Background: At present, trastuzumab and pertuzumab has become the standard treatment for HER2-positive early breast cancer at high risk of recurrence and metastatic breast cancer who have not received prior anti-HER2 therapy or chemotherapy for metastatic disease. There is currently no clinical trials exploring the efficacy of pyrotinib for HER2-positive advanced breast cancer after prior trastuzumab and pertuzumab. The aim of this study is to analyze the efficacy and safety of pyrotinib-based therapy in patients after prior trastuzumab and pertuzumab.

Methods: The pathological and clinical data of 77 HER2-positive advanced breast cancer patients treated with pyrotinib after prior trastuzumab and pertuzumab were retrospectively analyzed. Observation indexes included PFS, CBR, ORRand adverse events.

Results: A total of 77 patients were enrolled in this study at the Breast Oncology Department of the Fifth Medical Center of the PLA General Hospital from February 2019 to March 2023. Median age of the patients was 52 years (28-73 years), 64.9% were HR positive, 63.6% had visceral metastases, and 27.3% had brain metastases. 50(64.9%) of the patients received pyrotinib combined with capecitabine, 8(10.4%) received pyrotinib combined with vinorelbine, 3(3.9%) received pyrotinib combined with nab-paclitaxel, and 16(20.8%) received pyrotinib combined with endocrine therapy. The median line of pyrotinib was 2 (1-7), the median number of anti-HER 2 targeted therapy was 2 (2-6). Median follow-up was 17.8 months (1.6-51.4months) by the data cutoff date (May 2023). The median PFS was 13.6 months (95%CI: 8.3-18.9). The ORR was 50.0% in the 56 patients with evaluable lesions,the CBR was 54.5%, and the mPFS was 10.8 months (95%CI: 7.7-13.9). 46 patients who progressed on prior trastuzumab and pertuzumab had evaluable lesions, the ORR was 43.5%, CBR was 69.6%, and the mPFS was 9.2 months (95%CI: 6.4-12.0). The most common adverse events was diarrhea in the study.

Conclusions: This study first retrospectively analyze the value of pyrotinib in the era of dual anti-HER2 therapy, preliminarily showing good efficacy and safety of pyrotinib in patients after prior trastuzumab and pertuzumab.

454P Real-world genomic profiling of patients with advanced or metastatic triple-negative breast cancer in the UK and EU4: A systematic literature review

B. Singh[1], G. Kaur[2], S. Attri[2]

[1]HEOR, Pharmacoevidence, London, UK; [2]HEOR, Pharmacoevidence, Sas Nagar, India

Background: Advanced or metastatic triple-negative breast cancer (A/M TNBC) is a detrimental disease with limited treatment options. Molecular subtyping of A/M TNBC has the potential to enhance diagnostic accuracy and further enable targeted therapies, given its high degree of heterogeneity. This systematic literature review (SLR) aimed to identify real-world evidence for genetic alterations among A/M TNBC patients.

Methods: Key biomedical databases (EMBASE®, MEDLINE®, MEDLINE-in-process) were searched to identify real-world studies assessing genomic alterations among A/M TNBC patients in the UK and EU4. The current review followed a standard HTA compliant two review process methodology for screening and data extraction.

Results: A total of three of 203 studies fulfilled the inclusion criteria. All three studies were conference proceedings, with one study each conducted in Spain, Italy, and the UK. A total of 399 A/M TNBC patients were analyzed for genetic profiling across these studies, using either digital droplet PCR (ddPCR), error-corrected 73-gene targeted panel (Guardant360), or AVENIO Expanded ctDNA Analysis Kit. In the Gruppo Italiano Mammella 14 BIOMETA study, BRCAmu+ was detected among 8% of 195 mTNBC patients. Further, in the RegistEM study, 50% of 32 Spanish mTNBC patients had TP53mu+, followed by MAP2K1mu+ and APCmu+ (25% each). In the UK plasmaMATCH study, PIK3CA mutation was more prevalent (9.3% and 14.7% by ddPCR and targeted ctDNA panel, respectively), while ESR1mu+ was the least prevalent (0% and 0.7% by ddPCR and targeted ctDNA panel, respectively). The targeted ctDNA sequencing identified definite genomic profiles compared to ddPCR.

Conclusions: The current SLR highlights the scarcity of real-world evidence on genetic alterations in A/M TNBC. Molecular subtyping exhibits a significant potential in identifying specific genetic alterations, emphasizing the need for further research and larger-scale studies.

455P Post progression treatments after endocrine therapy (ET) plus palbociclib in patients with HR+/HER2- metastatic breast cancer (MBC): A prospective, real-world study

R. Palumbo[1], G. Saltalamacchia[2], E. Quaquarini[1], B. Tagliaferri[1], C.M. Teragni[1], C. Barletta[1], M. Frascaroli[1], E. Biscaldi[1], A. Malovini[3], L.D. Locati[4], F. Sottotetti[1]

[1]Medical Oncology, IRCCS ICS Maugeri Pavia, Pavia, Italy; [2]Medical Oncology, Humanitas University, Pieve Emanuele, Italy; [3]Laboratory of Informatics and Systems Engineering for Clinical Research, IRCCS Pavia - Fondazione Salvatore Maugeri, Pavia, Italy; [4]Medical Oncology Unit, IRCCS ICS Maugeri, Pavia, Department of Internal Medicine and Therapeutics, University of Pavia, Pavia, Italy

Background: The association of ET and CDK 4/6 inhibitors (CDK 4/6i) is the gold standard of treatment in women with HR+/HER2- MBC. The optimal therapeutic strategy after CDK 4/6i progression is still a matter of debate. The present study aimed to evaluate the benefit of the different treatments adopted in a real-world context.

Methods: In this prospective study we included women with HR+/HER2- MBC progressing to ET plus palbociclib (P). Either ET or chemotherapy (CT) were prescribed taking into account:1) site and burden of disease (visceral/plurimetastatic *vs* bone only/oligometastatic); 2) median PFS1 ($<$4 months *vs* $\geq$4 months); 3) tolerability profile; 4) patient's preferences. Primary objective was median progression-free survival 2 (PFS2). Secondary aims: analysis of the determinants of physician's choice, clinical benefit rate (CBR), impact of neutrophil-to lymphocyte ratio (NLR), monocyte-to lymphocyte ratio (MLR), platelet-to lymphocyte ratio (PLR) and body mass index (BMI) on PFS2.

Results: From May 2017 to October 2021, 78 pre- and postmenopausal patients were enrolled and 56 were evaluable for the final analysis: 18 had received ET plus P as 1st line, 38 in $\geq$2nd line; 22 patients were excluded because they were still on therapy at the time of the last follow-up. At progression 15 patients (26.7%) received ET (everolimus+exemestane 8, fulvestrant 7) and 41 (73.2%) were treated with CT (eribulin, capecitabine, nab-paclitaxel, vinorelbine). In the whole population mPFS1 was 17.5 months; mPFS2 was 5 months in the overall cohort (95% CI = 4-48 months) with a significant difference between ET and CT (10 months *vs* 5 months, p=0.035); CBR was 50% and 55.2%, in ET and CT, respectively. At multivariate analysis CT prescription was associated to a higher visceral burden and a shorter mPFS1. Elevated NLR and PLR were correlated with worse PFS2 in both treatment groups, while no impact of MLR and BMI was observed.

Conclusions: In this real life experience, treatments beyond ET plus P failure provided limited but comparable clinical benefit. The physician's choice was clearly driven by visceral burden of disease; the inflammatory status seems to have a detrimental effect on PFS2.

Clinical trial identification: Ethical Committee number 2295 approved 09.01.2017.

S. Loginov DZM, Moscow, Russian Federation; [10]Clinical Development & Analytics, Novartis Pharmaceuticals Corporation, East Hanover, NJ, USA; [11]Oncology, Novartis Pharma AG, Basel, Switzerland; [12]Biostatistics, Novartis Pharmaceuticals Corporation, East Hanover, NJ, USA; [13]Emerging Growth Markets Department, Novartis Pharma AG, Basel, Switzerland; [14]Internal Medicine Department, AUBMC - American University of Beirut Medical Center, Beirut, Lebanon

Background: RIGHT Choice showed a statistically significant median progression-free survival benefit of $\approx$1 yr with first-line RIB + ET vs combo CT (HR, 0.54; P=0.0007) in patients (pts) with aggressive HR+/HER2− ABC. As QOL data provide information on real-life treatment (tx) benefit as well as impact tx choice and duration, a QOL analysis was performed.

Methods: Pre/perimenopausal pts with no prior systemic therapy for aggressive HR+/HER2− ABC were randomized 1:1 to RIB + ET or combo CT. The FACT-B scores were determined by a questionnaire administered at protocol-defined time points. The median time to deterioration (mTTD) in overall health status, nausea or pain was defined as a composite endpoint of time from randomization to either first occurrence of $\geq$10% deterioration in FACT-B scores with no later improvement or date of discontinuation due to progressive disease, death, or adverse events. Only pts with baseline and at least one post-baseline pt reported outcome assessment were included. Pts without events were censored at the last evaluation prior to the earliest of cutoff date, end of tx, start of new tx, or when lost to follow-up, or at consent withdrawal. Descriptive summary of change from baseline in FACT-B total score was also summarized.

Results: The composite endpoint of mTTD in overall health status was delayed with RIB + ET (N=111) vs combo CT (N=96;16.8 vs 10.6 mo; HR, 0.63; Table). The mTTD in subdomains of nausea (18.4 vs 10.4 mo; HR, 0.56) and pain (13.0 vs 10.4 mo; HR, 0.70) was also delayed in pts on RIB + ET vs combo CT. A numerical trend in change from baseline in FACT-B total scores during tx favoring RIB + ET over combo CT was observed.

Table: 456P

End Points	Outcomes	RIB + ET (N=111)	Combo CT (N=96)
TTD in overall health status	**Deterioration events, n**	67	66
	FACT-B score decrease, n_1/n (%)	24/67 (35.8)	22/66 (33.3)
	Tx discontinuation, n_2/n (%)	43/67 (64.2)	44/66 (66.7)
	mTTD, mo	16.8	10.6
	HR; 95% CI	0.63; 0.44-0.90	
TTD in nausea	**Deterioration events, n**	67	69
	FACT-B score decrease, n_1/n (%)	29/67 (43.2)	30/69 (43.5)
	Tx discontinuation, n_2/n (%)	38/67 (56.7)	39/69 (56.5)
	mTTD, mo	18.4	10.4
	HR; 95% CI	0.56; 0.39-0.79	
TTD in pain	**Deterioration events, n**	72	65
	FACT-B score decrease, n_1/n (%)	34/72 (47.2)	22/65 (33.8)
	Tx discontinuation, n_2/n (%)	38/72 (52.8)	43/65 (66.2)
	mTTD, mo	13.0	10.4
	HR; 95% CI	0.70; 0.49-0.99	

Conclusions: This analysis suggests that first-line RIB + ET is associated with better QOL than combo CT for pts with aggressive HR+/HER2− ABC, providing supportive evidence for RIB + ET use in this pt population.

Clinical trial identification: NCT03839823.

457P Disparities in receipt of CDK4/6 inhibitors with endocrine therapy as therapy for hormone receptor-positive, HER2-negative metastatic breast cancer in the real-world setting

G. Kimmick[1], A. Pilehvari[2], W. You[2], G. Bonilla[3], R. Anderson[2]

[1]Medicine, Duke University Medical Center, Durham, NC, USA; [2]Public Health Sciences, The University of Virginia, Du, VA, USA; [3]Cancer Center, The University of Virginia, Charlottesville, VA, USA

Background: This retrospective study, using real-world evidence (RWE), compared outcomes for patients receiving treatment for hormone receptor-positive (ER+), HER2-negative, metastatic breast cancer (MBC) with CDK4/6 inhibitors (CDK4/6i) in combination with endocrine therapy (ET) versus ET alone and explored disparities in use of CDK4/6i.

Methods: We used the nationwide electronic health record-derived Flatiron Health de-identified database to examine real-world impacts of CDK4/6i and ET. A total of 3,917 patients received CDK 4/6i+ET (n=2170) or ET alone (n=1747) in the first-line setting between February 2015, and November 2021. Characteristics of patients receiving CDK4/6i+ET versus ET alone were compared using statistical tests. Baseline characteristics were balanced using inverse probability weighting (IPW). Kaplan-Meier method and Cox proportional hazards were used to test the impact of CDK4/6 treatment on rwPFS and rwOS.

Results: Compared to patients receiving ET alone, those received CDK4/6i+ET were younger, more likely to have presented with de novo MBC (36% vs. 29%, p<0.001), had better performance status (50% vs. 40% patients with ECOG value 0, p=0.001), and more likely to have lower number of comorbidities (30% vs. 27% with at least 1 comorbidity, p=0.04). After IPW adjustment, CDK4/6i+ET treatment was associated with significantly longer median PFS compared to ET alone (27 vs 17 months; hazard ratio [HR]=0.61, p<0.001). Median OS was 52 months in the CDK4/6i+ET group and was 42 months with ET alone (HR=0.74, p<0.001).

Conclusions: RWE confirms the added PFS and OS benefit of adding CDK4/6i to endocrine therapy in patients with ER+, HER2-negative MBC. We found disparities in CDK4/6i use by age, stage at diagnosis, baseline Ecog value, and number of comorbidities. Future work is needed to improve access to this important class of drugs.

458P Metastatic breast cancer: How and how often do we communicate? Results from an Italian national survey

C. Lisanti[1], A. Costantini[2], B. Pastò[3], M. Garutti[1], S. Bolzonello[1], L. Da Ros[1], P. Di Nardo[1], S. Corsetti[1], L. Gerratana[1], S. Scalone[1], S. Spazzapan[1], M.S. Nicoloso[1], S. Della Rossa[3], M. Rizzetto[3], A. Membrino[3], S. Cinieri[4], A. Bonifacino[5], F. Puglisi[1]

[1]Medical Oncology, CRO Aviano - Centro di Riferimento Oncologico - IRCCS, Aviano, Italy; [2]Servizio di Psico-Oncologia, Azienda Ospedaliero - Universitaria Sant'Andrea, Rome, Italy; [3]Dipartimento di Area Medica, University of Udine, Udine, Italy; [4]Medical Oncology Department, Ospedale A. Perrino, Brindisi, Italy; [5]Unità di Diagnosi e Terapia in Senologia, Azienda Ospedaliero - Universitaria Sant'Andrea, Rome, Italy

Background: Communication is a complex process; an effective communication requires a two-way relationship between patients (pts) and healthcare providers (hp). The areas of communication concern diagnosis, prognosis and treatment. In this context, a tailored communication approach is suggested to keep pts involved in the clinical decision-making process.

Methods: Between 21 June and 4 October 2022, a 38-question web survey, promoted by the IncontraDonna Foundation and carried out in collaboration with both the Italian Society of Psycho-Oncology (SIPO) and the Italian Association of Medical Oncology (AIOM), was sent to oncologists members of AIOM. The aim of this study was both to investigate how and how much oncologists communicate with metastatic breast cancer pts (mBCp) and to probe clinicians' opinions and needs.

Results: 140 oncologists from 19 Italian regions participated in the survey. Responders reported discussing prognosis with their mBCp both in terms of residual life (96%), goals of care (98%) and likelihood of treatment response (94%), in the last two cases especially at the time of the first oncological visit (67% and 60%, respectively). As many as 93% of responders stated that they investigate the degree of understanding of the information provided. In communicating the prognosis, 49% of responders considered the presence of a caregiver "very useful" and 61% considered her/his absence "very disadvantageous". About the organization of one's department, the time dedicated to doctor-patient communication was considered "quite sufficient" in 16%", "little but sufficient" in 44%, "scarce" in 31% and "insufficient " in 10% of cases. In 89% of cases the presence of a psycho-oncology service was reported, to which mBCp would be referred regularly in only 14% of cases. Specific training courses for hp (69%) and periodic meetings with expert psycho-oncologists (59%) are the improvement actions most requested by clinicians.

Conclusions: The results of this survey highlighted heterogeneity in the management of communication in mBCp across the Italian country. Although the figure of the psycho-oncologist is considered important, its integration into the therapeutic process still appears complex.

459P Progression-free survival (PFS) assessment by local investigators versus blinded independent central review (BICR) in randomized clinical trials (RCTs) in metastatic breast cancer (MBC): Is it really needed?

F. Jacobs[1], C. Molinelli[2], E. Agostinetto[3], D. Martins Branco[3], G. Nader Marta[3], M. Salmon[4], L. Ameye[4], M. Piccart[5], M. Lambertini[6], E. de Azambuja[3]

[1]Oncology Department, Humanitas University, Milan, Italy; [2]Dipartimento di Oncologia Medica 2, IRCCS AOU San Martino - IST-Istituto Nazionale per la Ricerca sul Cancro, Genoa, Italy; [3]Academic Trials Promoting Team (ATPT), Université Libre de Bruxelles (ULB), Hôpital Universitaire de Bruxelles (HUB), Institut Jules Bordet, Brussels, Belgium; [4]Data Center, Université Libre de Bruxelles (ULB), Hôpital Universitaire de Bruxelles (HUB), Institut Jules Bordet, Brussels, Belgium; [5]Medical Oncology Department, Université Libre de Bruxelles (ULB), Hôpital Universitaire de Bruxelles (HUB), Institut Jules Bordet, Brussels, Belgium; [6]Department of Medical Oncology, IRCCS AOU San Martino - IST-Istituto Nazionale per la Ricerca sul Cancro, Genoa, Italy

Background: In RCTs, BICR is used to minimize the heterogeneity and risk of bias associated with radiological response evaluation by local investigators. However, BICR adds costs and complexity in trial management, which questions its practical utility. We aimed to assess the discrepancy index between PFS assessment by local investigators and by BICR in RCTs of MBC.

Methods: A systematic search of PubMed, Embase, Cochrane databases and conference proceedings (ASCO, SABCS and ESMO meetings) was performed up to January 4, 2023. All RCTs published from 2000 to 2022, including MBC patients treated in first or second-line, and reporting PFS assessed by local investigators and BICR were included (PROSPERO - CRD42021229865). The agreement between hazard ratios (HRs) of PFS assessed by local investigators and BICR was measured using intraclass correlation coefficient (ICC). A discrepancy index, defined as the ratio of BICR-assessed HR by the corresponding investigator-assessed HR, was calculated for each trial to quantify the level of agreement in the estimated effect.

Results: A total of 24 studies with 13,338 patients were included in the analysis. Among them, 19 (79%) were in first line, 18 (75%) were phase III trials and 23 (96%) had PFS as primary endpoint. The overall combined discrepancy index was 0.97 (95% CI 0.85-1.10; ICC = 0.831, p-value <0.001) suggesting no statistically significant difference in PFS assessment by local investigators vs BICR. This result was consistent across all subgroups analyzed (the table).

Table: 459P Discrepancy index and 95% confidence intervals in the overall population and in subgroups

	Discrepancy index (95% CI)
Overall	0.97 (0.85-1.10)
Line of treatment	
First line	0.98 (0.84-1.15)
Second line	0.94 (0.75-1.17)
Study phase	
Phase II	1.05 (0.66-1.66)
Phase III	0.96 (0.84-1.10)
Study design	
Double blind	0.97 (0.83-1.13)
Open label	0.97 (0.78-1.21)
BC subtype	
HER2+	0.96 (0.70-1.28)
Luminal	0.94 (0.67-1.30)
TNBC	0.96 (0.67-1.39)
Study start year	
Before 2010	0.97 (0.83-1.13)
After 2011	0.97 (0.77-1.21)
RECIST	
1.0	0.97 (0.82-1.14)
1.1	0.96 (0.78-1.18)
PFS primary endpoint	
Yes	0.97 (0.85-1.10)
No	0.87 (0.25-3.07)

Conclusions: The good concordance between local investigator and BICR assessments supports the reliability of local investigator-assessed PFS as primary endpoint for RCTs in MBC. The resources used for BICR might be reallocated to other areas, such as translational research, decreasing the burden of clinical trial conduction.

460P Impact of fulvestrant utilization on prognostic outcome among patients with HR+ve/HER2-ve metastatic breast cancer: Results from a real-world dataset

S. Dawood[1], G. Hernández-Ibarburu[2]

[1]Oncology Department, Mediclinic City Hospital, Dubai, United Arab Emirates; [2]Biostatistics, UPM - Universidad Politecnica de Madrid - ETSIT, Madrid, Spain

Background: Overall survival (OS) of pts with HR+ve/HER2-ve MBC has improved with the use of CDK4/6i and sequential use of endocrine therapy. The selective estrogen receptor modulator (SERM) Fulvestrant has been shown to work well post progression on aromatase inhibitors (AI) in an endocrine resistant cohort. Clinical trials have shown no difference in progression free survival with the use of an AI or fulvestrant in combination with a CDK4/6i in the first-line setting. The objective of this retrospective analysis was to look at trends in use of and associated prognostic outcome associated with fulvestrant among pts with HR+ve /HER2-ve MBC in the real-world setting.

Methods: We utilized a federated network of de-identified health data representing approximately 107 million pt lives available through the TriNetX Research Network. We identified 47,999 pts with HR+ve /HER2-ve MBC treated with endocrine therapy. OS was computed using the Kaplan Meier product limit method.

Results: Mean age was 60 yrs. 17.5% (n=8390) received fulvestrant at any time of whom 24% received it in the first-line setting. Use of fulvestrant increased from 1.04% in the period 2005-2009 to 9.03% in the period of 2015-2019. 20.6% (n=9,908) received CDK4/6i at any time of whom 39.7% received it in the first-line setting. 2-year OS among pts who did and did not use fulvestrant was 80.3% and 77.5% respectively (HR 0.8, p<0.01). 2-yr OS among pts who did and did not use fulvestrant as first-line therapy was 69.9% and72.6% respectively(HR 1.05, p = 0.41). 2-year OS among pts who did and did not use CDK4/6i was 84.6% and 78.3% (HR 0.64, p < 0.01). 2-yr OS among pts who did and did not receive CDK4/6i as first-line therapy was 78.3% and 73.8% respectively (HR 0.74, p < 0.01). 2-yr OS among pts receiving CDK4/6i with or with out fulvestrant in the first-line setting was 74.7% and 79.1% respectively (HR 1.27, p = 0.06).

Conclusions: Fulvestrant use has increased over time. Real world data indicate OS benefit to use of fulvestrant at some time point in the therapy of pts with HR +ve/ HER2-ve MBC. Use of fulvestrant with CDK4/6i in the first-line setting does not improve prognostic outcome compared to use of CDK4/6i + AI in the first-line setting in keeping with the results of clinical trials.

Background: POLARIS is a prospective, observational real-world study of pts with HR+/HER2− ABC receiving palbociclib in routine clinical practice. As part of this study, we evaluated the impact of comorbidities on pt quality of life (QoL) using the EORTC-QLQ-C30 questionnaire.

Methods: EORTC data were collected at baseline, monthly for the first 3 months, and every 3 months thereafter until palbociclib discontinuation; here we report absolute global QoL and functional/symptom subscales scores according to pt baseline Charlson comorbidity index (CCI) score (grouped 0, 1−2, and 3+) at study baseline, month 6, 12 and 18. EORTC differences of ≥10 between CCI groups at each timepoint and within a CCI group over time were considered clinically meaningful. Differences in global QoL/subscale scores between CCI groups at each timepoint were compared using a two-sample t-test.

Results: Between January 2017 and December 2018, 1285 pts were enrolled, and 1250 received ≥1 dose of palbociclib. At baseline, pts had a median of 2 (range 0−9) comorbidities. 30.2%, 54.6% and 15.3% of pts had a CCI score 0, 1−2, and 3+, respectively. The most frequent comorbidities were vascular (54.3%), psychiatric (26.6%), blood/lymphatic system (18.4%), and metabolic/nutritional (18.2%) disorders. Generally, absolute mean global QoL and functional/symptom subscale scores (range: 0 to 100) were preserved from baseline to Month 18 within each CCI group (Table). Overall, differences in mean global QoL scores (and functional/symptom subscale scores) between the CCI 0 and CCI 1−2 were similar at each timepoint; while notably lower scores (less favorable) were observed for the smaller CCI 3+ group.

Table: 461P Global QoL in pts with HR+/HER2− ABC by CCI

*Absolute mean**	Time point	CCI score 0		1−2		3+	
	Baseline	69.89 (n=336)		62.95 (n=651)		56.90 (n=180)	
	Month 6	73.29 (n=219)		69.69 (n=400)		60.40 (n=113)	
	Month 12	74.23 (n=151)		70.42 (n=262)		59.98 (n=71)	
	Month 18	75.08 (n=103)		69.28 (n=198)		62.02 (n=52)	
Diff in means		CCI 0 vs 1-2		CCI 0 vs 3+		CCI 1-2 vs 3+	
		Diff	p-value	Diff	p-value	Diff	p-value
	Baseline	6.94	<0.0001	12.99	<0.0001	6.06	0.0028
	Month 6	3.60	0.0401	12.89	<0.0001	9.29	<0.0001
	Month 12	3.81	0.0546	14.25	<0.0001	10.44	0.0002
	Month 18	5.80	0.0225	13.06	0.0004	7.26	0.0314

*Higher scores more favorable. Subscales were consistent with global QoL.
Data cut off January 2023.
CCI, Charlson comorbidity index; Diff, difference; QoL, quality of life.

Conclusions: QoL of pts with HR+/HER2- ABC treated with palbociclib differed by comorbidity level, with a general preservation in their relationship over 18 months.

Clinical trial identification: NCT03280303.

462P Health outcomes of treatment sequences with eribulin or other single agents' chemotherapy for treating relapsed metastatic HER2-negative breast cancer

S. Rivolo[1], K. Ndirangu[2], D. Teloian[3], A. Ambavane[4], C. Jackisch[5], P.S. Hall[6]

[1]Modeling & Simulation, Evidera, Milan, Italy; [2]Global Value & Access, Eisai Inc., Nutley, NJ, USA; [3]Modeling and Simulation, Evidera, Budapest, Hungary; [4]Modeling & Simulation, Evidera, Dubai, United Arab Emirates; [5]Department of OB GYN & Breast Cancer Center, Sana Klinikum Offenbach, Offenbach, Germany; [6]Edinburgh Cancer Research Centre, University of Edinburgh. Edinburgh Cancer Centre, Western General Hospital, NHS Lothian, Edinburgh, UK

Background: Treatment of HER2- metastatic breast cancer (MBC) is driven by biomarker status (HR+ vs. triple negative [TNBC]). Single agent chemotherapy (ChT) is recommended for patients relapsing on targeted therapies including endocrine therapy or immunotherapies, with ChTs optimal sequence not yet established. The study objective was to compare the health outcomes (life years [LYs], quality adjusted LYs [QALYs]) in sequences starting ChT with eribulin (ERI), capecitabine (CAP) or treatment of physician choice (TPC), in second-line (2L) to fourth-line (4L) settings.

Methods: A stochastic microsimulation was developed tracking a MBC cohort through 2L-4L, with patients starting the next line of therapy due to progression or serious adverse events (SAEs) discontinuation. After each line, patients could receive another active therapy or best supportive care. Treatment sequences across three treatment pathways, capturing ChT initiation in 2L, 3L or 4L (the table), were based on clinical guidelines, real-world data and clinical interviews. Clinical inputs were stratified by biomarker and treatment line, with QALYs driven by progression status, response rates and SAEs. The analysis time horizon was 20 years, with outcomes discounted at 3.5%.

Results: In the HR+ subgroup, sequences with ERI used earlier than CAP/TPC led to higher LYs (1.62 - 2.24 vs. 1.57 - 2.22) and QALYs (0.75 -1.28 vs. 0.69 − 1.27), across the three pathways, driven by improved ERI efficacy and safety profile vs. CAP/TPC. Similarly, in the TNBC subgroup, earlier use of ERI vs. CAP/TPC led to higher LYs (1.19 - 1.64 vs. 1.16 - 1.63) and QALYs (0.55 - 0.86 vs. 0.49 - 0.85) when used in 2L or 4L, while 3L ERI vs. 3L TPC led to higher QALYs (0.70 vs. 0.67 - 0.68), but comparable LYs (1.40). The results were consistent across the sensitivity analyses conducted.

Table: 462P

Pathway	2L HR+	3L	4L	2L TNBC	3L	4L
ChT post taxane/anthracycline in 1L or post adjuvant settings	CAP	TPC	ERI	CAP	TPC	ERI
	CAP	ERI	TPC	CAP	ERI	TPC
	ERI	CAP	TPC	ERI	CAP	TPC
	ERI	TPC	CAP	ERI	TPC	CAP
ChT post 2L taxane	PAC	CAP	TPC	PAC	CAP	TPC
	PAC	CAP	ERI	PAC	CAP	ERI
	PAC	TPC	CAP	PAC	TPC	CAP
	PAC	TPC	ERI	PAC	TPC	ERI
	PAC	ERI	CAP	PAC	ERI	CAP
	PAC	ERI	TPC	PAC	ERI	TPC
HR+: ChT post 2L CDK4/6 inhibitors and 3L taxane **TNBC:** ChT post 2L taxane and 3L SAC	FUL + PAL	PAC	CAP	PAC	SAC	ERI
	FUL + PAL	PAC	ERI	PAC	SAC	CAP
	FUL + PAL	PAC	TPC	PAC	SAC	TPC

CDK = cyclin-dependent kinase; FUL = fulvestrant; PAC = paclitaxel; PAL = palbociclib; SAC = sacituzumab. Note: TPC includes vinorelbine, gemcitabine, capecitabine, taxanes, anthracyclines and hormonal therapy.

Conclusions: Starting single agent ChT with ERI vs. CAP or TPC is associated with improved health outcomes for 2L-4L HER2- MBC management.

Background: The Sars Cov-2 pandemic and the national lockdowns disrupted healthcare systems in 2020. We assessed the impact on care pathways and clinical outcomes for new breast cancers (BCs) in Paris area.

Methods: We performed a retrospective multicenter cohort study on the data warehouse of Greater Paris University Hospitals (APHP). We identified pts newly referred with BC between Jan 2019, and Dec 2020. We assessed the delays of care management, the initial tumor stage from pathology and baseline PET/CT and CT-scan reports, and the trt categories: breast surgery, exclusive systemic therapy, exclusive radiation therapy, or exclusive best supportive care (BSC). We calculated pts' 1-year overall survival (OS) and compared indicators for 2019 and 2020.

Results: In 2019 and 2020, 2,303 and 2,258 patients were newly referred with a BC diag among whom 2,055 and 1,988 female patients underwent a BC treatment, respectively. During the 1st and the 2nd lockdowns, the number of BC diag varied by -18% and by +23% compared to the same periods of 2019. Between 2019 and 2020, the rate of *de novo* metastatic disease (respectively 15% and 15%, p=0.95) did not differ, neither did the pTNM and the ypTNM distributions (p=0.37 and p=0.31). The time from 1st multidisciplinary meeting to trt did not differ (p=0.23). Pts' access to reconstructive surgery (15% and 17%, p=0.08) and distribution across trt categories did not vary: tumor resection (73% and 72%), exclusive systemic trt (13% and 14%), exclusive radiation trt (9% and 9%), and exclusive BSC (5% and 5%) (p=0.8), respectively. Age-based subgroup analyses yielded to similar results (p=0,95). The rate of neoadjuvant trt for resected pts was lower in 2019 (16%) compared to 2020 (20%) (p=0.02), especially in patients aged < 50 years (15% vs 21%, p=0,01), respectively. The 1-year OS rates in 2019 vs. 2020 were 99.3% vs. 98.9% (HR=0.96; 95% CI, 0.77-1.2), 72.6% vs. 76.6% (HR=1.28; 95% CI, 0.95-1.72), 96.6% vs. 97.8% (HR=1.09; 95% CI, 0.61-1.94), and 15.5% vs. 15.1% (HR=0.99; 95% CI, 0.72-1.37), in the trt groups, respectively.

