile of the combination therapy of proxalutamide and fulvestrant for HR+/HER2-/AR+ mBC patients in the ≥2nd-line settings. Moreover, it may provide survival benefits for these patients, warranting further investigation in a larger population.

Background: RIB+ET has demonstrated a statistically significant survival benefit across three phase 3 MONALEESA trials, irrespective of menopausal status, line of therapy, or combination partner. RIBANNA (CLEE011ADE03), a prospective, noninterventional study assessing the efficacy and safety of 1st-line treatment options including RIB+ET in pre-, peri- and postmenopausal women with HR+, HER2— ABC is ongoing in Germany since October 2017. In this 5th IA from RIBANNA, efficacy, safety, and tolerability for elderly pts will be presented.

Methods: Pts were included in accordance with the German tx guideline. For individual age subgroups (≤75 years; >75-80 years; >80 years) efficacy of RIB+ET vs. endocrine monotherapy will be compared by adjusting for baseline characteristics including Charlson comorbidity index. Furthermore, data for patient-reported outcomes (PRO) and treatment-emergent adverse events including time to onset, frequency, dose adjustment and outcome will be analyzed.

Results: At data cutoff Sep 6, 2022, for age subgroup ≤ 75 years, >75-80 years and for age subgroup >80 years data from n=1377 (RIB+ET) respectively n=109 (ET), n=281 (RIB+ET) respectively n=42 (ET), and n=153 (RIB+ET) respectively n=41 (ET) are available. The mean Charlson comorbidity index (standard deviation [SD]) increases with increasing age subgroup in the RIB+ET cohort (0.5 [1.2]; 0.8 [1.4]; 0.8

[1.3]) vs. ET cohort (0.6 [1.2]; 0.9 [1.5]; 0.9 [1.4]) respectively. Excluding interruptions, the mean daily RIB dose decreases with increasing age subgroups (527.7 mg vs. 504.8 mg vs. 471.3 mg). Most relevant differences in mPFS are seen in subgroup >75-80 (HR=0.555; 95% CI: 0.307-1.001; p=0.05). Overall number of treatment-emergent adverse events (all grade) in the RIB+ET cohort were similar between age subgroups (32.33% vs. 29.34% vs. 25.71%).

Conclusions: RIBANNA study showed diverse population characteristics among pts who received RIB tx in a real-world setting. For investigated age subgroups RIB+ET showed high efficacy over ET alone with manageable safety profile without new signals in the clinical routine.

410P Patients treated with pertuzumab followed by T-DM1 for breast cancer in France from 2014 to 2021: A survival analysis of 10,408 patients from the French National Hospital discharge summary database (PMSI)

J. Lemaitre[1], E. Chazard[2], P-Y. Cren[1], L. Lebellec[3], N. Penel[1], C. Cheymol[4]

[1]Medical Oncology, Centre Oscar Lambret, Lille, France; [2]CERIM, CHU Lille - Centre Hospitalier Régional Universitaire de Lille, Lille, France; [3]Hauts de France, Centre Oscar Lambret, Lille, France; [4]Centre Oscar Lambret, Lille, France

Background: Breast cancer represents a major public health issue in which numerous therapeutic advances have been made, particularly for those with HER2 overexpression. The standard of care until mid-2022 has been based on the combination of Trastuzumab - Pertuzumab - Docetaxel in first line, followed by T-DM1 in second line. Limited data are available on survival outcomes of patients receiving these treatments in a real-life setting. We aimed to analyse them in this study.

Methods: We searched the French PMSI (French National Hospital Discharge Summary Database) database and extracted 10,408 patients treated with Pertuzumab between 2014 and 2021, with a C50* code (coding for breast cancer) and with an index stay in a public or private non-profit hospital. We then extracted administrative data, comorbidities, types of metastases and survival. We collected and analyzed the same data for patients receiving T-DM1 after Pertuzumab.

Results: Median survival for patients treated with Pertuzumab was not reached at time of analysis (February 2023). Survival rate at 5 years was 61.9 % (CI95% [60.6, 63.1]). Several risk factors were identified : an intensive care unit stay, age and a code for hydroelectrolytic disorders, metastases (particularly cerebromeningeal, liver, bone, and lung metastases), infection, diabetes, undernutrition and cytopenias. Median survival for patients treated with T-DM1 after Pertuzumab was 2.8 years (CI95% [2.65, 2,99]), with a 5-year survival rate of 36.9% (CI95% [34.6 , 39.4]). Risk factors were : a code for liver or cerebromeningeal metastases, undernutrition, and age.

Conclusions: To our knowledge, this is the largest real-life cohort of patients with breast cancer treated with Pertuzumab followed by T-DM1, and our results are consistent with available data, both from the lead CLEOPATRA and EMILIA studies and other retrospective studies.

Background: RIBANNA (CLEE011ADE03) is a prospective, noninterventional study assessing the efficacy and safety of RIB+AI/FUL, endocrine therapy (ET) alone, or chemotherapy (CT) in 1L and subsequent therapy lines in pre-, peri- and postmenopausal women with hormone receptor-positive, human epidermal growth factor receptor-2-negative advanced breast cancer. Herein we present real-world data on therapy management for RIB, including therapy-related adverse events (AEs), dose adjustment, and efficacy outcomes in special subgroups resulting from the 5th IA from RIBANNA.

Methods: Pre-, peri- and postmenopausal patients within the study were treated according to German treatment guidelines. For the RIB cohort the number of dose adjustments, reason and time until dose adjustment and/or discontinuation will be presented. Effectiveness analysis for PFS in 1L will be performed for patients with and without dose adjustments. Safety analysis and the median time to toxicity will be explored, with focus on AEs of special interest (AESIs): liver toxicity, cardiac events and neutropenia.

Results: At data cutoff Sep 6, 2022, 2581 patients were enrolled in the study (RIB+AI/FUL, n = 2163; ET, n = 237; CT, n = 181). The mean RIB exposure (standard deviation [SD]) in 1L was 597.7 [459.2] days with a mean daily dose of 280.7 [132.3] mg/day and 519.1 [117.4] mg/day including and excluding interruptions, respectively. The unadjusted KM estimate for median PFS was 32.2 months (95% CI, 29.3—34.8) in the RIB + AI/FUL cohort. Regarding the AESIs (all grade): an increased alanine- and aspartate-aminotransferase was recorded in 3.9% (78) and 3.8% (75) of patients, respectively. Similarly, 3.7% (73) of patients had a prolonged QT interval on the electrocardiogram. Neutropenia was documented for 25.8% (511) of the patients, being one of the most frequent treatment-emergent adverse events.

Conclusions: The RIBANNA study encompasses a diverse patient population receiving RIB therapy. Data on the 1L therapy management in real-world settings including dose adjustments, efficacy in special populations and safety will be presented at the conference.

412P Sacituzumab govitecan versus chemotherapy for metastatic breast cancer: A meta-analysis on safety outcomes

A. Rizzo[1], L. Rinaldi[1], R. Massafra[1], A. Cusmai[1], D.C. Guven[2], D. La Forgia[1], A. Latorre[1], F. Giotta[1]

[1]Oncological Institute, Istituto Tumori Bari Giovanni Paolo II - IRCCS, Bari, Italy; [2]Department of Medical Oncology, Hacettepe University Oncology Hospital, Ankara, Turkey

Background: Although Sacituzumab Govitecan (SG) had a manageable safety profile across clinical trials, this antibody-drug conjugate (ADC) has a specific set of treatment-related adverse events, which may limit adherence to treatment. However, few data are available regarding the comparison of SG versus chemotherapy in breast cancer (BC) patients. Herein, we performed a systematic review and meta-analysis aimed to systematically compare the safety profile of SG versus chemotherapy in phase II and III metastatic BC (mBC) clinical trials.

Methods: Following the Preferred Reporting Items for Systematic Reviews and Meta-analyses (PRISMA) guidelines, all phase II and III randomized clinical trials that compared SG versus chemotherapy in mBC patients were retrieved. The outcomes of interest were grade 3-4, and all grade neutropenia, leukopenia, anemia, nausea, diarrhea, and fatigue in clinical trials comparing SG versus chemotherapy for mBC patients. The risk of alopecia, febrile neutropenia, and treatment discontinuation rate were also assessed.

Results: Two eligible trials were selected in this meta-analysis, encompassing a total of 999 patients (SG=526; chemotherapy=473). The pooled Odds Ratios (ORs) for outcomes such as grade 3-4 and all grade neutropenia, leukopenia, anemia and other nonhematological adverse events showed a higher risk for patients receiving SG versus chemotherapy. No statistically significant differences were observed in grade 3-4 fatigue, all grade nausea, febrile neutropenia and treatment discontinuation due to adverse events.

Conclusions: Despite our research revealing the presence of a higher risk of some adverse events in patients receiving SG than those treated with chemotherapy (e.g., diarrhea), our pooled results suggested no statistically significant differences in terms of treatment discontinuation and febrile neutropenia, which is commonly considered an important and often life-threatening event. Our data, coupled with a statistically significant and clinically meaningful survival benefit, support the use of SG as an important therapeutic option for mBC. Further analysis is needed in the future, and real-world evidence is required to better explore this topic.

413P Characteristics of patients (pts) with previously treated, oestrogen receptor-positive, HER2-negative advanced breast cancer (ER+, HER2− aBC) who had rapid progression (RP) in acelERA BC

M. Martin Jimenez[1], S. Hilz[2], A. Collier[2], A. Chibly[3], J. Sohn[4], A. Bardia[5], E. Lim[6], M. Chavez Mac Gregor[7], J. Martinalbo[8], P.D. Pérez-Moreno[9], H.M. Moore[2]

[1]Hospital Gregorio Marañón, Universidad Complutense, GEICAM, CIBERONC, Madrid, Spain; [2]Oncology Biomarker Development, Genentech, Inc., South San Francisco, CA, USA; [3]Bioinformatics, Genentech, Inc., South San Francisco, CA, USA; [4]Department of Internal Medicine, Yonsei University, Seoul, Republic of Korea; [5]Massachusetts General Hospital, Harvard Medical School, Boston, MA, USA; [6]Garvan Institute of Medical Research, St Vincent's Clinical School, University of New South Wales, Darlinghurst, NSW, Australia; [7]Department of Health Services Research, Division of Cancer Prevention and Population Sciences, The University of Texas MD Anderson Cancer Center, Houston, TX, USA; [8]Oncology Drug Development, F. Hoffmann-La Roche Ltd, Basel, Switzerland; [9]Product Development Oncology, Genentech, Inc., South San Francisco, CA, USA

Background: The phase II acelERA BC study (NCT04576455) compared the oral, selective ER antagonist and degrader (SERD) giredestrant (G) with physician's choice of endocrine therapy (PCET) in previously treated ER+, HER2− aBC. G was not superior to PCET for progression-free survival (PFS) despite a numerical improvement, which was more pronounced in pts with *ESR1* mutations (m). RP (PFS <3 months) has been noted in pts with late-line aBC receiving ET, including oral SERDs. We present exploratory biomarker analyses of circulating tumour (ct)DNA dynamics and characteristics of pts with RP.

Methods: Baseline and Cycle 2, Day 1 ctDNA was evaluated by FoundationOne Liquid CDx. Gene expression was profiled by RNAseq on tumour tissue representing the post-first-line setting (>30 days after aBC diagnosis).

Results: As of 15/07/22, 87/293 pts (30%) with evaluable PFS (10 censored within the first 3 months) had RP. RP did not differ by arm: G 42/145 (29%); PCET 45/148 (30%). Pts with RP were more likely to have received a prior CDK4/6 inhibitor (i; 61% vs. 33%; $p < 0.01$). In pts with *ESR1*m, 35/88 (40%) had RP vs. 30/137 (22%) in pts without. Comparing RP vs. non-RP in pts with *ESR1*m: G2M checkpoint, E2F target and ER gene expression signatures were among those decreased; the proportion of Luminal A PAM50 subtype was increased; and baseline ctDNA levels were significantly higher for pts with RP ($p < 0.01$), with enrichment of *DNMT3A*, *PIK3CA* and *RB1* mutations vs. non-RP. Among pts with *ESR1*m regardless of RP status, those who were CDK4/6i-naive showed meaningful increases in gene pathways associated with inflammatory processes, including IFNα ($p < 0.01$), IFNγ ($p < 0.01$) and IL6 ($p = 0.03$) vs. those with prior CDK4/6i. PFS was improved in pts with undetectable *ESR1*m levels on-treatment, compared with those whose levels increased ($p = 0.03$).

Conclusions: Data suggest that RP occurs regardless of *ESR1*m and is associated with prior CDK4/6i treatment and higher tumour burden, as measured by ctDNA levels. In pts with *ESR1*m, distinct signalling and mutational profiles were observed, dependent on RP status and prior CDK4/6i. Additional observations will inform ongoing pt selection and drug combination research.

Clinical trial identification: NCT04576455; 6 October 2020.

414P Trastuzumab deruxtecan for HER2-positive breast cancer brain metastasis: A systematic review and meta-analysis

I.F. Michelon[1], M. Silveira Vilbert[2], A.D. Marinho[3], C.E.D.R. Castro[4], M.I. Dacoregio[5], C. Stecca[6], L.R. Soares[7]

[1]Medicine Department, Catholic University of Pelotas, Pelotas, Brazil; [2]Department of Clinical Oncology, UHN - University Health Network - Princess Margaret Cancer Center, Toronto, ON, Canada; [3]Medicine, HUGG - UNIRIO - Hospital Universitario Gaffree e Guinle, Rio De Janeiro, Brazil; [4]UnB - Universidade de Brasília - Faculdade do Gama (FGA), Brasilia, Brazil; [5]Medicine, Universidade Estadual do Centro Oeste, Guarapuava, Brazil; [6]Department of Medicine, Center of Oncology of Parana, Curitiba, Brazil; [7]Mastology Program, Federal University of Goias, Goiania, Brazil

Background: Brain metastases (BMs) affect approximately half of the patients with human epidermal growth factor receptor 2 (HER2)-positive breast cancer (BC) and holds a poor prognosis. Trastuzumab deruxtecan (T-DXd), an antibody-drug conjugate, has shown promising results in patients with breast cancer brain metastases (BCBMs). Thus, we conducted a systematic review and meta-analysis to evaluate the effectiveness and safety of T-DXd in the HER2-positive BCBM population.

Methods: We searched PubMed, Embase, and Cochrane Library databases, as well as ASCO, ESMO, and SABCS websites for clinical trials (CTs) and observational studies evaluating T-DXd in the HER2-positive BCBM patients. Heterogeneity was assessed with the Cochran Q test and I2 statistics. Random effects models were used for all statistical analyses, which were performed using R software (v.4.2.2).

Results: Ten studies were included, six clinical trials (N=189) and four observational studies (N=147), with a total of 336 patients. The mean progression-free survival was 15 months (95% CI 13.9 to 16.1 months). The objective response rate (ORR) was 61% (95% CI 53-68%), and the intracranial (IC)-ORR was 62% (95% CI 55-70%). No significant differences in ORR and IC-ORR were observed between CTs and observational studies (p=0.56, and p=0.46, respectively). The clinical benefit rate (CBR) was 86% (95% CI 72-94%), and the IC-CBR was 69% (95% CI 59-79%). The ORR was 64% (95% CI 53-73%) in the subgroup of patients with stable BMs and 61% (95% CI 49-73%) in patients with active BMs, with no significant difference between groups (p=0.78). Adverse events (AE) of any grade were reported in 98% of cases (95% CI 90-100%). Dose reduction and drug interruption due to AE were reported in 29% (95% CI 10-60%) and 31% (95% CI 19-42%) of cases, respectively.

Conclusions: Our systematic review and meta-analysis supports the intracranial activity of T-DXd in both patients with stable BM and active BM. HER2-positive BCBM patients treated with T-DXd achieved ORR and IC-ORR higher than 50% in the clinical trials setting and in real-world data.

415P Patterns of time-to-progression intervals across clinical and liquid biopsy (LB) features in hormone receptor-positive (HR+) HER2-negative (HER2-) metastatic breast cancer (MBC) patients (pts) treated with first-line endocrine therapy (ET)

L. Cucciniello[1], C. Noto[1], S. Bolzonello[2], E. Molteni[1], L. Da Ros[2], B. Pastò[1], A. Franzoni[3], S. Spazzapan[2], S. Russo[5], L. Foffano[1], S. Buriolla[1], G. Targato[1], L. Allegri[1], A. Dri[1], S. Della Rossa[1], M. Bonotto[4], G. Damante[1], B. Belletti[5], L. Gerratana[2], F. Puglisi[2]

[1]Dipartimento di Area Medica, University of Udine, Udine, Italy; [2]Unit of Medical Oncology and Cancer Prevention, IRCCS CRO, Aviano, Italy; [3]Institute of Human Genetics, ASU FC - Azienda Sanitaria Universitaria Friuli Centrale, Udine, Italy; [4]Department of Oncology, Santa Maria della Misericordia University Hospital, Azienda Sanitaria Universitaria Friuli Centrale (ASUFC), Udine, Italy; [5]Molecular Oncology, IRCCS CRO, Aviano, Italy

Background: ET + a CDK 4/6 inhibitor (CDK4/6i) is the standard first-line therapy (1L) for HR+ HER2- MBC. Currently, imaging schedules are arbitrarily derived from clinical trials without margins of personalization. Aim of this study was to analyze the role of clinical and LB features in defining patterns of progression in HR+ HER2- MBC.

Methods: Pts were enrolled in the prospective multicenter CRO-2018-56 trial from January 2018 to January 2023. Serial CT scans and LB were performed. Prognostic factors were tested in terms of progression free survival (PFS) and overall survival (OS) through stepwise Cox regression. Progression distribution was estimated through smoothed hazard function.

Results: Of the 114 enrolled pts, 35% had *de novo* MBC, 15% invasive lobular carcinoma (ILC), 75% PgR+ disease. Bone was the most common metastatic site (75%). Most pts (96%) received ET + CDK4/6i (54% palbociclib, 37% ribociclib, and 9% abemaciclib). At baseline LB, 10% had *ESR1*-mutant (mut) MBC, 24% *PIK3CA*-mut. No *ERBB2* mutations were detected. Median follow up was 34.8 months (mos). Histotype (ILC versus ductal [IDC], HR 5.66, P <0.0001) and liver involvement (HR 2.21, P = 0.027) were significantly associated with worse PFS. Significant prognostic factors for OS were histotype (HR 12.07, P <0.0001), PgR+ (HR 0.19, P = 0.003), *de novo* MBC (HR 6.89, P = 0.04) and *PIK3CA*-mut (HR 3.44, P = 0.03). Marked peak-hazard differences across timepoints were observed to histotypes (55 mos vs 2 mos for IDC and ILC, respectively), PgR status (55 mos for PgR+ vs 1.2 mos for PgR-) and liver involvement (55 mos for liver- vs 7.6 mos for liver+). Consistent distributions were observed for lung and bone involvement, *de novo* MBC, *ESR1*-mut and *PIK3CA*-mut.

Conclusions: Effective disease monitoring should balance the need for appropriate disease characterization while maintaining pts' quality of life. Hazard distribution in HR+ HER2- MBC pts does not reduce overtime, but rather has different patterns across subgroups of interest. Further analyses are planned to define specific subgroups for personalized monitoring strategies.

416P Cost-effectiveness of first-line (1L) ribociclib use vs palbociclib in the treatment of postmenopausal women with HR+/HER2− advanced breast cancer (ABC): Analysis based on final overall survival (OS) results of MONALEESA-2 (ML-2) and PALOMA-2 (PAL-2)

S. Sehdev[1], C. Brezden-Masley[2], D. Soliman[3], K. El Ouagari[4], C. Biswas[5], M. Kalra[5], V. Sharma[5]

[1]Oncology, The Ottawa Hospital Regional Cancer Centre, Ottawa, ON, Canada; [2]Oncology, Mount Sinai Hospital, Toronto, ON, Canada; [3]Health Economics, Novartis Pharmaceuticals Canada Inc, Montreal, QC, Canada; [4]HEOR, Novartis Pharmaceuticals Canada Inc, Montreal, QC, Canada; [5]Patient Access, Novartis Healthcare Pvt Ltd., Hyderabad, India

Background: To evaluate cost-effectiveness of ribociclib vs palbociclib, using final ML-2 and PAL-2 OS data, in 1L treatment of postmenopausal women with HR+/HER2− ABC from Canadian payer perspective.

Methods: Partitioned survival model was developed considering 3 states (progression-free survival, progressive disease, and death) with a 1-month cycle length. Hazard ratios (HRs) for PFS and OS for ribociclib vs palbociclib (with letrozole) were derived using an anchored matching-adjusted indirect comparison (MAIC) to adjust for differences in baseline characteristics between ML-2 and PAL-2. Cost inputs included drug acquisition, healthcare resource, subsequent therapies, and adverse

event costs. Trial data and published literature were used to derive utility values. Costs and effects were discounted at 1.5% per year over a lifetime horizon.

Results: Total cost of treatment with ribociclib and palbociclib were $250,004 and $254,052, respectively. For treatment with ribociclib vs palbociclib, quality-adjusted life years (QALYs) were 4.948 vs 3.981, respectively. Ribociclib was the dominant treatment as it was both cost-saving (-$4,048) and more effective (+0.968 QALYs) than palbociclib. Drug cost with ribociclib was found to be $31,819 lower than palbociclib. Probability of ribociclib being cost-effective at $50,000 per QALY was 100%. Ribociclib remained cost-effective when HRs, utilities, ribociclib drug cost, and health state costs were varied.

Conclusions: Post MAIC, significantly longer OS benefit was observed with ribociclib vs palbociclib. Ribociclib remained dominant 1L treatment option over palbociclib. Hence, ribociclib should be the preferred CDK4/6 inhibitor based on the clinical and the economic benefit.

Background: CDK4/6i with endocrine therapy (ET) still represents the best 1st-line (1L) choice for HR+/HER2- MBC pts. At progression, the optimal subsequent strategy remains an open question. The HERMIONE-13 study aims to describe the efficacy of 2L choices in terms of Progression Free Survival (PFS) and Clinical Benefit Rate (CBR), in HR+/HER2- MBC pts relapsed after CDK 4/6i + ET.

Methods: HERMIONE-13 is a retrospective and prospective multicentric observational trial conducted in 15 Centers in Italy. Data of pts with at least one disease' revaluation during 2L therapy are being collected from January 2016 until January 2024. Here we present the first data of pts enrolled until December 2020.

Results: Among 114 pts enrolled, 16 (14%) were primary endocrine resistant, 70 (61.4%) had visceral metastases and 64 (56%) have received Palbociclib. Median 1L PFS (mPFS) was 11 months (mo) (interquartile range (IQR): 5-18). The 2L preferred choice was a chemotherapy (CHT)-based regimen (69.3%), with a predominance of single agent Capecitabine (22,2%); ET + target therapy (TT) was chosen in 16.7% of pts and ET monotherapy in 14%. An ET-based treatment was more frequently chosen for pts with a PFS$\geq$6 mo to previous CDK4/6i (35.4%), with respect to those with a PFS$<$6mo (13.3%) (P=0.024). A significant improvement in CBR, defined as absence of disease progression at 1st reassessment, was observed with CHT versus ET (20%, P=0.047). Among CHT treatments, a metronomic schedule of oral Capecitabine +/- Vinorelbine +/-Cyclophosphamide was used in 22.8% of pts, with a mPFS of 6 mo.

Table: 417P

	N° of pts (%)	2L mPFS,in mo (IQR)	CBR 2L (%)
All treatment	114	6 (3-10)	55 (48.2)
ET +/- TT	35 (30.7)	5 (3-7)	12 (34.3)
CHT +/- TT	79 (69.3)	6 (4-12)	43 (54.4)
Non-metronomic CHT	61 (77.2)	6 (3-11)	32 (52.5)
Metronomic CHT	18 (22.8)	6 (4-12)	11 (61.1)

Conclusions: In Italy, the preferred 2L treatment after CDK 4/6i remains CHT, especially with single-agent or metronomic schedule. mPFSs of 2L choices are very similar each other, around 6 mo. Further efforts to understand the type of resistance to CDK4/6i are warranted to better select 2L therapy.

418P Two-year follow-up data on the efficacy and safety of KN026, a HER2-targeted bispecific antibody combined with docetaxel as first-line treatment for HER2-positive recurrent/ metastatic breast cancer

Q. Zhang[1], J. Wang[1], Q. Ouyang[2], X. Wang[3], D. Lin[4], J. Wang[5], L. Gan[6], Z. Ouyang[7], T. Xu[8], Y. Liu[9], Y. Lv[10]

[1]Oncology, Harbin Medical University Cancer Hospital, Harbin, China; [2]Oncology, Hunan Cancer Hospital, Changsha, China; [3]Oncology, Zhejiang Cancer Hospital - Cancer Research Institute, Hangzhou, China; [4]Oncology, Jiang Men Central Hospital/ Affiliated Jiangmen Hospital of Sun Yat-Sen University, Jiangmen, China; [5]Oncology, Tumor Hospital in Linyi City, Linyi, China; [6]Oncology, The First Affiliated Hospital of Chongqing Medical University, Chongqing, China; [7]Oncology, The First Affiliated Hospital of Xiamen University, Xiamen, China; [8]Jiangsu Alphamab Biopharmaceuticals Co., Ltd., Suzhou, China; [9]Medical, Jiangsu Alphamab Biopharmaceuticals Co., Ltd., Suzhou, China; [10]Biostatistic, Jiangsu Alphamab Biopharmaceuticals Co., Ltd., Suzhou, China

Background: KN026 is a novel bispecific HER2-targeted antibody. *Fully humanized, IgG1-like antibody binds to two distinct HER2 epitopes, the same domains as trastuzumab and pertuzumab.* Preliminary safety and efficacy results (data as of Aug 18, 2022) were presented at SABCs 2022(PD18-08), showed promising efficacy and tolerability. Herein, we update the 2-year follow-up results.

Methods: Eligible subjects with recurrent/metastatic breast cancer, HER-2 positive and treatment-naive were enrolled. Subjects received KN026 30 mg/kg combined with docetaxel 75 mg/m^2 Q3W until disease progression, unacceptable toxicity, or other reasons. The primary endpoints were ORR and DoR. The secondary endpoints included safety, PFS and OS.

Results: As of data cut-off date (Mar 10, 2023), 57 subjects were enrolled, the median age was 52 y (min:30, max:67), 100% were female, and 91.2 % (52/57) were stage IV. The confirmed ORR within 55 evaluable subjects was 76.4% (42/55) and DoR was 24.0m (95% CI 20.27, NE). The median study follow-up was 24.2m (95%CI:22.80, 25.56). The mPFS was 25.4m (95% CI:17.97, NE) and the mOS was not reached. The OS rates at 12m, 24m and 30m were 93.0% (95% CI:82.37, 97.31), 83.7% (95% CI:70.97, 91.19) and 83.7% (95% CI:70.97, 91.19). The mPFS of subjects with or without visceral metastasis were 23.6m and 28.1m. The mPFS of subjects with or without brain metastasis were 13.7m and 25.4m, respectively. The incidence of KN026-related Grade$\geq$3 TRAE was 38.6% (22/57), including neutrophil count decreased 26.3% (15/57), leucopenia 24.6% (14/57), alanine aminotransferase increased 14.0% (8/57) and others less than 10%. The incidence of serious adverse events was 19.3% (11/57), including febrile neutropenia 5.3% (3/57), leucopenia 3.5% (2/57), and others $\leq$ 2%. There was no KN026 -related death.

Conclusions: KN026 in combination with docetaxel is well tolerated and has shown promising clinical benefit as 1L treatment for HER2-positive BC. After 2 years follow-up, mPFS was 25.4m and the 30-m OS rate was 83.7%, which is very promising. Robustness of efficacy and safety results will be further confirmed in an ongoing randomized phase 3 clinical trial with PTH as control.

Clinical trial identification: NCT04165993.

Background: Saci is FDA approved for mTNBC and metastatic HR-positive BC based on ASCENT (Bardia et al., NEJM 2022) and TROPiCS-02 (Rugo et al., JCO 2022). In ASCENT, patients with heavily pre-treated mTNBC, including CNS metastases, had improved PFS and OS with Saci. It remains to be seen whether clincial trial results are uniformly applicable to real-world patients. The objectives of this study are to examine patients treated with Saci for mTNBC at our institution and to determine if clinical trial results can be replicated in the real-world setting.

Methods: We retrospectively identified all patients treated with Saci at our institution. Patient demographics, tumor characteristics, response and outcomes were assessed. Statistics are reported descriptively.

Results: From July 2018-June 2022, 188 patients with MBC were treated with Saci at our institution. Of those, 126 patients with mTNBC received at least one dose of Saci. Patients received a median of 2 lines (0-8) of therapy for metastatic disease prior to Saci. At commencement of Saci, 69.8% of patients had visceral metastases and 23% had CNS metastases. The median PFS with Saci was 3 months (0-13). The clinical benefit rate (CR/PR/SD) with Saci was 59.5% and 15% of patients remained on Saci at the time of reporting. The median OS was 21 months (2-50) and the median survival from Saci to death was 6 months (0-33).