Conclusions: Despite an initial decrease in new BCs, we did not observe any tumor stage shift, and OS did not vary significantly during Sars-Cov-2.

464P Developing a prognostic risk stratification model and treatment options for HER2-positive breast cancer brain metastasis

J. Chen[1], Y. SH[2], J. Zhou[1], H. Zhang[1], Z. Jiang[1], J. Yang[3], L. Xu[4], T. Wang[1]

[1]Oncology, The 5th Medical Center of Chinese PLA General Hospital, Beijing, China; [2]Oncology, Fujian Medical University - Qishan Campus, Fuzhou, China; [3]Medical Oncology Department, The First Affiliated Hospital of Xi'an Jiaotong University, Xi'an, China; [4]Oncology, Peking University First Hospital, Beijing, China

Background: Brain metastasis occurs in about 50% of advanced HER2-positive BC patients. Moreover, there are still a lot of unresolved clinical issues, such as how to classify patients and adapt targeted therapy to better prolong survival.

Methods: The study recruited HER2-positive BCBM patients who attended the Fifth Medical Center of PLA General Hospital from 2003 to 2022. 32 HER2-positive BCBM patients treated between 2008 and 2022 at the First Hospital of Peking University and 43 HER2-positive BCBM patients from 2012 to 2022 at Xi'an Jiaotong University First Affiliated Hospital were included as an independent test set. All statistical methods and survival analyses were performed in SPSS 22.0 and R version 4.2.1.

Results: This study included 300 patients with HER2-positive BCBM. According to multi-factor analysis, the age, the number of brain metastases, radiotherapy after BCBM, and anti-HER2 therapy after BCBM were all independent factors influencing survival after diagnosis of BCBM. Different independent prognostic factors comprised the patient hierarchical evaluation model. Patients' warning scores range from 0 to 7. We divided the patients into three groups with obvious differences in prognosis: Low-risk (score≥1), median-risk group (score≥3), and high-risk group (score≥6). The patient prognosis was worse when the warning score was high. The results of the survival analysis showed significant differences between the three groups of patients ($P<0.0001$). The mean AUC values for 1-year, 2-year prognosis prediction was 0.69, 0.71, respectively. We acquired clinical data from 75 patients from other centers to further assess our model's generalization capabilities. Patients are categorized using the prognostic grading evaluation model, and prognostic analysis is performed ($P<0.0001$). The AUC values for 1-year, 2-year prognostic forecasts were 0.94. Patients in the median-risk group who received drug therapy combined with radiotherapy had significantly prolonged BMOS compared with the patients who received only drug therapy or radiotherapy ($P=0.01$).

Conclusions: A survival and prognostic stratification model was constructed based on the clinicopathological characteristics of a large cohort of HER2-positive BCBM patients.

Legal entity responsible for the study: The authors.

465P Reporting of older subgroups enrolled to registration breast cancer trials, 2012-2021

C. Mac Eochagain[1], A. Ring[2], N.M.L. Battisti[3]

[1]Breast Cancer Unit, Royal Marsden Hospital, London, UK; [2]Breast Unit, Royal Marsden Hospital Institute of Cancer Research, Sutton, UK; [3]Department of Medicine - Breast Unit, The Royal Marsden Hospital, Sutton, UK

Background: Although older women comprise a large and rapidly growing proportion of patients diagnosed with breast cancer, the trial-level evidence base for treating this population is limited. This study assessed the completeness of reporting of older subgroups enrolled to registration trials in breast cancer between 2012-2021.

Methods: Trials which supported novel FDA approvals of systemic therapies in breast cancer between 01/2012 and 12/2021 were included. Individual trial-level PUBMED searches according trial/drug name, and trial registration number, were conducted on 31/08/22. Following title/abstract review, relevant publications and supplementary material were retrieved. Clinicaltrials.gov registry data was also retrieved. Non-efficacy (n = 1), site-agnostic (n = 1) biosimilar (n = 4), and trials conducted exclusively among premenopausal women (n = 1), were excluded. Immature endpoints (n = 5), for which no interim data were available in the full cohort, and studies which did not collect HRQOL data (n = 3), were excluded from relevant analyses. The availability and completeness of data for baseline characteristics, protocol-defined (co-)primary and secondary efficacy endpoints, toxicity, and HRQOL among older subgroups, was assessed systematically by two reviewers according to methods adapted from Chan & Altman (JAMA, 2004).

Results: 27 trials were included. 785 unique publications were identified, of which 569 were excluded. 216 publications (median: 6 per trial, IQR: 4), and registry data, were assessed in full. 20.3% of enrolled patients were aged ≥65. 70.0% of patients were ECOG 0; 29.8% ECOG 1, and 0.2% ECOG 2. The completeness of data across efficacy endpoints, baseline characteristics, toxicity and HRQOL domains are reported in the table.

Table: 465P Completeness of reporting of geriatric subgroups enrolled to registration trials in breast cancer 2012-2022

		n	Complete	Partial	Qualitative	Unreported
Efficacy endpoints						
	All efficacy endpoints	133	37 (27.8%)	3 (2.3%)	8 (6.0%)	95 (71.4%)
	Primary endpoints	33	24 (72.7%)	3 (9.1%)	1 (3.0%)	5 (15.2%)
	Secondary endpoints	110	13 (11.8%)	0 (0.0%)	7 (6.4%)	90 (81.8%)
	Overall survival	22	11 (50.0%)	1 (4.5%)	2 (9.1%)	8 (36.4%)
Baseline Characteristics		27	6 (22.2%)	2 (7.4%)	0 (0.0%)	19 (70.4%)
Toxicity		27	12 (44.4%)	0 (0.0%)	0 (0.0%)	15 (55.6%)
HRQOL		24	1 (4.2%)	0 (0.0%)	2 (8.3%)	21 (87.5%)

Rows 1-4: n Endpoints (%) Rows 5-7: n Trials (%).

Conclusions: This study identified significant gaps in the reporting of older subgroups enrolled to registration breast cancer trials. Improved reporting practices are required to support evidence-based decision making in this population.

466P Integrated analysis of potential prognosis and differential expression between primary and metastatic foci for COL12A1 in breast cancer

L. Tang[1], H. Xu[1], X. Fei[2], Y. Xu[3], F. Zhang[1]

[1]Oncology Department, Suzhou Kowloon Hospital Shanghai Jiao Tong University School of Medicine, Suzhou, China; [2]Department of Pathology, Ruijin Hospital Affiliated to Shanghai Jiao Tong University School of Medicine, Shanghai, China; [3]Oncology Department, Renji Hospital Affiliated to Shanghai Jiao Tong University School of Medicine, Shanghai, China

Background: Extracellular matrix (ECM) plays a key role in tumorigenesis and progression. Collagen XII, expressed by the COL12A1 gene, is an important component of the ECM. COL12A1 is associated with tumorigenesis and poor prognosis in several cancers, but its role in breast cancer (BC) is unclear, especially the different expression between primary and metastasic foci of BC has not been reported.

Methods: We analyzed the expression of COL12A1 in tumor tissue and normal tissue, plotted a Kaplan-Meier curve by GEPIA, and analyzed mutation by COSMIC and cBioPortal in BC. PPI, GGI and pathway and process enrichment analysis were performed by STRING and Metascape. GeneMANIA was used to map gene interaction networks. BC cases with paired primary and metastatic foci were found out from TCGA database for analyzing different expression of COL12A1 in primary and metastatic foci. Immunohistochemical (IHC) staining was performed in paraffin tissue samples of paired primary lesion and lung metastases from triple-negative breast cancer (TNBC) patients.

Results: The results showed that COL12A1 in BC tissues was upregulated and was associated with poor prognosis of BC and the Luminal A+Luminal B subgroup. 3.04% of BC patients had COL12A1 gene alteration. Missense substitution (37.59%) was the most frequent mutation type. Among the 10 related genes, COL3A1, COL5A2, MMP12, P4HA1, P4HA2, P4HA3 and SERPINH1 were significantly upregulated in tumor tissue. The 20 most relevant genes in the GGI network are COL11A1, ID1, COL8A1, MMP9, COL5A1, MMP2, ISLR, LUM, COL7A1, COL3A1, COL1A2, MMP3, COL10A1, COL6A1, COL11A2, COL8A2, MMP8, MMP12. SERPINH1 and MMP13, which are enriched in several pathways including collagen degradation, collagen formation, collagen metabolic process, endodermal cell differentiation, collagen fibril organization and so on. Furthermore, analysis of paired cases from the TCGA-BRCA database revealed that COL12A1 was expressed with higher level in primary foci than metastatic foci. IHC staining revealed that the expression of COL12A1 was upregulated in primary foci of TNBC.

Conclusions: In conclusion, COL12A1 may be a poor prognostic predictor and a specific therapeutic target for primary foci in BC, especially in TNBC.

Background: CDK 4/6 inhibitors have revolutionized the treatment of HER2-negative luminal breast cancer, with median progression-free survival (PFS) of over 25 months and overall survival (OS) of over 60 months. After more than five years since their commercialization in our country, the Canarian Breast Cancer Group decided to analyze the results obtained in our region.

Methods: We collected data on the characteristics of patients treated with cyclin inhibitors in the first line, including their diagnosis, treatment, and evolution, in the 7 oncology centers across the archipelago.

Results: From January 2017 to December 2022, 583 patients were registered, median age of 60 y. Of these, 65% had relapsed, with 30% relapsing more than one year after completing adjuvant hormonal therapy (HT) and the remaining 35% relapsing during the HT. The median PFS was 15 months, in de novo patients and in those who had completed HT more than one year before was 20 months. The OS was 52 months, in de novo patients having a higher OS of 58 months. Patients treated with abemaciclib

tended to have higher PFS and OS rates in cases of hormone resistance and visceral disease. No differences were found in patients diagnosed under 50 years of age.

Conclusions: Our patients experienced lower PFS and OS rates than those reported in clinical trials, which may be due to a higher number of patients exposed to HT and up to 46% of patients presenting with visceral disease at diagnosis. Further follow-up is required to confirm differences between cyclin inhibitors.

468P Impact of low HER2 status on CDK4/6 inhibitor and endocrine therapy in metastatic HR+ breast cancer: A retrospective multicenter study

E. Caliskan Yildirim[1], E. Atag[1], E. Yuzugullu[2], O.U. Unal[3], A. Celebi[4], M. Keser[5], M. Uzun[1], M. Keskinkilic[6], E. Tanrikulu Simsek[7], M. Sari[8], T. Yavuzsen[6]

[1]Medical Oncology Dept., Dokuz Eylul University - Faculty of Medicine, Izmir, Turkey; [2]Medical Oncology, Haydarpasa Numune Education and Research Hospital, Istanbul, Turkey; [3]Medical Oncology, Tepecik Education and Research Hospital, Izmir, Turkey; [4]Medical Oncology Dept., Marmara University Pendik Training and Research State Hospital, Istanbul, Turkey; [5]Medical Oncology Department, Tepecik Training and Research Hospital, Izmir, Turkey; [6]Medical Oncology Dept., Dokuz Eylul University School of Medicine, Izmir, Turkey; [7]Medical Oncology Dept., Haydarpasa Numune Education and Research Hospital, İstanbul, Turkey; [8]Medical Oncology Department, Marmara University Pendik Training and Research State Hospital, Istanbul, Turkey

Background: CDK4/6 inhibitors combined with endocrine therapy have revolutionized the treatment of metastatic HR+ breast cancer. However, the influence of low HER2 expression on treatment response and progression-free survival (PFS) remains unclear.

Methods: We conducted a multicenter retrospective study including 204 HR+ breast cancer patients who received a combination of CDK4/6 inhibitor and endocrine therapy. Among them, 138 (68%) patients exhibited HER2-zero disease, while 66 (32%) patients had HER2-low disease. We analyzed treatment-related characteristics and clinical outcomes, with a median follow-up of 22 months.

Results: In the HER2-low group, the objective response rate (ORR) was 72.7%, compared to 66.6% in the HER2-zero group (p=0.54). Median PFS did not significantly differ between the HER2-low and HER2-zero groups (19 months vs. 18 months, p=0.89). Notably, a trend towards longer PFS was observed in the HER2-low group for first-line treatment (24 months progression-free survival rate: 63% vs. 49%). For recurrent disease, the median PFS was 25 months in the HER2-low group and 12 months in the HER2-zero group (p=0.08), while in de novo metastatic disease, the median PFS was 18 months in the HER2-low group and 27 months in the HER2-zero group (p=0.16). Independent variables affecting PFS were identified as the order of CDK4/6 inhibitor use and the presence of visceral metastasis.

Conclusions: Low HER2 expression did not significantly impact treatment response or PFS in HR+ breast cancer patients treated with a CDK4/6 inhibitor and endocrine therapy. Because of the conflicting results in the literature, further prospective studies are needed to evaluate the clinical significance of HER2 expression in HR+ breast cancer.

Background: Improving the quality of life, in addition to survival, is one of the main objectives of treating metastatic breast cancer. Among the primary treatments for most of these patients are hormonal therapies + CDK inhibitors or chemotherapy, which have varying toxicity profiles and impacts on quality of life. Hormonal therapies have been associated with improvements in quality of life based on questionnaires, but we have limited objective parameters to assess quality of life.

Methods: We analysed circadian rhythms in 55 metastasic breast cancer patients who were compared to healthy controls (digital twin) matched by age, weight, and height. The healthy controls were recruited from the Kronohealth database, which includes more than 10,000 subjects. The patients were divided in two groups by kind of treatment. Group 1 patients with first or second chemotherapy line and Group 2 patients with cyclin dependant kinasa inhibitor plus hormonal therapy All participants had Performance status 0 or 1. EUROQOL-5D 5L quality of life test was performed.

Results: The EQ-5D-5L scale did not show significant differences in any of the five aspects analyzed: pain, anxiety, mobility, usual activities, and self-care were evaluated as either without problems or with mild problems regardless of the treatments received. However, patients in group 1 exhibited patterns of aged rhythms compared to healthy controls, with decreased time and amplitude of movements (motor activity) and increased hours of sleep. Patients in group 2 maintained levels of physical activity similar to those of the control group, and there were no differences in sleep patterns. Body temperature was decreased in both groups of patients, and the recovery of temperature after the initiation of activity was slowed down compared to controls.

Conclusions: CDK Inhibitors plus hormonotherapy have a lesser impact on the quality of life compared to chemotherapy treatments in patients with metastatic breast cancer, as these patients maintain better levels of physical activity and less disrupted sleep patterns. We have observed a significant decrease in body temperature in oncology patients, which will be the subject of future investigations.

470P Increased risk of vertebral fractures in healthy bone in metastatic breast cancer patients treated with CDK4/6 inhibitors combined with endocrine therapy

M. Bergamini, R. Pedersini, C. Brentegani, V. Baluta, G. Schivardi, D. Cosentini, P. di Mauro, M. Zamparini, M. Laganà, V. Amoroso, L. Vassalli, A. Alberti, L. Laini, E.L. Simoncini, A. Berruti

Medical Oncology Unit, ASST Spedali Civili di Brescia, Brescia, Italy

Background: CDK4/6 inhibitors (CDK4/6-i) combined with endocrine therapy (ET) have become the standard of care for ER-positive HER2-negative metastatic breast cancer (mBC) and have significantly improved clinical outcomes. In long-term survivors, bone health is a crucial issue. The risk of fragility fractures associated to ET is well established. Preclinical data suggest that CDK4/6-i could have an effect on the bone microenvironment, however no clinical data are available. The aim of this study is to evaluate vertebral fractures (VFs) progression in mBC patients (pts) treated with CDK4/6-i combined with ET.

Methods: A series of 211 ER-positive HER2-negative mBC pts treated with CDK4/6-i combined with ET and referred to Medical Oncology and Breast Unit of ASST Spedali Civili, Brescia, from 2017 to 2023 were enrolled. VFs were evaluated through CT scan at baseline and at subsequent CT restaging and were classified as mild, moderate and severe based on Genant classification.

Results: All pts were female, with a median age of 55.5 years (32-79). CDK4/6-i were administered as first, second and third line of treatment in 113 (53.6%), 65 (30.8%) and 6 (2.9%) pts, respectively. ETs were aromatase inhibitor and fulvestrant in 104 (49.3%) and 107 (50.7%) pts, respectively. At baseline, 141 patients (66.8%) had bone metastases. 102 (48.3%) pts were treated with bone-targeted agents (BTAs). VFs in healthy bone were detected in 22 (10.4%) pts at baseline and in 37 (17.5%) pts after a mFU of 24 months ($p<0.001$), with 21 (10.1%) pts experiencing VFs progression, defined as the onset of a new VF of the worsening of pre-existing VFs. Among pts receiving BTAs, VFs in healthy bone were detected in 6 (5.9%) pts at baseline and in 16 (15.7%) pts after a mFU of 24 months ($p = 0.006$). Correlations between fracture risk factors and VFs progression as well as the comparison between patients receiving and patients not receiving BTAs will be presented at the meeting.

Conclusions: These data suggest a detrimental effect of CDK4/6-i and ET combination on bone health. Studies with a prospective design, a control arm with ET alone and longer follow-up are needed to better explore this issue.

471P Liver toxicities during cyclin-dependent kinase inhibitors (CDKi) in patients affected by hormone receptor-positive breast cancer (BC)

C. Paratore[1], M. Audisio[1], S. Bombaci[1], M. Bungaro[2], R. Dionisio[3], G. Ferrari[4], E. Gaudino[1], L. Grassi[1], A. Hotca[1], C. Loddo[1], G. Manuguerra[1], E. Manzin[1], S. Novello[4], G. Numico[5], I. Persano[5], C. Sculli[1], P. Sperone[4], A.A. Valsecchi[3], G. Zucchini[2], G. Vellani[1]

[1]Medical Oncology, Ivrea Community Hospital, Ivrea, Italy; [2]Medical Oncology, Ospedale Michele e Pietro Ferrero - ASL CN2 Alba e Bra, Verduno, Italy; [3]Department of Oncology, University of Turin, Ordine Mauriziano Hospital, Turin, TO, Italy; [4]Department of Oncology, San Luigi Hospital, University of Turin, Orbassano, Italy; [5]Division of Medical Oncology, Department of Oncology, University of Turin, Santa Croce e Carle Hospital, Cuneo, Italy

Background: CDKi are standard of care for patients (pts) with advanced hormone-positive (HR+) BC, with recent results even in the adjuvant setting. Nevertheless, management and clinical implication of hepatotoxicity during CDKi are not well described in literature, even if it is reported in a non-negligible rate within trials.

Methods: A multicenter Italian retrospective study was conducted in 2023, collecting and pooling data of pts affected by HR+ HER2- BC, treated with CDKi and aromatase inhibitors (AI) or fulvestrant (FULV). This study aims to describe the incidence and the management of liver adverse events (AEs) during CDKi in a real-world setting. A descriptive analysis was performed as pivotal evaluation for designing an observational study.

Results: 256 pts were included across 5 centres: 96% of pts received CDKi in the metastatic setting. Pts were treated with ribociclib (42%), abemaciclib (25%) and palbociclib (33%) associated with AI or FULV. Liver AEs occurred in 16% of pts, with a median time of onset of 90 days. 19 pts (46%) experienced grade $\geq$3 (G$\geq$3) liver AEs: mostly with elevated liver enzymes (95%). No acute liver failure was reported. The rate of liver AEs was 20% for ribociclib, 17% for abemaciclib and 11% for palbociclib. Ribociclib and abemaciclib were associated with 79% and 21% of G$\geq$3 liver AEs. Diagnostic assessments were performed in 37% of pts with liver AEs: hepatotropic viruses screening (68%), autoimmunity screening (28%) and radiological exams (4%). Only one liver biopsy was performed with a diagnosis of drug induced liver injury. Recovery of normal liver function after CDKi discontinuation was achieved in 68% of pts, with a median time of 30 days. After resolution of G$\geq$3 liver AEs, 26% of pts discontinued any treatment, 5% continued only AI or FULV, 48% resumed CDKi with dose reduction and 21% shifted to another CDKi without any further G$\geq$3 liver AEs.

Conclusions: In our cohort the incidence of liver AEs was significant, with a relevant number of G$\geq$3 AEs. Since hepatotoxicity is defined by diagnosis of exclusion, a prompt screening for differential causes is crucial in case of abnormal liver function. After non serious liver AEs, resumption of lower dose or shift to another CDKi may be a safe therapeutic option.

472P Prevention of metastasis formation by combination therapy targeting Her2 and PD-L1 in Her2-expressing tumors based on observed efficacious vaccination against Her2-positive tumors

J. Tobias[1], S. Högler[2], M. Kundi[3], D. Shih-Cheih Lin[4], Y. Chao[4], E. Garner-Spitzer[1], N. Ede[5], C. Zielinski[6], A. Good[5], U. Wiedermann[1]

[1]Institute for Specific Prophylaxis and Tropical Medicine, MedUni Wien - Medical University of Vienna, Vienna, Austria; [2]Laboratory Animal Pathology, University of Veterinary Medicine, Vienna, Vienna, Austria; [3]Department of Environmental Hygiene and Environmental Health, MedUni Wien - Medical University of Vienna, Vienna, Austria; [4]Deparment of Oncology, Taipei Veterans General Hospital, Taipei City, Taiwan; [5]Imugene Limited, Sydney, NSW, Australia; [6]Central European Cancer Center, Wiener Privatklinik, and Central European Cooperative Oncology Group (CECOG), Universitätskliniken der MedUni Wien - AKH Wien, Vienna, Austria

Background: The overexpression of human epidermal growth factor receptor Her2 is associated with a more aggressive cancer phenotype. We have formulated a Her2 vaccine (HER-Vaxx), comprising B-cell peptide from the trastuzumab binding site, inducing anti-tumor immune responses and immunological memory in pre-clinical and clinical investigations. In the phase 1b evaluation (NCT02795988) of the vaccine, one patient had progressed with a new metastatic lesion with no Her2 expression. The vaccine's pre-clinical evaluation was shown to significantly reduce Her2 lung metastases size in a murine model, and was associated with Her2 loss and upregulation of tumoral PD-L1 expression. In light of the preclinical observation, the patient's primary tumor at the pre- and post-treatment time points was evaluated with regard to expression levels of Her2 and PD-L1.

Methods: Biopsies of the patient's primary tumor from the pre- and post-treatment time points were evaluated by immunohistochemistry (IHC) and fluorescence in situ hybridization (FISH) for Her2, and combined positive score (CPS) for PD-L1 expression. The murine Her2 lung metastases model was employed to further investigate the proteins' expression association.

Results: The assessment of the patient's primary tumor biopsies indicated Her2 3+ (IHC), Her2 /CEP17 ratio of 4.98 (FISH) and 0% PD-L1 CPS at the pre-treatment time point. At the post-treatment time point, the primary tumor's assessment showed a loss of Her2 expression: 0 (IHC) and Her2 /CEP17 ratio of 1.63 (FISH), with 5% PD-L1 (CPS) expression. In the mouse model, vaccination with HER-Vaxx resulted in a significant reduction of Her2 and upregulation of PD-L1 expression 6 weeks or longer after tumor cell implantation, at transcriptional and translational levels in the same tumors of the metastasized lungs of the vaccinated mice.

Conclusions: These results strongly suggest an immune evasive tumor cell response with an upregulation of PD-L1 expression in both, the clinical and preclinical settings. A combination therapy targeting both Her2 and PD-L1 in Her2-overexpressing tumors might efficiently prevent metastasis formation and immune evasion.

Background: The combination of endocrine therapy (ET) and cyclin-dependent kinase 4/6 inhibitors (CDKi) for ER+HER2neg metastatic breast cancer has been associated with 13% of drug-induced liver injury (DILI). In a previous work (Vega et al, ESMO Breast 2023), we identified 26 cases of DILI (5.5%), defined as AST/ALT elevation $\geq$G2, among 472 patients (pts) treated. Here, we present a case-control study to evaluate the clinical factors associated with DILI.

Methods: The case-control study includes i) 89 pts without DILI randomly selected and retrospectively analyzed (control group) and ii) 26 cases with DILI previously reported. 15 potential predictive factors were evaluated either individually or in combination. Baseline liver steatosis was based on computed tomography reports. To study the association with DILI, odds ratios (ORs) were calculated using logistic regression.

Results: The main characteristics of the 115 pts are shown in the table. In the univariate analysis, no baseline risk factor alone was statistically associated with DILI, steatosis and AST/ALT baseline elevation had the best results ($p<0.15$). However, the combination of steatosis and pre-menopause status (n=9, 7.8%) significantly increased the risk to 66.7% vs 19% (20/105) (OR=8.6, 95% CI 2.1-43.6; p=0.004). No other variables, including cardiovascular risk factors, ET partner or liver metastasis predicted DILI development.

Table: 473P Baseline characteristics of cases and control

	Cases n=26	Controls n=89
Palbociclib	8	32
Abemaciclib	9	29
Ribociclib	9	28
Age (median)	61	60
Overweight	33%	36%
Obesity	26%	28%
Pre-Menopause	54%	35%
Hypertension	27%	27%
Diabetes mellitus	4%	11%
Dyslipidemia	31%	29%
Aromatase inhibitor	65%	57%
Fulvestrant	35%	43%
Liver metastasis	27%	30%
Steatosis	31%	15%
Baseline ALT or AST >35 IU/mL	36%	17%

Conclusions: In our case-control series, the combination of premenopausal status and steatosis was the strongest predictor for CDKi-related DILI. Our findings suggest that metabolic changes due to ovarian factor suppression cooperate with CDKi to induce DILI in pts with underlying steatosis. A prospective study is needed to validate these findings.

Background: Circulating tumor DNA (ctDNA) is an emerging technology to predict outcome in cancer patients and monitor treatment response including immune checkpoint blockade (ICB). So far, data on ctDNA dynamics during ICB in breast cancer are lacking. Moreover, in the context of ICB, most of the ctDNA assays focus on detection of mutations, while many cancer types including breast cancer are mainly driven by copy number alterations (CNA). Here we present ctDNA-based CNA dynamics in patients with metastatic triple-negative breast cancer (mTNBC) treated with anti-PD1 in the TONIC-trial.

Methods: Low-coverage (0.5x) whole genome sequencing was performed on plasma samples taken at baseline and after 8 weeks of treatment for a subset (n=30) of patients with mTNBC treated with nivolumab in the TONIC trial (Voorwerk et al., Nat Med 2019). 16 patients had progressive disease; 14 patients ('responders') responded to nivolumab or had stable disease for at least 24 weeks. CNA profiles were generated with QDNASeq, NoWaves and CGHcall, followed by calculating copy number profile abnormality (CPA) scores.

Results: ctDNA CNA profiles were significantly correlated with tumor CNA profiles with an average correlation of 0.5 (range 0.21 - 0.86). Baseline ctDNA levels and ctDNA-based CPA scores were not associated with response to anti-PD1. While in non-responders ctDNA levels increased during ICB ($p = 0.008$), in responders CPA scores decreased ($p = 0.0004$). Higher on-treatment CPA scores were negatively correlated with overall survival (OS) and progression-free survival (PFS) ($p = 0.000005$, $p = 0.0008$, respectively).

Conclusions: ctDNA-based copy number alterations dynamics in patients with mTNBC was highly correlated with anti-PD1 response. This pilot study is the first report on the potential utility of low coverage ctDNA-based surveillance during ICB treatment and warrants further validation in TNBC and other tumor types.

475P Dynamics of TROP2 expression in triple-negative breast cancer

A.C. Garrido-Castro[1], J. Gomez Tejeda Zanudo[1], J. Navarro[1], A.M. Barkell[2], A. Frangieh[1], A. Mohammed-Abreu[1], M.E. Hughes[1], B. Binboga Kurt[1], R.J. Hill[3], T.A. King[4], E.A. Mittendorf[4], M.C. Rebelatto[5], D. Carroll[2], N.U. Lin[1], S.M. Tolaney[1], E.C. De Bruin[2]

[1]Medical Oncology, Dana Farber Cancer Institute, Boston, MA, USA; [2]Translational Science, AstraZeneca, Cambridge, UK; [3]Translational Science, AstraZeneca, Little Chesterford, UK; [4]Surgery, Dana Farber/Brigham and Women's Cancer Center, Boston, MA, USA; [5]Precision Medicine, AstraZeneca, Gaitherburg, MD, USA

Background: With the approval of antibody drug conjugates (ADC) for metastatic TNBC (mTNBC), understanding prevalence and changes in ADC target expression from early-stage to metastatic breast cancer is key. Here we report TROP2 expression in a cohort of patients (pts) diagnosed with TNBC with collection of matched tumor samples over time.

Methods: Pts were identified from an institutional database of pts who underwent surgery for stage I-III TNBC at Dana-Farber/Brigham Cancer Center between 2015-2018, and a prospective biopsy protocol for pts who developed mTNBC. TROP2 immunohistochemistry (IHC), RNA and exome sequencing were performed in samples at diagnosis (DX), residual disease (RD) post-neoadjuvant therapy (if applicable), and recurrence (MR). TROP2 IHC (tumor cell membrane expression) was scored by a trained pathologist and classified: low, L (H score <100); medium, M (100-<200); high, H (200-300). RNA expression was quantified using log2p1-transformed and normalized transcripts per million.

Results: TROP2 IHC was performed in 161 samples (62 DX, 54 RD, 45 MR) from 94 pts (Table). TROP2 H/M distribution was similar at DX (90.3%; 56/62) vs MR (88.9%; 40/45). In samples with available TROP2 and HER2 IHC, TROP2 H/M distribution was 88.8% (71/80) in HER2-0 and 91.3% (42/46) in HER2-low TNBC. In 20 pts with paired DX and RD, TROP2 IHC was discordant (H/M vs L) in 15% (3/20). Of 17 TROP2 H/M DX tumors, 2 (11.8%) were L at RD. In 15 pts with paired DX and MR, TROP2 IHC was discordant in 26.7% (4/15). Of 14 TROP2 H/M DX tumors, 3 (21.4%) were L at MR. Correlation between TROP2 IHC and *TACSTD2* expression was observed (n=53; Pearson r=0.38; p=0.005). *TACSTD2* expression was numerically higher in TROP2 H/M vs L (p=0.09). Increased gene expression was also observed for L vs H (p=0.06) and M vs H (p=0.047). No *TACSTD2* mutations were identified.

Table: 475P Distribution and changes in TROP2 IHC (n samples) in pts diagnosed with TNBC. A) TROP2 IHC by sample type. B) From DX to RD; C) From DX to MR. Discordant cases (H/M vs L) are highlighted in grey

A)		TROP2 (DX, RD, MR)			
		Low	Med	High	TOTAL
Sample type	DX	6	11	45	62
	RD	4	13	37	54
	MR	5	8	32	45
	TOTAL	15	32	114	161
B)		**TROP2 (RD)**			
		Low	Med	High	TOTAL
TROP2 (DX)	Low	**2**	**0**	**1**	3
	Med	**0**	1	1	2
	High	**2**	4	9	15
	TOTAL	4	5	11	20
C)		**TROP2 (MR)**			
		Low	Med	High	TOTAL
TROP2 (DX)	Low	0	**1**	**0**	1
	Med	**0**	**1**	1	2
	High	**3**	1	8	12
	TOTAL	3	3	9	15

Conclusions: TROP2 IHC was H/M in the majority of samples, with similar distribution at DX and MR, and between HER2-0 and HER2-low TNBC. In paired DX/RD or DX/MR, discordance between TROP2 H/M and L groups was low.

476P Allosteric PI3K-alpha inhibition reverses on-target resistance to orthosteric inhibitors mediated by secondary PIK3CA mutations

A. Varkaris, et al.

Cancer Center, MGH - Massachusetts General Hospital, Boston, MA, USA

Late withdrawal

477P Do ESR1-related mutations generate neoantigens in hormone-receptor-positive HER2-negative metastatic breast cancer?