Table: 419P Patient and tumor characteristics (n = 126)

Characteristics		n (%)
Median age at diagnosis: Years (range)		52 (27-86)
BRCA1/2 mutation status	Positive	7 (6%)
	None	90 (71%)
	Unknown/Not tested	29 (23%)
Tumor stage at Dx	T1	22 (18%)
	T2	58 (46%)
	T3	15 (12%)
	T4	3 (2%)
	Tx	23 (18%)
	Unknown	5 (4%)
Nodal status at Dx	N0	38 (30%)
	N1	37 (29%)
	N2	15 (12%)
	N3	8 (6.5%)
	Nx	23 (18.5%)
	Unknown	5 (4%)
Metastatic disease at Dx	M0	101 (80%)
	M1	20 (16%)
	Unknown	5 (4%)
Prior systemic therapy	Taxane	119 (94%)
	Anthracycline	92 (73%)
	Capecitabine	77 (61%)
	Platinum	75 (60%)
	Immunotherapy	55 (44%)
	PARPi	19 (15%)

Conclusions: In this real-world series, we report on a patient population similar to that studied in the ASCENT trial. The median PFS was numerically shorter in this series compared to the ASCENT study (3.0 vs 4.8 months) despite our patients being less heavily pre-treated (median 2 vs 4 prior lines). The median OS was numerically longer in this series (21 vs 11.8 months). Further work is ongoing to evaluate real-world outcomes of patients treated with Saci for HR-positive disease and translational work seeks to establish biomarkers of resistance to Saci and other ADCs.

Background: Here, we investigated the potential predictive and elucidating efficacy of cell-free DNA (cfDNA) changes on clinical outcomes and biological effects, respectively, after short-term palbociclib and fulvestrant treatment for patients with hormone receptor (HR)-positive and human epidermal growth factor 2 (HER2)-negative advanced or metastatic breast cancer (ABC).

Methods: In this secondary analysis of the Japan Breast Cancer Research Group-M07 (FUTURE) trial, blood cfDNA was obtained before palbociclib treatment and on day 15 of cycle one (28-day cycle). Target enrichment was performed using next-generation sequencing; progression-free survival (PFS) was compared based on cfDNA changes between baseline and day 15 of cycle one after combination therapy.

Results: Fifty-six patients (112 paired blood samples) were examined. The median follow-up time was 8.9 months. *PIK3CA* (30.4%, 17/56), *FOXA1* (30.4%, 17/56), and *ESR1* (28.6%, 16/56) were most frequently mutated at baseline. The number of mutated genes was significantly decreased on day 15 compared with that at baseline (paired t-test: P-value = 0.025). No significant difference was observed in PFS (decrease group, 7.9 m vs the others, 9.3 m; log-rank P-value = 0.75; hazard ratio, 1.13; 95% confidence interval, 0.53-2.41). Among patients without previous aromatase inhibitor treatment (n = 15), three (20%) had *ESR1* mutations after progression to fulvestrant.

Conclusions: No significant association was observed between changes in mutated genes after short-term palbociclib and fulvestrant treatment and disease progression; a significant reduction in cfDNA mutation level was observed on day 15 of cycle one. Clinical meanings of cfDNA should be investigated in the future trials.

Clinical trial identification: The study protocol was registered with the University Hospital Medical Information Network, Japan (UMIN000029294) and Japan Registry of Clinical Trials (CRB2200002).

Editorial acknowledgement: We thank TAKARA bio for the genomic analysis. We greatly appreciate all women who participated in this trial. We also thank all investigators and their collaborators for their dedication to this study, Mebics for their data entry assistance, and the Japan Breast Cancer Research Group (JBCRG) for their administrative assistance.

422P UK real-world data (RWD) of cyclin-dependent kinase 4/6 inhibitor (CDK4/6i) use in metastatic breast cancer (MBC)

G. Gullick[1], C. Owen[2], S. Cook[3], J. Helbrow[4], R. Squires[1], H.M. Reed[1], S. Park[5], E. Weir[5], F. Aquilina[5], N. Webber[6], E. Nye[6], C. Atkinson[3], C. Blair[1], A. Halstead[1], E. Daniels[4], A. Alves[1], S. Chew[5], W. Thomas[4], S. Spensley[3], T. Robinson[2]

[1]Medical Oncology Department, Bristol Cancer Institute, Bristol, UK; [2]Faculty of Health Sciences, University of Bristol - Bristol Medical School, Bristol, UK; [3]Oncology Department, Musgrove Park Hospital - Taunton and Somerset NHS Foundation Trust, Taunton, UK; [4]Oncology Department, Gloucestershire Oncology Centre - Cheltenham General Hospital - Gloucestershire Hospitals NHS Foundation Trust, Cheltenham, UK; [5]Oncology Department, Royal Devon and Exeter Hospital (Wonford) - NHS Royal Devon University Healthcare, Exeter, UK; [6]Oncology Department, Royal United Hospitals Bath - NHS Foundation trust, Bath, UK

Background: Many studies support the use of CDK4/6i in MBC with aromatase inhibitors or fulvestrant. We assessed the efficacy and tolerability of CDK4/6i using RWD.

Methods: RWD was collected retrospectively from 5 UK centres. Patients with a diagnosis of ER+/HER2- MBC treated with a CDK4/6i between Apr 17 and Nov 22 were included. We used Kaplan-Meier statistical analysis to calculate follow-up time, progression free survival (PFS) and overall survival (OS).

Results: 665 patients were included (median age 66 (range 23-92)). 243 (36.5%) were documented as pre- and 343 (51.6%) as post-menopausal. 543 (81.7%) had 1st-line CDK4/6i and 122 (18.3%) had $\geq$ 2nd-line treatment. 536 (80.6%) received Palbociclib (P), 85 (12.8%) Abemaciclib (A) and 44 (6.6%) Ribociclib (R). The median follow-up time was 28 months (range 0-76; IQR 18-41). 1st-line PFS was P - 31 months (25-35), A - 16 months (9-NR) and R - 44 months (21-NR). $\geq$ 2nd-line PFS was P - 12 months (10-29), A - 15 months (11-30) and R - 15.5 months (10-NR). OS data is immature. Overall, 527 (79.2%) patients suffered any grade toxicity (P - 414 (77.2%), A - 72 (84.7%) and R - 41 (93.1%)) and 248 (37.2%) $\geq$Grade 3 ($\geq$G3) (P - 203 (37.9%), A - 22 (25.9%) and R - 23 (52.3%)). The table outlines the most common toxicities by drug and grade. 366 (55%) patients had 1 dose reduction (DR): P - 290 (54.1%), A - 50 (58.8%) and R - 26 (59%). The median time to DR was 2 months (1-63), with no significant difference noticed between CDK4/6i. 113 (17%) patients had >1 DR: P - 96 (17.9%), A - 6 (13.6%) and R - 11 (12.9%).

Table: 422P

Toxicity	P (n=536)		A (n=85)		R (n=44)	
	Any grade (%)	G3 (%)	Any grade (%)	G3 (%)	Any grade (%)	G3 (%)
Neutropenia	38.2	30.3	15.3	7.1	36.4	15.9
Fatigue	37.1	1.9	31.8	2.4	34.1	4.5
Diarrhoea	9.1	0.7	61.2	10.6	15.9	2.3
Mucositis	12.1	0.6	4.8	0	2.3	0
Hepatoxicity	2.8	1.3	1.2	1.2	27.3	20.5
Nausea	9.9	1.3	17.6	5.9	25.0	2.3
Rash	3.2	0	2.4	0	9.1	2.3

Conclusions: This large, RWD-set demonstrates PFS comparable to that of published trial data, but outcomes for A and R are impacted by small numbers and short follow up. $\geq$G3 toxicity was highest for P and R compared to A and lower than previously described, though DR rates were similar, suggesting significant side-effects were experienced. As their use increases and extends to the adjuvant setting, complete and mature RWD examining CDK4/6i toxicity, PFS and OS is required, especially for A and R.

423P A real-world study on the clinical value of apatinib-based regimens in metastatic triple-negative breast cancer

H.W. Wei[1], C. Qi[2], S. Kun[2], W. Xi[2], H. Jian[3], L. Jian[1], W. Li[1], W. Fan[1], X. Chen[1], L. Ni[1], H. Yi[1], C. Ian[1]

[1]Department of Medical Oncology, Fujian Cancer Hospital and Fujian Medical University Cancer Hospital, Fuzhou, China; [2]Biomedical Research Center of South China, Fujian Normal University, Fuzhou, China; [3]Department of Breast Surgical Oncology, Fujian Cancer Hospital and Fujian Medical University Cancer Hospital, Fuzhou, China

Background: Apatinib is an oral, highly potent tyrosine-kinase inhibitor targeting VEGFR2. The published studies have shown probable efficacy and safety. However, the recommended dose of apatinib (500mg/day) is associated with difficult-to-tolerate adverse reactions. To this end, we aim to investigate whether low-dose apatinib (250mg/day) in combination with chemotherapy could benefit metastatic triple-negative breast cancer (mTNBC) in the real-world setting.

Methods: Patients with mTNBC who were treated at Fujian Medical University Cancer Hospital from October 2011 to January 2023 were screened. Patients included in this study were divided into two groups, low-dose apatinib (250mg/day) and/or palliative chemotherapy. Descriptive statistics were used to summarize adverse reactions and demographic data. Progression-free survival (PFS) and overall survival (OS) were estimated by the Kaplan-Meier method. Secondary outcomes included objective response rate (ORR), disease control rate (DCR), and safety profiles.

Results: A total of 163 patients were included in this study and retrospectively analyzed. The Apatinib-based group (n = 56) showed significant benefits in terms of progression-free survival (PFS) and overall survival (OS) comparing with the chemotherapy-based treatment group (n = 107), with median PFS of 8.5 months (95% CI, 6.6-12.8) versus 2.8 months (95% CI, 2.4-4.4) (HR = 0.33, 95% CI, 0.22-0.50, P < 0.001) and OS of 21.1 months (95% CI, 15.5-NR) versus 10.5 months (95% CI, 9.1-12.8) (HR = 0.28, 95% CI, 0.17-0.47, P < 0.001). The overall response rate (ORR) and the disease control rate (DCR) were 53.6% versus 26.2% (P < .001) and 85.7% versus 44.9% (P < .001), respectively. The second- and later-line subgroup showed significant benefits. The grade 3/4 toxicity of apatinib plus chemotherapy was mainly manifested as neutropenia (8.8%) and hypertension (5.9%). No treatment-related serious adverse events or deaths were reported.

Conclusions: Low-dose apatinib plus chemotherapy showed better survival benefits than chemotherapy alone, with significantly improved non-hematological toxicity and increased patient tolerability for mTNBC. Much more investigation is warranted and necessary for further exploration.

Clinical trial identification: NCT05019690.

Background: Patients with HER2-positive advanced breast cancer and primary resistance to trastuzumab have a poor clinical outcome and lack good evidence to inform clinical decision. Compared with acquired resistance, primary trastuzumab resistance may have different resistance mechanisms, such as intrinsic resistance and HER2

independency. This multicenter phase 2 trial investigated the efficacy and safety of pyrotinib plus capecitabine in this population.

Methods: Patients received pyrotinib 400 mg once daily and capecitabine 1000 mg/m^2 twice a day on days 1-14 of each 21-day cycle until disease progression or intolerable toxicity. Based on the definitions used in prior clinical trials, primary trastuzumab resistance was defined as progression during (neo)adjuvant trastuzumab (subgroup A) or within 12 months of completing (neo)adjuvant trastuzumab (subgroup B), or progression within 6 months after initiation of first-line trastuzumab for advanced disease (subgroup C). The primary endpoint was investigator-assessed progression-free survival (PFS). This report updated survival results.

Results: Between June 20, 2019 and September 19, 2021, 100 patients were enrolled. As of April 31, 2023, the median follow-up duration was 29.7 months (95% CI, 26.9-31.5). Thirty-five deaths occurred, and the estimated median overall survival (OS) was 41.7 months (95% CI, 32.2-not reached). Subgroup B (n=49) had the longest median OS (41.7 months) and PFS (17.8 months). In patients with available data of subsequent anti-HER2 therapy after progression, 61.4%, 38.6%, and 36.4% received monoclonal antibody, tyrosine kinase inhibitor, and antibody-drug conjugate, respectively. The extended follow-up showed unchanged median PFS (11.8 months [95% CI, 8.4-15.1]) and objective response rate (70.0% [70/100]).

Conclusions: The updated OS analysis highlights the long-term efficacy of pyrotinib plus capecitabine in HER2-positive advanced breast cancer patients who have shown primary resistance to trastuzumab. Even in the era of modern anti-HER2 therapies, this clinical setting warrants more investigations to meet unmet needs.

Clinical trial identification: NCT04001621.

425P Real world quality of life (QoL) in breast cancer (BC) patients treated with cyclin-dependent kinase 4/6 inhibitors (CDK4/6i)

B.I. Tavara, M.L. Garrido, L. Lopez, M. Lopez Flores, C. Castañón, S. Abella Alvarez, S. Medina Valdivieso, A. Rodriguez Sanchez, A. García Palomo-Pérez, A. López

Medical Oncology Department, Complejo Asistencial Universitario de León - Hospital de León, León, Spain

Background: Palbociclib, ribociclib and abemaciclib play an important role in the treatment of hormone receptor-positive (HR+)/human epidermal growth factor receptor 2-negative (HER2-) BC based on their impressive efficacy; however, there seem to be some differences in toxicity profiles which can adversely affect their QoL. This study aims to evaluate health-related QoL (HRQoL) in advanced BC patients treated with CDK4/6i with the help of digital apps.

Methods: HRQoL was assessed in women with HR+/HER2- metastatic BC treated with CDK4/6i plus endocrine therapy using the Functional Assessment of Cancer Therapy-Breast (FACT-B) questionnaire via online platform in Spanish patients with a cut-off date of August 2022.

Results: A total of 264 patients were analyzed. 85% had between 40-69 years. 30% were employed. The most used CDK4/6i was palbociclib (46.2%), followed of ribociclib (39.8%) and abemaciclib (14%). 33% had a dose reduction. 69.7% of patients had received chemotherapy previously; of these, 91.8% consider that their QoL is better with CDK4/6i. Of all patients who are undergoing with CDK4/6i, 87.5% feel content with the treatment. Overall scores from the FACT-B questionnaire were comparable between all CDK4/6i (Table). Notably, 45.9% and 37.8% of patients in the abemaciclib group reported diarrhea and nausea, respectively. Better scores were registered in the palbociclib arm for fatigue, pain, insomnia and better sexual enjoyment.

Table: 425P

FACT-B*	Palbociclib	Ribociclib	Abemaciclib	*p* value
N (%)	122 (46.3%)	105 (39.7%)	37 (14%)	
Age (%)	11 (9.02%)	14 (13.33%)	7 (18.98%)	0,232
≤ 39 years	105 (86.07%)	89 (84.76%)	30 (81.08%)	
40-69 years	6 (4.92%)	2 (1.91%)	0	
≥ 70 years				
Physical well-being, median (range)	22 (4-28)	21 (1-28)	20 (9-27)	0,431
Social/family well-being, median (range)	17 (0-27)	18 (0-24)	18 (5-26)	0,48
Emotional well-being, median (range)	14 (3-24)	10 (0-18)	13 (6-20)	0,005
Functional well-being, median (range)	13.5 (0-26)	14 (1-27)	13 (1-23)	0,855
Breast cancer subscale, median (range)	24 (7-39)	23 (4-35)	20 (13-32)	0,027
Total score, median (range)	90 (24-135)	86 (29-127)	83 (53-104)	0,049

*Higher scores indicate a better QoL.

Conclusions: The CDK4/6i play an eminent role in the therapy of advanced BC; nevertheless, the impact of treatment in QoL should be considered in addition to efficacy and safety, especially in the non-curative setting. Our HR-QoL results seems to confirm those obtained in clinical trials. To our knowledge this is the first study about HR-QoL in HR+/HER2- BC patients treated with CDK4/6i in Spanish real-world setting.

426P The overall survival data of FUTURE-C-PLUS: Combination of famitinib with camrelizumab plus nab-paclitaxel as first-line treatment for advanced, immunomodulatory triple-negative breast cancer, an open-label, single-arm, phase II trial

Z. Wang[1], L. Chen[2], L. Fan[3], Z. Shao[4]

[1]*Breast Surgery Department, Minhang Branch of Fudan University Affiliated Cancer Hospital, Shanghai, China;* [2]*Breast Surgery Department, Fudan University Shanghai Cancer Center, Shanghai, China;* [3]*Surgery Department, Fudan University Shanghai Cancer Center, Shanghai, China;* [4]*Department of Breast Oncology, Fudan University Shanghai Cancer Center, Shanghai, China*

Background: Camrelizumab and nab-paclitaxel demonstrated promising anti-tumour activity in metastatic immunomodulatory triple-negative breast cancer (IM-TNBC) in FUTURE trial. Anti-angiogenic agents have been reported to facilitate immune infiltration. Famitinib is a tyrosine kinase inhibitor targeting VEGFR-2, PDGFR and c-kit. The FUTURE-C-PLUS trial (NCT04129996) which added famitinib to camrelizumab and nab-paclitaxel is a single-arm, phase 2 trial evaluating this triplet combinatorial strategy in advanced IM-TNBC. Study design and the primary endpoint ORR has been reported (Zhi-ming Shao, et al. ASCO 2021, Abstract 1007). The final PFS data had been published in Clinical Cancer Research (Clin Cancer Res 2022;28:2807—17). Here, we reported the updated overall survival.

Methods: This study enrolled women aged 18-70 years, with previously untreated, unresectable, locally advanced, recurrent or metastatic IM-TNBC. IM-TNBC was defined as CD8 expression on at least 10% of cells using IHC analysis. Eligible patients received the triple therapy.

Results: Forty-eight patients were enrolled between Oct 2019 and Oct 2020. The median follow-up was 33.1 months (range, 31.8—34.4). 39 (81.3%, 95% CI 70.2-92.3) patients had a confirmed objective response which has been reported in ASCO 2021. At this updating data cutoff (May 1, 2023), the median progression-free survival was 13.6 months (95% CI, 8.4-18.8). While overall survival was 29.4 months (95% CI, 23.3-35.5). The most common treatment-related grade 3 or 4 adverse events were neutropenia (16 [33.3%]), anemia (5 [10.4%]), febrile neutropenia (5 [10.4%]), and thrombocytopenia (4 [8.3%]). No new safety concerns were detected. No treatment-related deaths were reported.

Conclusions: These data, combined with our previous reports, provide further evidence for the triplet combination as an active therapy in advanced IM-TNBC. To our knowledge, this is the best over survival reached in first-line treatment of advanced TNBC. A randomized controlled FUTURE-Super trial (NCT04395989) is ongoing to further validate these findings.

427P Pyrotinib plus trastuzumab versus pertuzumab plus trastuzumab in patients with HER2-positive metastatic breast cancer: A multicenter, retrospective study

B. Wang[1], S. You[1], Y. Xie[1], F. Xu[2], D. Sang[3], T. Luo[4], P. Yuan[5]

[1]*Department of Breast and Urologic Medical Oncology, Fudan University Shanghai Cancer Center, Shanghai, China;* [2]*Medical Oncology Department, Sun Yat-Sen University Cancer Center, Guangzhou, China;* [3]*Medical Oncology Department, San Huan Cancer Hospital, Beijing, China;* [4]*Head and Neck Oncology Department, West China School of Medicine/West China Hospital of Sichuan University, Chengdu, China;* [5]*Medical Oncology Department, Peking University Cancer Hospital and Institute, Beijing, China*

Background: Pyrotinib has shown to be an effective antitumor agent in HER2-positive metastatic breast cancer (MBC). Pertuzumab, combined with trastuzumab and docetaxel, is the standard first-line dual anti-HER2 therapy for HER2-positive MBC. No

direct comparison has been made between pyrotinib plus trastuzumab (PyroH) and pertuzumab plus trastuzumab (HP) in the treatment of HER2-positive MBC.

Methods: We retrospectively evaluated medical records for all patients with HER2-positive metastatic breast cancer who received PyroH plus chemotherapy or HP plus chemotherapy between 2017 and 2022 at five institutions in China. The primary endpoint was progression-free survival (PFS).

Results: This study included 333 patients, among which 161 received PyroH and 172 received HP. There was no significant difference between the two groups in either first-line or post second-line of systemic treatment (median PFS: 14.46 vs. 22.90 months, p=0.057; 8.67 vs. 7.92 months, p=0.286, respectively). Although HP group showed a significant longer PFS than PyroH group in the overall real-world setting (median PFS: 9.30 vs. 13.01 months, p=0.005), the treatment group is not an independent predictor of PFS in multivariate analysis (HR 1.134, 95% CI 0.710-1.811, p=0.598). PyroH demonstrated a longer PFS than HP when taxane was not utilized (median PFS: 10.12 vs. 8.15 months, p=0.017). In patients with brain metastases receiving first-line treatment, PyroH showed a potential advantage over the HP group, although this difference did not reach statistical significance (median PFS: 14.29 vs. 7.98 months, p=0.955). PyroH group had a higher incidence of grade 3/4 diarrhea (34.3% vs. 3.0%), but the overall incidence of adverse events did not differ between the two groups.

Conclusions: In real-world setting, although HP showed unshakable position when combined with taxane in first-line treatment, PyroH presented comparable effectiveness in post second-line treatment and patients with brain metastasis and even better efficacy in patients without combination of taxane. Toxicities in both groups were tolerable.

Clinical trial identification: NCT05572645.

428P Palbociclib dose patterns in Swedish patients with metastatic breast cancer: 5-year update from the SIRI study

A. Valachis[1], H. Lindman[2], R. Lauppe[3], M. Lilja[3], M. Jakobsson[4], D. Nyqvist[5]

[1]Oncology, Faculty of Medicine & Health, Örebro University, Örebro, Sweden; [2]Oncology, University Hospital Uppsala/Akademiska Sjukhuset, Uppsala, Sweden; [3]Quantify Research, Quantify Research AB, Stockholm, Sweden; [4]Pfizer AB, Pfizer AB, Sollentuna, Sweden; [5]Medical Affairs, Pfizer AB, Sollentuna, Sweden

Background: Although palbociclib combined with endocrine therapy is a well-established treatment option in patients with hormone receptor-positive (HR+), human epidermal growth factor receptor 2 (HER2)-negative metastatic breast cancer (MBC), there is limited evidence on patterns of dose reductions in real-world setting. The Swedish Ibrance Registries Insights (SIRI) study investigated real-world dose patterns using a nationwide cohort of palbociclib-treated MBC patients.

Methods: This was a retrospective study utilizing population-based Swedish Health Data Registers. The cohort included all patients $\geq$ 18 years with $\geq$ 1 dispensation of palbociclib from January 2017 – June 2022. Minimum follow-up was 3 months. Starting dose and dose changes for the full population and for different age groups, in total and over time, was investigated.

Results: 2058 patients were identified and the median (IQR) age at treatment initiation was 68.4 (15.7) years. Patients were stratified into three age groups: <50, 50-69, $\geq$70 years, with the following distribution: 9.9%, 46.1%, and 44.0%, respectively. Most patients were initiated on 125 mg (82.0%), with a lower share for older patients ($\geq$70 years; 74.4%). In total, 45.5% of patients had $\geq$ 1 dose reduction, with a higher frequency for older patients ($\geq$70 years; 48.5%). Median (IQR) time to first dose reduction was 2.4 (3.9) months, and 5.9 (7.5) months to second dose reduction, with little variation across age groups. The probability for dose reduction was equal across age groups during the initial 6 months of treatment, whereafter it slightly increased for older patients ($\geq$70 years). For patients starting with lower dose (100 mg) compared to standard dose (125 mg) at treatment initiation, the probability for dose reduction was similar during the first 3 months of treatment, whereafter it increased.

Conclusions: Most Swedish palbociclib-treated patients were initiated on the recommended dose, but a lower starting dose and a higher frequency of dose reductions were observed for older patients. The time to dose reduction was equal across age groups, whereas the probability for dose reduction increased over time for older patients, and for patients with a start dose of 100 mg.

Background: The prognostic significance of Human Epidermal Growth Factor Receptor 2 (HER2)-low status in patients with hormone receptor-positive (HR+)/HER2-negative advanced breast cancer (aBC) who receive first-line endocrine therapy combined with cyclin-dependent kinase (CDK) 4/6 inhibitors remains uncertain. Two major studies in this area have yielded conflicting results, indicating the need for further research. Therefore, Our objective is to examine the effect of HER2 status on overall survival (OS) outcomes among patients who are undergoing first-line treatment with CDK 4/6 inhibitors.

Methods: Our study is a multi-center, retrospective, real-world data analysis focusing on patients diagnosed with hormone receptor-positive, HER2-negative metastatic breast cancer who were treated with CDK 4/6 inhibitors as first-line therapy.

Results: Our study included 160 patients from five tertiary hospitals. The median follow-up time was 19.90 $\pm$ 0.82 months, and mOS could not be reached. Of the patients, 83 were included with recurrent metastatic disease. 118 were postmenopausal. 63 patients were treated with palbociclib and 97 were treated with ribociclib. 111 had HER2 negative and 49 had HER2 low status. The median overall survival in the HER2 low group was 49.03 months, while the mOS could not be reached in the HER2-negative group (HR: 0.87, p=0.818). There was no difference in OS between patients treated with palbociclib and ribociclib (p=0.416).

Conclusions: Our study is one of the few with a large sample size, examining the relationship between CDK 4/6 inhibitors' efficacy and HER2 status. Previous research includes two studies with a high number of patients and three with a low number of patients, with inconsistent results in the two larger studies. In our study, which included a significant number of patients, we showed that CDK 4/6 inhibitors had a similar overall survival in the HER2 low group and the HER2-negative group. In our study, there was no significant difference in overall survival between the use of palbociclib and ribociclib.

430P Real-world patient characteristics and treatment patterns in HR+/HER2+ metastatic breast cancer patients in 5 European countries

C. Criscitiello[1], K. Lewis[2], A. Lambert[2], G. Thomason[2], E. Broughton[3]

[1]Division of Experimental Therapeutics, IEO - Istituto Europeo di Oncologia IRCCS, Milan, Italy; [2]Oncology Franchise, Adelphi Real World - Adelphi Group, Bollington, UK; [3]Worldwide Health Economics and Outcomes Research, Pfizer Inc, New York, NY, USA

Background: For patients (pts) with HR+/HER2+ metastatic breast cancer (mBC) with no contraindication for chemotherapy (CT), the ESMO mBC Living guidelines recommend first-line CT in combination with dual anti-HER2, followed by endocrine therapy (ET) with dual anti-HER2 agents upon CT completion as maintenance therapy. This study assesses patient characteristics and treatments patterns for adults with HR+/HER2+ mBC in 5 European countries.

Methods: Data were collected using the Adelphi Advanced BC Disease Specific Programme. Oncologists in France, Germany, Italy, Spain, and the UK abstracted data from patient medical records. This study included pts who had previously received

Table: 430P Treatment sequencing in pts with HR+/HER2+ mBC

	Induction regimen				
	ChT + dual anti-HER2	ChT + single anti-HER2	ChT only	Dual anti-HER2	Single anti-HER2
Maintenance regimen	n=372	n=71	n=30	n=14	n=8
ET + dual anti-HER2 (n=273), n (%)	264 (71)	2 (3)	4 (13)	3 (21)	0 (0)
ET + single anti-HER2 (n=130), n (%)	48 (13)	56 (79)	17 (57)	7 (50)	2 (25)
Single anti-HER2 (n=25), n (%)	9 (2)	7 (10)	4 (13)	1 (7)	4 (50)
ET monotherapy (n=21), n (%)	13 (3)	3 (4)	1 (3)	2 (14)	2 (25)
Other* (n=46), n (%)	38 (10)	3 (4)	4 (13)	1 (7)	0 (0)

* Includes dual anti-HER2 and ET + 3 anti-HER2 regimens

induction therapy and were receiving maintenance treatment for HR+/HER2+ mBC at time of data abstraction (July 2022 to February 2023).

Results: 495 pts with HR+/HER2+ mBC were included. At time of data abstraction: mean (SD) age was 62 (9.88) years; 81% had de novo mBC; 63% had visceral metastases; pain was the most common symptom (22%). Among pts who received early-stage BC treatment (n=78), 63% received CT and ≥1 anti-HER2 agent. 89% of pts received CT and a single/dual anti-HER2 agent(s) as 1L regimen for mBC, with 81% of pts then receiving ET and a single/dual anti-HER2 agent(s) as a maintenance regimen (Table). CT only was received by 6% of the sample as an induction regimen, with 70% then receiving ET and a single/dual anti-HER2 agent(s) as a maintenance regimen. The remaining 4% of pts received a single/dual anti-HER2 agent(s) as an induction regimen, with single anti-HER2 +/- ET the most common maintenance regimens.