M. Lopez[1], L. Spehner[1], M. Ramseyer[2], A. Bouard[2], E. Dobi[1], E. Curtit[1], C. Borg[1], L. Mansi[1]

[1]*Team Thérapeutique Immuno-Moléculaire des Cancers, CHRU Besancon - Hopital Jean Minjoz, Besancon, France;* [2]*Doubs, UMR1098, Besancon, France*

Background: Breast Cancer (BC) is the most common type of cancer in women and 80% of cases are hormone-receptor positive. In 20 % a key mechanism of endocrine resistance to the standard first line is mutation of the ligand-binding domain of Estrogen Receptor 1 (ESR1) encoding estrogen receptor a. These mutations are clustered in a "hotspot" within the LBD. Four mutations are known in positions 537 and 538 (D538G, Y537C, Y537N, and Y537S), and lead to cell proliferation and potentially enhanced metastatic capacity. This project aims to identify if ESR1 receptor mutations are neoantigens in patients with HR+ HER2- metastatic BC, and thus resistant to endocrine therapy.

Methods: We identified candidate ESR1-derived-peptides, to evaluate the immunogenicity of these peptides we conducted a vaccination assay on a humanized mouse model. We administered 100 µg of each peptides and 50 µg of CpG on day 0 (D0). We achieved three boosts with 50 µg of each peptides and 30 µg of CpG on D7, D14 and D21. Spleen and lymph nodes were isolated on D23 and immunogenicity tests were conducted. We also evaluated the immunogenicity of ESR1-derived peptides in PBMC on 30 healthy donors (HD) and 25 patients with mBC HR+ BC by ELISpot assay. Furthermore, we cloned T-cells with 2 stimulations in 30 days, to demonstrate that T-cells can lyse tumour cells.

Results: Preliminary results validated the HLA-A2 ESR1 peptide immunogenicity in humanized mice. In the same way, we demonstrated the ESR1 peptide immunogenicity in HD and patients with BC. Our results showed that 40% of patients had specific immune responses. and these patients presented secondary hormone-resistance. These data allow the selection of the most relevant peptides which are either weakly or not observed at all with HD. These results support that the ESR1 mutation generates neoantigens in hormone-receptor-positive metastatic breast cancer.

Conclusions: From the perspective of those results, we will try to demonstrate the natural ESR1-specificity T cell clones to recognize and kill transduced ESR1 tumour cells. Additionally, we will analyze HLA Class I expression in mutated/non-mutated ESR1 patients by bioinformatics in order to understand if tumour resistance may be linked to the loss of HLA expression.

Background: Although available evidence establishing the impact of germline PV of DNA-repair genes in patients with luminal MBC is conflicting, the standard treatment is represented by CDK 4/6i plus ET.

Methods: In this retrospective multicenter study, HR+ HER2- MBC pts tested for gBRCA1/2 genes and who received CDK 4/6i plus ET from 1st Jan 2017 to 31th December 2021, were included. The objectives were the evaluation of outcome (primary/secondary end-points: progression free survival [PFS]/overall survival [OS]) according to gBRCA1/2 status (PV *versus* wild type [wt]/variants of uncertain significance [VUS]), estimated by Kaplan-Meier method. Cox model was used to assess the correlation between baseline variables and outcomes.

Results: 249 pts in 13 centers were included in the study: 40 (16.1%) pts carried gBRCA1/2 PV (N=31 with gBRCA2 PV), 20 (8.0%) pts had VUS BRCA1/2, 189 (75.9%) pts were wt. Baseline charateristics were: median age 52 years (range: 26 − 83 yrs); male 2.8% (N=7; with 3 gBRCA2 PV); premenopausal 46.6% (N=116); visceral metastases 78% (N=194); ECOG PS 0 80% (N=199); 1st line CDK4/6i plus aromatase inhibitor (AI) 53% (N=132); chemotherapy (CT) before CDK4/6i plus ET 16.5% (N=41). The two groups differed for ECOG PS $\geq$ 1 (32.5 vs. 17.7%; p= 0.032) and previous CT (32.5% vs. 13.4%; p= 0.003). With a median follow up of 37.5 months (95%CI 31.4 − 43.5) the mPFS was 10.7 vs. 26.7 months for pts with gBRCA1/2 PV and wt, respectively (p< 0.001). Similarly, mOS was shorter for gBRCA1/2 PV pts (40.1 vs. 69.0 months; p= 0.013). After adjusting survivals for ECOG PS status and use of previous CT for MBC, the worse outcome was confirmed for pts with gBRCA1/2 PV (HR for PFS, 1.61; 95%CI: 1.09 − 2.44; p= 0.017 and HR for OS, 1.72; 95%CI: 1.01 − 2.94; p= 0.047). Among gBRCA1/2 PV pts, PARP inhibitor and CT were the treatments after CDK4/6i progression in 15.6% (N=5) and 62.5 % (N=20; 8 pts had platinum based treatment), respectively.

Conclusions: These data reported gBRCA1/2 PV as a negative prognostic factor for HR+ HER2- MBC pts treated with CDK4/6i plus ET. Different strategies are urgently needed for this subgroup of pts.

Pascale, Naples, Italy;* [8]*Department of Pathology, CHU de Montpellier - Hopital Gui de Chauliac, Montpellier, France;* [9]*Medical Oncology, ICM Regional Cancer Institute of Montpellier, Montpellier, France*

Background: Significant discordance rates in HER2 status between primary breast cancer (BC) and brain metastases (BCBM) have been reported, potentially affecting clinical decision-making. Biological recharacterization of BCBMs is difficult due to inherent neurosurgery risks. We here assess the potential of radiomics to non-invasively assess HER2 status of BCBMs.

Methods: We retrospectively identified BC patients from 2 centers, for which HER2 status evaluated on BCBMs (HER2-positive versus HER2-negative by ASCO-CAP) and preoperative brain MRI were available. A total of 218 radiomics features, complying with Imaging Biomarker Standardization Initiative feature definition, were extracted from manually segmented BCBMs using Python. Robust features (selected using LASSO) associated with HER2 status in univariate analysis (p<0.05) were tested in multivariate analysis. Linear regression model (LRM) and non-linear logistic regression model (NLRM) were constructed. Machine learning (ML) algorithms

(decision tree, k-nearest neighbor, and support vector machine [SVM]), were tested, by spliting the dataset into 70% for training, 20% for testing, and 10% for validation. Classifiers were trained and tested using the cross-validation approach 10 times; median values for AUC, accuracy, sensitivity and specificity were obtained. The performance of the best classifiers was evaluated on the validation dataset. Analyses were performed using MATLAB R2021b Statistics and Machine Toolbox (MathWorks).

Results: We identified 54 BC patients, for which HER2 status evaluated on 56 BCBMs (HER2+ N=27, HER2- N=29) and preoperative brain MRI was available. At univariate analysis, 9 features were significantly associated with HER2 status, but diagnostic accuracy was low (maximum 67%). Using LRM and NLRM, including the 9 significant features at univariate analysis, accuracy increased to 79%. Using the ML approach, the best classifier among the pattern recognition approaches tested was a SVM including the 9 significant features, which reached an AUC of 0.97 and an accuracy of 91% and 86% on test and validation set, respectively.

Conclusions: Radiomics using machine learning approach shows potential to non-invasively predict HER2 status of BCBMs.

480P Prognostic significance of somatic DNA gene rearrangement and structural atypia in metastatic breast cancer

H. Tada[1], J. Yasuda[2], H. Shirota[3], M. Miyashita[1], N.S. Harada[1], Y. Hamanaka[1], A. Ebata[1], M. Sato[1], T. Ishida[1]

[1]Department of Breast and Endocrine Surgical Oncology, Graduate School of Medicine, Tohoku University, Sendai, Japan; [2]Center of Medical Genomics, Miyagi Cancer Center, Natori, Japan; [3]Department of Medical Oncology, Tohoku University Hospital, Sendai, Japan

Background: Comprehensive genomic profiling (CGP) testing for breast cancer has become widely used to identify genetic alterations, including somatic DNA gene rearrangement and structural atypia. The prognostic impact of somatic DNA gene rearrangement/structural atypia in metastatic breast cancer (MBC) is unclear. In this study, we aimed to clarify the prognostic significance of DNA gene rearrangement and structural atypia.

Methods: We evaluated 1790 cases of MBC who received cancer gene panel tests under the national health insurance system using FoundationOne CDx(R) between June 2019 and October 2022. Genomic and clinical data were collected from the Center for Cancer Genomics and Advanced Therapeutics (C-CAT) Research-Use Portal in Japan. Patients were divided into two groups based on the presence or absence of somatic DNA gene rearrangement/structural atypia described in the reports: the rearrangement group (with at least one DNA gene rearrangement/structural atypia) and the others (without). Genomic alterations and overall survival from the date of diagnosis were evaluated.

Results: One hundred sixty-four patients (9.2%) had one or more DNA gene rearrangements or structural atypia. Overall, 285 DNA gene rearrangements/structural variants were found, with FGFR1 rearrangement being the most common (n=10), followed by MTOR rearrangement (n=7), FGFR2 rearrangement (n=6), NOTCH2 rearrangement (n =5). The rearrangement group had significantly better overall survival than the others (rearrangement group, NA, the others, 162.3m; log-rank P-value = 0.0006; hazard ratio, 0. 43; 95% confidence interval, 0.26-0.71).

Conclusions: MBC patients with one or more DNA gene rearrangements and structural atypia had a significantly better prognosis. Further investigations of the prognostic and biological significance of these alterations in MBC patients are warranted.

481P Second generation oral selective estrogen receptor degraders (SERDs) in breast cancer: A systematic review and meta-analysis of clinical trials

M. Silveira Vilbert[1], D. Pinheiro Xavier[2], M. Goldner Cesca[3], L.V. Ravani[4], J. Chamadoira[5], C. Stecca[6], R. Costa[7], L. Cavalcante[8]

[1]Department of Clinical Oncology, UHN - University Health Network - Princess Margaret Cancer Center, Toronto, ON, Canada; [2]Department of Medicine, Universidade Federal do Para-Health Science Institute, Belém, Brazil; [3]Department of Clinical Oncology, A.C. Camargo Cancer Center - Fundacao Antonio Prudente, Sao Paulo, Brazil; [4]Department of Medicine, University of Sao Paulo - Faculty of Medicine, Sao Paulo, Brazil; [5]Department of Medical Imaging, St. Michael's Hospital - University of Toronto, Toronto, ON, Canada; [6]Medical Oncology Department, Center of Oncology of Parana, Curitiba, Brazil; [7]Breast Oncology, H. Lee Moffitt Cancer Center & Research Institute - Magnolia Campus, Tampa, FL, USA; [8]Medical Oncology Department, Novant Health Cancer Institute, Charlotte, NC, USA

Background: SERDs are effective treatment options for breast cancer (BC) patients (pts) after progression on first-line therapy, especially for those harboring estrogen-receptor 1 (*ESR*1) mutations (mut). Several studies have explored the potential of SERDs to overcome endocrine resistance, yielding promising results.

Methods: We conducted a systematic review and meta-analysis to assess oral SERDs in hormone receptor-positive, HER-2-negative BC pts. Efficacy was evaluated by tumor response according to *ESR1*mut, and the number of pts with variant allele frequency (VAF) decreased with SERD therapy. We searched Pubmed, Scopus, and Cochrane Library databases and congress websites for randomized and non-randomized clinical trials. We used a random effects model for data pooling; heterogeneity was assessed with I^2 statistics.

Results: We included 19 studies with 1,798pts. Of 855 pts tested, 387 (45%) had *ESR1*mut. *ESR1*mut frequency and respective overall response rate (ORR) are described in the table. We found 80% of pts(95%CI 0.72-0.88 $I^2$56%) had a decrease in VAF with SERD therapy. The estimated risk of all-causality adverse events (AE) was 86% (95% CI 0.80-0.92), and grades 3 or 4 AE were 19% (95% CI 0.11-0.28). SERD plus Palbociclib resulted in higher rates of AEs (p<0.01). Elacestrant had numerically higher G3-4 AEs compared to the other SERD (p=0.05). The most common AEs were nausea (35%), diarrhea (30%), and fatigue (23%). Arthralgia was reported in 15%, and only 1% of pts had to discontinue treatment due to AE.

Table: 481P Characterization of *ESR1*mut and response to SERD (Amcenestrant, Elacestrant, and Camizestrant)

*ESR1*mut	Prevalence of *ESR1*mut(%)	Patients assessed for response(n)	ORR(%)
D538G	34	25	44
Y537S	28	23	61
E380Q	8	8	25
Y537N	7	11	45
L536H	6	4	75
Others	16	13	15

Conclusions: Our study supports the favorable safety profile of the new generation oral SERD and presents its efficacy according to *ESR1*mut. Further studies shall assess the potential biomarker role of individual *ESR1*mut.

482P Precision imaging with human epidermal growth factor receptor 2-positron emission tomography (HER2-PET) for refined treatment selection in patients with HER2-low breast cancer

S. af Burén[1], R. Axelsson[2], E. Jussing[3], M. Karlsson[4], A. Blomgren[4], N. Brun[5], F.Y. Frejd[6], T.A. Tran[3], R. Altena[3]

[1]Department of Clinical Science, Intervention and Technology, Karolinska Institutet, Huddinge, Sweden; [2]Department of Molecular Medicine and Surgery, Karolinska Institute, Stockholm, Sweden; [3]Department of Oncology-Pathology, Karolinska Institutet, Stockholm, Sweden; [4]Department of Medical Radiation Physics and Nuclear Medicine, Karolinska University Hospital, Stockholm, Sweden; [5]Copenhagen Centre of Regulatory Science, University of Copenhagen, Copenhagen, Denmark; [6]Department of Immunology, Genetics and Pathology, Uppsala University, Uppsala, Sweden

Background: HER2-low metastatic breast cancer (mBC) is a clinically relevant subgroup with promising treatment options. Challenges relate to establishing HER2-low status when biopsies are not feasible, and little is known about disease heterogeneity. PET-imaging with a HER2-specific tracer could shed light on these issues.

Methods: At the Karolinska Comprehensive Cancer Center in Stockholm, Sweden we conducted a proof-of-concept prospective imaging study with the [^{68}Ga]Ga-ABY-025 tracer in patients with mBC with a previous HER2-low tumor biopsy, who were scheduled for a new line of systemic therapy. A HER2-PET and tumor biopsy (immunohistochemistry [IHC] and in situ hybridization [ISH]) were performed. The study was funded by the Swedish Breast Cancer Society and Stockholm's Region.

Results: Seventeen patients were informed, ten patients provided written consent and in ten, paired PET and biopsy results are available (Table). No unexpected side effects were noted. In all, HER2-PET revealed areas with [^{68}Ga]Ga-ABY-025 maximal Standardized Uptake Value (SUV_{max}) higher than background ratio. HER2-low status was confirmed in tumor biopsies in eight, whereas two patients had HER2 0 in a tumor lesion that was avid on HER2-PET. Substantial heterogeneity was observed in [^{68}Ga]Ga-ABY-025 uptake between different lesions within the same patient.

Conclusions: The visualization of HER2-expressing mBC with [^{68}Ga]Ga-ABY-025 PET/CT is feasible and safe. An intriguing finding is the fact that we noted tracer uptake in lesions that are HER2 0. A continued study is planned where patients with HER2-low mBC are selected for HER2-antibody drug conjugate based on HER2-status on PET and/or IHC.

Clinical trial identification: NCT05619016 EU CT 2022-500448-39-00.

Background: Androgen receptor (AR) is expressed in around 30% of triple-negative breast cancer (TNBC) tumors, and presents with different clinical evolution and resistance to standard chemotherapy. Sacituzumab govitecan (SG) is an antibody-drug conjugate recently approved in TNBC advanced tumors.

Methods: We conducted a retrospective study in 8 French University Hospitals and cancer centers. All patients with TNBC MBC treated with SG were included. The primary endpoint was progression-free survival (PFS) as per AR expression (cut-off 10%). Secondary endpoints included overall survival (OS). Univariable and multivariable analyses were performed.

Results: A total of 127 patients were included, of which 88 (69%) were AR-. The median age was 51yo (range 25 - 77), with younger patients in AR- (47yo) vs. AR+ (55.5yo; p=0.02). AR- tumors were mostly ductal subtype (95.5% vs. 82.1%; p=0.005) and higher grade III (79.8% vs. 58.3%; p=0.021). No differences were observed between AR- and AR+ in the median number of prior treatments at SG start: 2 (0 - 11) and the median number of SG cycles: 6 (1 - 28) with 27 patients (21.3%) still on SG at the time of analyses. With a median FU of 10.4m [95%CI 8.3-11.2], median PFS was 4.1m [3.7-4.7] with no differences based on AR expression (4.1m vs. 4.3 m, AR- vs. AR+, respectively; HR 0.83 [95%CI: 0.53-1.32], p=0.432). In univariable analysis, age at SG treatment (HR 0.98 [0.97-1.00]; p=0.028), adjuvant capecitabine (HR 1.65 [1.06-2.56]; p=0.025), and metastasis-free interval (MFI) (HR 2.39 [1.38-4.14] and 1.09 [0.63-1.91] for 6-24m and > 24m respectively vs. < 6m) were associated with PFS. Short MFI remained significant for worse prognosis in a multivariable analysis (HR (6-24m vs. <6m) 2.0 [1.04-3.88]; p=0.039). The mOS was 9.7m [7.1-12.2] with 67 (52.8%) patients still alive. AR was not associated with OS in the univariable (HR 0.66 [0.37-1.19]; p=0.165] or multivariable analyses (HR=0.69 [0.34-1.38]; p=0.290].

Conclusions: Despite AR+ tumors being described as lesser chemo-sensitive, in this large retrospective cohort, AR expression was not associated with benefit in terms of PFS and OS from SG in patients with advanced TNBC.

484P Multi-platform characterization of HER2 expression in triple-negative breast cancer

A.C. Garrido-Castro[1], J. Gomez Tejeda Zanudo[1], J. Navarro[1], E.T. Richardson[2], A. Frangieh[1], A.M. Barkell[3], A. Mohammed-Abreu[1], M.E. Hughes[1], B. Binboga Kurt[1], T.A. King[4], E.A. Mittendorf[4], D. Carroll[3], S.M. Tolaney[1], E.C. De Bruin[3], N.U. Lin[1]

[1]Medical Oncology, Dana Farber Cancer Institute, Boston, MA, USA; [2]Pathology, Brigham and Women's Hospital, Boston, MA, USA; [3]Translational Science, AstraZeneca, Cambridge, MA, UK; [4]Surgery, Dana Farber/Brigham and Women's Cancer Center, Boston, MA, USA

Background: To improve quantification methods of antibody drug conjugate (ADC) targets, it is critical to understand differences in expression across assays. Here we report HER2 expression per local (L-IHC) and central (C-IHC) IHC, RNA sequencing (seq), and copy number amplification (CNA) by exome seq in patients (pts) with TNBC using matched tumor samples over time.

Methods: Pts were identified from an institutional database of pts who underwent surgery for stage I-III TNBC, and a prospective biopsy protocol for pts who developed metastatic TNBC. Samples were collected at diagnosis (DX), residual disease (RD) post-neoadjuvant therapy (if applicable) and recurrence (M). Clinical pathology records were reviewed for L-IHC; slides were blindly reviewed by a pathologist for C-IHC. HER2 IHC was classified as HER2-0 if IHC 0, and HER2-low if 1+ or 2+/ISH non-amplified. RNA expression was quantified using log2p1-transformed and normalized transcripts per million. Normal subtype samples were excluded.

Results: L-IHC and C-IHC were available in 96 samples (28 DX, 11 RD, 57 M) from 61 pts (Table). HER2-low prevalence was 25.0% (24/96) per L-IHC and 35.4% (34/96) per C-IHC. Discrepant HER2 category was observed in 16.7% of samples (16/96). In 67 samples with L-IHC and RNA seq, *ERBB2* expression was higher in HER2-low (n=21) vs HER2-0 (n=46) groups (p=0.03). A similar trend in *ERBB2* expression was observed with C-IHC (p=0.32). HER2-enriched (HER2E) subtype was present in 23.8% (5/21) of HER2-low vs 6.5% (3/46) of HER2-0 tumors (p=0.10). Basal subtype was 71.4% (15/21) in HER2-low vs 89.1% (41/46) in HER2-0 tumors (p=0.09). Among 17 paired DX/RD and M, 6 pairs had change in L-IHC with no difference in *ERBB2* expression (p=0.83). Of 90 samples with L-IHC and exome seq, none had *ERBB2* CNA.

Table: 484P Distribution of HER2 C-IHC and intrinsic subtype (research-based PAM50) according to HER2 L-IHC in samples from pts with TNBC. Discordant HER2-low and HER2-0 cases are highlighted in grey

A)		L-IHC			
		IHC 0	IHC 1+	IHC 2+	TOTAL
C-IHC	IHC 0	59	**2**	**1**	62
	IHC 1+	**13**	11	4	28
	IHC 2+	**0**	0	6	6
	TOTAL	72	13	11	96

B)		L-IHC			
		IHC 0	IHC 1+	IHC 2+	TOTAL
Intrinsic subtype	Basal	41	11	4	56
	HER2-E	3	3	2	8
	Luminal A	0	0	1	1
	Luminal B	1	0	0	1
	Non-classified	1	0	0	1
	Normal	6	3	1	10
	TOTAL	52	17	8	77

Conclusions: Most discrepant cases between L-IHC and C-IHC resulted in change from HER2-0 to HER2-low. Correlation between HER2 IHC and gene expression was observed in TNBC pts. HER2E subtype was numerically more prevalent in HER2-low vs HER2-0 tumors.

Background: Integrins are known to play a crucial role in the adhesion, invasion and migration of tumor cells. Recent studies revealed the association of certain integrin subunits in organotropic metastasis of breast cancer. In this study, we investigated the biological properties associated with different integrin subunits gene expression in CTCs.

Methods: The study included 81 patients with non-metastatic invasive breast carcinoma of no special type (T1-4N0-3M0, all molecular subtypes). Single-cell cDNA libraries were prepared using the Single Cell 3′ Reagent Kit v3.1 and a 10x Genomics Chromium Controller. The ready cDNA libraries were sequenced on NextSeq 500 and NextSeq 2000 (Illumina, USA).

Results: CTCs were identified based on the expression of one or more epithelial markers: *KRT5, 7, 8, 14, 18, EPCAM, MUC1* and *CDH1* (E-cadherin). In total, expression of 14 integrin subunits was detected in CTCs: nine α-subunits and five β-subunits. In each cell, the combination of different integrin subunits was evaluated, and if complementary α and β-subunits gene expression detected in one cell, we suggested that CTCs potentially could synthesize functionally complete integrin heterodimers. Depending on the combinations of different subunits in CTCs, 455 cells were divided into nine groups. In each group, we assessed the proportion of cells with expression of genes relevant to the most important functions that determine the malignant potential of tumor cells: stemness, EMT, invasion. The most differences were observed in the group of CTCs potentially capable to express the $\alpha6\beta4$ heterodimer. Namely, integrins $\alpha6$- and $\beta4$-positive CTCs more frequent expressed stemness (*ALDH1A1, CD133, KLF4, MYC*) and invasion markers (*RAC1, RHOC, ROCK, MMP1,2*). A combination of epithelial (*KRT 8, 10, 18, 19* and *MUC1*) with mesenchymal features (absence of *EPCAM* expression, expression of *CDH2, VIM, ZEB1)* indicates a hybrid state of EMT.

Conclusions: A novel approach to scRNA sequence analysis has identified subpopulations of CTCs with pronounced biological properties which can play role of

"seeds". The simultaneously presence of integrin α6 and β4-subunits in CTCs was associated with stemness, EMT and invasiveness of CTCs in breast cancer patients.

486P The influence of NF1 germline and somatic mutations on breast cancer patient survival

R.A. Kallionpää[1], R. Huovinen[2], S. Peltonen[3], J. Peltonen[1]

[1]Cancer Research Unit and FICAN West Cancer Center, University of Turku - Institute of Biomedicine, Turku, Finland; [2]Deparment of Oncology, Turku University Hospital (Tyks), Turku, Finland; [3]Department of Dermatology and Allergology, University of Helsinki - Faculty of medicine, Helsinki, Finland

Background: Somatic inactivation of the *NF1* gene is frequent in breast cancer, particularly in advanced stages, and it has been suggested as a potential mechanism of resistance to endocrine therapy. Pathogenic germline variants of the *NF1* gene cause neurofibromatosis 1 (NF1) syndrome that is associated with an increased risk for breast cancer and reduced estrogen receptor expression in breast cancer. The present study aims to explore the consequences of somatic and germline *NF1* mutations in hormone receptor positive and negative breast cancer.

Methods: In order to study germline *NF1* alterations, a Finnish cohort of 1,811 individuals with verified NF1 syndrome (926 women) and a ten-fold control cohort were cross-referenced with the Finnish Cancer Registry. The process identified 49 women with NF1 and 226 controls who had been diagnosed with breast cancer between 1996 and 2020. The analysis was limited to non-localized disease. Register-based information on endocrine therapy was used as a proxy for hormone receptor status. Survival after breast cancer with or without somatic *NF1* deficiency was analyzed using the METABRIC dataset, which contained 582 breast cancers harboring somatic alterations of the *NF1* gene, and 1,392 tumors where the *NF1* gene was intact. Cox proportional hazards models were used to estimate hazard ratios (HRs) and their 95% confidence intervals (CI).

Results: Somatic *NF1* alterations were associated with worse prognosis compared to tumors with normal *NF1* after estrogen receptor positive breast cancer (HR 1.53, 95% CI 1.16-2.02) while the *NF1* alteration status had no effect on survival after the diagnosis of an estrogen receptor negative breast cancer (HR 1.10, 95% CI 0.80-1.52). In contrast, pathogenic germline variants of the *NF1* gene were not associated with decreased survival in patients with or without endocrine therapy (HR 0.76, 95% CI 0.28-2.04; and HR 1.04, 95% CI 0.40-2.70, respectively).

Conclusions: Only somatic alterations of the *NF1* gene modify endocrine therapy outcomes in breast cancer. This suggests that estrogen receptor-positive breast cancer employs a different pathway for estrogen receptor signaling in women with pathogenic germline *NF1* variants than in the setting of somatic *NF1* inactivation.

Background: CF33-hNIS-anti-PD-L1 (CHECKvacc) is a novel chimeric orthopoxvirus with robust anti-cancer activity in TNBC xenografts. CHECKvacc increased CD8+ T cell infiltration and favorably modulated the tumor microenvironment (TME) in xenograft models. Here we report data from the ongoing first-in-human clinical trial of CHECKvacc intratumoral (IT) injections in patients with mTNBC.

Methods: This is a phase I, single center, single arm trial of CHECKvacc IT. Eligibility criteria include patients with mTNBC that progressed on $\geq$ 2 chemotherapy regimens and have at least 1 tumor amenable to IT injections. Patients receive CHECKvacc IT at 1 of 8 assigned escalating dose levels on Days 1 and 15 of each 28-day cycle for 3 cycles. Primary objective is to evaluate safety and tolerability. Secondary objectives are to determine recommended phase II dose and efficacy. Exploratory objectives include assessment of TME immune modulation. Formalin fixed tissue biopsies were assessed by multiplex immunofluorescence for CD3, CD8, PD-L1, and pan-cytokeratin and digitally quantified for densities of immune phenotypes. PD-L1 expression was also assessed by a pathologist for a combined positive score (CPS).

Results: From October 2021 to December 2022, 8 patients were enrolled in this ongoing study and received $\geq$1 dose of CHECKvacc at 1 of the first 3 dose levels (1x105, 3x105, 1x106 PFU). There were no dose limiting toxicities. Six patients had evaluable baseline and post-treatment tissues for immune quantification. From baseline to cycle 1 day 2, CD8+ T cells in the TME increased in 5 of 6 patients (median increase: 34%; range: 9-251%). CD4+ T cells increased in 4 of 6 patients (median increase: 39%; range: 23-73%). PD-L1 expression by CPS increased in 5 of 6 patients (range of increase: 4-50%; p=0.063 by Wilcoxon signed-rank test).

Conclusions: CHECKvacc induces tumor infiltration of CD4+ and CD8+ T cells. Upregulation of PD-L1 within the TME further suggests immune activation by CHECKvacc. The clinical trial is ongoing to further assess dose escalation, tumor response, and the potential for future combination trials with systemic therapies, such as checkpoint blockade and chemotherapy.

Clinical trial identification: NCT05081492.

488P Comprehensive genomic profiling to identify actionable alterations for breast cancer brain metastases in the Chinese population

Q. Lu[1], F. Xu[2], N. Wang[2], P. Sun[3], K. Jiang[2], P. Zhang[2], S. Wang[2]

[1]Radiology, Sun Yat-sen University Cancer Center, Guangzhou, China; [2]Medical Oncology, Sun Yat-sen University Cancer Center, Guangzhou, China; [3]Pathology, Sun Yat-sen University Cancer Center, Guangzhou, China

Background: Breast cancer brain metastasis (BCBM) is an significant issue in the treatment of breast cancer and always leads to poor prognosis. Novel therapeutic targets are needed in clinical practice. In this study, we aimed to identify potential actionable targets in brain metastases utilizing the FoundationOne® CDx (F1CDx).

Methods: Formalin-fixed paraffin-embedded (FFPE) specimens including 17 primary tumors, 49 BCBMs and 7 extra-cranial metastases from 54 patients who underwent surgery for BCBM were tested by F1CDx. Tumor infiltrated lymphocytes (TILs) of BCBM were also tested by hematoxylin-eosin staining.

Results: The median tumor mutation burden (TMB) and TILs were 5.0 (range: 0- 29) Muts/Mb and 1.0 (range: 0- 5) respectively in BCBMs. High TMB (>10 Muts/MB) were detected in 3 BCBMs. Genomic alterations(GAs) were detected in all samples. The top-ranked mutated genes in BCBMs were TP53(81.6%), PIK3CA(34.7%), MLL2(22.4%), BRCA2(14.3%) and ATM(14.3%); and the most prevalent copy number alterations (CNAs) were ERBB2(57.1%), CDK12(36.7%), CCND1(28.6%),FGF19 (26.5%), and MYC (22.4%). ATM mutation was detected in 7 BCBMs while none in primary tumors, although without statistically significant difference. The most prevalent GAs were relatively consistent between paired primary and BCBMs. Actionable GAs were detected in 93.9% of all BCBMs and consistent rate were 54.5% (6/11) between paired primary and BCBMs. Compared to matched primary tumors, reduced actionable GAs were found in 4 BCBMs and additional actionable GAs were discovered in only one BCBM.

Conclusions: TMB and TILs was relatively low in BCBMs. Comparable consistency of actionable GAs was identified between primary and BCBMs. It was reasonable to treat BCBM according to genomic profiling of primary tumors if BCBM specimens were unavailable since possibility to find additional therapeutic targets was relatively low.

489P Liquid biopsy with combination of cell & cell-free analysis identifies HER2-expression in patients with metastatic breast cancer

F. Yan[1], G. Di Caro[2], E. Lam[3], K. Horne[2], R.J. Wenstrup[2], Q. Zhao[4]

[1]Oncology, Swedish Cancer Institute - Medical Oncology - First Hill, Seattle, WA, USA; [2]Translational Research, Epic Sciences Inc., San Diego, CA, USA; [3]Bioinformatics, Epic Sciences Inc., San Diego, CA, USA; [4]Medical Oncology, Banner MD Anderson Cancer Center, Gilbert, AZ, USA

Background: Circulating Tumor Cells (CTCs) are non-invasive diagnostic approaches that can inform treatment decisions for patients with metastatic breast cancer (MBC) when a conventional tissue biopsy is not feasible. Recently, the novel anti-HER2 antibody-drug conjugate, T-DXd, has shown effectiveness against MBCs with low HER2 expression detected by tissue biopsy. In this report, we present data from a comprehensive liquid biopsy platform that includes immunofluorescent HER2 protein expression in CTCs (ctcIF), determination of *ERBB2* amplification by single-cell CTC genomics (ctcDNA), and ctDNA alterations in plasma.

Methods: Blood samples were collected from 531 patients with MBC and patient's HER2 status was determined by the ordering healthcare provider based on previous tissue biopsy results, which were documented on the DefineMBC test requisition form. After isolation, nucleated cells were plated, and slides and plasma were stored in a biobank. CTCs were identified using Epic Sciences digital imaging and machine learning algorithms, and ctcIF allowed for HER2 low determination. ctcDNA was analyzed by low-pass whole-genome sequencing in individual CTCs, and ctDNA alterations were analyzed using a validated NGS panel.

Results: Among the 531 patients, 51% (n=276) were reported HER2 negative but did not have documented HER2 IHC expression, and 15% (n=80) were reported as 0 by IHC from the most recent tissue biopsy. Therefore, 67% (n=356) may not be eligible for T-DXd treatment. Among the 356 patients with unknown IHC status or IHC 0, 93% (331/356) had DefineMBC test results reported to clinicians. DefineMBC identified HER2 expression by ctcIF with no ERBB2 amplification by ctcDNA or ctDNA, which is consistent with HER2-low in 29% (74/258) of patients with unknown IHC status, and 27% (20/73) in patients with HER2 0 by IHC and may indicate for T-DXd treatment.

Conclusions: A liquid biopsy platform combining ctcIF, ctcDNA, and ctDNA with high sensitivity and specificity can determine clinically actionable HER2 expression in MBC that can impact therapeutic decision-making for patients with MBC who do not have documented HER2 IHC expression or HER2 0 by IHC from a previous tissue biopsy.

490P Metastatic breast cancer is associated with increased levels of soluble forms of TIM-3 and LAG-3 and decreased levels of soluble forms of GITR, GITR-L, CD27, CD28, CD40, CD86, ICOS, PD-L1, CTLA-4 and BTLA

[1]Research, The Medical Oncology Centre of Rosebank, Johannesburg, South Africa; [2]Department of Health, University of Pretoria, Pretoria, South Africa; [3]Department Oncology, The Medical Oncology Centre of Rosebank, Johannesburg, South Africa; [4]Surgery, Breast Care Centre of Excellence, Johannesburg, South Africa

Background: Breast cancer (BC) cells exploit the up-regulation or down-regulation of immune checkpoint molecules (ICM) to evade anti-tumor immune responses.ICMs can be measured in human plasma; however, their biological and clinical significance remains essentially unknown. The present analysis aimed to measure plasma ICMs in metastatic BC patients (pts) and compare them to healthy controls.

Methods: Soluble forms of ICM and RANTES, arginase, TGF-b1, CD163, and CD206 were measured using Multiplex® bead array and ELISA technologies. Plasma samples from 20 metastatic breast cancer (MBC) pts and 45 healthy controls were analyzed for each protein, and compared between MBC pts and healthy controls using a non-parametric test (Mann-Whitney).

Results: The median age of the cohort was 53 years (range 34-79 years). The performance status was as follows; PS=0 (11 pts), PS=1 (7 pts) and PS=2 (2 pts). The soluble co-stimulatory molecules, GITR ($p<0.0011$), GITRL ($p< 0.0000$), CD27 ($p< 0.0039$), CD28 ($p<0.0069$), CD40 ($p< 0.0022$), CD86 ($p< 0.0000$) and ICOS ($p< 0.0157$), as well as the co-inhibitory molecules, PD-L1 ($p< 0.0002$), CTLA-4 ($p< 0.0002$) and BTLA ($p<0.0145$) levels were significantly lower in MBC pts compared to healthy controls. Conversely, the co-inhibitory molecules, TIM-3 ($p< 0.0001$) and LAG-3 ($p<0.0000$ were significantly higher than those of healthy controls. Other biomarkers with raised plasma concentrations included TLR ($p<0.0039$). Plasma CD80 ($p<0.0992$), PD-1 ($p<0.2325$), HVEM ($p<0.062,6$), RANTES ($p<0.4861$) CD163 ($p<0,8565$) and CD206 ($p<0,2454$) levels were not significantly different between the MBC pts and the healthy controls.

Conclusions: We identified lower levels of CD27, CD28, CD40, ICOS, GITR, GITRL, CD86, PD-L1, CTLA-4, BTLA, arginase, and TGF-β1, and higher levels of TIM-3 and LAG-3 immune checkpoint molecules in MBC pts compared to healthy controls. These results indicate that a down-regulation of soluble ICM pathways and an up-regulation of some inhibitory ICM pathways are associated with MBC patients. To our knowledge, this is the first study to describe soluble immune checkpoint molecules in MBC pts.

491P Comparison of ctDNA profiles from HR+/HER2-low and HR+/HER2-0 advanced breast cancer patients

N. Dobrić[1], N. Dandachi[1], E.V. Klocker[1], C. Suppan[1], R. Graf[2], S. Hasenleithner[2], P.J. Jost[1], E. Heitzer[2], M. Balic[1]

[1]Division of Oncology, Department of Internal Medicine, Medical University of Graz, Graz, Austria; [2]Institute of Human Genetics, Medical University of Graz, Graz, Austria

Background: Despite the substantial progress in systemic treatment of hormone receptor-positive (HR+) breast cancer, a significant proportion of patients has dismal prognosis. A meaningful proportion of these patients has HER2-low disease. Circulating tumor DNA (ctDNA) profiles between HER2-low and HER2-0 have not yet been comprehensively investigated.

Methods: 67 plasma samples from 59 metastatic breast cancer patients (HR+/HER2-low, n=53; HR+/HER2-0, n=14) were collected either before starting 1st line or 2nd line treatment. Tumor fractions were assessed using an untargeted aneuploidy screening and expressed as z-scores (mFAST-SeqS). The mutational landscape of ctDNA was established using a 77-gene panel (AVENIO ctDNA Expanded). Tumor fractions, the number of somatic variants and variant allele frequencies (VAF) were compared between HER2-low and HER2-0 patients.

Results: HER2-low patients had significantly higher z-scores compared to HER2-0 patients (median 3.22 vs. 1.65, rank-sum p-value 0.025). In contrast, neither the highest nor the average VAF differed significantly between the two groups. HER2-low patients had a median of 3 detected variants (range 1-20), with a median of 2 clonal (range 0-9) and 1 subclonal (range 0-19) variants. HER2-0 patients presented with a median of 5 variants (range 1-12), including a median of 3 clonal (range 1-4) and 1 subclonal (range 0-8) variants. In contrast to previous reports, *PIK3CA* mutations were more prevalent in HER2-0 patients (57.1%) compared to HER2-low patients (35.8%), whereas *TP53* mutations were identified at the same extent with 28.6% in HER2-0 and 22.6% in HER2-low patients.

Conclusions: Our results suggest a significant difference in the tumor fractions in plasma between HER2-0 and HER2-low patients. Moreover, the mutational landscape of our cohort revealed differences from previous reports, indicating that further investigations are needed to elucidate and establish the distinct features of HER2-low breast tumors.

492P Wound stress stimulation promotes lung metastasis of breast cancer by regulating CXCL12/CXCR4 axis through MDSC exosome miR-126a-5p

X. Yin, X. Ma

Department of Targeting Therapy & Immunology, Cancer Center, West China Hospital of Sichuan University, Chengdu, China

Background: Surgery is one of the necessary treatment methods for breast cancer patients. However, wound caused by surgery is the main source of clinically related stress stimulation, and can promote tumor metastasis. Currently, as an important component of the tumor microenvironment, myeloid-derived suppressor cells (MDSC) have become a hotspot in the study of tumor metastasis.

Methods: We comprehensively explored the influence of wound stress on tumor growth, EMT related metastasis, and the recruitment of MDSC in the tumor microenvironment in a subcutaneous 4T1 tumor model.

Results: We found that wound stress stimulation promoted breast cancer growth and lung metastasis in mice, and enhanced the recruitment of stressed MDSC in the tumor microenvironment. The expression of Vimentin increased, suggesting EMT transformation. In vitro, bone marrow MDSC cells from mice undertaking stress stimulation promoted the EMT transformation in 4T1. The exosomes were extracted and the expression of mmu-miR-126a-5p was low in stressed MDSC exosomes. Mmu-miR-126a-5p overexpression suppressed tumor growth, lung metastasis and EMT transformation. Through the database screening of the target gene of mmu-miR-126a-5p combined with the results of sequencing analysis, CXCL12 was predicted to be the target gene of mmu-miR-126a-5p, which was verified by double luciferase reporting assay. CXCL12 and CXCR4 were highly expressed in the wound stress stimulation model, indicating mmu-miR-126a-5p induces breast cancer EMT transformation by targeting CXCL12/CXCR4 axis.

Conclusions: Here, we found that surgical stress stimulation can elicit the recruitment of stressed MDSC in the tumor microenvironment. Reduced exosome miR-126a-5p released by stressed MDSC leads to EMT transformation of tumor cells by attenuating the inhibition of CXCL12/CXCR4 axis in 4T1 cells and ultimately promotes increased lung metastasis. From the perspective of tumor microenvironment, these findings explain the phenomenon of increased lung metastasis caused by surgical stress stimulation and optimize new targets for MDSC, thus providing new ideas for breast cancer treatment.

493P Identifying genomic changes in breast tumours that metastasise to the brain

I.C. Olivares[1], N. Ajaykumar[1], L.D. Birch[1], H. Allamsetty[1], K. Elango[1], D. Huen[1], T.P. Dawson[2], K. Ashton[2], C. Davis[2], M.D. Jenkinson[3], W. Wang[1], T.J. Warr[1], M.R. Morris[1]

[1]Research Institute in Healthcare Science, Faculty of Science and Engineering, University of Wolverhampton, Wolverhampton, UK; [2]Neurosciences, Lancashire Teaching Hospitals NHS Foundation Trust, Royal Preston Hospital, Preston, UK; [3]Neurosurgery, The Walton Centre, Liverpool, UK

Background: The development of metastatic tumours after what appears to be a successful treatment of breast cancer remains a major problem. Many of these late-developing, secondary metastatic tumours occur specifically in the brain and metastatic brain tumours have very poor prognoses. Identifying genomic alterations in breast-to-brain metastatic tumours may provide new opportunities for treatment and prognosis.

Methods: Whole Exome Sequencing of 26 breasts to brain metastases was carried out on a high output V2 150 cycle flowcell (Illumina) as a 75 paired. Bioinformatic analysis was performed to identify recurrent mutations. Confirmation of mutated variants by Sanger sequencing. Functional analysis was conducted on a CRISPR_Cas9 knockout candidate gene in the MCF7 breast cancer cell line.

Results: Following analysis of Whole Exome Sequencing data, we identified $>$ 13000 nonsynonymous variants. To eliminate potential germline polymorphisms, variants with a MAF $\leq$1% were maintained. All variants were screened for their consequence on the protein product (via SIFT and Polyphen2), and the variants with scores related to pathogenicity were retained. This screening generated a list of 286 variants found across the 26 tumours analyzed. Protein domain analysis showed that most mutated variants are found within conserved protein domains. This sequencing identified frequent mutations in a gene encoding a member of the ARFGEF family of proteins. Furthermore, Following CRISPR_Cas9 knockout of this ARFGEF protein, the expression of neurotransmitter subunits was observed. This suggests that this protein may be implicated in the regulation of neuronal signalling, presenting a rationale for brain colonization by breast to brain metastatic tumour cells.

Conclusions: We expect that the identification of these commonly mutated genes may lead to the development of prognostic biomarkers that could be used to predict the risk of brain metastases from breast tumours and provide essential molecular information relating to the existing metastatic tumour. Additionally, these genes can contribute to the development of novel therapeutic approaches.

494P Proviral insertion in murine 1 (PIM1) kinase expression and clinical outcomes in advanced breast cancer (ABC)

S. Graff[1], A. Elliott[2], R. Mahtani[3], S. Sammons[4], A. Tan[5], C. Nabhan[6], S.L. Holder[7]

[1]Legorreta Cancer Center and Warren Alpert Medical School at Brown University, Lifespan Cancer Institute/Rhode Island Hospital, Providence, RI, USA; [2]Clinical and Translational Research, Caris Life Sciences - Headquarters, Irving, TX, USA; [3]Medical Oncology Department, Miami Cancer Institute - Baptist Health South Florida, Miami, FL, USA; [4]Breast Medical Oncology, Dana Farber Cancer Institute, Boston, MA, USA; [5]Medical Oncology, Levine Cancer Institute, Charlotte, NC, USA; [6]Precision Oncology Alliance, Caris Life Sciences - Headquarters, Irving, USA; [7]Warren Alpert Medical School of Brown University, Providence, RI, USA

Background: Prior and current data has shown PIM1 Kinase Expression (PIM1) in renal cell carcinoma (RCC) is associated with a poor prognosis.[1] CDK4/6 inhibitor (CDK4/6i) abemaciclib (A), but not palbociclib (P) may specifically target PIM1.[2] Given the differential efficacy of CDK4/6i in ABC without a biomarker beyond hormone receptor (HR+), we explored the relationship between PIM1 and patient outcomes. 1 An Analysis of PIM1 Kinase Expression and Clinical Outcomes in Renal Cell Carcinoma (RCC) Holder SL, et al. ESMO Congress 2023 Submission #2301 2 Small J, et al. Addition of abemaciclib to sunitinib induces regression of renal cell carcinoma xenograft tumors. Oncotarget. 2017 Jul 27;8(56):95116-95134.

Methods: Whole transcriptome sequencing (WTS) data in Caris Life Sciences real-world database breast cancer (BC) patient tumors were stratified by PIM1 expression quartiles and BC subtypes (HR+ and triple negative (TN]). Overall survival (OS; defined as time from diagnosis to last contact or death) and time on treatment (TOT) were obtained from insurance claims data.

Results: In 8,104 BC tumors, high PIM1 (Q4) had worse OS (27.3 mos) compared to low PIM1 (Q1, 41.9 mos). Median PIM1 transcripts were higher in TNBC vs HR+ (7.93 vs 4.46). In HR+ ABC, PIM1 Q4 was associated with different co-mutation frequencies (Table) and worse OS (Q1 57.7 vs Q4 45.3 mos, HR 1.28 95%CI=1.03-1.58 p=0.023). In TN ABC, PIM1 quartiles had similar co-mutation profiles, and no OS difference was noted (Q1 23.8 vs Q4 26.1 mos, HR=1.06 95%CI: 0.83-1.35 p=0.67). In HR+, PIM1 Q4 had significantly shorter TOT for A only (5.6 vs 2.6 mos, HR=1.68 95%CI: 0.99-2.82 p=0.049), no difference with P or R.

Table: 494P Co-mutation frequencies in hormone receptor-positive advanced breast cancer by PIM1 expression

HR+ BC WTS	PIM1-low (Q1), %	PIM1-high (Q4), %	p-value	q-value
TP53	31.7	47.0	0.0011	0.0017
PIK3CA	46.1	41.4	0.2952	0.3384
CDH1	18.5	11.4	0.0301	0.0402
CHEK2	0.4	4.3	0.0073	0.0105
ARID1A	15.7	4.2	0.0025	0.0037

495P Prognostic value of PIK3CA mutational status in tissue & plasma in HR+/HER2- breast cancer (BC)

R. Lozano Mejorada[1], E. Terán Brage[1], J.A. Muñoz León[1], Á. López Gutiérrez[1], L. Figuero Pérez[1], A. Rodrígues Francoso[1], R. Seijas Tamayo[1], D. Morchón Araujo[1], M.D.C. Garijo Martínez[1], J. Roldán-Ruiz[1], M.M. Abad Hernández[2], M. Sancho de Salas[2], E. Fonseca Sánchez[1], C.A. Rodríguez Sánchez[1]

[1]Medical Oncology Department, University Hospital of Salamanca, Salamanca, Spain; [2]Pathology Department, University Hospital of Salamanca, Salamanca, Spain

Background: *PIK3CA* mutations are described in about 30-40% of BC. They confer resistance to endocrine therapy and overall worse prognosis. Concordance between testing methods (tissue & plasma) are not widely studied. We aim to correlate tissue & plasma assays and to analyze the prognostic value of *PIK3CA* mutations in HR+/HER2- BC.

Methods: Retrospective and unicentric analysis of *PIK3CA* mutational status in tissue & plasma samples in patients (p) with HR+/HER2- BC from Feb/21 to Mar/23. *PIK3CA* test: Cobas®PIK3CA Mutation Kit. We correlated both diagnostic methods and analysed progression-free survival (PFS) in *PIK3CA* mutated (*PIK3CAm*) vs wild-type (wt).

Results: We analyzed 225 samples in 161p with HR+/HER2- BC (149 in tissue & 76 in plasma). *PIK3CA* mutations were detected in 62p (38.5%), of which 39.6% (59p) in tissue and 11.8% (9p) in plasma. *Hotspot* mutations: H1047X (45.7%), E545X (20%) and E542K (12.8%). Tissue & plasma correlation was conducted in 64p (M1 stage), with overall correlation rate of 70.3%. 19 cases (29.7%) were positive in tissue but not in plasma. 80p received treatment with CDK4/6 inhibitors + endocrine therapy. PFS was shorter in *PIK3CAm* vs wt (24m vs 30m; HR=1.39 [95%CI,0.7-2.4], p=0.25). A sub-analysis was performed based on exons 9 & 20, showing a significantly lower PFS in *PIK3CAm* exon 9 vs 20 population (9.7m vs 30.3m; HR=2.84 [95%CI,1.1-7.4], p=0.02). Although we observed a poorer PFS in p with visceral involvement in *PIK3CAm* (21.9m vs 30.1m; HR=2.82 [95%CI,0.6-12.3], p=0.14), in a multivariate analysis, mutations in exon 9 were an independent poor prognostic factor regardless visceral involvement; p=0.027.

Table: 495P

		Tissue		
		Mutated	Wild-type	**Total**
Plasma	**Mutated**	**9 (32.1%)**	0 (0%)	9 (14.1%)
	Wild-type	19 (67.8%)	**36 (100%)**	55 (85.9%)
	Total	28 (100%)	36 (100%)	64 (100%)
		Positive agreement: 9/28 (32.1%)		
		Negative agreement: 36/36 (100%)		
		Overall agreement: 45/64 (70.3%)		

Conclusions: Our results support the determination of *PIK3CA* in tissue as the diagnostic method of choice, although further studies are needed to assess the role of liquid biopsy in the detection of *PIK3CAm*. In our population, the presence of *PIK3CAm* confers worse prognosis in luminal BC, being significantly worse in mutation carriers in exon 9 regardless visceral involvement.

496P Comprehensive genomic profiling of advanced HR+/HER2- breast cancer patients using liquid biopsy

B. Shao[1], H. Tang[2], X-R. Liu[1], G. Song[1], L. Di[1], F. Xie[2], C. Jia[1], Y. Zhang[2], S. Jia[2], H. Li[1]

[1]Department of Breast Oncology, Beijing Cancer Hospital, Beijing, China; [2]Translational Medicine, Huidu (Shanghai) Medical Technology Co., Ltd., Shanghai, China

Background: Breast cancer is the most common cancer among women, and HR+/HER2- is the most frequent subtype. This type of cancer is characterized by a complex genomic landscape. However, obtaining tissue biopsies from patients with recurrent metastasis can be challenging. Moreover, previous liquid biopsy studies had limited success in detecting gene copy number loss. In this study, we present a comprehensive genomic profiling analysis of advanced HR+/HER2- breast cancer patients using liquid biopsy.

Methods: 76 patients with advanced HR+/HER2- breast cancer were retrospectively recruited, and blood samples were collected prior to receiving chemotherapy or CDK4/6 inhibitor treatment. The study applied PredicineCARE, a targeted NGS liquid biopsy assay, to detect somatic alterations in ctDNA of blood.

Results: In total, 370 somatic mutations and 85 copy number variants were identified in 76 patients. The most commonly altered genes included TP53 (38%), PIK3CA (37%), ATM (24%), ESR1 (22%), FAT1 (22%), RAD50 (22%), and BRCA2 (17%). Among all patients, 27 were Ki67 negative, 43 were Ki67 positive, and the Ki67 status of 6 patients was unknown. The prevalence of NBN gene variations was significantly higher in the Ki67 positive group than in the Ki67 negative group (Ki67+: 8/43 vs. Ki67-: 0/27, $p<0.05$). Seventeen patients had metastasis at the time of initial diagnosis, among which the prevalence of FAT1 variations was significantly higher than that of non-metastasis patients (metastasis+ 10/17 vs. metastasis- 7/59, $p<0.05$). Of all 76 patients, 39 were treated with CDK4/6 inhibitors, and 37 were treated with chemotherapies. Patients treated with CDK4/6 inhibitors had a prolonged overall survival time compared to those treated with chemotherapies. The median overall survival time of the two groups was 38.7 months (chemotherapy) vs. not reached after 34.2 months (CDK4/6 inhibitors), $p<0.001$.

Conclusions: This study presents a comprehensive analysis of the mutational landscape of advanced HR+/HER2- breast cancer patients using liquid biopsy. Additionally, it compares the molecular profiles of patients with different clinical features receiving diverse treatments, thus identifying potential biomarkers for prognosis and targeted therapies.

497P Metastatic potential of the somatic alteration associated with TCA-cycle in breast cancer

N.S. Harada, H. Tada, M. Miyashita, Y. Hamanaka, A. Ebata, M. Sato, T. Ishida

Department of Breast and Endocrine Surgical Oncology, Graduate School of Medicine, Tohoku University, Sendai, Japan

Background: Cancer metastasis is considered to occur through a complicated process in which cancer cells from the primary tumor migrate via the vascular and lymphatic systems. The mechanism of metastasis has previously been focused on the expression of molecules; however, their ability to form metastasis, and metastatic potential to target organs remains unknown. Because glucose metabolism is essentially active in brain tissue, FDG is substantially accumulated even in normal tissue. As a consequence, it is absolutely necessary for cancer cells to have the ability to survive in the brain microenvironment, in which glucose is unavailable. In this study, we investigated whether metabolic reprogramming of the TCA cycle, which enables energy production from sources other than glucose, plays a pivotal role in forming brain metastases (BM).

Methods: The genomic information was obtained from the Center for Cancer Genomics and Advanced Therapeutics (C-CAT) Research-Use Portal. 2,629 cases of MBC who received cancer gene panel testing (Foundation One CDx (R)) between June 2019 and October 2022 were subjected to this analysis. The relationship between the somatic alteration associated with the TCA-cycle (TCA-alteration) and overall survival (OS) or BM incidence was examined.

Results: 221 patients (8.4%) had TCA-alteration. The median of OS was 6,217 days in TCA-alteration and 5,050 days in others (log-rank p=0.8377, n.s). TCA-alteration was discovered in 27 of 243 BM patients (11.1%) and 194 of 2,386 non-BM cases (8.1%) (p=0.11, n.s).

Conclusions: Despite the fact that metabolic reprogramming is necessary for metastatic potential, there was no significant difference in survival or the incidence of BM and TCA-alterations. In addition to genetic profiling, a metabolic approach will be necessary to understand the metabolic tumor microenvironment.

Background: Grade 2 gliomas are slowly progressive brain tumours with poor long-term prognosis. Current treatments are not curative and can be associated with toxicities. Mutations in isocitrate dehydrogenase (IDH) 1 or 2 occur in nearly all grade 2 gliomas and are a disease-defining characteristic in the World Health Organization 2021 definition. Vorasidenib (VOR) is an oral, brain-penetrant, dual inhibitor of mutant (m)IDH1/2 enzymes.

Methods: In this double-blind phase 3 study, patients (pts) were randomized 1:1 to receive VOR 40 mg daily or placebo (PBO) daily in 28-day cycles, stratified by 1p19q status and baseline tumour size. Key eligibility criteria: age ≥12 y; Karnofsky performance scale (KPS) >80; residual or recurrent grade 2 mIDH1/2 oligodendroglioma or astrocytoma; measurable non-enhancing disease; no prior treatment for glioma with most recent surgery 1–5 years from randomization; and not in immediate need of chemotherapy/radiation. Primary endpoint: radiographic progression-free survival (PFS) by blinded independent review committee (BIRC). Key secondary endpoint: time to next intervention (TTNI).

Results: As of 6 Sep 2022 (2nd planned interim analysis data cut-off date), 168 pts were randomized to VOR and 163 to PBO (median age, 40.4 y; KPS=100, 53.5%; oligodendroglioma, 172; astrocytoma, 159; median time from last surgery to randomization, 2.4 y). Median follow-up was 14.2 mo. PFS by BIRC was significantly improved with VOR vs PBO (hazard ratio [HR] 0.39, 95% CI 0.27–0.56; 1-sided P=0.000000067). Median PFS: VOR, 27.7 mo; PBO, 11.1 mo. TTNI was significantly improved with VOR vs PBO (HR 0.26, 95% CI 0.15–0.43; 1-sided P=0.000000019). Median TTNI: VOR, not reached; PBO, 17.8 mo. In pts with IDH1-R132H variant (n=284, 85.8%) the HR for PFS by BIRC was 0.33 (95% CI 0.22–0.50). Adverse event of grade ≥3 elevated alanine aminotransferase was seen in 9.6% of pts with VOR (and 0% with PBO).

Conclusions: In the first randomized phase 3 study of a targeted therapy in grade 2 mIDH1/2 glioma, VOR significantly improved PFS by BIRC compared with PBO, with a manageable safety profile. Findings show the clinical benefit of VOR in pts for whom chemotherapy and radiotherapy are being delayed. (NCT04164901 funded by Servier Pharmaceuticals LLC).

499O A phase II study to explore the efficacy and safety of FCN-159 in recurrent or progressive pediatric low-grade glioma (pLGG) with MAPK pathway-activated

W. Li[1], Y. Mao[2], Z. Kang[1], W. Hua[2], S. Li[1], Z. Wu[3], H. Liu[4], J. Hu[4], J. Guo[5], W. Zhong[6], X. Wang[7]

[1]Neuro-Oncology,Cancer Center, Beijing Tiantan Hospital, Capital Medical University, Beijing, China; [2]Neurosurgery, Huashan Hospital, Shanghai Medical College, Fudan University, Shanghai, China; [3]Clinical Oncology, Beijing Fosun Pharmaceutical Research and Development Co., Ltd., Beijing, China; [4]Clinical Oncology, Beijing Fosun Pharmaceutical Research and Development Co., Ltd., Shanghai, China; [5]Translational Medicine, Beijing Fosun Pharmaceutical Research and Development Co., Ltd., Shanghai, China; [6]Biometrics and Data Sciences, Beijing Fosun Pharmaceutical Research and Development Co., Ltd., Shanghai, China; [7]Global R&D Center, Shanghai Fosun Pharmaceutical Development Co.,Ltd, Shanghai, China

Background: The MAPK pathway over-activation is the primary driver in most of pLGG, mainly including $BRAF^{V600E}$, KIAA1549-BRAF fusion and $NF1^{mut}$ with limited therapeutic options available. FCN-159 is an oral inhibitor of MEK1/2 with highly potent selectivity, and is expected to be an efficacious targeted therapy of pLGG. A multi-center, single-arm phase II study was designed to evaluate safety and efficacy of FCN-159 in pediatric patients (pts) with recurrent or progressive LGG.

Methods: Pediatric pts with recurrent or progressive LGG were enrolled and received FCN-159 monotherapy continuously 5mg/m^2 once daily based on body surface area

(BSA). The primary endpoint was to assess preliminary efficacy of FCN-159 by RANO criteria.

Results: As the cut-off date of July 31th, 2023, 23 subjects have been enrolled. Median age is 8 years (range: 3-17) at study entry, 56.5% were female. All pts were identified as *BRAF* or *NF1* alterations (*BRAF*^{V600E} 12/23, 52.2%, *KIAA1549-BRAF* fusion 8/23, 34.8% and *NF1*^{mut} 3/23, 13.0%). At a median follow-up of 7.79 months, 22 pts were evaluated for efficacy: 6 partial response (PR, 27.3%, unconfirmed PR 3), 9 minor response (MR, 40.9%, unconfirmed MR 2), and 7 stable disease (SD, 31.8%). Among 23 pts, 22 pts (95.7%) experienced treatment-emergent adverse events (TEAEs), which were reported to be drug-related. Most common TEAEs (incidence $\geq$ 20%) included blood lactate dehydrogenase increased, α-hydroxybutyrate dehydrogenase increased, blood creatine phosphokinase increased, upper respiratory tract infection, paronychia and rash. Majority were grade 1 or 2, and 2 pts reported grade 3, no grade 4 or above reported. One pt experienced serious adverse event as liver function test abnormal. TEAEs leading to drug interruption were reported in 16 pts, and 10 pts were related to study drug. No TEAEs leading to drug dose reduction, discontinuation or death were reported.

Conclusions: The preliminary study results showed that treatment of FCN-159 was remarkably efficacious for pLGG pts. FCN-159 is well tolerated and easily manageable, without new safety signal observed. Long-term efficacy and safety follow-up are ongoing.

Clinical trial identification: ChiCTR2300069156.

Background: Trotabresib (TROTA) is a novel bromodomain and extraterminal protein inhibitor that has shown brain tumor tissue penetration, encouraging tolerability and preliminary efficacy in combination with standard of care (SOC) concomitant TMZ + RT and adjuvant TMZ in pts with ndGBM. We present long-term follow-up for part A (dose escalation) and an update on part B (expansion) of the ph 1b/2 CC-90010-GBM-002 study (NCT04324840).

Methods: Study design has been previously described (Vieito et al. SNO 2022 . Abstr CTNI-21). Part B enrolled pts with IDH wild-type ndGBM; pts were randomized 2:1 to TROTA + SOC then maintenance TROTA (arm A) vs SOC alone (arm B).

Results: As of 20 Jan 2023, part A has closed with 32 pts enrolled (concomitant, n = 14; adjuvant, n = 18); part B has enrolled 136 pts (arm A, n = 91; arm B, n = 45). In part A, no new safety events were observed with longer follow-up; median follow-up was 21.6 mo (range 3.4—27.6). The most frequent grade (G) 3/4 treatment-related adverse event (TRAE) was thrombocytopenia (8/14 pts [57%] in the concomitant group and 9/18 pts [50%] in the adjuvant group). Efficacy in part A is shown in the table. At last follow-up, 8 pts (4 per group) remained on treatment, including 1 pt with ongoing complete response at cycle 24. In part B, the most common all-cause G 3/4 AE was thrombocytopenia occurring in 21/88 (24%) and 5/43 (12%) patients in arms A and B, respectively. TRAEs related to TROTA led to treatment discontinuation in 3 pts (arm A), and TRAEs related to TMZ led to discontinuation in 4 pts (2 in each arm); no treatment-related deaths reported. Enrollment of part B was recently completed; efficacy data are not yet mature.

Conclusions: Addition of TROTA to SOC followed by maintenance TROTA in pts with ndGBM was well tolerated with no new safety signals in parts A and B, and promising efficacy in part A. Follow-up is ongoing.

Table: 500O

Outcome	Concomitant TROTA: 15 or 30 mg/day* (n = 14)	Adjuvant TROTA: 15, 30 or 45 mg/day* (n = 18)
Median duration of treatment, weeks (range)	43 (10—102)	37 (6—121)
Median PFS, months (95% CI) Range	14.0 (5.8—NE) 2.1—22.3	10.3 (5.0—24.8) 0.03—26.5
Median OS, months (95% CI) Range	21.3 (11.1—NE) 3.4—22.7	21.6 (10.7—NE) 5.9—27.6
12-month OS rate, % (95% CI)	77 (44—92)	72 (46—87)

*Administered on days 1—4 of each 28-day cycle. 30 mg/day is the recommended phase 2 dose. NE, not estimable; OS, overall survival; PFS, progression-free survival.