Conclusions: Most pts were de novo mBC, with two thirds of the population having visceral metastases. While most pts in our study received treatment aligned with ESMO guidelines, some regimens did not align to the guidelines. Further investigation is required to understand the factors that drive treatment decisions and adherence to the guidelines.

431P Distribution and prognostic role of HER2 status of circulating tumor cells (CTCs) and tumor-derived extracellular vesicles (tdEVs) in HER2- metastatic breast cancer (MBC) patients (pts)

E. Nicolo[1], L. Munoz-Arcos[1], P. D'Amico[2], Y. Zhang[2], L. Gerratana[3], M. Serafini[1], L. Pontolillo[4], K. Strickland[1], M. Manai[1], A.A. Davis[5], J. Donahue[1], H. Liu[6], W.J. Gradishar[2], A.N. Shah[2], G. Curigliano[7], C. Reduzzi[1], M. Cristofanilli[8]

[1]Medicine, Weill Cornell Medicine, New York, NY, USA; [2]Department of Medicine-Hematology and Oncology, Robert H. Lurie Comprehensive Cancer Center of the Northwestern University, Chicago, IL, USA; [3]Medical Oncology, CRO Aviano - Centro di Riferimento Oncologico - IRCCS, Aviano, Italy; [4]Medical Oncology Department, Fondazione Policlinico Universitario Agostino Gemelli - IRCCS Rome, Rome, Italy; [5]Medicine Department- Division of Hematology And Oncology, Washington University School of Medicine in St. Louis, St. Louis, MO, USA; [6]Departments of Pharmacology and Medicine-Hematology and Oncology, Robert H. Lurie Comprehensive Cancer Center of the Northwestern University, Chicago, IL, USA; [7]Early Drug Development for Innovative Therapies Division, IEO - Istituto Europeo di Oncologia, Milan, Italy; [8]Medicine, Weill Cornell Medicine, New York, NY, USA

Background: CTCs and tdEVs predict clinical outcome in MBC pts. The detection of HER2+ CTCs has been associated with poor prognosis in HER2- MBC. In the blood of MBC pts, it is also possible to detect cytokeratin negative (CK-) CTCs. The clinical significance of HER2 expression in CK- CTCs and tdEVs is understudied.

Methods: This study retrospectively analyzed 258 pts with HER2- MBC enrolled at Northwestern University (Chicago, IL) between 2016 and 2021 (NU16B06 trial). Baseline blood samples were processed for CTCs with the CellSearch® system using an anti-HER2 antibody. CTCs were manually counted and classified according to HER2 staining intensity. The ACCEPT software was applied to evaluate HER2 status on CK- CTCs and tdEVs.

Results: 122 pts (47%) had ≥ 5 CTCs/7.5 mL of blood. HER2 status of CTCs was assessed in 198 pts: 92 (47%) had ≥1 CTCs with moderate or strong staining (i.e. HER2+ CTCs). CK- HER2+ CTCs were detected in 220 pts (85%); CK+ HER2+ tdEVs were detected in 51 pts (20%). The distribution according to CTCs is shown in the table. CTCs and tdEVs were significantly associated with overall survival (OS). Overall, detection of ≥1 HER2+ CTC was associated with shorter OS (19 vs 47 months, p<0.001). In pts with ≥ 5 CTCs, HER2+ CTCs were associated with a numerical decrease in OS (25 vs 15 months; p=0.069). Pts with ≥1 CK- HER2+ CTCs had worse outcome (23 vs 33 months; p=0.029) whereas HER2+ tdEVs were not significantly associated with OS. In multivariate analysis, hormone receptor status, therapy line, CTC count, CTC-HER2 status, and tdEV count independently predicted OS.

Table: 431P

	CTC < 5	CTC ≥ 5	p value
CTC CK+ HER2+	0 [0-0]	3 [1-9]	<0.001
tdEV CK+	4 [1-13]	153 [51-464]	<0.001
CTC CK- HER2+	3 [1-6]	4 [2-10]	<0.001
tdEV CK+ HER2+	0 [0-0]	0 [0-0]	0.461
tdEV CK- HER2+	31 [10-83]	40 [14-98]	0.131

Conclusions: HER2 expression can be detected in CTCs from HER2- MBC pts representing a prognostic factor and a possible therapeutic target. The prognostic role of CK- HER2+ CTCs suggests their tumor origin as cells with mixed epithelial-mesenchymal phenotype; additional studies on these CTCs are needed. HER2 expression on tdEVs was not associated with outcome.

432P Ki67 and progesterone receptor status could be predict sensitivity to cyclin-dependent kinase inhibitor

L. Navarro Berlanga, B. Teso, P. Flores Paco, J. De la Haba Rodriguez, A. Armenta, F. Mora, B. Rodriguez Alonso, C. Morales Estevez, I. Porras Quintela, P. Sanchez Mauriño, E. Aranda Aguilar

Medical Oncology, Hospital Universitario Reina Sofia, Cordoba, Spain

Background: Cyclin-dependent kinase 4/6 inhibitor (CDK4/6i) combined with endocrine therapy has been approved as first-line treatment for hormone receptor-positive(HR+) advanced breast cancer (ABC). A challenge is finding biomarkers to identify patients who respond to treatment with CDK4/6i.

Methods: We identified all patients in treatment with CDK4/6i for ABC in our centre. Restrospectively, we analyzed the values of Ki 67 and progesterone receptor(PR) detected by inmunohistochemistry and their impact on CDK4/6i duration and progression-free survival(PFS). PFS was evaluated by Kaplan Meier method and survival curves were compared using the longrank test. Results were considered statistically significant with a p value <0'05. Analyses were realized with SPSS.

Results: Between January 2018 and January 2023, 210 patients received CDK4/6i treatment at our institution, 68'6% (144) received palbociclib, 24'3%(51) ribociclib and 7'1%(15) abemaciclib. The media age was 52 years (36-91). The median follow up time was 21 months (range 1-69 months). Ki 67 and PR expression were analyzed both as continuos and dichotomized variables and PR was classified as positive or negative. In the total population, patients with Ki67 >30% had significant shorter CDK4/6i treatment duration versus Ki 67<30% (16'80 months vs not reached, p=0'04). In regard to PR expression, we observed patients with PR positive had longer CDK4/6i treatment duration compared with PR negative (17'54 vs 7'55 months, p=0'027). Also, if we analyzed PFS, we observed patients PR positive had longer PFS versus PR negative (45'50 months vs 17'71 months, p=0'02), we recorded

PFS as the duration from the beginning of treatment to disease progression or death, whichever happened first.

Conclusions: In clinical practical, there is a high individual variability in clinical response in patient with CDK4/6i treatment. Actually, there are not biomarkers that predict which patients respond to treatment. In this study, we investigated the impact of Ki67 and PR values on CD4/6i treatment in HR-positive ABC patients. Also, we revealed that PFS seemed to be negatively influenced by elevated Ki 67 values (>30%) and negative PR expression. We have to corroborate these data in prospective studies.

433P Effectiveness and safety of vinorelbine + inetetamab + pyrotinib in ≥second-line treatment of HER2-positive metastatic breast cancer

W. Fan

Department of Medical Oncology, Fujian Medical University Cancer Hospital, Fuzhou, China

Background: In real-world settings, patients with HER2-positive metastatic breast cancer (MBC) who cannot receive antibody-drug conjugates (ADCs) as standard second-line regimen and who have no preferred regimen in ≥third line by NCCN guidelines, require new regimens to meet their clinical needs. This study aimed to explore the effectiveness and safety of vinorelbine + inetetamab + pyrotinib (VIP) for ≥second-line treatment of HER2-positive MBC.

Methods: Patients with HER2-positive MBC who received ≥second-line treatment at our hospital from June 2020 to December 2022 were enrolled. Progression-free survival (PFS), objective response rate (ORR), clinical benefit rate (CBR) and adverse reactions were assessed. Patients received VIP regimen until disease progression or unacceptable toxicity and were evaluated every two cycles according to the RECIST 1.1 criteria.

Results: Eight-nine patients were included based on the inclusion and exclusion criteria. Among them, 45 patients received second-line treatment who couldn't use T-DM1 or T-DXd, and 44 patients received ≥third-line treatment. The median PFS of the second-line treatment subgroup was 17months, the ORR and CBR were 60.0% and 86.7%, respectively, which were significantly higher than those in the ≥third-line treatment subgroup and numerically superior to T-DM1 as a second-line treatment option. Additionally, the median PFS of patients with baseline brain metastasis who did not receive radiotherapy was 7 months, and ORR and CBR were 27.3% and 72.7%, respectively. The most common adverse events observed were leukopenia (37.1%), neutropenia (42.7%), anemia (34.8%) and diarrhea (67.4%). The incidence of grade 3-4 leukopenia, neutropenia, anemia and diarrhea were 11.2%, 15.7%, 5.6% and 27.0%, respectively. A total of 8 patients (8.9%) discontinued medication due to adverse reactions.

Conclusions: The VIP regimen demonstrated good efficacy and controllable toxicity as a second-line treatment for HER2-positive MBC. This therapeutic regimen provides a viable alternative option for patients who are unable to receive ADCs as the second-line treatment.

434P Incidence and prognostic value of HER2-low expression metastatic breast cancer in Asian population: A 10-year retrospective study

T. Dajsakdipon[1], W. Pipatsakulroj[2], T. Dejthevaporn[3]

[1]Department of Medicine, Ramathibodi Hospital, Bangkok, Thailand; [2]Department of Pathology, Mahidol University - Faculty of Medicine Ramathibodi Hospital, Bangkok, Thailand; [3]Internal Medicine Department, Mahidol University - Faculty of Medicine Ramathibodi Hospital, Bangkok, Thailand

Background: The natural disease across each molecular subtype of breast cancer are variable. Although novel drugs for the treatment of human epidermal growth receptor (HER2) overexpression subtype metastatic breast cancer have been widely utilized, the treatment options for HER2 low expression is limited. The epidemiology and clinical outcome of metastatic HER2-low expression breast cancer among the Asian population have not been thoroughly described.

Methods: A 10-year retrospective cohort study was conducted from the Ramathibodi Cancer Registry database during 2011-2021. We aimed to investigate the incidence and compare the overall survival (OS) of non-HER2 expression and HER2-low metastatic breast cancer. Prognostic factors for survival were analyzed by logistic regression analysis.

Results: Out of 8,633 patients, 491 met the study criteria. Of those, 104 (21.2%) had HER2-low expression tumors, while 247 (50.3%) had HER2-negative expression tumors. When stratified by hormonal receptor status, 85 patients (81.7%) were hormonal receptor (HR)-positive and 19 patients (18.3%) were HR-negative. The median OS (IQR) was significantly longer in patients with HER2-low expression tumors compared to those with HER2-negative expression tumors (median OS 41 (26-56) months vs. 23 (19-27) months; HR, 0.66, 95% CI (0.49-0.88), p = 0.004). Among the HR-positive tumors, patients with HER2-low expression also had a significantly longer OS than those without HER2 expression (median OS 54 (42-66) months vs. 30 (26-34) months; HR, 0.65, 95% CI (0.46−0.92), p= 0.014). In the HR-negative group, the survival in patients with HER2-low expression tumors was comparable to those without HER2 expression tumors (median OS 13 (8-18) months vs. 14 (11-17) months; HR, 1.09, 95% CI (0.64−1.86), p=0.76).

Conclusions: One in five Asian patients with metastatic breast cancer could develop HER2 low-expression tumors. Those with HER2 low-expression tumors, particularly in the HR-positive subtype, tend to have longer survival than those without HER2 expression tumors among patients with metastatic breast cancer.

435P Phase II single arm study of durvalumab and olaparib (D+O) in heavily pretreated triple-negative breast cancer (TNBC) with or without germline BRCA mutation (gBRCAm)

T. Fujii, S. Lipkowitz, A.D.S. Zimmer, E. Villanueva, B.B. Solarz, J-M. Lee

Women's Malignancies Branch, National Cancer Insitute - Center for Cancer Research, Bethesda, MD, USA

Background: PARP inhibitors (PARPis) induce STING-cGAS activation and increase tumor mutational load in TNBC preclinical models, making TNBC sensitive to immune checkpoint blockade. The MEDIOLA phase II study demonstrated a 63.3% overall response rate (ORR) defined as CR+PR with D+O in PARPi naïve gBRCAm BC (1 median number of prior therapies [range 0-4]). We evaluated D+O activity in heavily pretreated TNBC.

Methods: Key eligibility criteria include metastatic TNBC, adequate performance status and organ function. Patients (pts) with prior use of D or PARPi, and active CNS or leptomeningeal disease were not eligible. No limit on the number of prior systemic therapies. For germline BRCA wild type (gBRCAwt), Simon's 2-stage design with a target of 30% ORR with α=0.1 and β=0.1 was used. If ≥ 2 responses in the first stage (16 pts), 9 additional pts were planned to enroll. 5 ≥ of 25 responses warrant a further later stage study. For gBRCAm, a pilot single stage design was used with a stopping rule. If 1≥ response in the first 5 pts, another 5 pts were planned to enroll. RP2D determined in our earlier phase I study; D 1500 mg iv q4w and O 300 mg BID po (28-day cycle) was administered until PD or intolerable toxicity. The primary endpoint was ORR by RECIST v1.1 (CT q2mo). Secondary objectives were safety by CTCAE v4.03, clinical benefit rate (CBR) defined by CR+PR+SD≥4mo, and PFS.

Results: 14 of 15 pts were RECIST evaluable (11 gBRCAwt and 3 gBRCAm). The median number of prior therapies are 3 (range 0-9). A majority of pts (78.6%; 11/14) had ≥ 3 prior systemic therapies and 64.3% (9/14) had previous platinum. Of note, 4 pts had either HR+/HER2-BC (n=3) or HR+/HER2+BC (n=1) at diagnosis which converted to TNBC at recurrence. ORR was 28.5% (3/3 gBRCAm [3 PR] and 1/11 gBRCAwt [PR for 10.3 mo]). One pt with gBRCAm remains on the study with PR >4 yr (96% reduction at best). CBR was 42.9% (3/3 gBRCAm and 3/11 gBRCAwt). Median PFS was 3.7 mo (IQR 1.9-10.3). There were no new safety signals. Accrual is ongoing.

Conclusions: D+O exhibited modest clinical activity in heavily pretreated TNBC pts with or without gBRCAm. Comprehensive biomarker and pharmacodynamic studies are ongoing for the exceptional responder with gBRCAm.