Clinical trial identification: NCT04324840.

501O Glasdegib in combination with temozolomide and radiotherapy in patients with newly diagnosed glioblastoma: Phase Ib/II GEINO 1602 trial

M.Á. Vaz[1], S. del Barco[2], J.M. Sepúlveda[3], M. Alonso[4], E. Pineda[5], C. Balana[6], M. Martínez-García[7], R. Gironés[8]

[1]Medical Oncology Department, Hospital Universitario Ramón y Cajal, Madrid, Spain; [2]Medical Oncology Service, Institut Català d'Oncologia Girona, Girona, Spain; [3]Medical Oncology Service, Hospital Universitario 12 de Octubre, Madrid, Spain; [4]Medical Oncology Service, Hospital Virgen del Rocío, Seville, Spain; [5]Medical Oncology Service, Hospital Clínic de Barcelona, Barcelona, Spain; [6]Medical Oncology Service, Institut Català d'Oncologia, Badalona, Barcelona, Spain; [7]Medical Oncology Service, Hospital del Mar, Barcelona, Spain; [8]Medical Oncology Service, Hospital Universitario y Politécnico la Fe de Valencia, Valencia, Spain

Background: Glioblastoma (GB) resistance against anticancer therapies is enhanced by Smoothened (SMO) signaling. Glasdegib (GLG), a SMO inhibitor, may lead to improved efficacy of the Stupp scheme.

Methods: Newly diagnosed GB patients (pts) received GLG with standard radiotherapy (RT)/ temozolomide (TMZ) followed by maintenance with GLG monotherapy. The study was carried out in two phases. In phase Ib the primary objective was the recommended phase 2 dose (RP2D) in a 3+3 dose escalation strategy. The dose of 75 mg/QD of GLG was declared the RP2D. The primary objective in phase II was 15-m overall survival (OS) rate. The study established a futility threshold of 60% for 15-m OS to consider the trial positive; accrual required: 70 evaluable pts in phase II. Secondary objectives included progression-free survival (PFS) according to RANO criteria, safety, changes in performance status, pharmacokinetic and exploratory biomarker analysis.

Results: Between 2018 and 2020, 79 GB pts were enrolled, and 74 (98.7%) pts received GLG at 75mg/QD. The median age was 55 years (range: 28-78), 54% were male, 58.1% were ECOG 1, 39.2% were MGMT methylated, and 1 pts had an IDH1/2 mutation. Complete surgical resection was achieved in 35 (47.3%) pts. GLG treatment lasted a median of 6.9 m (range 0.7-24). 68 (91.9%) finalized concomitant period with RT/TMZ, 64 (86.5%) started adjuvant therapy with TMZ, 33 (51.6%) finalized adjuvant period, and 28 (37.8%) continued GLG monotherapy. 53 pts (71.6%) presented stable disease. After a median follow up of 14.8 m (range 0.7-36.4), mPFS was 7 m (95% CI: 6.1-8.6), and the 12-m PFS rate was 22.2% (95% CI: 14.4-34.2). The mPFS based on MGMT status was 8.4 m (95% CI: 6.5-16.9) and 7.3 m (95% CI: 4.9-9.1) for MGMT methylated and unmethylated respectively ($p = 0.044$). The mOS was 15.3 m (95% CI: 14-21.2). At data cut-off, 22 (29.7%) pts alive. The mOS was 25.6 m (95% CI: 16-NR) and 14.3 m (95% CI: 11.7-19) for MGMT methylated and unmethylated respectively ($p = 0.005$).

Conclusions: The addition of GLG to standard RT and TMZ showed preliminary efficacy for newly diagnosed GBM, with almost 30% pts still alive at data cutoff. Long-term survival will be updated. No new safety alerts were reported.

Clinical trial identification: NCT03466450, EudraCT 2017-002410-31.

502MO Target therapy matched to genomic alterations in patients with recurrent IDH wildtype glioblastoma: A real-life cohort analysis from Veneto Institute of Oncology, Padua (Italy)

G. Cerretti[1], M. Padovan[1], C. De Toni[1], M. Maccari[1], A. Bosio[1], M. Caccese[1], M. Corrà[1], I. Cestonaro[1], A. Pittaro[2], A. Guerriero[3], M. Coppola[4], G. Lombardi[1]

[1]Department of Oncology, Oncology 1, IOV - Istituto Oncologico Veneto IRCCS, Padua, Italy; [2]Radiology Unit, IOV - Istituto Oncologico Veneto IRCCS, Padua, Italy; [3]Department of Medicine (DIMED), Surgical Pathology Unit, Azienda Universitaria Ospedaliera di Padova, Padua, Italy; [4]Pharmacy Unit, IOV - Istituto Oncologico Veneto IRCCS, Padua, Italy

Background: Next-generation sequencing (NGS) allows to identify patients (pts) that may respond to target therapies (TT). Only a few data are available regarding TT for recurrent glioblastoma (rGBM).

Methods: We retrospectively analyzed a cohort of pts with rGBM treated with TT based on NGS profile obtained on formalin-fixed paraffin-embedded tissue samples. We identified 7 druggable alterations, classified according to ESCAT: BRAFV600E (IB), NTRK fusions (IC), FGFR1-3 alterations (IIB), ROS1 fusions, MET amplification/fusions, PIK3CA mutations and PTEN loss/mutations (IIIA).

Results: Between 03/20 and 03/23, 37 pts received TT. All pts received radiotherapy and temozolomide as first-line. Median line of TT was 3 (range 2-7). TT was dabrafenib/trametinib (9 pts), larotrectinib (2 pts), erdafitinib (4 pts), entrectinib (1 pt), vebreltinib (2 pts), capmatinib (1 pt), alpelisib (6 pts), ipatasertib+/-atezolizumab (12 pts). At data cut-off (05/23), 24 patients had died. In the entire cohort, median overall survival and progression-free survival (PFS) after starting TT was 8.19 and 2.11 months (mo), respectively. The dabrafenib/trametinib (D/T) subgroup had the longest median PFS (5.23 mo), a disease control rate (DCR) of 77%, an objective response rate of 22%, and a median duration of response of 22.5 mo. 7/9 pt had died and 2 are continuing D/T. The pt with ROS1-GOCP fusion maintained a complete response for 12 mo with entrectinib. A multifocal rGBM patient with PTPRZ1-MET fusion, identified by Caris MI-Transcriptome, had impressive PR after 8 weeks of vebreltinib in third-line during participation in APL-101-01 study (NCT03175224): duration of response is pending as TT is ongoing. Among the others, no complete/partial responses were detected. DCR was 67% in MET-inhibitors, 50% in larotrectinib and erdafitinib, 8% in ipatasertib+/-atezolizumab subgroups. No toxicities were reported with D/T. Among all pts, no grade 4 adverse events were observed and in any case, TT was interrupted for toxicity.

Conclusions: Our results confirm the activity of D/T in BRAFV600E mutant rGBM. We had a dramatic response to a MET inhibitor. Deeper explorations are needed in targeting FGFR e ROS1.

Doce de Octubre, Madrid, Spain

Background: Based on our proposal for the first ESMO Scale for Clinical Actionability of molecular Targets (ESCAT) classification for brain tumors [Mirallas et al. ESMO 2022] and the descriptive analysis of real-world data in gliomas [Mirallas et al. ASCO 2023], we aim to define the clinical actionability of molecular alterations (MA) detected by next-generation sequencing (NGS) in a multicentric glioma cohort.

Methods: Patients (pts) with glioma who had NGS at seven Spanish institutions were included between Jan 2018 and Dec 2022. For predictive associations, pts were classified into Tier1/2, Tier3/4 or wild type (WT) group according to their ESCAT score. Groups were compared using Kruskal-Wallis or Chi-squared tests. To explore prognostic markers, pts with grade 4 glioblastoma (GBM) IDH WT tested within 1 year from diagnosis who had TERT or TP53 genomic results were analyzed. Overall survival (OS) was estimated using the Kaplan-Meier method and Cox hazard ratio were fitted.

Results: Of 580 pts included, 567 pts (98%) underwent NGS testing. A total of 395/567 (71%) had a diagnosis of GBM and 165 (29%) harbored a Tier 1/2 MA. Median age was 51y (IQR: 39-61), 381 (67%) had ECOG $\geq$1, 223 (40%) were women, and 148 (26%) were 40 or younger. Most common MAs in the entire cohort were PI3KCA (29%), CDKN2A/B loss (28%), EGFR gain (26%), IDH1 (22.4%), EGFRvIII and ATRX (both 17%). Tier 1/2 MAs were more prevalent in younger pts (56% vs 10% in $<$40y vs $>$40y), non-GBM (65% vs 9% in non-GBM vs GBM), and TP53 mut (52% vs 24% in mutant vs WT) [all $p<0.001$]. Meanwhile, Tier 3/4 MAs were more typical for grade 4 gliomas with EGFR MAs (57% vs 2% in WT), TERT mut (55% vs 33% in WT) and CDKN2A/B loss (43% vs 13% in WT) [all $p<0.001$]. Among pts with grade 4 GBM-IDH WT, 53% had TERT mut and 26% had TP53 mut. In this subset of pts, median OS in case of incomplete resection (R1) was 29.5 months [95%CI 20-40.3] for those with

TERT WT and 17 months [95% CI 14-22] in TERT mut pts (p=0.01), but no differences in OS were found in TP53 mut vs WT pts.

Conclusions: Most common actionable MA were IDH, PIK3CA, EGFR, ATRX, suggesting NGS value for identifying potential candidates for targeted treatment. TERT mut was prognostic of worse OS in pts with grade 4 GBM-IDH WT after incomplete tumor resection.

504MO Validation of a spectroscopic liquid biopsy for the earlier detection of brain cancer

J.M. Cameron[1], A. Sala[1], J.J.A. Conn[2], G. Antoniou[2], D.S. Palmer[2], M.J. Baker[3]

[1]Research Dept., Dxcover Limited, Glasgow, UK; [2]Data Science, Dxcover Limited, Glasgow, UK; [3]Medicine & Dentistry, University of Central Lancashire, Preston, UK

Background: Brain cancer has a very high fatality rate with only one third of patients surviving five years or more after a diagnosis. Early referral for brain imaging is crucial, but existing symptom-based referral guidelines inadequately stratify patients for brain imaging. Delayed detection leads to 62% of brain tumor patients receiving a diagnosis when they present to the emergency department (ED). A liquid biopsy could rapidly triage the symptomatic population in primary care. The most at-risk patients would be fast-tracked for urgent brain imaging, whereas those with a negative result can be monitored with routine follow-up.

Methods: We initially recruited 988 patients prospectively with non-specific symptoms associated with a brain tumor in NHS Lothian (Edinburgh, UK). Patient blood serum samples were analyzed using the Dxcover® Brain Cancer liquid biopsy. This technology utilizes infrared spectroscopy combined with a diagnostic algorithm to predict the presence of intracranial disease. Sensitivity analysis explored cost-effectiveness across possible combinations of sensitivity and specificity defined by the receiver operating characteristic (ROC) curve. Thereafter, an additional 500 patients were recruited for a verification study, in preparation for an EU-IVDR Performance Evaluation trial. In this clinical performance study, multiple sites across the UK and Europe will collect and analyze patient samples for clinical validation of the test.

Results: In our initial feasibility studies, the liquid biopsy reported an area under the ROC curve of 0.8. The algorithm detected 96% of the patients with brain tumors, and the diagnostic models can be tailored towards higher sensitivity (or specificity) depending on clinical priorities. We will also present the results of our verification study, the cost-effectiveness analysis and an interim analysis of the EU-IVDR trial at the meeting.

Conclusions: This simple, non-invasive blood test facilitates the triage and radiographic diagnosis of brain tumor patients, while providing reassurance to healthy patients. By decreasing the time to diagnosis, the morbidity from treatment can be reduced, which in turn would improve the quality of life of brain cancer patients.

505MO A phase 0/Ib study of AZD1390 plus radiotherapy in recurrent glioblastoma patients

N. Sanai, S. Desai, T. Margaryan, C. Lo Cascio, M. Elliott, J. Molloy, J. Harmon, A. Hong, E. Luna Melendez, J. Wanebo, K. Braun, W. Kennedy, M. Garcia, W. Yoo, A. Tovmasyan, A-C. Tien, S.N. Mehta

Ivy Brain Tumor Center, Barrow Neurological Institute, Phoenix, AZ, USA

Background: ATM inhibition has been hypothesized to potentiate the effects of radiation by preventing acute phase DNA damage repair, and a phase 1 trial of this combination in patients with GBM is ongoing (NCT03423628). To test this hypothesis, this phase 0/1b study aimed to evaluate the pharmacokinetics (PK) and pharmacodynamics (PD) of AZD1390, an ATM inhibitor with BBB penetration, in combination with ex vivo radiation in patients with GBM (NCT05182905).

Methods: Recurrent GBM patients received 3 days of AZD1390 prior to planned resection at 2-4, 4-6 or 23-25 hours following the final dose. Tumor tissue, cerebrospinal fluid (CSF), and plasma were collected. Total and unbound drug concentrations were measured using validated LC-MS/MS methods. A PK 'trigger' determined eligibility for the therapeutic expansion phase. ATM inhibition was assessed via *ex vivo* radiation and quantification of pRAD50 levels compared to non-radiated control. Patients exceeding the PK threshold were eligible for an expansion phase of study drug plus radiotherapy followed by maintenance regimen.

Results: In 12 patients treated to date, AZD1390 was consistently measured in the Gd-non-enhancing tumor region. All patients (n=12) exceeded the PK threshold to qualify for the expansion phase of the study. With 5Gy ex-vivo radiation of surgical specimen, pRAD50 expression was significantly suppressed in AZD1390 treated patients compared to untreated controls (median 2.1% vs 34.8%, average 94% reduction, $p<0.01$). Median 6-month progression-free survival has not been reached at a median clinical follow-up of 4.4 months.

Conclusions: AZD1390 is well-tolerated in recurrent GBM patients, achieving pharmacologically relevant concentrations in non-enhancing tumor tissue, and substantially suppressing induction of pRAD50 levels *ex vivo* post-radiation. This is the first pharmacodynamic evidence that AZD1390 may be a potent radio-potentiator in patients with GBM.

Clinical trial identification: NCT05182905.

506MO A phase I dose-expansion cohort of SYHA1813, a vascular endothelial growth factor receptor (VEGFR) 1-3 /colony-stimulating factor 1 receptor (CSF1R) inhibitor, in patients (pts) with recurrent meningioma

W. Li[1], Z. Kang[1], Z. Wu[2], S. Li[1], M. Huang[1], W. Pu[3], X. Yang[3], J. Lin[3], M. Liu[3]

[1]Department of Neuro-Oncology,Cancer Center, Beijing Tiantan Hospital, Capital Medical University, Beijing, China; [2]Department of Neurosurgery, Beijing Tiantan Hospital, Capital Medical University, Beijing, China; [3]Department of Clinical Development, CSPC Pharmaceutical Group Limited, Shijiazhuang, China

Background: SYHA1813 is a highly potent inhibitor, mainly against VEGFR1-3/CSF1R, and exerts synergistic anti-tumor effects by blocking tumor angiogenesis and modulating tumor microenvironment. Here, we report early findings from pts treated with SYHA1813 in the recurrent meningioma cohort.

Methods: Adult pts (Karnofsky performance status $\geq$ 60) with recurrent histologically confirmed meningioma not amenable to surgery or radiotherapy were enrolled and treated with 15mg or 20mg SYHA1813 once daily. The primary endpoints were objective response rate (ORR) and the 6-month progression-free survival rate (PFS-6) per Response Assessment in Neuro-Oncology Criteria for meningioma. The secondary endpoints included incidence, type, and severity of adverse events, graded by Common Terminology Criteria for Adverse Events (Version 5.0).

Results: As of Apr. 12, 2023, 11 eligible pts (5 males) with a median age of 50 (range 34-76) were enrolled, including 1 with World Health Organization (WHO) grade I tumor, 6 WHO grade II, and 4 WHO grade III. The median number of prior surgeries were 2 (range 1-4). With a median treatment duration of 1.45 months (range 0.23-6.24), ORR was 45.5% [95% confidence interval (CI) 16.8%—76.6%], with 1 partial response (PR), 2 minor response (MR), 1 unconfirmed PR and 1 unconfirmed MR. Tumor regression in target lesions was observed in 10 out of 11 pts, of which 6 reached $\geq$ 25% reductions in tumor size. PFS-6 was 75.8% (95% CI 30.5%-93.7%). All

pts experienced treatment-emergent adverse events (TEAEs), of which 6 (54.5%) were ≥ grade 3, and all of them were recovered within 7 days. Of these ≥ grade-3 TEAEs, hypertension occurred in ≥ 2 patients. One patient with a complex surgery history developed a serious TEAE, grade-4 intracranial hemorrhage, which was resolved quickly after interventions. No grade-5 TEAEs were reported.

Conclusions: SYHA1813 showed encouraging objective responses with a well-tolerated safety profile in pts with recurrent meningioma.

Background: In the randomized phase 2 REGOMA trial, regorafenib (REG) showed promising activity in recurrent glioblastoma (GBM) patients (PTS); subsequently, in Italy the National Health System has permitted the reimbursement of the REG as second-line treatment. We performed a large multicenter, prospective and observational study to confirm REGOMA data in a real-world setting.

Methods: Major inclusion criteria were: histologically confirmed diagnosis of GBM according to WHO 2016 and relapse after Stupp treatment, good performance status (ECOG PS 0-1), good liver function. REG was administered at the standard dose of 160mg/die for 3 weeks on/1 week off. Brain MRI was performed within 14 days before starting REG and every 8-12 weeks, subsequently. The primary endpoint was overall survival. RANO criteria were used for response evaluation, CTACAE v. 5 for adverse events.

Results: From Sept 2020 to Oct 2022, 192 recurrent GBM PTS were enrolled from 29 Cancer Centres in Italy: median age was 58ys (IQR 52.8-67.0), 68% male, ECOG PS was 0 in 85 (44%), 115 PTS (60%) undertook steroids at baseline. MGMT was methylated in 43%, IDHwt in 92%. Median follow-up was 16.6 months (IQR 12.6-19.6). Median OS was 8.2ms (95% CI 6.5-9.6), 12ms-OS was 34.7% (95%CI 27.2-42.4); median PFS was 2.6ms (95%CI 2.3-2.9), 6ms-PFS was 14.3%. The radiological response was PR and SD in 12 (8%) and 25 (16%) PTS. 77 (44%) PTS received third-line therapy. The median of REG cycles per patient was 3 (IQR 2.0-4.0). Grade 3-4 adverse events (AE) were reported in 53 (28%) PTS; reduction/delay and permanent discontinuation due to AE in 36% and 8% of PTS. No death was considered as treatment-related AE.

Conclusions: Compared to the REGOMA trial, this large Italian multicenter, prospective and observational real-world trial confirmed the results in terms of overall survival with a good toxicity profile of REG in recurrent GBM PTS.

Background: Radiotherapy (RT) causes upregulation of CXCL12, a chemokine facilitating recruitment of tumor-associated macrophage (TAM) precursors promoting neovasculogenesis and the formation of an immunosuppressive tumor microenvironment (TME). Here, we report an in-depth analysis of the immune TME (iTME) in patients of the multicentric phase 1/2 GLORIA trial (NCT04121455) which combines RT and CXCL12 inhibition with the RNA-Spiegelmer NOX-A12.

Methods: We analyzed tumor tissue of 10 GLORIA patients with newly diagnosed, incompletely resected (n=8) or biopsied (n=2) GBM with ECOG≤2 lacking MGMT promoter methylation. All patients received standard RT and escalating dose levels of continuous (24/7) i.v. infusions of NOX-A12. Two patients underwent re-surgery, whereas one was diagnosed with pseudoprogression (PsP) and one with recurrence. To characterize the iTME, we used highly multiplexed immunofluorescence (mIF) imaging. As a comparison to the GLORIA cohort, we investigated the pre/post-therapeutic iTME of reference patients receiving standard-of-care (n=7) treatment.

Results: In all samples analyzed, CXCL12 co-localized with endothelial cells. Unlike in the reference cohort, matched pre-/post-treatment tissue analysis of the patient with PsP revealed endothelial and gliomal CXCL12 depletion following treatment with NOX-A12, confirming the mode of action of the drug. Both post-treatment GLORIA samples showed intralesional clustering of activated $CD8^+$ T cells. In the non-responder diagnosed with recurrence, a pro-tumorigenic spatial rearrangement of the iTME was observed, characterized by a presence of M2-like TAMs in the proximity of the perivascular T cell clusters, confirmed by nearest neighbor analysis. None of the reference patients showed similar alterations of the iTME.

Conclusions: m IF of matched pre-/post-therapy tissue samples from the ongoing GLORIA trial supports the proposed modes of action of RT and NOX-A12 counteracting vasculogenesis and modulating the iTME reflected through its spatial rearrangement. This opens up the question of a targetable, compartment-specific role of CXCL12 to be further assessed.

509P Spatial analysis of tumor-associated macrophages within the tumor microenvironment of primary tumors and matched brain metastases

M. Kleinberger[1], D. Cifci[2], C. Paiato[1], E. Tomasich[1], M. Mair[1], A. Steindl[1], Z. Carrero[2], L. Berchtold[1], J.A. Hainfellner[3], L. Müllauer[4], G. Heller[1], J.N. Kather[5], M. Preusser[1], A.S. Berghoff[1]

[1]Department of Medicine I, Division of Oncology, Medical University of Vienna, Vienna, Austria; [2]Clinical AI, Else Kröner Fresenius Zentrum für Digitale Gesundheit, Dresden, Germany; [3]Department of Neurology, Division of Neuropathology and Neurochemistry, Medical University Vienna, Vienna, Austria; [4]Department of Pathology, Medical University Vienna, Vienna, Austria; [5]Medical Oncology Department, Technische Universität Dresden - Carl Gustav Carus Faculty of Medicine, Dresden, Germany

Background: Novel immunotherapies (IO) show mixed responses, particular in context of brain metastases (BM). We therefore aimed to investigate the density of tumor-associated macrophages (TAM) in primary tumors (PT) and matched BM tissue samples.

Methods: We retrospectively identified patients who received resection of PT and BM between 01/1990 and 10/2022. Immunohistochemical staining and density quantification (positive cells/mm^2) of TAMs (CD68$^+$ & CD163$^+$) was performed. Generated heatmaps were analyzed for heterogeneity as quantified by Shannon Entropy.

Results: We included 62 patients (61.3% male, 38.7% female) with matched samples: 46/62 non-small cell lung cancer, 8/62 breast cancer (BC), 8/62 renal cell carcinoma. Median CD163$^+$ TAM density was 733 cells/mm^2 (range 105-5110 cells/mm^2) in BM and 407 cells/mm^2 (range 52-1786 cells/mm^2) in PT. Median CD68$^+$ TAM density was 924 cells/mm^2 (range 119-5521 cells/mm^2) in BM and 744 cells/mm^2 (range 99-2164 cells/mm^2) in PT. CD163$^+$ TAM density was significantly higher in BM compared to PT over all entities ($p<.05$). For CD68$^+$ TAM, a significant difference was only observed in BC with higher density in BM than in PT ($p=.016$). Median difference in CD163$^+$ TAM density between PT and BM was 163 cells/mm^2 (range -1258-3602 cells/mm^2) and 348 cells/mm^2 (range -1390-4390 cells/mm^2) in CD68$^+$ TAM. No correlation between TAM density difference and clinical outcome (time to BM and OS from BM) was observed ($p>.05$). Median entropy for CD163$^+$ TAM in BM was 15.8 (range 1.5-76.2) and 14.3 (range 0.5-45.2) in PT. Concerning CD68$^+$ TAM, median entropy was 19.9 (range 1.8-88.7) in BM and 23.9 (range 1.9-54.9) in PT. A significant difference in entropy was only observed in BC as primary breast cancer CD68$^+$ TAM showed lower entropy indices ($p=.02$). Median difference in entropy between PT and BM was 3.4 (range -34.8-41.3) in CD163$^+$ TAM and 1.41 (range -34.4-39.9) in CD68$^+$ TAM. No correlation of TAM entropy and clinical outcome (time to BM and OS from BM) was observed ($p>.05$).

Conclusions: TAM density is significantly higher in BM compared to PT. In BC, higher CD68$^+$ TAM entropy was observed in BM, indicating higher herterogeneity. Further analyses with enlarged cohort and additional immune cell markers are ongoing.

510P CD47 regulates cellular and metabolic plasticity in glioblastoma

R. Polara

Centre for Cancer Biology, University of South Australia, Adelaide, SA, Australia

Background: Glioblastoma (GBM) is the most common and aggressive form of primary brain tumor with poor survival rates. While conventional therapies including surgery, chemotherapy, and radiotherapy extend patient survival, recurrence within 6-9 months is common with no effective therapy. Thus, novel treatment strategies that have greater specificity and efficacy are warranted. Analyzing the Ivy Glioblastoma Atlas Project's transcriptomics data based on anatomic structures (http://www.brain-map.org/), we identified that CD47, a ubiquitously expressed receptor known to block phagocytosis by interacting with SIRPα on myeloid cells, is abundantly expressed on the leading invasive edge of GBM patient tumors. Increased expression of CD47 is also associated with poorer survival in GBM patients. Importantly, the role of CD47 in GBM besides promoting immune escape is not well understood. Therefore, we propose to identify cell-intrinsic mechanisms that CD47 regulates in GBM.

Methods: To identify intracellular mechanisms regulated by CD47 in GBM, we created a CD47 CRISPR knock-out (KO) cell line using U87 GBM cells. Using the control and CD47 KO cells, we performed a clonogenic assay and transwell migration assay to assess changes in cellular phenotype. Subsequently, we performed bulk RNA-seq followed by gene set enrichment analysis to identify pathways regulated by CD47. To address changes in cell metabolism, a seahorse assay followed by non-targeted metabolomics and metabolic flux analysis was also conducted.

Results: We have found that loss of CD47 in GBM cells reduces cell migration and proliferation in the absence of myeloid cells, suggesting a cell-autonomous function of CD47. Consistently, gene set enrichment analysis in control and CD47 KO GBM cells indicates that cell polarity, axonal guidance, cell differentiation, and cell proliferation pathways are driven by CD47 signaling. Furthermore, our data shows that CD47 regulates metabolic plasticity. We found that CD47 KO cells exhibit elevated levels of several glycolytic metabolites which correlates with increased mitochondrial spare respiratory capacity and mitochondrial biogenesis.

Conclusions: We have identified a novel immune-independent function of CD47 in linking cellular and metabolic plasticity in GBM.

511P Immunodisruptive conditions and glioma diagnosis: 24-year retrospective study of an under-recognized scenario

S. Cabezas-Camarero[1], R. Pérez-Alfayate[2], M.J. Sotelo Lezama[3], P. Pérez Segura[4]

[1]Medical Oncology Department, Hospital Clinico Universitario San Carlos, Madrid, Spain; [2]Neurosurgery, Hospital Clinico Universitario San Carlos, Madrid, Spain; [3]Medical Oncology Department, Hospital Maria Auxiliadora, Lima, Peru; [4]Dept. Medical Oncology, Hospital Clinico Universitario San Carlos, Madrid, Spain

Background: Disruption of the immune system is known to favor carcinogenesis and cancer breakthrough. Gliomas constitute de most prevalent primary malignant brain tumors. We aimed to study the occurrence of immune disruptive conditions (IDC) in patients with gliomas at our institution.

Methods: Retrospective study of patients (pts) diagnosed with a glioma at Hospital Clínico Universitario San Carlos, Madrid (Spain). IDCs included autoimmune diseases (AID), organ transplantation (OT) requiring chronic immunosuppressive therapy (IST), and hematological malignancies (HM). A descriptive study, as well as time since IDC, time under IST, and progression-free survival (PFS) and overall survival (OS) since glioma diagnosis were analyzed.

Results: Within the period January 1999 – April 2023, among 481 patients diagnosed with a glioma, 30 (6.2%) patients harbored IDCs. Male/Female: 14/16. Age: 63y (32-83). WHO 5th Ed.: IDH-WT GB: n=26 (MGMTmeth: 50%, MGMTunmeth: 50%), IDH-MUT Astro: n=3, Pleomorphic xanthoastro: n=1. Frontal: n=14, Temporal: n=8, Parietal: n=6. Unilobar: n=23, Bilobar: n=4, Trilobar: n=1. Right: n=8, Left: n=19, Bilateral: n=3. Resection: GTR=8, STR=1, Partial=3, Biopsy=14. RTx=20 pts, CRTx=18, Adj CTx=13. Median PFS and OS since diax were 9 and 10 months (m), respectively. No. of IDCs: 1 (n=21 pts), $\geq$ 2 (n=9 pts). IDC type: AID (n=27 pts) among which: endocrine (4: Addison, Hypothyroidism, Hashimoto's thyroiditis), respiratory (7: asthma, sarcoidosis, alergic rinoconjunctivitis), cutaneous (7: chronic eccema, psoriasis), neurological (4: multiple sclerosis, Guillain-Barré), digestive system (2: inflammatory bowel disease), rheumatological (13: Horton's disease, Sjöegren's syndrome, systemic lupus erithematosus, uveitis, vasculitis); HM (1: chronic lymphocytic leukaemia); OT (2: renal). IST for IDCs used in 20 pts (systemic IST in 17). Median time since IDC: 101 m (10-411). Median time under IST: 108 m (0-283).

Conclusions: Within a large 24-year long retrospective series, a minority of pts with glioma harbored an IDC, most commonly rheumatological, respiratory, or cutaneous. Studies should be conducted to unveil if gliomas occurring in pts with IDCs are biologically and immunologically distinct.

512P Heterozygous germline Fanconi anemia-related gene mutations increase susceptibility to central nervous system germ cell tumors

G. Wang[1], X. Yue[1], B. Liu[1], R. Tao[2], N. Luo[3], T. Han[3], M. Ge[3]

[1]Department of Neurosurgery, Children's Hospital Affiliated to Shandong University, Jinan, China; [2]Department of Oncology, Shandong Cancer Hospital Affiliated to Shandong University, Jinan, China; [3]The Medical Department, Jiangsu Simcere Diagnostics Co., Ltd, Nanjing, China

Background: Central nervous system germ cell tumors (CNS GCTs) are a group of rare heterogeneous CNS tumors. CNS GCTs are usually in midline location and mainly affect children and adolescents. The incidence of CNS GCTs is higher in Asia (11%) than that in Western Europe (4%) with a male predominance. The different tumor distribution demographically and high incidence in East Asia suggests a probable genetic background.

Methods: We collected samples including tissue and blood leukocyte control from 17 patients with CNS GCTs. All samples were tested using a 551-cancer related gene profiling, and somatic mutations, TMB, MSI and germline mutations were analyzed. The pathogenicity of germline mutations was categorized based on American College of Medical Genetics and Genomics guidelines. We screened out the pathogenic and likely pathogenic (P/LP) mutations of germline mutations and calculated the relative risk (RR) in our cohort compared to that in a control population (gnomAD). Then the relationship between mutation characteristics and clinical features were further analyzed, as well as the correlation with patient prognosis.