Clinical trial identification: NCT02484404 Release date: June 29, 2015.

Legal entity responsible for the study: J-M. Lee.

Funding: Intramural Research Program of the NCI, CCR (grant number: #ZIA BC011525; to J-M. Lee) Durvalumab and olaparib were supplied to the CCR, NCI under a Cooperative Research and Development Agreement between the CCR/NCI and AstraZeneca. Research funding was also provided by AstraZeneca to the institution.

436P Preliminary results from a prospective study of inetetamab in combination with pyrotinib and utidelone for HER2-positive metastatic breast cancer (IPUtrial)

H. Cao[1], T. Sun[1], Z. Li[2], M. Yan[3], X. Cui[4], C. Zhou[5], M. Jing[1], X. Guo[1], Y. Wang[1]

[1]Breast Internal Medicine, Liaoning Cancer Hospital & Institute, Shenyang, China; [2]Department of Internal Medicine-Oncology, Anshan No.4 People's Hospital/ Anshan Cancer Hospital, Anshan, China; [3]Galactophore, Henan Cancer Hospital/Affiliated Cancer Hospital of Zhengzhou University, Zhengzhou, China; [4]Medicine-Oncology, Chaoyang Central Hospital, Chaoyang, China; [5]Medicine-Oncology, Huludao Central Hospital, Huludao, China

Background: Anti-HER2 therapy combined with chemotherapy is the standard therapy for HER2-positive metastatic breast cancer (MBC). Efficacy and safety of inetetamab and pyrotinib in advanced first-line and second-line treatment of HER2-positive breast cancer have been confirmed. Utidelone, a genetically engineered epothilone analogue, has demonstrated antitumor activity in MBC. This study aimed to explore efficacy and safety of the new regimen combined with these three drugs.

Methods: IPUtrial is a prospective, multicenter, single arm, phase 2 study. The study enrolled HER2-positive MBC patients (pts) with first/second line therapy. Pts received inetetamab (8 mg/kg in cycle 1 and 6 mg/kg in subsequent cycles, day 1, IV), pyrotinib (400 mg/d, qd, po) and utidelone (30mg/m^2, days 1-5, IV) of each 21-day cycle until disease progression or intolerable toxicity. The primary endpoint was objective response rate (ORR) per investigator (INV). The secondary endpoints included INV-assessed progression-free survival (PFS), overall survival (OS) and safety.

Results: At date cutoff (1 Apr 2023), we enrolled 47 pts (29 patients were evaluable for response with median cycles of 8 (4-20) and still undergoing treatment, 19 (65.5%) for the first-line therapy and 10 (34.5%) for the second-line therapy). We reported the efficacy and safety from 29 pts. Partial response (PR) was achieved in 23 pts and stable disease (SD) in 4 pts, the ORR was 79.3% and DCR was 93.1%. The median PFS was not reached. Most of the treatment-related adverse events (TRAEs) were grade 1 or 2 and were considered manageable and reversible. The most common TRAEs was diarrhea (29[100%]). Grade 3 diarrhea was reported in 24 pts (82.8%) with the combination therapy. No treatment-related discontinuation or deaths occurred.

Conclusions: Inetetamab plus pyrotinib and utidelone may be an excellent scheme for HER2-positive metastatic breast cancer. This trial is still ongoing and needs long-term follow-up.

437P Improving safety and convenience for breast cancer patients receiving CDK 4/6 inhibitor treatment via a telemedicine app

B. Mrinakova[1], J. Simko[2], J. Eggova[3], M. Hancinova[1], B. Vertakova Krakovska[4], S. Putekova[5], J. Homolova[1], D. Ondrus[1], F. Lehocki[2]

[1]Department of Oncology, Comenius University and St. Elisabeth Cancer Institute, Bratislava, Slovak Republic; [2]Faculty of Informatics and Information Technologies, Slovak Technical University, Bratislava, Slovak Republic; [3]Faculty of Medicine, Comenius University, Bratislava, Slovak Republic; [4]Medical Oncology Department, St. Elisabeth Cancer Institute, Bratislava, Slovak Republic; [5]Faculty of Health Care and Social Work, Trnava University, Trnava, Slovak Republic

Background: CDK 4/6 inhibitors, including palbociclib, ribociclib, and abemaciclib, have become an essential component of breast cancer treatment. These targeted therapies require monitoring of blood counts, biochemistry, drug interactions, and synergic side effects like QTc prolongation. Post-COVID-19, a telemedicine app was developed for a more convenient and safe patient management approach.

Methods: A prospective pilot study enrolled breast cancer patients on CDK 4/6 inhibitors to use a telemedicine app, allowing them to return home after blood collection, receive results and recommendations, register adverse reactions, and, in ribociclib cases, monitor ECG with automatic QTc evaluation. The app offered comprehensive information on drug interactions and synergic side effects with concomitant medications. App performance was assessed using EORTC QLQ-C30 and FACT-B questionnaires at baseline and after app usage.

Results: 20 patients participated in the study. According to the EORTC QLQ-C30 global health status and FACT-B scores, the patients' quality of life was effectively maintained. The app reduced waiting room time by an average of 127 minutes per visit ($p<0.01$). In addition, the physicians involved in the study reported increased confidence in patient safety due to the comprehensive information provided by the app.

Conclusions: The telemedicine app offers a valuable tool for optimizing the management of patients on targeted therapies. It not only maintains patients' quality of life but also enhances overall healthcare efficiency by reducing waiting times and strengthening physicians' perception of patient safety. Future studies should explore the long-term impacts of the app, particularly on patient adherence, survival rates, and cost-effectiveness. With an enlarged patient cohort, there is substantial potential for notable enhancements in quality of life. This expanded investigation could offer deeper insights, enabling us to tailor our telemedicine approach more effectively, thus promoting a higher standard of patient care.

438P Phase I study of ZV0203, a first in class pertuzumab ADC, in patients with HER2+ advanced solid tumors

F. Lin[1], Y. Huang[2], Y. Lu[2], X. Rao[3], F. Wang[2], Y. Huang[4], X. Huang[5]

[1]Medical Oncology, Shanghai East Hospital, Tongji University, Shanghai, China; [2]Translational Medicine, Hangzhou Adcoris Biopharma Co., Ltd, Hang Zhou, China; [3]Medical Oncology, The First Affiliated Hospital of Nanchang University, Nanchang, China; [4]Medical Department, Hangzhou Adcoris Biopharma Co., Ltd., Hangzhou, China; [5]PK, Hangzhou Adcoris Biopharma Co., Ltd., Hangzhou, China

Background: ZV0203, a first in class pertuzumab antibody-drug conjugate (ADC), targets HER2+ tumor cells with tubulin inhibitor duostatin-5 (DUO5) as its payload via a stable and protease-cleavable valine-citrulline linker. In preclinical studies, ZV0203 demonstrated superior antitumor activity compared to Kadcyla in multiple tumor cell line xenograft models with no noticeable toxicity. GLP toxicity studies indicated that ZV0203 was well tolerated with an estimated therapeutic index of 35.

Methods: This was an open-label, multicenter, phase 1, dose-escalation study in patients (pts) with HER2+ advanced solid tumors. Primary objectives were safety, tolerability and recommended phase 2 dose. Secondary objectives included pharmacokinetics (PK), immunogenicity and preliminary clinical efficacy. ZV0203 was administered intravenously Q3W on a 21-day cycle. An accelerated titration design was used for the 0.3 and 0.6 mg/kg doses, followed by a 3+3 design for 1.2, 1.8, 2.7 and 3.6 mg/kg dose levels.

Results: As of August 23, 2023, 15 pts with solid tumors (breast [11], colorectal [2], gastric [1], lung [1]) were enrolled across doses of 0.3-3.6 mg/kg with a median age of 52 years (range 35-65), of which 9 pts received prior HER2-targeted therapy (trastuzumab $\pm$ pertuzumab) and 11 pts completed 21-day DLT assessment (0.3 mg/kg and 0.6 mg/kg [1 each], 1.2 mg/kg, 1.8 mg/kg and 2.7 mg/kg [3 each]) with no DLT incidence. Treatment-related adverse events (TRAE) occurred in 11 (73.3%) pts. The most frequent TRAEs were elevated liver enzymes [6], corneal epitheliopathy [5], dry eyes [4], leukopenia, neutropenia, proteinuria and anemia [3 each], and most were grade 1-2 in severity. 2 pts experienced grade 3 TRAEs: lymphocytopenia (1.8mg/kg [1]) and blurred vision (2.7 mg/kg [1]), which were manageable during treatment. TRAEs led to 6.7% (1/15) treatment discontinuation. Among 11 pts evaluated, 2 pts achieved a best tumor response of PR; 5 pts had SD; 1 pt had Non-CR/Non-PD per RECIST v1.1. Thus, disease control rate was 73% (8/11). Interim PK results demonstrated that the PK profile of total antibody was similar to that of ZV0203 ADC, whose systematic exposure increased in a dose-dependent manner. Concentration of DUO5 remained scarce, suggesting good stability of ZV0203.

Conclusions: ZV0203 has a manageable safety profile with preliminary antitumor activity in heavily pretreated pts with HER2+ cancer. Further evaluation at higher doses is underway.

Clinical trial identification: NCT05423977.

439P Testing HR+ / HER2- patients with advanced or metastatic breast cancer for identification of tissue mutations in the PIK3CA gene: Results of a national program by the Hellenic Society of Medical Oncology (HeSMO)

A. Boutis, M. Nikolaou, A. Ardavanis, C. Tolis, K. Loga, I. Korantzis, A. Koumarianou, A.N. Christopoulou, G. Papatsimpas, A. Bokas, K. Pliarchopoulou, E. Kampletsas, G. Kesisis, E. Biziota, K. Psianou, S. Karageorgopoulou, E.A. Sogka, N.G. Tsoukalas, N. Chatzifoti, Z. Saridaki-Zoras

HeSMO, Hellenic Society of Medical Oncology, Athens, Greece

Background: PIK3CA mutations have been identified in approximately up to 40% of breast cancer cases and PIK3CA targeting has already been incorporated in treatment algorithms, especially in the second line of ER+/HER2- patients. HeSMO launched a national program to provide PIK3CA mutation testing, which is officially not reimbursed, with the aim to identify mutations in the PIK3CA gene, and, therefore, lead to more therapeutic options.

Methods: All HR+/HER2- patients with a diagnosis of metastatic breast cancer were eligible to participate in this program. The result of the test was obtained using the COBAS® PIK3CA method, a diagnostic test specifically designed to detect mutations in the PIK3CA gene in tumor tissue samples (FFPE) attained by biopsy or surgically, which detects 17 different mutations in the PIK3CA gene, including the most commonly occurring in Exons 9 and 20.

Results: From June 2022 to March 2023, 149 patients from across the country were tested within this program. Sixty one (61) patients (40.94%) were detected with mutation in PIK3CA gene and 88 (59.06%) without mutation (Table). 23 patients had Exon 9 mutations (37.70%), 33 in Exon 20 (54.10%), and 8 had mutations in the remaining Exons 1, 4 and 7 (13.11%). In 1 sample 4 mutations were detected: (Exon 7/9/20), and 2 mutations in another 2 samples (Exon 9: E545X, Q546X and Exons 1/20), while in all other samples just 1 mutation was detected in each.

Table: 439P PIK3CA mutation results of HeSMO's program

Exon	Mutation	Samples	Mutation percentage in all patients detected with PIK3CA gene mutation (61)	Mutation percentage in all patients tested (149)
Exon 1	R88Q	2	3,28%	1,34%
Exon 4	N345K	3	4,92%	2,01%
Exon 7	C420R	3	4,92%	2,01%
Exon 9	E542K	7	11,48%	4,70%
Exon 9	E545X	12	19,67%	8,05%
Exon 9	Q546X	2	3,28%	1,34%
Exon 9	E545X, Q546X	1	1,64%	0,67%
Exon 9	E542K, E545X	1	1,64%	0,67%
Exon 20	H1047X	32	52,46%	21,48%
Exon 20	G1049R	1	1,64%	0,67%

Conclusions: In our series, 40.94% of the patients tested, were detected with mutations in PIK3CA gene, in accordance with published data. Apart from the significant implications for treatment possibilities in a substantial patients' population, these results provide valuable epidemiological data and strengthen our efforts for reimbursement of PIK3CA mutation testing in Greece.

440P Palliative radiotherapy in metastatic breast cancer: Does molecular subtype predict patient response to radiotherapy?

M. El Bessi, Z. Naimi, M. Bohli, R. Ben Amor, A. Hamdoun, R. Haddad, G. Bouguerra, L. Kochbati

Department of Radiation Oncology, Abderrahmen Mami Hospital, Ariana, Tunisia

Background: This study aimed to determine whether molecular subtype does impact patient response to palliative radiotherapy in metastatic breast cancer.

Methods: All metastatic breast cancer patients referred for palliative radiotherapy (either for pain-relief or spinal cord/nerve decompression), between 2017 and 2022, were included in this study. Patient response to radiotherapy was evaluated at 3 weeks from radiotherapy. Re-irradiation need was assessed. Radiotherapy outcomes were statistically analyzed with regards to breast cancer molecular subtypes.

Results: Data of 137 metastatic breast cancer patients were evaluated. Ductal cell carcinoma was the most common histological type. Patients' distribution according to molecular subtype was as follow: 17% of luminal A tumors, 72% of luminal B tumors, 6% of Her2 tumors and 5% of triple-negative tumors. All patients received single fraction palliative radiotherapy with a prescription dose of 8 Gy and 6 Gy respectively in 77 % and 13 % of cases. Forty-six patients were lost to follow-up and one patient didn't complete treatment. Complete response to radiotherapy was reported in 21%, 54% and 50% of cases, respectively for luminal A, luminal B and Her2 tumors. No complete response was found in the triple-negative breast cancer subgroup. The "no response to radiotherapy" rate for luminal A and luminal B tumors, was 21% and 20% respectively. Re-irradiation of the same metastatic subsite was performed in 8 patients, all with luminal B molecular subtype. Although not statistically significant, luminal tumors tended to respond better to palliative radiotherapy when compared to non-luminal tumors, with a complete response rate of 48% versus 30% respectively ($p=0.3$). No statistically significant correlation was found between breast cancer molecular subtype and radiotherapy outcomes.

Conclusions: This study suggests that breast cancer subtypes do exhibit differential responses to palliative radiotherapy. Yet molecular subtype failed to reliably predict radiotherapy outcomes and identify patients who would derive greater than average benefit from palliative radiotherapy. Further studies are needed to identify reliable biomarkers predictive of likely radiotherapy sensitivity.

Background: RIBANNA (CLEE011ADE03) is a prospective, noninterventional study assessing the efficacy and safety of RIB+AI/FUL, or endocrine therapy (ET) or chemotherapy (CT) in pre-, peri- and postmenopausal women with hormone receptor-positive (HR+), human epidermal growth factor receptor-2-negative (HER2-) advanced breast cancer (ABC) in a broad patient population. Real-world data on the efficacy of RIB in subgroups of special interest resulting from the 5th IA from the RIBANNA study will be presented at the conference.

Methods: Efficacy outcomes in subgroups of special interest will be determined. Adjusted progression-free survival (PFS) for 1L RIB will be separately analyzed for patients with visceral vs. non-visceral metastases (lung, liver, central nervous system), pre- vs postmenopausal patients, patients receiving AI vs FUL as Ribociclib combination partner, de novo vs. recurrent and endocrine-resistant vs. -sensitive disease. In addition, conditional PFS (this is, the probability of survival without progression for further months given a previous survival for a defined number of months) will be analyzed for patients without progression at 6, 12, and 24 months in the overall study population.

Results: At data cutoff Sep 6, 2022, 2581 patients were enrolled in the study (RIB+AI/FUL, n = 2163; ET, n = 237; CT, n = 181). At baseline there were 189 pre/peri and 1605 postmenopausal patients and 750 patients with visceral metastases in the RIB cohort included in the study. 1566 patients received AI and 415 received FUL in the RIB cohort at baseline. At study start 381 de novo and 1765 recurrent patients were included over all treatment cohorts. The unadjusted KM estimate for median PFS was 32.2 months (95% CI, 29.3—34.8) in the RIB + AI/FUL cohort. Herein, efficacy data (PFS, conditional PFS) in the specified patient subgroups will be presented.

Conclusions: The RIBANNA study analyses the use of RIB in a diverse patient population in the clinical routine. RIB showed efficacy superiority over ET and CT in the overall patient population. Data on the real-world efficacy of specific patient subgroups will be presented at the conference.

Clinical trial identification: CLEE011ADE03.

Background: CDK4/6 inhibitors added to hormone therapy (CDKi-HT) is the standard first-line (1L) treatment for patients with HR+/HER2- advanced breast cancer (ABC). After CDKi-HT, treatment strategies are associated with shorter progression-free survival (PFS), and therapeutic strategies are usually tailored to clinical factors and predictive biomarkers. Our aim was to explore prognostic factors in the second-line (2L) treatment setting and determine clinical factors associated with treatment efficacy.

Methods: Retrospective cohort of HR+/HER2- ABC patients, from 17 public and private facilities in Argentina. Patients were included if started 2L treatment between November 2015 and October 2022. Clinical factors associated with treatment decisions were evaluated with t and chi-square tests. Kaplan-Meier method was used for survival analysis. Cox regression tests were applied to explore prognostic factors. $p<0,05$ was considered statistically significant.

Results: 280 patients were analyzed (Mean age 52.4+/-14, 57% postmenopausal). 98.5% received CDKi-HT in the 1L setting (med. PFS 17.8m, CI95% 8.1-28.4). Among the 240 patients with evaluable data, 39.2% received chemotherapy (CT) for the 2L setting and 53.7% received hormone therapy with or without other agents. With a median follow-up of 26 months, med. 2L-PFS was 6.6 months (CI 95% 5.8-7.6). After applying multivariate analysis, menopausal status (adj. HR 0.65 CI95% 0.44-0.98; p=0.038) and primary sample Ki67 (adj. HR 2.37 CI95% 1.14-4.9, p=0.02) were associated with 2L-PFS. An interaction was observed between selected treatment agents and menopausal status (p=0.015). In patients that did not receive CT, Median 2L-PFS was 4.66 (CI95% 4.06-6.03) and 8.7 (CI95 7-11.16) months for premenopausal and postmenopausal patients respectively (p=0.0006).

Conclusions: Real-world evidence is relevant to obtain further information regarding prognostic and predictive factors. Treatment selection should be carefully individualized in patients that experienced disease progression after CDKi-HT. The implications of our results should be carefully analyzed incorporating the experiences of other collaborative efforts.

Background: No data on the efficacy of cyclin-dependent kinase 4/6 inhibitors (CDKi) were presented in randomized clinical trials in patients with metastatic breast cancer (mBC) with bone marrow involvement. This study aimed to investigate the efficacy and safety of CDKi in patients with mBC with bone marrow involvement.

Methods: The data of patients with bone marrow-involved hormone receptor-positive (HR+) Her2-negative mBC between 2019- 2022 who received ribociclib or palbociclib in combination with endocrine therapy (ET) were retrospectively analyzed within the thirteen centers.

Results: The median age of 23 patients included in the study was 48 (range: 29-75). Eleven (48.8%) of the patients were denovo metastatic. Eight of the patients (34.8%) received CDKi treatment in the first line, 5 (21.7%) in the second line, and 10 (43.5%) in $\geq$ the 3rd line. In addition to bone marrow metastasis, 39.1% of the patients had bone +/- lymph nodes, and 56.5% had bone + visceral organ metastasis. Of the patients, 15 (65.2%) received ribociclib and 8 (34.8%) received palbociclib. When the CDKi response was evaluated, 2 (8.7%) of the patients had a complete response, 11 (47.8%) had a partial response, 8 (34.8%) had stable disease, and 2 (8.7%) had progressive disease. Median follow-up was 15.1 (95% CI: 5.8-24.5) months. The progression-free survival (PFS) of patients who received CDKi in first-line was 21.3 (95% CI: 0.8-41.9) months, those who received CDKi in second-line 13.1 (95% CI: 6.9-19.3) months, and those who received CDKi in $\geq$3rd line 5.3 (95% CI: 3.9-6.7) months (p=0.004). CDKi dose reduction was required in 60.9% of patients. CDKi was discontinued in 2 (8.7%) patients due to cytopenias and 56.5% due to disease progression. Eleven (47.8%) patients had grade $\geq$3 neutropenia, and 5 (21.7%) patients had grade $\geq$3 thrombocytopenia. No treatment-related death was detected.

Conclusions: It has been shown that PFS similar to those in randomized clinical studies can be achieved with CDK 4/6 inhibitors combined with ET in treating hormone receptor-positive Her2-negative bone marrow-involved metastatic breast cancer. The CDKi discontinuation associated with cytopenia was also meager showed that CDKi treatment could be safe in this patient group.

Background: Antiangiogenic drugs have demonstrated synergistic effect with anti-PD-1 antibody in advanced triple-negative breast cancer (TNBC). Anlotinib is an oral multi-target tyrosine kinase inhibitor (TKI) that strongly inhibits VEGFR, PDGFR, FGFR, and c-kit. Preclinical studies showed that metronomic chemotherapy inhibited angiogenesis and enhanced the efficacy of immunotherapy in TNBC via modulation of the tumor immune microenvironment. We hereby conducted a trial to investigate the efficacy and safety of sintilimab (anti-PD-1 antibody) plus anlotinib and metronomic chemotherapy as a potential novel therapeutic strategy in advanced TNBC and explore potential biomarkers.

Methods: 43 cases were planning to be included in this trial. The eligible patients who had received no more than two lines of chemotherapy for metastatic disease were enrolled and received sintilimab (200 mg iv q3w) and anlotinib (12 mg po d1-14 q3w) plus capecitabine (500 mg po, tid) or vinorelbine (40 mg po, tiw) until disease progression or intolerable toxicity. The primary endpoint is objective response rate (ORR).

Results: As of April 2023, a total of 38 patients were enrolled, and 36 patients were evaluable for efficacy. 3 patients (8.3%) achieved complete response (CR). 6 patients (16.7%) achieved partial response (PR). 21 patients (58.3%) achieved stable disease (SD). The ORR is 25.0% (95%CI 0.12-0.42) and DCR is 83.3% (95%CI 0.67-0.94). The median PFS was 6.6 months (95%CI 2.12-11.08). The most common grade 1 or 2 adverse events (AEs) include elevated thyroid stimulating hormone (58.33%, 21/36), elevated bilirubin (27.78%, 10/36) , hand-foot syndrome (22.22%, 8/36), leukopenia (19.44%,7/36) and nausea (16.67%, 6/36) . Grade 3 AEs include elevated bilirubin (2.78%, 1/36), hypertension (2.78%, 1/36) and herpes zoster (2.78%, 1/36). No grade 4 or 5 AEs occurred.

Conclusions: Our date showed that sintilimab in combination with anlotinib plus metronomic chemotherapy have shown favorable efficacy and acceptable safety profile in patients with advanced TNBC.

Clinical trial identification: ChiCTR2100044725.

445P Tyrosine kinase inhibitors (TKIs) in HER2-positive metastatic breast cancer after trastuzumab emtansine (T-DM1) failure: A multicenter real-world study

C. Sun, Y. Yin, W. Li, X. Huang, Y. Hua, N. Jin

Department of Oncology, Jiangsu Province Hospital - The First Affiliated Hospital of Nanjing Medical University, Nanjing, China

Background: Trastuzumab emtansine (T-DM1) is recommended as the standard treatment of second-line therapy of HER2-positive metastatic breast cancer (MBC) previously treated with trastuzumab. However, subsequent therapeutics after T-DM1 failure remain controversial. This study investigated the effectiveness and safety of tyrosine kinase inhibitors (TKIs)-based therapy in HER2-positive MBC with T-DM1 resistance.

Methods: From September 2018 to October 2021, 53 patients with HER2-positive MBC who received TKIs-based therapy after T-DM1 failure were enrolled in this multicenter real-world study. The primary endpoint was progression free survival (PFS). Secondary endpoints included objective response rate (ORR), overall survival (OS), clinical benefit rate (CBR) and safety.

Results: 53 patients received TKIs-based therapy in 2 or later line treatment. The median PFS of TKIs-based therapy was 11.9 months (95% CI 7.9-15.9). ORR and CBR were 19.6% and 72.5%, respectively. A median PFS of 10.5 months (95% CI 7.5-13.5) and an intracranial ORR of 33.3% were observed among patients with brain metastasis (n=12). A better PFS was observed among patients with pyrotinib (n=21) compared with lapatinib (n=30), and patients who derived favorable benefit from T-DM1 (PFS $\geq$ 6 months). Hormone receptor status (HR) and T-DM1 response were independent indicators for curative effect of TKIs-based therapy. The most commonly adverse events were thrombocytopenia (23.6%), diarrhea (15.7%), leucopenia (15.7%), and hand-foot syndrome (15.7%).

Conclusions: TKIs-based therapy showed promising efficacy and safety in patients with HER2-positive MBC after T-DM1 failure, including those with brain metastases. Patients who benefited from prior T-DM1 achieved a significantly longer PFS in subsequent TKIs-based therapy.

446P CDK4/6 inhibitors in the first-line treatment of postmenopausal women with HR+/HER2- advanced or metastatic breast cancer: An updated network meta-analysis and cost-effectiveness analysis

N. Zeng[1], J. Han[2]

[1]*Department of Head and Neck Oncology, West China Medical Center of Sichuan University, Chengdu, China;* [2]*Department of Oncology, West China School of Medicine/ West China Hospital of Sichuan University, Chengdu, China*

Background: Recently updated results of clinical trials have confirmed that palbociclib, ribociclib and abemaciclib plus letrozole/anastrozole significantly prolonged survival compared to placebo plus letrozole/anastrozole in the first-line treatment for postmenopausal women with HR+/HER2- metastatic breast cancer. However, the high cost of CDK4/6 inhibitors imposes a huge financial burden on patients and healthcare systems.

Methods: Studies estimating CDK4/6 inhibitors plus NSAI for HR+/HER2- ABC were searched. A network meta-analysis was made with the main outcomes HRs of OS and PFS. The costs and efficacy of four first-line therapies for HR+/HER2- ABC were evaluated by Markov model. The main outcomes in the cost-effectiveness analysis were incremental cost-utility ratios (ICURs), incremental monetary benefit (INMB), and incremental net-health benefit (INHB). The robustness of the model was assessed by one-way, three-way, and probabilistic sensitivity analyses.

Results: Seven studies involving 5347 patients were included in the NMA. The three first-line CDK4/6 inhibitors plus NSAI groups provided significant PFS and OS superiority to NSAI alone. Abem+NSAI represented a significant statistical advantage on PFS and indicated a trend in best OS benefit compared to the Placebo+NSAI group. Abem+NSAI, Palbo+NSAI, and Ribo+NSAI groups resulted in additional costs of $12,602, $20,391, and $81,258, with additional effects of 0.38, 0.31, and 0.30 QALYs, respectively, leading to an ICUR of $33,163/QALY, $65,777/QALY, and $270,860/QALY. Additional pairwise comparisons showed Abem+NSAI was the only cost-effective option in three CDK4/6 inhibitors plus NSAI groups. The sensitivity analyses showed that the proportion of receiving subsequent CDK4/6 inhibitors and the cost of abemaciclib significantly influenced the results of Abem+NSAI.

Conclusions: From the Chinese payers'perspective, Abem+NSAI was a cost-effective treatment compared with Placebo+NSAI at the willingness-to-pay of $38,029/QALY. The Palbo+NSAI and Ribo+NSAI groups were cost-effective unless adjusting drug prices to 50% or 10% of current prices is probably cost-effective.

447P Efficacy and safety of trastuzumab with or without a tyrosine kinase inhibitor for HER2-positive breast cancer: A systematic review and meta-analysis

L. Li, D. Zhang, Y. Wu, F. Ma

Department of Medical Oncology, Chinese Academy of Medical Sciences and Peking Union Medical College - National Cancer Center, Cancer Hospital, Beijing, China

Background: This study aimed to explore whether the combination of trastuzumab and small molecule tyrosine kinase inhibitor (TKI) can further improve the efficacy of HER2-positive breast cancer without adding additional adverse events.

Methods: PubMed, Embase, Cochrane, and Web of Science were systematically searched for relevant articles from inception until Nov 2022. Overall survival (OS) and progression-free survival (PFS) were the primary outcomes. Subgroup analyses were performed based on disease status and TKI types.