Results: In 17 patients with CNS GCTs, 4 patients (4/17) were found harboring germline pathogenic or likely-pathogenic mutations, respectively, in *FANCA, FANCD2, FANCE, SDHA*. All the four genes are Fanconi anemia (FA)-related genes. The RR of total FA mutations in patients with CNS GCTs was 21.589 (95% CI, 28.934-257.728; P value, 3.22E-07) compared to gnomAD controls. Then the 17 patients were divided into two groups, the FA group (with FA-related gene heterozygous germline P/LP mutations) and the non-FA group (without P/LP mutation). The results showed that pathological classification (P=0.00588) and site of lesion (P=0.00714) were significantly different in the two groups. There was no significant difference in gender, age and TMB between the two groups. The 4 recurrent patients were all in the non-FA group, but there was no statistical difference in prognosis between the two groups.

Conclusions: FA-related gene germline P/LP mutations increase the susceptibility to CNS GCTs. Moreover, the germline FA mutation may be related to the pathological subtype, site of lesion and prognosis, which needs to be verified with a large sample.

513P Cyclin pathway in oligodendrogliomas IDH mut and 1p/19q codeleted

M.A. Vaz Salgado[1], J.M. Sepulveda Sanchez[2], J. Earl[3], A. Perez[4], H. Pian[5], Y. Ruano[6], J. Gutierrez[6], A. Carrato Mena[1], L.L. Ley[7], M. Villamayor[1], V. López[1], I. Martínez Delfrade[1], V. Albarrán[1], J. Chamorro-Perez[1], D.I. Rosero Rodriguez[8], B.I. Morón[1], A.H. Iain[9]

[1]Medical Oncology Department, Hospital Universitario Ramon y Cajal, Madrid, Spain; [2]Medical Oncology Department, Hospital Universitario 12 de Octubre, Madrid, Spain; [3]IRYCIS, Hospital Universitario Ramon y Cajal, Madrid, Spain; [4]Neurosurgery, Hospital Universitario 12 de Octubre, Madrid, Spain; [5]Pathology, Hospital Universitario Ramon y Cajal, Madrid, Spain; [6]Pathology, Hospital Universitario 12 de Octubre, Madrid, Spain; [7]Neurosurgery, Hospital Universitario Ramón y Cajal, Madrid, Spain; [8]Oncology, Hospital Universitario Ramon y Cajal, Madrid, Spain; [9]UCM - Universidad Complutense de Madrid, Madrid, Spain

Background: Oligodendrogliomas (OLIG), are rare tumors of the central nervous system. The current WHO classification requires the presence of IDH mutation and 1p/19q codeletion. Grade 3 OLIG presents a higher number of chromosomal alterations than grade 2, indicating that progression to malignancy is associated with the acquisition of multiple genetic abnormalities. An increased incidence of deletions in the short arm of chromosome 9 has been found. CDKN2A is located on chromosome 9 and encodes for 2 proteins p16 (or p16INK4a) and p14arf. Previous studies have found CDKN2A involvement at 9p21 with homozygous deletion in 25% of grade 3 oligodendrogliomas. Many of these studies were performed in a series of patients with OLIG diagnosed by histopathological criteria, but not by current molecular criteria. This study analyzed the cyclin pathway in a series of oligodendrogliomas with IDH mutation and 1p/19q codeletion.

Methods: Cases with a morphological diagnosis of oligodendroglioma were identified (182 cases). This same cohort was subsequently reclassified according to current WHO criteria (91 cases). The median follow-up of this case series was 9 years. In the reclassified cohort, p16, pRb and D1 cyclin were studied by immunohistochemistry.

Results: There was no p16 expression in 16 of 71 cases (22.5%). The absence of expression was significantly associated with a worse prognosis. Median OS in the absence of p16 of 9 years (95%IC 9.36-17.35) vs 13.35 years when there was p16 expression (95%IC 9.36-17.35) p=0.023 HR 0.41. In grade 2 oligodendrogliomas, the median OS was 10.86 vs 13.35 p=0.754, and in grade 3, 4.76 vs 17.49 p=0.010. According to a multivariate analysis including data on the extent of surgery, tumor grade, adjuvant treatment, and p16, only the absence of p16 showed a statistically significant prognostic value (p=0.034). There was no correlation between the loss of p16 and the presence of microvascular proliferation, necrosis, or uptake on MRI. In grade 2 oligodendrogliomas, high cyclin D1 expression was associated with worse survival; 12.3 vs 0.78 years (p=0.001).

Conclusions: Loss of p16 is more frequent in grade 3 than in grade 2 oligodendrogliomas and is associated with worse survival.

514P Immunophenotypic profile of glioblastoma microenvironment: A cohort study

L. Gatto[1], C. Agostinelli[2], V. Di Nunno[1], S. Righi[2], A. Tosoni[3], F. Ambrosi[4], U. Vardy[5], S. Bartolini[3], L. Ranieri[3], S. Asioli[6], E. Franceschi[3]

[1]Department of Oncology, Azienda Unità Sanitaria Locale (AUSL) Bologna, Bologna, Italy; [2]Department of Medical and Surgical Sciences, University of Bologna, Bologna, Italy; [3]Nervous System Medical Oncology Department, IRCCS Istituto delle Scienze Neurologiche di Bologna, Bologna, Italy; [4]Pathology Unit, Department of Experimental, Diagnostic and Specialty Medicine (DIMES), University of Bologna, Bologna, Italy; [5]School of Medicine and Surgery, University of Bologna - Alma Mater Studiorum, Bologna, Italy; [6]Department of Biomedical and Neuromotor Sciences (DIBINEM), University of Bologna, Bologna, Italy

Background: Glioblastoma (GBM) is the most aggressive brain tumor in adults and is characterized by an immunosuppressive microenvironment. Different factors shaping its tumor microenvironment (TME) regulate tumor initiation, progression, and treatment response. The aim of this study was to characterize the TME and the expression of immunomodulatory targets in patients (pts) with GBM.

Methods: Immunohistochemistry for CD3, CD4, CD8, programed death ligand 1 (PD-L1) and programed death 1 (PD1) was performed on surgical tumor specimens from pts diagnosed with GBM, according to the CNS WHO 2021 criteria. A descriptive statistic was applied to the data set. OS and PFS were estimated through the Kaplan-Meier method and analyzed by the means of a log-rang test.

Results: We included 30 pts, with median age of 59.8 years [range 40.2-69.1 years]. All pts were treated with surgery followed by temozolomide concurrent with and adjuvant to radiotherapy. MGMT was methylated in 46.7% of pts and unmethylated in 53.3% of pts. Overall CD4+ lymphocytes, both intratumoral and perivascular, were significantly more represented than CD8+ lymphocytes in the GBM TME (p= 0.01). A lower density of CD4+ lymphocytes (<10%) was found to be a favorable prognostic factor for GBM outcome (p= 0.02). Pts with MGMT methylated and unmethylated tumors exhibited a distinct TME composition, with a significant higher number of perivascular CD8+ lymphocytes (p= 0.002), intratumoral CD8+ lymphocytes (p= 0.0024) and perivascular CD4+ lymphocytes (p=0.014) in MGMT unmethylated compared to MGMT methylated tumors. PD-L1 expression in GBM cell surface was 13.3% (n=4) and PD1 was expressed in 30% (N=9) of the GBM-infiltrating T cells, with predominantly perivascular distribution.

Conclusions: CD4+ lymphocytes lower density (<10%) correlates with improved survival. Given the small numbers of our cohort, the prognostic value of CD4+ lymphocytes density needs to be validated in large-scale studies. MGMT methylated and unmethylated tumors exhibit different immune profiles, reflecting the different biology of these tumors. The expression of PD-L1 and PD1 in GBM patients is confined to a small subpopulation.

515P A MRI-based radiomics model for predicting the response to anlotinb combined with temozolomide in recurrent malignant glioma patients

S. Zhou[1], Y. Li[1], W. Xu[1], Y. Fei[1], M. Wu[1], J. Yuan[1], L. Qiu[1], Y. Cao[2]

[1]Department of Radiation Oncology, Nanjing Medical University First Affiliated Hospital, Nanjing, Jiangsu, China; [2]Radiation Oncology, Jiangsu Province Hospital/The First Affiliated Hospital of Nanjing Medical University, Nanjing, China

Background: Anlotinib is a multitarget anti-angiogenic drug that combined with temozolomide (TMZ) can effectively prolongs the overall survival (OS) of recurrent malignant glioma(rMG), but some patients do not respond to anlotinib combined with TMZ. These patients were associated with a worse prognosis and lack effective identification methods. Therefore, there is a great need to differentiate patients who are likely to have a good response to anlotinb in combination with TMZ from those who are not, so as to provide more personalized targeted therapy and free patients who might have a poor treatment response from risk of those severe side effects and high cost.

Methods: A total of 53 rMG patients (42 in training cohort and 11 in validation cohort) receiving anlotinib combined with TMZ were enrolled. A total of 3668 radiomics features were extracted from the recurrent MRI images. Radiomics features are reduced and filtered by hypothesis testing and LASSO regression. Eight machine learning models construct the radiomics model, and then screen out the optimal model. The performance of the model was assessed by its discrimination, calibration, and clinical usefulness with validation.

Results: 53 patients with rMG were enrolled in our study. 34 patients displayed effective treatment response, showed a higher survival benefits than non-response group, the median PFS was 8.53 months versus 5.33 months(P=0.06) and the median OS was 19.9 months and 7.33 months (P=0.029), respectively. Three radiomics features were incorporated into the model construction as final variables after LASSO regression analysis. Compared with other models, LR model has the best performance with an AUC of 0.929 in validation cohort, which can effectively predict the response of rMG patients to anlotinib in combination with TMZ. The calibration curve confirmed the agreement between the observed actual and prediction probability. Within the reasonable threshold probability range (0.38-0.88), the radiomics model shows good clinical utility.

Conclusions: The above-described radiomics modle performed well, which can serve as a clinical tool for individualized prediction of the response to anlotinb combined with TMZ in rMG patients.

516P Building a new prognostic score for patients with central nervous system (CNS) tumors enrolled in early phase clinical trials

K. Beshiri[1], A. Rousseau[2], S. Ponce Aix[1], S.N. Dumont[3], R. Bahleda[1], M. Touat[4], J-M. Michot[1], A. Hollebecque[1], A. Gazzah[1], K. Ouali[1], C. Henon[1], C. Smolenschi[5], F-X. Danlos[1], D. Guyon[3], S. Ammari[6], C. Massard[7], A. Marabelle[1], P. Martin Romano[1], S. Champiat[1], C. Baldini[1]

[1]Drug Development Department (DITEP), Gustave Roussy - Cancer Campus, Villejuif, France; [2]Office of Biostatistics and Epidemiology, Institut Gustave Roussy, Villejuif, France; [3]Medical Oncology Department, Institut Gustave Roussy, Villejuif, France; [4]Neuro-Oncology Department, Hopital Pitié Salpetrière AP-HP, Paris, France; [5]Drug Development Department (DITEP), Gustave Roussy - Cancer Campus, Villejuif, (Select One), France; [6]Radiology Department, Gustave Roussy, Villejuif, France; [7]DITEP Department, Gustave Roussy - Cancer Campus, Villejuif, France

Background: Patients (pts) with primary CNS tumors are often excluded from early phase clinical trials because of doubts regarding the blood brain penetration, adherence to study treatment and use of corticosteroids in immunotherapy clinical trials. Scores built to help selectection of pts that would be good candidates for early phase clinical trials such as the Royal Marsden Score (RMH) or the Gustave Roussy Immune Score (GRIm) are not relevant to pts with primary CNS. We aimed to determine factors associated with prognosis to help physicians referring pts.

Methods: We conducted a retrospective analysis of all pts treated for a CNS tumor and enrolled in an early phase clinical trials at the Drug Development Department at Gustave Roussy between January 2013 and December 2022. Descriptive statistics were used to present the population and a multivariate Cox regression was used to determine prognostic factors in uni and multivariate analysis on overall survival (OS).

Results: A total of 108 pts were included in the study. Median age was 47 (18-82), most males (F/M=35/73), 44% were symptomatic in the three months before study entry, 46% had a multifocal disease at C1D1. The ratio between low grade glioma (LGG) and high grade glioma (HGG) according to the new molecular classification of 2021 were 24/84. Molecular alterations were: IDH mutation (59%), MGMT methylation (14.2%, 94 unknown), 1p19q codeletion (19.7%, 53 unkown). Targeted therapies were the most common drug used (44%), followed by immunotherapy (33.%) and epigenetic drugs (8.4%). Pts harbouring a BRAF mutation treated with a specific target therapy were 12; pts with an FGFR mutation or fusion treated in the same setting were 18. Median progression free survival (PFS) was 9.7 months, 40% of pts were progressing at 3 months. Altogether, 34% of pts were alive at 6 months. In multivariate analysis, lymphocyte counts ≥900/mm3 (HR=0.7 95% CI 0.46 - 1.07), absence of steroids at baseline (HR=2.3 95% CI 1.5 - 3.5), absence of antiepileptic drugs at baseline (HR=2.06 95%CI 1.2 - 3.7) were associated with a better overall survival.

Conclusions: Corticosteroid use, lymphocyte count and use of antiepileptics will be used to build a new score that will be presented at the conference.

517P Differentiating IDH-wildtype and IDH-mutant high grade gliomas with deep learning

K.J. Hewitt[1], C.M.L. Loeffler[2], M. van Treeck[2], H. Muti[2], G. Veldhuizen[2], O. Saldanha[1], L. Bejan[3], T. Millner[4], S. Brandner[5], J.N. Kather[2]

[1]Medizine III, RWTH Aachen, Aachen, Germany; [2]Clinical AI, Else Kröner Fresenius Zentrum für Digitale Gesundheit, Dresden, Germany; [3]School of Medicine, UCL - University College London, London, UK; [4]Division of Neuropathology, UCL - University College London, London, UK; [5]Department of Neurodegenerative Diseases, UCL Queen Square Institute of Neurology, London, UK

Background: Glioblastomas (GBM) are the most frequent primary malignant brain tumours affecting adults. Over 85% of GBM cases are *IDH-wildtype (IDHwt)*, which carry an expected survival of around 1 year. A small number of cases have the morphological features of GBM but harbour an *IDH-mutation (IDHmut)*. These cases, designated grade 4 *IDH-mutant* astrocytoma under the 5th edition WHO CNS classification, are important to identify due to superior prognosis and implications for clinical management. In practice, most neuropathology departments use immunohistochemistry (IHC) to determine *IDH* status. IHC is not infallible, however, and requires additional tissue and laboratory work. Multiple studies have demonstrated that Deep Learning (DL) can predict molecular alteration status directly from routine pathology whole slide images (WSI). Validating the use of AI for such applications has the potential to improve diagnostic precision and add further value to a digital pathology workflow. We hypothesise that DL can accurately differentiate *IDHwt* and *IDHmut* high-grade gliomas directly from WSI.

Methods: We used an attention-based multiple-instance learning (attMIL) approach and applied it to an international biorepository of digitised neuropathology images. Our primary cohort was obtained from University College London (UCL), through collaboration with BRAIN UK and comprised 774 WSIs. The Cancer Genome Atlas (TCGA) was used as a secondary cohort for external validation and comprised 332 WSIs.

Results: We found that DL was able to predict *IDH* status in high-grade glioma images. On internal cross validation in the UCL dataset, this gave an area under the receiver operating characteristic curve (AUROC) of 0.92. These findings were sustained on external validation in the TCGA dataset, with an AUROC of 0.79.

Conclusions: In the future, DL-based image analysis could be used as a screening tool in the setting of a digital pathology diagnostic environment to guide Pathologists on the targeted use of IHC.

518P Artificial intelligence real-world applications in pediatric neuro-oncology: The AICCELERATE project

F. D'Antonio[1], A.E. Tozzi[2], E. Pandolfi[2], G. Lacanna[2], A. Carai[3], F. Fabozzi[4], A. Mastronuzzi[4]

[1]Department of Experimental Medicine, Faculty of Medicine and Dentistry, Department of Experim Faculty of Medicine and Dentistry, Sapienza University of Rome, Rome, Italy; [2]Unità di Medicina Predittiva e Preventiva, Ospedale Pediatrico Bambino Gesù, Rome, Italy; [3]Neurosurgery Department, Ospedale Pediatrico Bambino Gesù, Rome, Italy; [4]Department of Oncohematology, Cell Therapy, Gene Therapies and Hematopoietic Transplantation, Bambino Gesù Children's Hospital (IRCCS), Ospedale Pediatrico Bambino Gesù, Rome, Italy

Background: Artificial Intelligence (AI) holds the promise to transform medicine during diagnosis, management and therapy of diseases. The AICCELERATE project will introduce an operational approach to develop AI-enabled digital solutions to improve medical processes by creating a digital twin. In our study, we performed the first pilot application of the AICCELERATE project at Bambino Gesù Children's Hospital in Rome (OPBG). The aim of our study is to design a supervised machine learning (ML) model to predict time to surgery and time to diagnosis based (outputs) on time from admission to first consultation and imaging (inputs) in newly diagnosed pediatric patients.

Methods: We included pediatric patients with new diagnoses of brain tumors, treated in OPBG from December 2017 to December 2022. We collected from EHR the following data: age and sex, start and end date of the first admission, department of hospitalization, consultations and radiological imaging date, diagnosis, and surgery date.

Results: We included 48 patients with a pediatric brain tumor, with a mean age of 8.6 years. We used a multiple linear regression model, which does not require large datasets such as more complex models. Our analysis showed that delayed consulting and imaging led to a delayed diagnosis, with the consulting presenting a higher importance than the imaging. This result was validated by the model's estimated regressors coefficients, with the consulting factor being assigned a larger weight β_C=1.81 than the imaging factor β_I=-0.33. Similarly, we observed that delayed consulting and imaging led to a delayed surgery, estimating a higher coefficient for the consulting β_C=0.71 than the one estimated for the imaging β_I=-0.06. While the ML model achieved a reasonable performance in both frameworks, the time to surgery was predicted with a lower MAE 4.45±0.87 compared to the diagnosis MAE of 6.74±0.95.

Conclusions: This preliminary study conducted in a small number of patients, suggests that decreasing time to consultation can shorten time to surgery in children with brain cancer. As the AICCELERATE is ongoing, more accurate models will be developed and will help to better understand how to optimize the journey of children with brain cancer.

519P The landscape of PDGFRA mutation in Chinese patients with glioma

Q. Lv[1], T. Han[2], M. Wang[2], D. Guo[2], R. Kong[2], Y. Dong[2], R. Ding[2], S. Chen[3], W. Deng[3], F. Bu[4]

[1]Department of Neurosurgery, Children's Hospital Affiliated to Zhengzhou University, Zhengzhou City, China; [2]The Medical Department, Jiangsu Simcere Diagnostics Co., Ltd., Nanjing, China; [3]Bioinformatics Department, Jiangsu Simcere Diagnostics Co., Ltd., Nanjing, China; [4]Operations department, Jiangsu Simcere Diagnostics Co., Ltd, Nanjing, China

Background: Glioma originated from the intracranial glial cells, represents the most aggressive subtype of brain tumors, with few treatments available. Platelet-derived growth factor receptor alpha (*PDGFRA*) is the second most frequently mutated tyrosine kinase receptor in glioblastoma (GBM). Mutations in *PDGFRA* are potential therapeutic targets. Here, we explore the *PDGFRA* mutation profile in Chinese adult glioma patients.

Methods: Next-generation sequencing (NGS) with 131-gene profiling was performed to analyze postoperative tissue from 4294 Chinese adult glioma patients from 2019 to 2023. Somatic mutations and copy number variations in tumor samples were detected using the NGS method according to standard operating procedures (SOP). We screened for *PDGFRA* mutations and calculated mutation frequencies and evaluated other co-mutations.

Results: *PDGFRA* mutations were observed in 185 of 4294 tumor samples (4.3%). The extracellular domain accounted for the majority of mutations (62.78%), followed by the tyrosine kinase domain (27.82%) and the transmembrane domain (9.40%). The main mutation hotspot was found to be in exon 5/6/7, accounting for 42.48% of the mutations. The most common mutations identified were p.C235Y (5.26%), p.Y288C (4.51%), and p.E229K (4.14%). The most common tyrosine kinase domain mutation is p.D842Y (1.82%) of exon 18 (9.39%), while p.D842V (1.12%) is also frequently observed, which should be noted that the *PDGFRA* mutation pattern in gliomas differs from that observed in solid tumors. The majority of the samples analyzed exhibited both *PDGFRA* mutation and *PDGFRA* amplification, with a small percentage (3.28%) showing *PDGFRA* fusion, specifically *KIT-PDGFRA* fusion.

Conclusions: The incidence of *PDGFRA* mutation in glioma patients is 4.3%. This type of mutation is mostly found in the non-tyrosine kinase domain. Investigating the *PDGFRA* map and *PDGFRA* inhibitors has significant exploratory value.

520P Copy number variation spectrum analysis of primary glioblastoma

C. Cheng[1], Y. Ji[1], W. Cheng[1], Y. Xia[1], Z. Qian[1], T. Han[2], M. Wang[2], D. Guo[2], R. Kong[2], R. Ding[2], S. Chen[3], W. Deng[3], F. Bu[4]

[1]Department of Neurosurgery, Department of Life Science and Medicine, The First Affiliated Hospital of University of Science and Technology of China, HeFei, China; [2]The Medical Department, Jiangsu Simcere Diagnostics Co., Ltd., Nanjing, China; [3]Bioinformatics Department, Jiangsu Simcere Diagnostics Co., Ltd., Nanjing, China; [4]Operations department, Jiangsu Simcere Diagnostics Co., Ltd, Nanjing, China

Background: Glioblastoma, IDH-wildtype (GBM) is the most common malignant tumor of the human central nervous systemwith a poor prognosis. The distribution of copy number variations and the molecular targeted therapy are unknown. Therefore, it is important to understand the somatic copy number genome profile of Chinese adult glioblastoma patients.

Methods: Next-generation sequencing of 131 genes was performed in postoperative tissues of 4294 Chinese adult glioma patients from 2019 to 2023. Standard operating procedures (SOP) were used to detect somatic mutations and copy number variations. We screened out copy number variants in glioblastoma and calculated mutation frequency and evaluated other co-mutations.

Results: Copy number variations was observed in 1871of 2839 glioblastoma samples (65.9%). The six most common genes with copy number variation were *CDKN2A* (48.8%), *CDKN2B* (47.1%), *EGFR* (24.3%), *PTEN* (17.1%), *CDK4* (11.3%), *PDGFRA* (9.3%). Patients with *EGFR* amplification often carried *CDKN2A* (16.2%), *CDKN2B* (15.4) and *PTEN* (7.0%), while patients with *PDGFRA* amplification often carried *KIT* (7.54%), *CDKN2A* (6.1%) and *KDR* (5.9%). *MDM2* (7.0%), *CDKN2A* (6.0%) and *CDKN2B* (6.2%) were common copy number variants in the *CDK4*-amplification group.

Conclusions: In our GBM patients, 65.9% present copy number variations *RB1* cell-cycle, *TP53*, and *RTK* pathways are common signaling pathway alterations. CDKN2A/B deletion had the highest incidence and were enriched in EGFR-amplified patient. The high frequency of copy number variations in *RB1* cell-cycle pathways in glioblastoma suggests that it may be a direction for targeted therapy.

521P Deciphering a three-miRNA signature as a prognostic biomarker in glioma patients: Correlation with DFS and OS

A.B. Diaz Mendez[1], M. Di Giuliani[1], A. Sacconi[2], G. Regazzo[1], S. Ramponi[3], G. Blandino[1], C. Garufi[3], M.G. Rizzo[1]

[1]Translational Oncology Research Unit, IRCCS Istituto Nazionale Tumori Regina Elena, Rome, Italy; [2]Biostatistics and Bioinformatics Unit, IRCCS Istituto Nazionale Tumori Regina Elena, Rome, Italy; [3]Medical-Oncology Unit, Azienda Ospedaliera San Camillo Forlanini, Rome, Italy

Background: Gliomas are diffusely growing brain tumors and challenging cancers for diagnosis and treatment. The identification of genetic/epigenetic markers has changed glioma classification. Among the key genetic events, IDH mutations are noteworthy from a diagnostic and a prognostic point of view. MiRNAs are important players in glioma modulating cancer-related processes, including invasion and progression. We recently identified a serum diagnostic/prognostic miR-1, miR-26a-1 and miR-487b signature deregulated in glioma patients according to IDH mutation profile. We also found that this signature displays oncosuppressive functions with a marked inhibitory effect on migration and invasion by the direct targeting of crucial genes for invadopodia activity such as SH3PXD2B (miR-1), SH3PXD2A (miR-26a-1) and EFHD2 (miR-487b).

Methods: TCGA and CGGA databases were used to evaluate the correlation of the gene expression with glioma recurrence and Overall survival (OS). GSEA tool was used to identify pathways. Digital PCR and qRT-PCR were used to analyze miRNA and gene expression, respectively.

Results: *In silico* analyses show that the three-miRNA signature target genes were significantly downregulated in primary respect to recurrent patients. We also found that the combination of 2 out of 3 target genes is a strong prognostic biomarker. Median OS was 94.5 months in the Low-expression group *versus* 27.1 months in the High-expression group (HR=2.82[2.26-3.52], p=7.8e-20). These data were confirmed in a validation cohort. We also identified potential pathways deregulated in patients overexpressing the two genes and interestingly we found enriched pathways related to the immune system, angiogenesis and cell cycle. Our on-going experiments aim to validate experimentally the *in silico* data using a cohort of 80 glioma patients, including paired primary and recurrent tumor tissues.

Conclusions: The identification of a prognostic/predictive miRNA signature and its target genes, with a potential key role in glioma progression/recurrence through the regulation of important biological processes, could represent a step forward for the development of novel complementary therapies useful for patients management.

522P Galectin 3 binding protein as potential biomarker in glioma diagnosis

R. Rana

Department of Research, Sir Ganga Ram Hospital, New Delhi, India

Background: Gliomas, or malignant brain tumors that grow from glial cells, are the most prevalent form. They account for roughly 40% of all primary brain tumors and 70% of all primary malignant brain tumors. The only procedures available for diagnosing different stages of glioma are surgical incision and biopsy; however, our work focuses on finding a minimally invasive way for early glioma diagnosis. Identification of proteins released by cancer cells is of particular interest in this area, as it could lead to a better understanding of tumor growth.

Methods: Extracellular vesicles (EVs) were extracted from pooled plasma of healthy individuals (n=03) and glioma patients of various grades (Grade I, II, or III). The size and concentration of Plasma derived-EVs marker were determined using nanoparticle tracking analysis, immunohistochemistry, western blot, and flow cytometry. In furthermore, an iTRAQ-based LC-MS/MS analysis of EVs protein was performed. The candidate protein galectin-3 binding protein was validated using ELISA and other methods (LGALS3BP).

Results: Total 123 proteins were identified from plasma derived pooled EVs and 34, 12 and 14 proteins were found to be differentially abundant by more than 1.3 in the different grades of glioma grade I, pilocytic astrocytoma; grade II, diffuse astrocytoma; grade III, anaplastic astrocytoma, respectively, in comparison with the control samples. A total of seven proteins-namely, CRP, SAA2, SERPINA3, SAA1, C4A, LV211, and LGALS3BP-showed differential abundance in all the three grades. LGALS3BP is the only protein which found to be strikingly high in all three grades in a progressive manner. Further ELISA and immunohistochemistry technique implemented to verify LGALS3BP in cohort of samples.

Conclusions: LGALS3BP was shown to be elevated across all grades, and ELISA analysis of individual blood plasma and plasma-derived extracellular vesicles validated the enhanced expression of LGALS3BP in glioma patients. That shows the possible biomarker for early diagnosis of glioma and improved patient survival. This study would further provides the information of progression and monitoring the tumor grades (grade I, grade II, grade III).

523P Analysis of DNA damage response (DDR) gene expression as a prognostic factor for glioblastoma patient mortality

A-T. Droesse, M.R. Jackson

School of Cancer Sciences, University of Glasgow, School of Cancer Sciences, Bearsden, UK

Background: Glioblastoma (GBM) is associated with an exceptionally poor prognosis with a median survival of 15 months. At present, standard of care involves initial maximal surgical resection, followed by radiotherapy as well as concomitant and adjuvant temozolomide chemotherapy. However, as current therapeutic strategies are insufficient in sterilising tumour cells, GBM represents an area of vital unmet clinical need. Upregulation of DNA damage response (DDR) gene expression in cancer is implicated in tumorigenesis and disease recurrence through the acquisition of driver mutations, evasion of cell death, and reversal of chemotherapy and radiotherapy cytotoxicity. However, DDR gene expression in GBM has not been widely studied. This bioinformatics study aimed to identify DDR genes with expression that is significantly associated with GBM patient survival.

Methods: Clinical and transcriptomic (RNAseq) data from 155 GBM and 4 non-tumour samples using the TCGA-GBM database were subjected to analysis. Kaplan-Meier stratified survival analysis following fitting of the Cox proportional hazard model was conducted on clinical data after stratification based on the median expression of each gene. Multivariate analysis considering the known prognostic significance of age, sex and O6-methylguanine- DNA-methyltransferase *(MGMT)* promoter methylation status was conducted on gene expression with significant p and q values.

Results: Only 1 out of 298 DDR genes subjected to analysis was significantly associated with patient prognosis after correction for multiple comparisons. This study identified that upregulation of *RDM1* gene expression is an independent predictor for detrimental patient prognosis after multivariate analysis in GBM (multivariate HR 1.61, 95% CI 1.03 to 2.51, p = 0.035).

Conclusions: Due to the small proportion of DDR genes with expression significantly associated with prognosis, DDR gene expression is unlikely to be a significant prognostic indicator in GBM patient survival. Further investigation into *RDM1* function is warranted to determine the mechanism by which this gene might influence patient outcomes and explore the potential development of novel *RDM1*-targeted therapies.

524P Cell line study of nucleosome-based biomarkers in the diagnosis and detection of relapses in glioblastoma

J. Decarpentrie[1], P. Van den Ackerveken[2], A. Govaerts[2], A. Lobbens[2], E. Beine[2], N. Donis[3], M. Herzog[2], J. Douxfils[1]

[1]Department of Pharmacy, University of Namur, Namur, Belgium; [2]Research and Development, Belgian Volition SPRL, Isnes, Belgium; [3]Research and Development Departement, QUALIblood, Namur, Belgium

Background: Currently, glioblastoma (GBM) diagnosis and monitoring rely on neuroimaging and histopathological confirmation. However, overall survival has not improved in last decades due to therapeutic failure and to a lack of biomarkers for relapses' detection. Liquid biopsies (i.e. blood or CSF) using nucleosomes-containing-histone post-translational modifications (PTMs) have the potential to become valuable biomarkers for diagnosis and monitoring GBM.

Methods: Four glioblastoma cell lines (SF-126, U-87MG, U-118MG, and U-138MG) compared to a healthy microglia cell line (HMC3) and other solid cancer cell lines including pancreas (MIA PaCa-2), liver (HepG2), and cervix/uterus (HeLa) have been analyzed to identify their epigenetic profile. Nucleosomes were extracted and analyzed with the Nu.Q® Discover immunoassays platform addressing 13 histone-PTMs. Quantitative results of PTMs expression were normalized on quantification of total nucleosomes (H3.1-nucleosomes). Moreover, to demonstrate the capacity of the Nu.Q® assays to quantitatively monitor PTMs, GBM cell line SF-126 (n=3) was treated with an EZH2 inhibitor (responsible of H3K27 methylation) (iEZH2) for 4-, 24-, and 48 hours.

Results: The immunoassay identified three candidate biomarkers compared to control cell lines (n=4): citrullinated-histone H3 (H3R8Cit) (control=4.68% ; GBM=13.88% ; $p<0.05$), phosphorylation of H3S10 (H3S10Ph) (control=2.31% ; GBM=5.57% ; $p<0.05$), and a trend in H3K4Me2 elevation (control=0.43% ; GBM=1.07% ; p=0.066) in GBM cell lines(n=4). These results were confirmed by western blot. In addition, PCA revealed a segregation between GBM and control cells, mainly driven by these three PTMs. Moreover, the monitoring assay revealed that, after 24 hours and 48 hours of exposure, the level of H3K27Me3 – expressed as ratio of total nucleosomes was decreased by 32% (control=14.67%±0.58% ; iEZH2=10.00%±1.73% ; $p<0.05$) and 41% (control=15.33%±1.53% ; iEZH2=9.00%±0.00% ; $p<0.05$), respectively. Those results were also confirmed by western blot analysis.

Conclusions: In conclusion, we identified three specific *in vitro* epigenetic-based marks of GBM and demonstrated that the Nu. Q® technology is a valuable tool to monitor the degree of PTMs expression.

Bufalini Hospital, Cesena, Italy; [7]Neurosurgery, M. Bufalini Hospital, Cesena, Italy

Background: Glioblastoma (GBM) is characterized by an "immune-deserted" tumor microenvironment (TME) consisting of tumor-associated macrophages (TAMs) and tumor infiltrating lymphocytes (TILs). We aimed to investigate the prognostic role of tumor tissue markers correlating with overall survival (OS) and progression-free survival (PFS).

Methods: By immunohistochemistry (IHC), we analyzed on 31 archival formalin-fixed paraffin embedded (FFPE) tissue specimens: CD3, CD4, CD8, CD20, CD45, CD68, CD163, CD66b and PDL-1. Expression values were classified according to density score from 0 to 4 (0=no expression; 1=1-25%; 2=26-50%, 3=51-74%; 4=75%-100%) in two areas: Vascular/perivascular (V) and diffuse in tumor parenchyma (D). Percentage of infiltrating immune system cell was calculated by the rate of absolute number of positive stained cells/total number of cells multiplied by 100.

Results: All tissues were negative for PDL1 and only two positive for CD20. We observed that CD68+ macrophage and CD66b+ neutrophils expressed in V showed a statistically significant prognostic role (p-value of 0.027 and 0.029 respectively) (Table). CD68-V showed a prognostic role for PFS (p-value 0.032), while CD66b-V expression did not. CD3, CD4, CD8, CD45 and CD163 were not associated with OS and PFS.

Conclusions: Despite having a smaller cohort of tissues, we showed a different expression of immune markers. In particular, CD68-V was associated with a significant positive impact on both OS and PFS. This relation could be partially explained because TAM do not raise only from peripheral blood, but also from resident microglia. Moreover, we observed high density of CD66b+ cells in V related to OS probably for growth factors overproduced by tumor cells with their recruitment from blood. Further studies are needed in large series to explore the prognostic role of selected TME immune molecules to develop therapeutic strategies that aim to hit different components of GBM.

526P In silico evaluation of the mutational profile of glioblastomas with high expression of PD1, CTLA4 and LAG3 identifies the ERBB-PI3K pathway as a druggable vulnerability target

C. Saiz-Ladera[1], J. Bartolome[1], A. Manzano Fernández[1], S. Cabezas-Camarero[1], G. Velasco[2], P. Pérez Segura[1], A. Ocana Fernandez[1]

[1]Medical Oncology Dept, Hospital Clinico Universitario San Carlos, Madrid, Spain; [2]Department of Biochemistry and Molecular Biology, UCM - Universidad Complutense de Madrid, Madrid, Spain

Background: Glioblastoma (GBM) is a major therapeutic challenge. Genomic studies have helped to decipher the molecular landscape of commonly deregulated genes in GBM. Unfortunately, approved immune checkpoint inhibitors, such as anti PD1, anti LAG3 and antiCTLA4 agents, have not shown clinical activity in GBM. In this study we explore the mutational profile of tumors with high expression of PD1, LAG3 and CTLA-4, to identify potential druggable vulnerabilities.

Methods: We interrogated TCGA with data from 528 patients. We explored the mutational profile of tumors with high expression of PD1, LAG3 and CTLA4 to explore the associations between the selected mutated genes and immune infiltration using TIMER2.0. Gene Ontology Biological processes related to each gene were explored with the EnrichR platform. Protein expression was evaluated using the Human Surfaceome Atlas.

Results: We selected 82 (15,53%) patients that had high hPDCD1 expression, 84 (15,9%) with elevated hLAG3 levels, and 70 (13,25%) with high hCTLA4. Among the total number of mutated genes in each subgroup we selected only those expressed in > 5% of the patients. As a result, we identified 23 mutated genes in the hPDCD1 subgroup, 66 in the hLAG3 and 69 in the hCTLA4 group. Genes highly mutated in the three subgroups included: TP53 24-30%, EGFR 20-37%, PTEN 15-30%, TTN 24-28% and MUC16 17-20%. This set of genes represented 21% of patients in the hPDCD1 group, 7,57% in hLAG3 and 7,24% in the hCTLA4 group. 21 mutated genes in the hPDCD1 group were shared with the other groups, 13 genes in the hCTLA4 and hLAG3 groups, and only one gene was commonly mutated between hPDCD1 and hLAG3, and between hPDCD1 and hCTLA4 tumors. These frequently mutated genes correlated with the expression of gamma-delta T cells (30% in hPDCD1, 35% in hLAG3 and up to 26% in hCTLA4). Gene set enrichment analysis included: PIK3 and ERBB2 signaling pathway, ion channel activity, protease/phosphatase binding, or C-X3-C chemokine binding.

Conclusions: GBM with high expression of PD1, CTLA4 and LAG3 display frequent mutations in the ERBB-PI3K signaling pathway including EGFR and PTEN. These genes correlated with presence of gamma-delta T cells in tumor infiltrates.

527P Targetable gene fusions and other alterations in central nervous system tumors assessed by RNA and DNA-based next-generation sequencing

L. Wang[1], Y. Wang[2], L. Teng[1]

[1]Pathology, Xuanwu Hospital Capital Medical University, Beijing, China; [2]Medical Department, Burning Rock Biotech, Beijing, China

Background: Central nervous system (CNS) tumors may have an underlying genetic mechanism, where oncogenic fusion proteins play an important role in tumorigenesis. This provides an opportunity to develop specific and effective therapies. Here, we used RNA and DNA- based next-generation sequencing (NGS) to identify actionable or potentially actionable oncogenic fusions and other molecular alterations in our patients with CNS tumors.

Methods: Pediatric and adult patients with CNS tumors treated in our hospital between 2018 and 2022 undergoing surgery were enrolled. Fusion transcript detection and mutation analysis in FFPE tumor samples were assessed by both DNA-based next-generation sequencing (NGS) assay (520-gene panel) (Burning Rock OncoScreen Plus, Burning Rock Biotech, China) and RNA-based NGS assay (115 fusion-related-gene panel) (OncoRNA, Burning Rock Biotech, China) to identify molecular alterations.

Results: NA-based NGS detected 50 tissue samples from 50 enrolled patients. RNA-based NGS successfully detected 49 samples, excluding 1 RNA degraded sample. Oncogenic fusions were identified in 63.2% (31/49) of patients by RNA-based NGS. At least 2 kinds of fusion transcripts were detected in 7 patients. Actionable fusions were KIAA1549::BRAF in 13 patients with pilocytic astrocytoma, FGFR1::TACC1 fusion in 2 patients with pilocytic astrocytoma and PTPRZ1-MET fusion in a patient with high-grade glioma. ZFTA::RELA fusions were found in 13 patients with ependymoma. A total of 31 patients (62.0%) were identified with at least an actionable or potentially actionable alteration by RNA- or DNA-based NGS. Besides targetable fusions, actionable alterations were most often located in SETD2 mutation (n=8), CDKN2A deletion (n=4) and CDKN2B deletion (n=4).

Conclusions: The combination of RNA- and DNA-based NGS provides information about molecular alterations for the management of patients with CNS tumors. Those with actionable gene fusions or other alterations may benefit from target therapy, especially in the setting of limited choice of treatments.

528P Progression risk after pregnancy in patients with glioma

A. Leibetseder[1], M. Mair[2], M. Aichholzer[3], G. Widhalm[4], F. Eckert[5], A. Wöhrer[6], S. Weis[7], R. Helbok[1], M. Preusser[2], J. Pichler[8], A.S. Berghoff[2]

[1]Department of Neurology, Kepler University Hospital GmbH, Johannes Kepler University Linz, Linz, Austria; [2]Department of Medicine I, Division of Oncology, Medical University of Vienna, Vienna, Austria; [3]Department of Neurosurgery, Kepler University Hospital GmbH, Johannes Kepler University Linz, Linz, Austria; [4]Department of Neurosurgery, Medical University of Vienna, Vienna, Austria; [5]Department of Radiooncology, Medical University of Vienna, Vienna, Austria; [6]Department of Neurology, Division of Neuropathology and Neurochemistry, Medical University of Vienna, Vienna, Austria; [7]Department of Pathology and Molecular Pathology, Division of Neuropathology, Kepler University Hospital GmbH, Johannes Kepler University Linz, Linz, Austria; [8]Department of Internal Medicine and Neurooncology, Kepler University Hospital GmbH, Johannes Kepler University Linz, Linz, Austria

Background: A significant proportion of women with diffuse gliomas are diagnosed in childbearing-age, resulting in the desire of patients to fulfil their family dream. However, data on glioma progression after and during pregnancy are sparse and controversial.

Methods: Female adult patients in their reproductive years (≥18 years and <46 years) with histopathological diagnosis of WHO grade 2 or 3 glioma from 2 academic centres between 01/01/2000 and 01/01/2019 have been included in the study. Diagnosis was updated according to WHO classification of CNS Tumours 2021 by a board-certified neuropathologist. Association of pregnancy and glioma progression was assessed in a time-dependent manner. The following parameters were included in the multivariate analysis: ECOG, extent of resection, WHO grading, adjuvant therapy after surgery, pregnancy after diagnosis.

Results: Of 159 women after a median follow up (FU) of 127.4 months (mo), 47 (29.6 %) were identified as nullipara, 89 (56 %) as primi-/multipara before glioma diagnosis and 23 (14.5 %) as primi-/multipara after diagnosis. Updated diagnosis according to latest WHO classification revealed 92 (57.8 %) astrocytomas (isocitrate dehydrogenase [IDH]-mutant) CNS WHO grade 2 and 3, 54 (33.9 %) oligodendrogliomas (IDH-mutant, 1p/19q codeleted) CNS WHO grade 2 and 3, 11 (7.1 %) glioblastomas (IDH-wildtype) CNS WHO grade 4, and 2 (1.3 %) diffuse midline gliomas (H3-K27-altered). Median overall survival (OS) and progression free survival (PFS) was 247.6 mo (95 % CI 155.7 − 339.5) and 67.9 mo (95 % CI 60.1 − 75.7), respectively. Among 23 patients with glioma diagnosis prior to pregnancy, mean time between diagnosis and conception was 54.6 mo (0.6 − 116 mo). Tumor progression happened in 17 (73.9 %) cases and death occurred in 4 (17.4 %) patients. Mean time from start of pregnancy to date of tumor progression/last-FU or death/last-FU was 35.3 mo (9 − 229.2 mo) and 107.2 mo (17.7 − 229.2 mo), respectively. In multivariate time-dependent analysis, pregnancy after diagnosis in comparison to nullipara or pregnancy before diagnosis was associated with shorter PFS ($p \leq 0.05$), but not with shorter OS ($p > 0.05$).

Conclusions: Pregnancy after glioma diagnosis is associated with shorter PFS. Longer follow up as well as larger cohorts are needed to investigate a potential impact on OS.

529P Post-marketing surveillance data from patients ≥70 years of age with central nervous system malignancies treated with Tumor Treating Fields (TTFields) therapy between 2011 −2022

W. Shi[1], M. Glas[2], M.M. Mrugala[3], F.M. Iwamoto[4], R.V. Lukas[5], J. Palmer[6], J. Suh[7]

[1]Department of Radiation Oncology, Thomas Jefferson University Hospital, Philadelphia, PA, USA; [2]Division of Clinical Neurooncology, Department of Neurology, University Hospital Essen, University Duisburg-Essen, West German Cancer Center (WTZ) and German Cancer Consortium, Partner Site, Essen, Germany; [3]Department of Neurology and Hematology-Oncology, Mayo Clinic Cancer Center, Phoenix, AZ, USA; [4]Division of Neuro-Oncology, New York-Presbyterian/Columbia University Medical Center, New York, NY, USA; [5]Department of Neurology, Northwestern University, Chicago, IL, USA; [6]The Department of Radiation Oncology, The James Cancer Hospital, Ohio State University Wexner Medical Center, Columbus, OH, USA; [7]Department of Radiation Oncology, Taussig Cancer Institute, Cleveland Clinic, Cleveland, OH, USA

Background: Glioblastoma (GBM) is among the most aggressive central nervous system (CNS) malignancies. Furthermore, older age is associated with increased risk of treatment-related systemic toxicity. TTFields are electric fields that exert physical forces to disrupt cellular processes critical for cancer cell viability. TTFields therapy is approved for recurrent and newly diagnosed GBM, following the pivotal phase 3 EF-11 (TTFields 200 kHz) and EF-14 studies (TTFields 200 kHz + temozolomide), respectively, which demonstrated clinical benefit without additional systemic adverse events (AEs). We report safety data from patients (pts) ≥70 years of age with CNS malignancies receiving TTFields from a global post-marketing surveillance (PMS) analysis.

Methods: Unsolicited PMS data were collected from pts receiving TTFields globally (October 2011—March 2022). Data from pts ≥70 years old are reported here. AEs were categorized using MedDRA version 25.1.

Results: Overall, 25,898 pts from the US, Europe and Israel, and Japan were included. Of these, 4,071 (16%) were ≥70 years old. Overall, 75% of patients ≥70 years old experienced ≥1 AE, with 56% being related to TTFields, which is comparable to the overall population (73% and 56%, respectively). The most common TTFields-related AEs in the ≥70-year-old population were skin reaction (45%; overall population: 43%), heat (warmth) sensation (11%; overall population: 14%), and electric (tingling) sensation (10%; overall population: 14%). Serious AEs for the ≥70-year-old and overall group were 27% and 22%, respectively. No systemic toxicities were reported, regardless of age.

Conclusions: These long-term, real-world PMS data demonstrate that TTFields has a tolerable safety profile in pts ≥70 years old with CNS malignancies, with no new safety signals. Most AEs were localized skin reactions which can be easily managed. Real-world data of TTFields therapy in elderly subgroups provides clinicians with insights on adapting strategies to optimize treatment management.

[1]Radiation Oncology, Health Care Global Enterprises, Nagpur, India; [2]Radiation Oncology, HCG Hospital, Bangalore, India; [3]Radiation Oncology, HCG HealthCare Global Enterprises Ltd, Bangalore, India; [4]Medical Oncology, HCG Bangalore Institute of Oncology Speciality Centre, Bangalore, India; [5]Oncology, Sakra World Hospital, Bangalore, India; [6]Medical Oncology Department, HCG HealthCare Global Enterprises Ltd, Bangalore, India; [7]Medical Oncology, Sagar Hospital and Research Centre, Bengaluru, India; [8]Radiation Oncology, HCG HealthCare Global Enterprises Ltd, Bangalore, Tanzania; [9]Neurosurgeon, Sakra World Hospital, Bangalore, India; [10]Neurosurgeon, Trustwell Hospital, Bangalore, India; [11]Neurosurgeon, Brains hospital, Bangalore, India; [12]Radiation Oncology, HCG Cancer Center, Gulbarga, India

Background: High grade gliomas are primary malignant brain tumors where surgery followed by radiotherapy and chemotherapy remains the standard of care. Majority of patients manifest with post treatment changes like necrosis, edema or pseudoprogression for which the management is challenging. Currently steroids remain the treatment of choice in such scenarios but have many dose limiting toxicities. Bevacizumab (BEV) is approved in recurrent HGG. Fewer studies with dose de escalation up to 50% of standard dose have attained similar results in control. However it's anti angiogenic/anti edema effect is quite unexplored in management of post treatment changes. In our study, we analyzed the role of BEVULTRA-100 in symptomatic/asymptomatic HGG as an alternative to steroids.

Methods: In this prospective, interventional single arm study, 117 patients of HGG treated with chemotherapy and radiotherapy as primary modality from July 2013 till April 2023 were included. All patients received Ultra-Low Dose Bevacizumab - 100 mg once in every month along with oral temozolomide. Complete blood counts and vitals were monitored before each cycle. All patients were assessed at regular intervals for clinical and imaging parameters-DOPA PETCT & MRI in regards with post treatment changes.

Results: Median age was 44.5 years Range: 9 to 70. M:F ratio of 1.54 :1. A Median of 12 cycles UltraBEV (Range:1 to 62) were received (1514 cycles in total). All patients tolerated well without any significant toxicities. None of the patients had intracranial/tumoral bleed. Use of steroids was markedly reduced in more than 90% patients with BEVULTRA-100 resulting in substantial improvement in the QOL. Similar pattern was observed in imaging parameters including reduction of post treatment edema.

Conclusions: This pilot study aims at providing a proof of concept for BEVUltra100 in management of post treatment changes in HGGs. This is a feasible, cost effective option with better compliance compared to steroids with improved survival. This study also paves a trailblazing path for exploring the field of radiation dose escalation and reirradiation with adequate control over toxicities improving the QOL, which might translate into improved survival.

531P Tumor treating fields therapy for glioblastoma: Identifying needs and satisfaction of new and long-term users

E.T. Batzianouli[1], R. Adams[2], H. Johnson[2], H. Abdullah[3]

[1]Global Medical Affairs, Novocure GmbH, Root, Switzerland; [2]US Medical Affairs, Novocure Inc, New York, NY, USA; [3]Global Medical Affairs, Novocure Inc, New York, NY, USA

Background: Tumor Treating Fields (TTFields) therapy uses electric fields to disrupt processes critical for cancer cell survival. TTFields therapy delivered by a wearable, portable device is approved in several counties for the treatment of newly diagnosed and recurrent glioblastoma (GBM), including Germany, Austria, Switzerland (DACH) and the US, and is under investigation for other tumour types.

Methods: Two surveys (independently developed and administered) were distributed (mail and online) in DACH and the US to patients/caregivers using TTFields (Optune(R); Novocure(R) GmbH, device manufacturer) as therapy for GBM.

Results: Between 1 January—31 December 2022, 545 (DACH) and 1282 (US) patients/caregivers returned surveys (response rates of 43% and 27%, respectively). In DACH, 43% had recently initiated therapy ("new starters"; 66% were male, 55% were ≥60 yrs of age). In the US, 31% of responses were from new starters; 69% were male and 63% were ≥60 yrs. Respondents with TTFields usage of >6 months (long-term users) accounted for 21% of DACH and 29% of US surveys; most were male (59% in DACH; 65% in US), and around half were ≥60 yrs of age (40% in DACH; 55% in US). Overall satisfaction (*very satisfied*, *satisfied*, *mixed*, *less satisfied* or *dissatisfied*) with TTFields was high; most respondents indicated they were very satisfied or satisfied (82% and 61% of new starters, and 67% and 74% of long-term users, in DACH and the US, respectively). Amongst long-term users, most noted that using TTFields required changes to daily life (63% DACH; 57% US). Frequently mentioned changes related to skin irritation, device handling, and impact of weight/portability on lifestyle. Despite this, the majority (74% in DACH; 73% in US) of long-term TTFields users/caregivers would recommend the treatment for GBM.

Conclusions: Surveys returned in DACH and the US showed the population of TTFields therapy users was representative of patients with GBM. Users from both surveys had a high level of satisfaction with the therapy and mostwould recommend it to others. Any potential concerns regarding device handling/portability can perhaps be mitigated by increased educational and communication efforts.

532P Nitric oxide is a target by a combo-drug for glioblastoma treatment

M.K. Tripathi, S.K. Ojha, H. Amal

School of Pharmacy, The Hebrew University of Jerusalem, Jerusalem, Israel

Background: Glioblastoma is the most common and aggressive type of primary brain tumor, with a high morbidity and mortality rate. Nitric oxide (NO) has been shown to have diverse effects on various cancers, including glioblastoma. Nitric oxide synthase (NOS) activation has been implicated in the growth and progression of glioblastoma. In this study, we investigated the effects of our novel two drugs HU-53 and HU-54, on the U87-MG cell line and a xenograft model of glioblastoma. Both drugs attenuate nitrative stress through different mechanisms.

Methods: NOD.CB17-Prkdc-scid/NCrHsd mice were used for the xenograft subcutaneous tumor model to evaluate the ability of HU-53 and HU-54 treatment regimens. Both treatments were given intraperitoneally. Tumor weight and volume were measured during the study. The experiments were also carried out on the human-derived U87-MG cells. Nitrite content was measured biochemically by Griess assay. Immunofluorescence and immunoblotting assessed nitrosative stress.

Results: We found that treatment with the combo-drug resulted in a significant decrease ($P<0.0001$) in cell viability and proliferation as compared to vehicle in the U87-MG cell line. The combo-drug also induced apoptosis as evidenced by increased caspase-3 activity. In addition, treatment with HU-53 and HU-54 resulted in a significant reduction ($p<0.0001$) in tumor growth in the xenograft model of glioblastoma, as demonstrated by decreased tumor volume and weight. Furthermore, we observed that the combo treatment resulted in a significant decrease in the level of nitrite content ($p<0.02$) and 3-Nitrotyrosine (a marker of nitrosative stress) which are important mediators of glioblastoma growth.

Conclusions: Our results suggest that targeting the nitrosative stress with HU-53 and HU-54 may be a promising therapeutic strategy for glioblastoma treatment.

533P Oligodendrogliomas: What is the impact after the introduction of the WHO molecular classification?

M.A. Vaz Salgado[1], J. Earl[2], J.M. Sepulveda Sanchez[3], Y. Ruano[4], J. Gutierrez[4], H. Pian[5], L.L. Ley[6], M.L. Villamayor Delgado[1], A. Carrato Mena[1], E. Fernandez[7], M. Martin[8], R. Ferreiro Monteagudo[1], F. Longo Muñoz[1], M. Rodriguez[1], V. Albarrán[1], J. Pozas Perez[1], P. Alvarez Ballesteros[1], M.V. San Roman Gil[1], A.H. lain[9]

[1]Medical Oncology Department, Hospital Universitario Ramon y Cajal, Madrid, Spain; [2]IRYCIS, Carretera Colmenar Km 9,10., Hospital Universitario Ramon y Cajal, Madrid, Spain; [3]Medical Oncology Department, Hospital Universitario 12 de Octubre, Madrid, Spain; [4]Pathology, Hospital Universitario 12 de Octubre, Madrid, Spain; [5]Pathology, Hospital Universitario Ramon y Cajal, Madrid, Spain; [6]Neurosurgery, Hospital Universitario Ramón y Cajal, Madrid, Spain; [7]Radiotherapy, Hospital Universitario Ramon y Cajal, Madrid, Spain; [8]Radiation Oncology Department, Hospital Universitario Ramon y Cajal, Madrid, Spain; [9]Av. de Córdoba s/n. Edificio; CAA, 6o Planta Bloque D, UCM - Universidad Complutense de Madrid, Madrid, Spain

Background: Oligodendrogliomas are rare tumors and affect young people. In 2016, the new WHO classification was introduced that includes molecular features (IDH mutation and 1p/19q codeletion) that were not present in previous classifications. Currently, there is no data indicating the impact of this new classification on our clinical practice. The objective of this study is to review the clinical evolution of a cohort of patients, before and after reclassification, using molecular criteria.

Methods: Cases with a diagnosis of grade 2 and grade 3 oligodendroglioma and oligoastrocytoma were identified in the registries of two tertiary hospitals. A total of 182 cases, corresponding to a period of 37 years (between 1977 and 2014), were identified and termed initial cohort. Subsequently, IDH mutation and codeletion of 1p/19q analysis were performed in this cohort. A total of 91 patients fulfilled these characteristics and were termed the reclassified cohort. The clinical evolution of both cohorts was analyzed.

Results: The mean age of the cohort was 45 years (14-75), with a Males: Female ratio of 61%/39%. Frontal lobe location 60%, 65% grade 2 and 22% oligoastrocytomas. Complete resection 47% (subtotal 22%, partial 20%, biopsy 7%). After surgery, 50% received radiotherapy, 30% chemotherapy, 36% did not receive adjuvant therapy. The median follow-up was 9 years. Unlike what was observed in the initial cohort, there were no statistical differences in median overall survival (OS) in the reclassified cohort regardless of grade; grade 2, 13.3y (95%CI 8.2-18.4), grade3, 12 years (95%CI 5.6-18.3), therefore, grade loses its prognostic impact with the new molecular classification. OS in the excluded cohort was 7.52years (95%CI 4.67-10.38). The OS in those cases without adjuvant treatment was 12 years. 30% of oligoastrocytomas in the initial cohort were reclassified to oligos.

Conclusions: Molecular classification allows a more accurate selection of oligodendrogliomas and implies that cases have a better prognosis, regardless of grade and treatment received. These data should be taken into account in clinical practice for a better selection of the risks and benefits of adjuvant treatment.

534P Glioblastoma treatment in patients older than 60 years: Hypofractionated radiotherapy and temozolomide versus conventional radiotherapy and temozolomide

T. Pacheco[1], M. Müller[2], D.D.C.M.E.S. Delgado[3], A.N. de Abrunhosa Branquinho[3], A. Figueiredo[1], L.A. Marques Da Costa[4], M.L. Albuquerque[4]

[1]Oncology Department, CHL Norte - Sta. Maria, Lisbon, Portugal; [2]Medical Oncology, HSM - Hospital Santa Maria - Centro Hospitalar Universitario de Lisboa Norte E.P.E., Lisbon, Portugal; [3]Radiotherapy Department, HSM - Hospital Santa Maria - Centro Hospitalar de Lisboa Norte E.P.E., Lisbon, Portugal; [4]Oncology Dept., HSM - Hospital Santa Maria - Centro Hospitalar Universitario de Lisboa Norte E.P.E., Lisbon, Portugal

Background: Treatment of glioblastoma patients under 70 years and with good Karnofski performance status (KPS>70) associates standard radiation therapy (SRT, 60 Gy in 30 fractions) with concomitant and adjuvant temozolomide for 6 monthly cycles (SRT-TMZ). Clinical trials of glioblastoma radiation treatment in patients older than 60 years (≥60-ys) showed no significant difference in survival comparing SRT to hypofractionated radiotherapy (HRT, 40.05 Gy in 15 fractions). Adding TMZ to HRT (HRT-TMZ) in patients ≥65-ys have translated into increased median overall survival (mOS) and progression-free survival (mPFS). In daily clinical practice, as in previous retrospective studies, older patients and/or those with KPS ≤70 may still be treated with radiation and temozolomide regardless of the MGMT tumor status, often opting for HRT-TMZ.

Methods: We retrospectively included all glioblastoma patients older than 60 years treated from 2017 to 2021 in our hospital with SRT-TMZ or HRT-TMZ. The primary endpoint was OS. The secondary endpoints were PFS, survival at 12 months (mo) and toxicity profile. Comparisons were made using Fisher's exact test and Mann-Whitney test. Survival curves were estimated using the Kaplan-Meyer method and compared using the log-rank test.

Results: 69 patients were treated, 33 with SRT-TMZ and 36 with HRT-TMZ. Median age was significantly different between these two groups (64 ys [range 60-70]) vs. 71 ys [range 62-85]), p<0.0001). KPS, extent of surgery, MGMT and IDH status did not show significant differences between groups. mPFS was 9 mo for SRT-TMZ vs. 10.2 mo for HRT-TMZ (p=0.57) and mOS was 14.8 mo vs. 13.8 mo (p=0.99), respectively. Treatment with SRT-TMZ was associated with increased thrombocytopenia events at the end of the first phase (p=0.01).

Conclusions: In real world, elderly glioblastoma patients pragmatically oriented to HRT-TMZ still had similar OS and PFS as younger patients treated with standard and potentially more toxic SRT-TMZ. This may support the extended use of HRT-TMZ in patients above 60 years.

535P Hypofractionated radiotherapy in fit elderly patients with glioblastoma: Relevant or detrimental?

C.M. Martín Abreu[1], R. Sun[2], S.N. Dumont[1], M-S. Minot This[1], T. Grinda[1], N. Epaillard[1], D. Guyon[1], G. Garcia[3], J. Pallud[7], E. Dezamis[4], N. Aghakhani[5], M. Bouchaala[5], C. Adam[6], R. Saffroy[7], P. Varlet[8], A. Tauziede-Espariat[9], I. Issoufaly[9], I. Benchara[1], F. Dhermain[9], S. Bockel[9]

[1]Medical Oncology Department, Institut Gustave Roussy, Villejuif, France; [2]Radiation Oncology Department, Institut Gustave Roussy, Villejuif, France; [3]Department of Imaging, Gustave Roussy - Cancer Campus, Villejuif, France; [4]Neurosurgery Department, Sainte-Anne Hospital, Paris, France; [5]Neurosurgery Department, Kremlin-Bicêtre Hospital, Paris, France; [6]Pathology Department, Kremlin-Bicêtre Hospital, Paris, France; [7]Molecular Biology Department, Kremlin-Bicêtre Hospital, Paris, France; [8]Pathology Department, Sainte-Anne Hospital, Paris, France; [9]Radiotherapy Department, Gustave Roussy, Villejuif, France

Background: Glioblastoma (GBM) is the most common malignant primary brain tumor in adults. It remains a relatively rare disease with an incidence of 3/100.000 in France, and an age-related peak in incidence at 70 years of age, which corresponds to the age limit inclusion criteria of the Stupp Trial on 2005, cornerstone of the GBM strategy. Therefore, treatment of GBM in elderly patients is not standardized and depends on several clinical and biological factors. The aim of this study is to compare survival outcome of elderly patients with glioblastoma treated with standard radiotherapy (SRT) versus hypofractionated radiotherapy (HRT) versus no radiotherapy (RT), with or without Temozolomide.

Methods: A single-center retrospective case series analysis was conducted, including newly diagnosed GB patients older than 70 from January 2010 to December 2021. The Log-Rank test was used to compare the PFS and OS of patients treated with SRT versus HRT versus no RT. Furthermore, a Cox regression analysis was performed to identify risk factors associated with OS. Statistical significance was considered when p<0.05.

Results: A total of 304 patients were included with a median age of 74.36 years [71.63, 78.62], among whom, 142 were women. Most patients had a performans status of 0 or 1. Median OS was 11.4 months [95% CI 10.4 − 12.3] while median PFS was 8.1 months [95% CI 7.4 − 9.1]. Overall, 231 patients (76%) were treated with RT, 94 (30.9%) with SRT, 129 (42.4%) with HRT and 73 (24%) did not receive RT. On univariate analysis, the SRT group showed a better OS compared to the HRT and no RT groups (23.1 months, 11.1 months and 4.7 months, respectively, p<0.01). Same trend was observed for median PFS (SRT 13.6 months, 8.08 months and 3.7 months respectively, p<0.05).

Conclusions: While previous randomized trials showed a benefit or non-inferiority of HRT over SRT in elderly glioblastoma patients, this large retrospective "real-life" cohort shows on the contrary a benefit in terms of OS of the standard normo fractionated RT regimen. Standard treatment should not always be degraded in elderly patient, and a proportion of them may still benefit from standard RT if their clinical status allows it.