Results: A total of 10,623 patients from 16 studies were included in this meta-analysis. Trastuzumab combined with TKI dual-target blockade showed significant improvement in PFS and OS compared with trastuzumab single-targeted therapy. A random-effects model was applied and the pooled HR was 0.52 (95% CI: 0.41—0.66, $P<0.001$), suggesting that trastuzumab plus TKI was highly associated with better PFS. Further subgroup analysis of the different TKI agents (including lapatinib, pyrotinib, and tucatinib) showed that combination therapy was related to better PFS in all subgroups. In the metastatic setting, patients receiving trastuzumab combined with TKI had significantly longer OS than those receiving trastuzumab monotherapy (HR=0.71, 95% CI: 0.58—0.87, P=0.001). Besides, higher objective response rate was observed with trastuzumab plus TKI (OR=2.17, 95% CI: 1.34—3.50, P=0.002). Patients receiving combination therapy had a higher incidence of discontinuation, and grade $\geq$3 diarrhea.

Table: 447P Subgroup analysis for the OS and PFS

Subgroup	OS			PFS		
	No. of patients	Pooled HR (95% CI)	*P* -value	No. of patients	Pooled HR (95% CI)	*P* -value
All patients	5,660	0.77 (0.67—0.88)	<0.001	1,439	0.52 (0.41—0.66)	<0.001
Treatment						
tucatinib+ trastuzumab	612	0.73 (0.59-0.90)	0.003	612	0.57 (0.47-0.70)	<0.001
lapatinib+ trastuzumab	5,048	0.78 (0.64-0.96)	0.022	237	0.62 (0.44-0.88)	<0.001
pyrotinib+ trastuzumab	-	-	-	590	0.41 (0.32-0.53)	<0.001

Conclusions: In summary, combining TKI with trastuzumab confers a significant improvement in clinical outcomes with tolerable toxicity for individuals with HER2-positive breast cancer, especially in advanced settings. The different efficacies of TKIs combined with trastuzumab may be related to the mechanism of action of the different TKIs.

448P Real-world experience with CDK4/6 inhibitors for HR+/HER2- metastatic breast cancer (MBC)

H.M.A. Abdallah, Y.I. Owoseni, A. Sultan, S. Ahmed, J. Wood, B. Varadhan, O. Ayodele

Medical Oncology, Leicester Royal Infirmary - University Hospitals of Leicester NHS Trust, Leicester, UK

Background: Metastatic hormone receptor-positive (HR+)/human epidermal growth factor receptor-2-negative (HER2-) breast cancer remains a significant cause of cancer-related mortality. First-line treatment with endocrine therapy (ET) with a cyclin-dependent kinases 4 and 6 inhibitor (CDK4/6i) has become the standard of care. Data on populations that have been treated in the real-world setting may provide an insight into changes of patient characteristics and prognosis over time.

Methods: Retrospective data of patients (pts) who received CDK4/6i with ET between 2017 and 2022 at University Hospitals of Leicester NHS Trust were analysed. Patient characteristics, efficacy and toxicity outcomes were examined. Kaplan-Meier survival curves were determined using SPSS program.

Results: In all, 235 pts who were on ET in combination with Palbociclib 51% (n=119), Ribociclib 41% (n=97) and Abemaciclib 8% (n=19) were included. The median age was 62 years (33-90). De novo MBC accounted for 33% (n=78) of pts. Most (n=180, 70%) were post-menopausal. The majority 74% (n=175) had visceral disease (lung, liver, peritoneum) vs 26% (n=60) with bone-only disease. The CDK4/6i was discontinued in 48% (n=113) due to disease progression. Over half (n=135, 57%) required at least one dose reduction (DR). The most common reason for DR was neutropenia. Sixty (26%) pts remain on treatment at the time of analysis. Thirteen pts had CDK4/6i switched within 3 months of starting treatment due to toxicities. Median duration on Palbociclib (P), Ribociclbib (R), and Abemaciclib (A) was 20 months; 95%

CI= 16.4-23.6, 18; 95% CI= 12.6-23.4 and 8; 95% CI= 0.7-15.3 months respectively. Median PFS between different CDK4/6i were P (24 months; 95% CI= 19.5-28.7), R (27 months; 95% CI= 20.5-33.3) and A (13 months; 95% CI= 6.8-18.9), p=0.22. The difference in median OS was statistically significant (p=0.004) between CDK4/6i; P (54 months; 95% CI= 42.4-58.8), R (46 months; 95% CI= 32.8-60.1) and A (26 months; 95% CI= 4.2-47.8).

Conclusions: CDK4/6i is safe and effective in this population with extensive burden of disease. Dose reduction did not appear to have an impact on efficacy. Survival outcomes observed were similar to randomised phase 3 clinical trials.

449P Cyclin-dependent kinase 4/6 inhibitors (CDK4/6i) plus endocrine therapy (ET) treatment in metastatic lobular breast cancer (mLBC): A retrospective cohort study

C. von Arx[1], A. Calabrese[1], C. Martinelli[2], V. Di Lauro[1], V. Grimaldi[3], M. Pensabene[1], R. Caputo[1], I. Cerillo[1], D. Cianniello[1], G. Buono[1], A. Verrazzo[2], C. Pacilio[1], F. Di Rella[1], F. Nuzzo[1], M. De Laurentiis[1]

[1]Department of Breast and Thoracic Oncology, Istituto Nazionale Tumori IRCCS - Fondazione G. Pascale, Naples, Italy; [2]Medical Oncology Department, Università degli Studi di Napoli Federico II - Scuola di Medicina e Chirurgia, Naples, Italy; [3]Biotecnologie del Farmaco, Università degli Studi di Napoli Federico II - Scuola di Medicina e Chirurgia, Naples, Italy

Background: CDK4/6i plus ET is the standard of care for HR-positive HER2-negative mBC. The trials that led to this combination approval included mainly patients (pts) with ductal breast cancer, while limited data are reported on LBC. However, LBC are characterised by a unique pattern of metastatic recurrence and different degrees of endocrine sensitivity. This study aims to analyse CDK4/6i combinations on mLBC pts survival outcomes.

Methods: In this retrospective cohort study, we analysed outcome data of pts with mLBC who received CDK4/6i plus ET as first-line treatment between January 2017 and December 2022. Kaplan-Meier method was used to estimate median progression-free survival (mPFS). Long-rank Mantel-Cox test was used to evaluate differences in outcomes between different subgroups and between drugs.

Results: The study included 30 pts with a median age at mBC diagnosis of 63.1 years. 8/30 (27%) pts had de-novo metastasis, and 22/30 (73%) had recurrent disease. As CDK4/6i, 13/30 (43%) pts received Palbociclib (P), 14/30 (47%) Ribociclib (R) and 3/30 (10%) Abemaciclib. As ET, 13/30 (43%) pts received Fulvestrant (F) and 17/30 (57%) Letrozole (L). The overall mPFS was 28.7 months (mos). There were no statistically significant differences in mPFS between pts treated with R vs P (29.5 vs 23.7 mos, HR 0.82 [0.31-2.21], p=0.7). Similarly, no significant differences were observed in pts with de-novo metastasis vs recurrent disease (29.5 vs 23.8 mos, HR 0.59 [0.20-1.74], p=0.3), and in pts with only-bone vs visceral metastasis (23.9 vs 28.7 mos, HR 0.92 [0.33-2.54], p=0.9). In line with the different endocrine sensitivity of the two groups, a much longer mPFS, even if not statistically different, was observed in pts treated with L vs F (35.1 vs 15.1 mos, HR 0.56 [0.20-1.57], p=0.2). A statistically significant difference was observed in mPFS of HER2-0 vs HER2-low LBC pts (29.5 vs 5.9 mos, HR 0.20 [0.05-0.79], p=0.02).

Conclusions: CDK4/6i plus ET is an effective treatment in pts with mLBC. However, there is a significant difference in clinical outcomes of pts with a HER2-0 vs HER2-low mLBC. This suggests that further research is needed to identify new biomarkers for a more tailored treatment choice in pts with LBC.

Background: The group of HER2-negative accounts for 70-80% of breast cancer and effective treatments for heavily pretreated patients with HER2-negative metastatic breast cancer are urgently needed. Irinotecan is a semi-synthetic water-soluble camptothecin derivative which can be used as a chemotherapeutic agent for HER2-negative breast cancer after failure of anthracycline and taxanes treatments. Anlotinib is a novel multitarget tyrosine kinase inhibitor targeting VEGFR, PDGFR, FGFR, and c-Kit. This study aimed to evaluate the efficacy and safety of irinotecan combined with anlotinib in second-line and above treatment of HER-2-negative advanced breast cancer.

Methods: This open-label, single-arm, phase II study enrolled women $\geq$ 18 years with HER2-negative breast cancer who underwent $\geq$1 line chemotherapy, All patients were treated with intravenous irinotecan (60mg/m^2 on days 1 and 8) and oral anlotinib (12 mg once daily on days 1-14). The combination regimen repeated every 21 days. The primary endpoint was objective response rate (ORR). Secondary endpoints were progression-free survival (PFS), disease control rate (DCR), overall survival (OS) and safety.

Results: From November 2020 to April 2023, 20 patients were enrolled in this study. Median follow-up was 10.8 months (95% CI 0-21.8). Median PFS was 4.8 months (95% CI 3.0-6.6). Of all the patients whose efficacy could be evaluated (15/20), no patient achieved complete response (CR); 4(26.7%) and 9(60%) patients got partial response (PR) and stable disease (SD), respectively. ORR was 26.7% (95% CI 7.8-55.1) and DCR was 86.7% (95% CI 59.5-98.3). OS has not reached. The major treatment-related adverse events were hypertension (30%), fatigue (25%), neutropenia(20%), hand foot syndrome (15%) and myelosuppression (10%). There was one case of grade 3 nausea, and no grade 3/4 adverse events occurred . 20% (4/20) of patients had dose reductions.

Conclusions: The combination of irinotecan and anlotinib showed better treatment response and tolerable toxicity in the treatment of second-line and above patients with HER2-negative metastatic breast cancer. Further studies enrolling more patients are still needed.

Clinical trial identification: ChiCTR2000037448.

Background: CDK4/6 inhibitor treatment in advanced breast cancer (ABC) has shown benefit in progression-free survival (PFS) and another clinical endpoints in landmark clinical trials. This study aims to comprehend real-world use of ribociclib, effectiveness and safety in the Portuguese population.

Methods: Retrospective-prospective study of Portuguese cohort adult women with HR+/HER2- ABC treated with ribociclib through 3 years. Ribociclib treatment patterns, PFS at 1 year follow-up after ribociclib initiation and others secondary endpoints are reported. Data collection began in January 2019 with analysis cut-off in March 2023. Confidence intervals and survival analyses were performed using R® software.

Results: Of the 270 patients included, 64 (23.7%) were pre/peri-menopausal and 206 (76.3%) were post-menopausal patients. Median follow-up duration was 11.9 months. Baseline characteristics were described previously. Regarding treatment patterns, 207 (76.7%) received ribociclib as first-line [61 (22.6%) *de novo* patients and 146 (54.1%) after prior therapy], 40 (14.8%) as a second line and 23 (8.5%) after second line. During first year's follow-up, mean ribociclib dose was of 488.4 [468.6; 508.2] and 114 (42.4%) patients reported dose adjustments. Of these 85 (74.6%) had a single dose adjustment. Patients had an average number of 12.1±5.3 clinical appointments, a mean of 3.4±2.5 imaging exams and 178 patients (65.9%) performed ECGs. Disease progression/death was experienced by 88 in 261 patients at a median of 407 days after ribociclib initiation, with a survival rate at 12 months of 0.782±0.027. At 12 months, complete response was achieved in 15 patients (5.6%), 80 patients (29.6%) had partial response and 52 (19.3%) remained stable. At cut-off, 175 (64.8%) patients were still being treated with ribociclib. Most common reasons for ribociclib discontinuation: disease progression (64, 67.4%) and AEs (21, 22.1%). Most common AEs were neutropenia (320, 42.3%), anemia (50, 6.6%), fatigue/asthenia (44, 5.8%), and leukopenia (42, 5.5%).

Conclusions: This is the first cohort of Portuguese patients to provide efficacy and safety data in a real-world setting, demonstrating similar clinical trial outcomes.

452P A phase II trial of anlotinib and fulvestrant in patients with metastatic breast cancer previously treated with an aromatase inhibitor

X. Wang[1], J. Huang[1], C. Wenyan[2], Z. Sun[3], S. Wei[2], L. Wang[3]

[1]Department of Medical Oncology, Zhejiang Cancer Hospital, Hangzhou, China; [2]Department of Breast Medical Oncology, Nanchang People's Hospital, Nanchang, China; [3]Department of Breast Surgery, Jiangxi Cancer Hospital, Nanchang, China

Background: Fulvestrant is used after aromatase inhibitor (AI) failure in metastatic breast cancer but resistance develops quickly. We hypothesized that using anlotinib, a novel multi-target tyrosine kinase inhibitor, may delay fulvestrant resistance in patients (pts) and thus improve its efficacy. This single-arm, phase II trial aims to evaluate the efficacy and safety of the combined regimen in pts with HR-positive and HER2-negative, previously AI treated, locally advanced or metastatic breast cancer.

Methods: The key enrolled criteria were women aged 18 years or older of any menopausal status (premenopausal or perimenopausal women received ovarian function suppression), ECOG PS 0-1, histologically confirmed HR-positive and HER2-negative breast cancer, and disease relapse within 12 months after a more than 24 months AI adjuvant setting or disease progress after a more than 6 months AI metastatic setting. Eligible pts received 500 mg fulvestrant by intramuscular injection on days 1 and 15 of cycle one and then on day one of each subsequent cycle (28 days). Pts were also given 12 mg oral anlotinib once daily for 2 weeks, followed by a week off in a 21-day cycle. The primary endpoints is progression-free survival (PFS) and the secondary endpoints include overall response rate (ORR), disease control rate (DCR), overall survival (OS), and safety.

Results: 22 pts have been enrolled from Aug 25, 2021, to Apr 7, 2023. After a median follow-up time of 5.5 months (95% CI, 3.4-7.6), 21 pts had the confirmed best overall response assessments which inferred the ORR of 19.0% (PR in 4 pts. 95% CI, 5.4-41.9) and the DCR of 81.0% (PR in 4 pts and SD in 13 pts. 95% CI, 58.1-94.6). The median PFS was 7.6 months (95% CI 4.2-11.0) and the mOS has not reached. Any adverse events (AEs) were observed in 95.2% of pts, and the frequent AEs (incidence $\geq$ 10%) included hypertension (57.1%), proteinuria (23.8%), increased TSH (23.8%), hand-foot syndrome (19.0%), wight loss (19.0%), and thrombocytopenia (14.3%).

Conclusions: Anlotinib combined with fulvestrant showed a promising efficacy with an acceptable safety profile for patients with metastatic breast cancer previously treated with AI. Further results are expected.

Clinical trial identification: NCT05075512 October 12, 2021.