536P Safety and efficacy of silibinin in patients with brain metastases after stereotactic radiosurgery (SRS): The SUSTAIN trial

N. Bertini[1], L. Visani[2], I. Bonaparte[1], M.G. Carnevale[1], B. Bettazzi[1], A. Romei[1], C. Becherini[2], D. Greto[2], B. Detti[2], I. Meattini[1], L. Livi[1], I. Desideri[1]

[1]Department of Experimental and Clinical Biomedical Sciences "M. Serio" - University of Florence, Azienda Ospedaliero-Universitaria Careggi, Florence, Italy; [2]Radiation Oncology Unit, Oncology Department, Azienda Ospedaliero-Universitaria Careggi, Florence, Italy

Background: Brain metastases (BMs) account for more than one-half of all intracranial tumors. In recent years, stereotactic radiosurgery (SRS) has become the mainstay of BMs treatment, providing high rates of local tumor control. Nevertheless, SRS alone is associated with a 30-50% risk of distant brain failure (DBF), consequently requiring careful follow-up and possible rescue treatments. Silibinin or silybin, a natural polyphenolic flavonoid, has shown promising antitumor activity, leading to improvement of BMs in patients with progressive non-small cell lung cancer. Therefore, our exploratory study aims to evaluate whether the use of a silibinin-based nutraceutical (SILLBRAIN, HEALTH4U S.r.l.) can significantly reduce DBF rate at 6 months in patients with first-diagnosed BMs treated with SRS with or without surgery.

Methods: SUSTAIN is an interventional, prospective, single-arm, phase II study. A total of 80 patients treated in our institution are planned to be enrolled. Patients receive 2 capsules of SILLBRAIN per day for the first month after SRS and 1 capsule per day thereafter. Primary endpoints are 6-month distant brain failure (DBF) rate and safety.

Results: Thirty patients have been enrolled at the time of the primary analysis. NSCLC and breast cancer were the prevalent histologies. Overall, the number of treated lesions was 73, with a median of 1 lesion (range 1-9). All patients underwent SRS,

with a median prescription dose and a median prescription isodose line of 24 Gy and 80%, respectively. After a 14-month enrollment period, with a median follow-up of 9 months, 6 patients reported DBF according to RANO-BM criteria, with a 6-month DBF rate of 20%. Only 1 treated lesion met the criteria for progression, accounting for a 6-month local control (LC) rate of 98%. Six patients died, with a 6-month OS rate of 80%. Two patients discontinued SILLBRAIN assumption due to G1 nausea. No other adverse events were reported.

Conclusions: At about half of our enrollment target, the results show a favorable trend towards 6-month DBF rate reduction. Toxicity proved manageable, consistent with the literature and limited to gastrointestinal effects. A larger sample and longer follow-up are needed to confirm our hypothesis.

537P S100A9 serum levels are associated with survival prognosis in patients with brain metastases

A. Steindl[1], A. Kienzle[2], E. Tomasich[3], J.M. Berger[4], C. Englisch[1], L. Gottmann[1], M. Korpan[1], M. Kleinberger[1], A.M. Starzer[5], B. Kiesel[6], G. Widhalm[6], F. Eckert[7], M. Preusser[8], A.S. Berghoff[9]

[1]Department of Medicine I, Medical University of Vienna, Vienna, Austria; [2]Department of Internal Medicine I, MedUni Wien - Medical University of Vienna, Vienna, Austria; [3]Division of Oncology, Department of Medicine I, Medical University of Vienna, Vienna, Austria; [4]Student, Medizinische Universität Wien, Vienna, Austria; [5]Oncology Clinical Division, Medicine Department I, Medizinische Universitaet Wien, Vienna, Austria; [6]Department of Neurosurgery, MedUni Wien - Medical University of Vienna, Vienna, Austria; [7]Department of Radiooncology, MedUni Wien - Medical University of Vienna, Vienna, Austria; [8]Division of Oncology, Department of Medicine I, Universitätskliniken der MedUni Wien - AKH Wien, Vienna, Austria; [9]Department of Medicine 1/Division of Oncology, Universitätskliniken der MedUni Wien - AKH Wien, Vienna, Austria

Background: Brain metastases (BM) are a clinical challenge in oncology. Further insight on pathobiology is the basis for new treatment approaches. Recently, S100A9 has been postulated as a novel potential biomarker for therapy resistance to radiotherapy in preclinical BM models. Therefore, we aimed to explore S100A9 levels in a real-life BM patient cohort.

Methods: S100A9 protein expression was measured in the serum of patients treated at the Medical University of Vienna between 2019-2023 using an enzyme-linked immunosorbent assay (ELISA) to correlate its levels with clinicopathological parameters. Sample concentrations below the lower limit of quantification (LOQ) were treated as 50% of LOQ's concentration and considered as non-quantifiable. Samples with a concentration above the upper limit of quantification were remeasured in dilutions.

Results: 80 patients (39% male; 61% female) with BM (n=69) and without BM (n=11) were included in this pre-liminary analysis. Median serum level of S100A9 was 23 pg/mL (IQR 16-97 pg/mL). No difference in median S100A9 levels were observed between patients with BM (23 pg/mL, IQR 16-114) and without BM (23 pg/mL, IQR 15-41) at time of blood sampling (p=0.7). Furthermore, no difference was found in median S100A9 levels in BM patients according to primary tumor's origin (lung cancer 23 pg/mL vs. breast cancer 16 pg/mL, p=0.6) or radiated versus non-radiated BM (37 pg/mL vs. 23 pg/mL, p=0.3). Median overall survival of patients with quantifiable S100A9 levels were significantly longer than patients with non-quantifiable S100A9 serum levels (HR 2.05; p=0.05).

Conclusions: Based on the results of these pre-liminary data, S100A9 levels did neither correlate with BM diagnosis, primary tumor's origin nor previously applied radiotherapy. However, detected S100A9 levels correlated with survival analysis in this real-life BM patients. Further studies are currently ongoing to further evaluate S100A9 as a diagnostic and predictive biomarker in larger real-world patient cohorts.

538P Single-center retrospective analysis of patients with brain metastases included in early phase clinical trials

G. Pretelli, K.I. Rojas Laimito, G. Alonso, M.J. Lostes Bardaji, A. Hernando Calvo, V. Galvao, A. Oberoi, B. Ortega Morillo, O. Saavedra Santa Gadea, J. Ginard Moya, C. Saura Manich, M.E. Elez Fernandez, C. Ortiz, E. Muñoz Couselo, I. Braña, A. Callejo Perez, J. Carles Galceran, E. Felip, E. Garralda, M. Vieito Villar

Department of Medical Oncology, Vall d'Hebron Institute of Oncology (VHIO), Barcelona, Spain

Background: Historically patients (pts) with brain metastases (BM) were excluded from early phase clinical trials due to concerns over prognosis, risk of toxicity or lack of brain penetrance. Recent trials allow the inclusion of pts with stable (asymptomatic and/or treated) BM, as recommended by the ASCO and Friends of Cancer Research Brain Metastases Working Group. We aimed to describe the outcomes of patients with BM enrolled in early phase clinical trials.

Methods: Retrospective cohort analysis of clinical and treatment (trt) response data of pts included in early phase clinical trials at Vall d'Hebron Institute of Oncology between January 2012 and April 2023. Objective response rate (ORR) and disease control rate (DCR) were calculated. Median progression free survival (PFS) and overall survival (OS) were estimated using the Kaplan-Meier method, survival between groups was compared using log-rank test and cox regression.

Results: A total of 815 pts treated at our center were analyzed; 51 pts had stable BM at inclusion, 28 (54.9%) male and 23 (45.1%) female. Most frequent types: lung (51.0%), melanoma/skin (23.5%). Forty-one pts (80.4%) received prior brain trt: 37 radiotherapy, 3 surgery and 1 both. Ten pts (19.6%) were included with asymptomatic untreated BM. Type of experimental trt: immunotherapy 72.5%, targeted therapy 21.6%, antibody-drug conjugates 5.9%. Phase of clinical trial in which pts were included: phase 1 dose escalation 23.5%, phase 1 expansion cohorts 70.6%, and phase 2 basket studies 5.6%. Median OS in pts without BM was comparable to those with: 9.1 months vs 6.3 (p=not significant); median PFS was superior in BM pts: 1.8 vs 2.6 (HR 0.52, $p<0.0001$). The rate of OS<3 months was 31.4% in BM pts and 33.3% had PFS>4 months. ORR and DCR were respectively 19.6% and 54.9%, intracranial ORR and DCR were 7.8% and 72.7%. Only 4 pts discontinued treatment due to isolated intracranial progression (iPD), and 2 had iPD as best response. There were no statistically significant differences in PFS and OS of pts with treated BM and asymptomatic untreated BM.

Conclusions: The trt response and survival data for pts with BM in our cohort support the recommendations of ASCO and Friends of Cancer Research on the inclusion of pts with BM in clinical trials.

Background: Lung cancer (LC) has the highest rate of brain metastases (BM). The aim of this study is to analyze the incidence, survival, and prognostic factors of LC patients with BM from a retrospective cohort.

Methods: Population-based study of LC patients with BM diagnosed in the province of Girona, Spain between 2010-2019. Clinical records were searched for BM in June 2021 and the end follow-up was 31 December 2022. The age-standardized rates (ASR) (2013 European) were calculated. Kaplan-Meier method and Cox regression model were used for analysis of survival and prognostic factors.

Results: 3,952 LC cases were identified, 15.8% (n=625) developed BM. According to histology, BM were more common in adenocarcinoma (ADC) (21.1% [306/1450]), followed by small cell lung cancer (SCLC) (20.3% [108/533]), not otherwise specified (NOS) (14.2% [133/936]), and squamous (SQ) (7.6% [78/1033]). Among the 625 patients with LC and BM, 72.6% were male and the median age was 63 years [IQR: 56-70]. Histologically, 49.0% had ADC, 21.3% had NOS, 17.3% had SQ, and 12.5% had SCLC. Most were diagnosed at stage IV (79.8%) and 68.7% had synchronous BM. The ASR of LC and BM was 9.3 cases per 100,000 p-y (95%CI: 8.6-10.1). During follow-up, 602 patients died; median survival was 2.8 months (95%CI: 2.5-3.2). However, median survival increased from was 2.4 months in 2010-2014, to 3.3 months in 2015-2019 (p=0.009). In multivariate analysis, histology, targetable mutant status, extra-cranial disease, number of BM, BM size, BM surgery, radiotherapy, and systemic treatment were statistically significant independent prognostic factors (Table).

Table: 539P Prognostic factors

	Multivariate analysis	
	HR (95%CI)	p-value
BM size	1.01 (1.00-1.02)	0.006
Histology		
Adenocarcinoma	1	0.005
Squamous	1.61 (1.18-2.21)	0.003
Small cell	1.45 (1.05-1.98)	0.022
NOS	1.45 (1.07-1.95)	0.015
Targetable mutations	0.60 (0.42-0.86)	0.006
Extra brain disease	1.28 (1.01-1.62)	0.045
Number of BM		
≥4	1.26 (1.00-1.59)	0.049
ECOG at diagnosis of BM		
≥2	1.73 (1.32-2.27)	<0.001
Brain surgery	0.49 (0.33-0.73)	<0.001
Brain radiotherapy	0.67 (0.52-0.85)	0.001
Systemic treatment BM	0.41 (0.31-0.53)	<0.001

Conclusions: There is a high rate of BM in patients with LC, especially in ADC and SCLC. Our data suggest that many factors may have an impact on the survival of patients. Although the prognosis for patients with LC and BM remains a major challenge, data show an improving trend.

540P Impact of adjuvant radiotherapy (ART) on survival time in patients with hemangiopericytoma (HPC): A population study

T.A. Alshwayyat[1], S.A. Alshwayyat[2], A.A. Erjan[3], M. Alshwayyat[1], H. Kamal[4]

[1]Faculty of medicine, JUST - Jordan University of Science and Technology, Irbid, Jordan; [2]Medicine School, JUST - Jordan University of Science and Technology, Irbid, Jordan; [3]Radiation Oncology, KHCC - King Hussein Cancer Center, Amman, Jordan; [4]Medicine, JUST - Jordan University of Science and Technology, Irbid, Jordan

Background: HPC is a rare solitary fibrous tumor of the central nervous system (CNS), accounting for only 1% of all vascular tumors. Surgery is the standard treatment. However, the role of ART remains controversial. Therefore, we conducted this study to evaluate the impact of ART on the overall survival (OS) and cancer-specific survival (CSS) of patients with HPC.

Methods: Data were obtained from the Surveillance, Epidemiology, and End Results (SEER) database between 2000 and 2019. Patients with a history of cancer or concurrent malignancies, lacking pathologic diagnosis, tumor not arising from the CNS, and those with unknown data were excluded. T-tests and chi-square tests were used to compare variables, while the Kaplan-Meier estimator, log-rank tests, and Cox proportional hazard regression were used to identify prognostic factors of OS and CSS.

Results: The study population comprised 395 patients. Among them 121 patients with "Surgery," 246 patients with "Surgery + ART", 10 patients with "Surgery + Chemotherapy" and 18 patients received "Surgery + ART + Chemotherapy". Of the patients, 55.2% were females, and 60.5% were over 50 years old. The average tumor size was 5 cm. The white group was the largest racial group (N=315). Most cases (51.9%) had a tumor size greater than 5 cm, with a median tumor size of 5 cm. Most cases were localized (65.8%), and a few had distant metastasis (8.6%, n=34). "Surgery + ART" had the best survival outcome 5-year OS of 81.5%, followed by "Surgery + ART + Chemotherapy" and "Surgery + Chemotherapy" both 80%, and "Surgery" at 61.1%. The therapeutic groups showed significant differences in the OS and CSS ($p<0.022$ and $p<0.017$, respectively). Localized stage positively impacted OS and CSS, while age and metastasis had a negative impact. Multivariable analysis confirmed that "Surgery + ART" improved both 5-year OS and CSS (HR=0.6, 95%CI:0.42-0.87 and HR=0.33, 95%CI:0.14-0.77, respectively).

Conclusions: Our results showed that ART may improve the OS and CSS in patients with HPC. These findings provide valuable insights into HPC treatment and may inform future clinical decisions. However, further research is needed to validate these results and investigate any potential confounding factors that may have affected the outcomes.

541P A multicenter study evaluating the clinical and molecular characteristics of adult patients with diffuse midline and non-midline K27M altered gliomas

M.A. Mazariegos Rubi[1], A. Ramos Fresnedo[2], M.E. Jentoft[2], D. Trifiletti[3], K. Chaichana[4], I. Otero Blas[5], T. Burns[4], A. Porter[6], W.J. Sherman[2], J.L. Campian[7], A. Quinones Hinojosa[4]

[1]Oncology Department, Clinic Hospital of Barcelona, Barcelona, Spain; [2]Neuro-Oncology, Mayo Clinic - Florida, Jacksonville, FL, USA; [3]Radiation Oncology, Mayo Clinic, Jacksonville, FL, USA; [4]Neurosurgery, Mayo Clinic - Florida, Jacksonville, FL, USA; [5]Oncology, University Hospital of Toledo, Toledo, Spain; [6]Neuro-Oncology, Mayo Clinic - Rochester, Rochester, MD, USA; [7]Oncology, Mayo Clinic - Rochester, Rochester, MD, USA

Background: Diffuse midline high grade glioma (DMG), H3 K27-altered previously known as DMG H3 K27M-mutant can appear both in childhood and in adulthood and the presence of this mutation is a well-known marker for poor prognosis with a median survival of around 9 months regardless of the histologic appearance. The goal of this retrospective study is to describe our multi-institutional experience with the clinical and molecular characteristics of these tumors in adults.

Methods: We retrospectively reviewed the electronic medical records (EMR) of all consecutive adult patients that underwent a surgical procedure for glioma excision and whose tissue was tested for the K27M mutation either by next generation sequencing (NGS) or immunohistochemistry (IHC) at the three main sites of our institution (Florida, Minnesota, and Arizona) from inception of the EMR to date.

Results: A total of 245 adult patients were included in this study, 138 (56.32%) male and 107 (43.68%) female with a median age of 48.50 years. Of these, n=72 (29.39%) had a K27M alteration and n= 173 were K27M wt. The most frequent location for the K27M altered and the K27M wt was the thalamus (n=30, 41.67% and n=45, 22.5%). In the H3K27M-altered group, the main 3 treatments were TMZ + RT in n= 36 (13.2%), RT alone in n= 19 (7%) and TMZ + RT + Optune device in n= 3 (1.1%). In the H3K27M-wt group, n= 122 received TMZ + RT (80.26%), n= 13 received RT alone (8.55%), and palliative care in n= 17 (11.18%). When comparing K27M altered vs GBM, both groups had similar OS with 18 months (95% CI 14.24-21.76) and 16 months (95% CI 10.29-21.70, p=0.57). In a subanalysis according to the tumor localization, the midlines showed an OS of 19 months (95% CI 15.041-22.96) vs. 13 months for the non-midline group ([95% CI 15.04-22.96], p=0.56).NGS was done in 93 patients (38%). The most frequent gene alterations were the TERT promoter mutation n= 61 (65.59%), TP53 gene mutation n= 34 (33.34%), and NF1 mutation n=31 (30.39%) and PIK3CA gene mutation n= 26 (34.67%).

Conclusions: Our study shows similar results in terms of survival to those reported in the literature, however the molecular alterations found in NGS show a small proportion of possible molecular targets that could help in the treatment of patients.

542P Drug screening in Li-Fraumeni syndrome brain tumor models

A.S. Kolodziejczak[1], F. Selt[1], H. Peterziel[1], N. Jamaladdin[1], N. Mack[1], K. Maaß[1], C. Meulenbroeks[2], M. Kool[2], C. Herold-Mende[3], A. El Damaty[4], I. Oehme[1], D.T.W. Jones[1], K.W. Pajtler[1], C. Kratz[5], S.M. Pfister[6], O. Witt[1], T. Milde[1]

[1]DKFZ - German Cancer Research Center, Heidelberg, Germany; [2]Tumor biology and modeling of medulloblastoma tumors, Princess Máxima Center for Pediatric Oncology, Utrecht, Netherlands; [3]Molekulare Neuroonkologie, IPMB, University of Heidelberg, Heidelberg, Germany; [4]Pädiatrische Neurochirurgie, UKHD - Universitätsklinikum Heidelberg, Heidelberg, Germany; [5]Pediatric Hematology and Oncology Dept., Hannover Medical School, Hannover, Germany; [6]Pediatric Neurooncology, HI-STEM - Heidelberg Institute for Stem Cell Technology and Experimental Medicine, Heidelberg, Germany

Background: Li-Fraumeni Syndrome (LFS) is a genetic disorder characterized by constitutional pathogenic *TP53* mutation. The affected individuals are predisposed to develop various types of cancer, frequently brain tumors. Radiation and DNA damaging agents tend to show decreased efficacy and increased toxicity in LFS patients. This study aims to find an efficacious and safe therapeutic approach for LFS-associated brain tumors.

Methods: A custom library consisting of 345 compounds was designed to target a total of 61 proteins. *In vitro* drug screening was carried out in two TP53^{mut} brain cancer cell lines (SJ-GBM2 and UW228-2) and primary fibroblasts obtained from a LFS patient. The performance of each drug was evaluated based on the efficacy (cell viability assay) and genotoxicity (micronucleus assay). Subsequently, selected compounds were tested in combinations using cancerous cell lines and *in vitro* patient-derived xenograft (PDX) organoid cultures.

Results: As a result of in vitro screening, we found 42 compounds that showed favorable toxicity in cancer cell lines compared to primary LFS fibroblasts. From these drugs, 26 caused little to no genotoxic effect measured by DNA damage in primary LFS fibroblasts. Inhibitors of ATM/ATR, CHK1/CHK2, and WEE1, as well as microtubule-associated compounds passed a validation step and were selected for combination testing. The combination of WEE1 inhibitor adavosertib and vinca alkaloid vincristine demonstrated the highest efficiency in cancer cell lines, which was later confirmed in in vitro PDX cultures of LFS-associated brain tumors.

Conclusions: Adavosertib and vincristine were identified as a drug combination that eradicates TP53mut cancer cells without inducing DNA damage in normal tissues. This qualifies them as a novel and promising therapeutic approach for LFS patients diagnosed with brain tumors. The further steps include confirming the efficacy and safety of adavosertib and vincristine in vivo using brain tumor PDXs and LFS mouse models.

543P Bevacizumab and hydroxyurea treatment in grade 2 and 3 meningioma: A monocentric experience

G. Cerretti[1], A. Bosio[2], M. Padovan[1], M. Caccese[1], M. Maccari[1], G. Lombardi[1]

[1]Department of Oncology, Oncology 1, IOV - Istituto Oncologico Veneto IRCCS, Padua, Italy; [2]Oncology Department, IOV - Istituto Oncologico Veneto IRCCS, Padua, Italy

Background: Various systemic treatments for recurrent meningiomas (MEN) have been investigated with controversial results. We analyzed and compared the role of bevacizumab (BEV) and hydroxyurea (HYD).

Methods: Retrospectively, we analyzed recurrent grade 2 and 3 MEN PTS receiving BEV or HYD at the Veneto Institute of Oncology (Padua, Italy) from Nov 2011 to March 2023. All pts were not more amenable for surgery or RT. NGS data (Foundation One) were also collected. Kaplan-Meier curves were for survival rate; RANO criteria were used for radiological assessment.

Results: 31 pts in the BEV cohort were included. Baseline data for the BEV cohort were: 13 (41.9%) female pts; 17 (54.8%) below 65 years old; 16 (51.6%) PS ECOG <2; ≤ 2 previous surgeries in 17 (54%); 28 (90.3%) with less than 2 previous treatments. BEV was administered at 5 or 10 mg/Kg q2w or 7.5 mg/Kg q3w schedule. 13 pts were included in the HYD cohort. Baseline data for the HYD cohort were: 9 (69%) female pts; 5 (38%) $<$ 65 years old; 6 (46%) ECOG PS <2; ≤ 2 previous surgeries in 8 (61%); 1 (8%) previously treated. HYD was administered at 1000 mg/day. Pts affected by NF2 were 1 (8%) in HYD cohort and 2 (6%) in the BEV cohort. Pts treated with BEV achieved a DCR of 86.7%; mPFS was 19.6ms [95%CI: 10.6-NA]; 6m-PFS rate was 84.6% [95% CI 71.6-99.8]; mOS was 16.1ms [95%CI: 11.4-NA]; median follow up was 17.5ms. Pts treated with HYD achieved a DCR of 53.8 %; mPFS 5.6ms [95%CI: 2.9-NA]; 6m PFS 49.4% [95% CI 27.4-88.9]; mOS 22.6ms [95%CI: 12.3-NA]; median follow up was 117,1ms. Difference in OS was not statistically significant (p-value 0.8256), but difference in PFS was statistically significant (p-value 0.0026). NGS data were available for 22 pts (71%) of the BEV cohort; NF2 mutations were detected in 14 (63.63%); PTEN loss/mutation in 3 (9.67%); FGFR, JAK, ALK each in 1 case (3.2%).

Conclusions: BEV can be considered a useful therapeutic option to control disease in recurrent MEN pts although it appears not to impact survival compared to HYD. Further analyses on predictive biomarkers of efficacy is needed.

544P Clinical and molecular features of primary central nervous system tumor with Lynch syndrome

N. Liu[1], R. Kong[2], T. Han[2], D. Guo[2], B. Li[2], S. Chen[3], R. Ding[2], W. Deng[3], F. Bu[4]

[1]Pathology, The First Affiliated Hospital of China Medical University, Shenyang, China; [2]The Medical Department, Jiangsu Simcere Diagnostics Co., Ltd., Nanjing, China; [3]Bioinformatics Department, Jiangsu Simcere Diagnostics Co., Ltd., Nanjing, China; [4]Operations department, Jiangsu Simcere Diagnostics Co., Ltd, Nanjing, China

Background: Central nervous system tumour (CNST) is a heterogeneous group of human tumors that vary significantly in incidence by age, sex, and race/ethnicity. Lynch syndrome (LS), caused by germline pathogenic variants (PVs) in mismatch

repair (MMR) genes, leads to 2-8% lifetime risk to CNST. We aimed to identify clinical features of CNST with MMR PVs.

Methods: Germline mutations of MMR genes (including *MLH1*, *MSH2*, *MSH6*, *PMS2*) and microsatellite instability (MSI) were detected by next-generation sequencing (NGS) in CNST patients(pts). The pathogenicity of germline mutations was categorized based on American College of Medical Genetics and Genomics (ACMG) guidelines.

Results: There were 47 of 4787 (0.98%) CNST pts identified with LS. The median age of LS CNST pts was 36 years (range: 3-77 years), and the detection rate of MMR PVs was higher in CNST pts< 40 years (n=28, p<0.05). Of 47 LS CNST included IDH-wildtype glioma (n=34, predominantly high-grade glioma), astrocytoma IDH-mutant(n=7), medulloblastoma(n=2), meningeal melanoma(n=1), pilocytic astrocytoma(n=1), diffuse hemispheric glioma H3 G34-mutant(n=1), ependymoma(n=1). This was the first report a pt with LS with meningeal melanoma. Unlike the conventional glioblastoma IDH-wildtype, LS-related high grade IDH-wildtype glioma did not have TERT promoter mutation, EGFR gene amplification, +7/−10 chromosome copy-number changes. In contrast, LS-associated high grade IDH-wildtype gliomas commonly harbor TP53, ATRX mutations. In addition, MSI-H was found in 31.9% (15/47) of LS CNST pts, MSI-L was found in 17.0% pts (8/47), and 51.1% (24/47) pts exhibited MSS.

Conclusions: MMR germline gene pathogenic mutations were carried by 1% of CNST pts, predominantly high-grade gliomas, and developed at an early age. Genetic profile of LS related high grade glioma was different from that of conventional GBMs, which suggested that the importance of adding MMR genes test to CNST.

545P Antibody-fragment based immunotherapeutic approaches for medulloblastoma and rhabdomyosarcoma

J. Niesen[1], C. Krüger[2], N. Kreuter[3], U. Schüller[2]

[1]Pädiatric Hematology and Oncology, Research Institute Childrens Cancer Center, University Medical Center Hamburg-Eppendorf (UKE), Hamburg, Germany; [2]Reserach Institute Childrens Cancer Center, UKE Universitätsklinikum Hamburg-Eppendorf KMTZ, Hamburg, Germany; [3]Université de montpellier, Université de montpellier, Montpellier, France

Background: Medulloblastoma (MB) with SHH-MB as most frequent subtyp is the most common pediatric brain tumor. Conventional therapy can result in severe brain damage and high relapse rates. Thus, targeted less immunogenic immunotherapy is needed. Neo-antigens are rare in pediatric cancers due to their low mutational load. But, SHH-MB overexpresses the EGF-receptor, a well-characterized immunotherapeutic target. Even though it is also expressed at low levels in healthy tissue, it was our immunotherapeutic-target of choice. We established a platform in order to test the target specificity in SHH-MB using EGFR-specific antibody fragments (scFv) as part of fusion proteins with a SNAP-tag. Then, the scFvs were used as part of immunotoxins (ITs) and bispecific T-Cell engagers (BiTEs). Apart from EGFR, *PIK3CA* mutations occur in SHH-MB and may also serve as therapeutic target. Besides MB the pediatric tumor rhabdomyosarcoma (RMS) also shows EGFR overexpression and abnormal signaling in the PI3-kinase pathway. RMS, the most common pediatric soft tissue sarcoma, shows brain metastasis. The Pi3-kinase inhibitor BKM-120, can therefore tested in combination with EGFR-specific immunotherapy.

Methods: ScFv-SNAP fusions were coupled to Benzylguanin-modified fluorophores under nucleophilic substituent reaction. Specific binding of all constructs was proved with flow cytometry, internalization with confocal microscopy. Impact on cell viability was tested in cell viability assays, luminescent cytotoxicity assays and AnnexinV-apoptosis assays. *In vitro*- Blood Brain Barrier (BBB) models were generated from hiPSCs (human inducible pluripotent stem cells).

Results: The EGFR-specific scFv shows specific binding and internalization to target cells. The IT demonstrates IC_{50}-values in the low nanomolar range and specific apoptotic effects. In combination with BKM-120 the IC_{50} decreases. BiTEs influence the cell viability with an effector to target cell ratio of 5:1 and show apoptotic effects. The IT and BKM-120 were used in the BBB-model showing preliminary results of permeability.

Conclusions: Targeted innovative scFv-based immunotherapy as highly specific and less immunogenic therapy for MB or RMS was established, also as combination therapy approach.

546P Early urinary potassium level is predictive of delayed methotrexate (MTX) elimination in patients with primary central nervous system lymphoma (PCNSL)

A. Bertucci, V. Harlay, C. Boucard, G. Petrirena, C. Campello, D. Autran, M. Barrie, O. Chinot, E. Tabouret

Neuro-Oncology, CHU La Timone Adultes, Marseille, France

Background: First-line treatment of PCNSL includes high dose MTX. Nevertheless, MTX is associated with renal toxicity, requiring prolonged hospitalization and potentially compromising chemotherapy completion and so prognosis. Our objective was to identify early predictive factors of MTX delayed elimination.

Methods: We prospectively included all patients referred to our department for newly-diagnosed PCNSL. Daily serum and urinary creatinine and ionogram were collected from the day before MTX administration until elimination. Standard elimination delay of MTX was defined by plasmatic MTX level $\leq$ 0.05 µg/L before 72 hours. We conducted 2 independent training (TC) and confirmation (CC) cohorts.

Results: We included 64 cures (20 patients) in the TC and 59 cures (22 patients) in the CC between November 2020 to May 2021 and January 2022 to May 2022, respectively. At inclusion, median ages were 71 years (range 33-86) and 74 years (range 47-87), median KPS were 70% (range 40-80%) and 80% (range 40-100%) and median elimination delay of MTX was 95 hours (range 47-205) and 96 hours (range 62-264) in the TC and the CC respectively. In the TC, median urinary potassium level at day 1 (uK+D1) was 23.9 mmol/L (range 5.5-64.1). In multivariate analysis, older age (p=0.004), low KPS (p=0.036) and high uK+D1 (p=0.001) were associated with delayed MTX elimination. Using a ROC analysis (p=0.008, AUC=0.712), an optimal cutoff for uK+D1 was defined at 17.1 mmol/L with a specificity of 81% and a positive predictive value of 84%. In the CC, we confirmed in multivariate analysis that older age (p=0.002), low KPS (p=0.007) and high uK+D1 (p=0.004) remained associated with delayed MTX elimination. After merging the cohorts, we were able to predict a standard MTX elimination probability based on age and uK+D1. Patients younger than 70 years had a standard MTX elimination probability of 84% versus 33%, depending on low and high uK+D1, respectively. Conversely, older patients had a probability of 26% and 14%, respectively.

Conclusions: uK+D1 may be predictive of delayed MTX elimination, opening personalized perspectives for young patient management. Its relevance as an element of decision making need to be validated in a larger prospective cohort.

547P Clinicopathological and molecular study of embryonal tumours with multilayered rosettes

L. Teng, L. Wang

Pathology, Xuanwu Hospital Capital Medical University, Beijing, China

Background: To analyze clinicopathological features of ETMRs.

Methods: A total of 14 cases of ETMRs from 2016 to 2021 in Xuanwu Hospital of Capital Medical University were retrospectively summarized. The clinical and imaging characteristics, pathological and molecular characteristics were analyzed, and the related literature was reviewed.

Results: All 14 patients (6 males and 8 females) aged from 9 months old to 3 years old (mean 2 years) mainly had a history of headache or/and vomiting. Twelve tumors were supratentorial and two infratentorial, seven of which occurred in the frontal lobe. The MRI findings showed that the lesions were located in the third ventricle, and the enhanced MRI showed abnormal enhancement signals. The MRI enhancement all showed an abnormal enhancement signal. Pathological finding showed that 12 cases had displaying the morphological characteristics of ETMR. The distribution of tumor cells is sparse and uneven, and some cells arrange in multiple layers and grow around blood vessels, partially forming a "Homm-rett group" structure, island-like structure can be seen. IHC showed Syn and Lin28a were immunopositive in all 14 cases (14/14). GFAP and Olig-2 were partially immunopositive in 3 cases (3/14). EMA was dot-and/or-ring immunopositivity in 2 cases (90%, 2/14). At the same time, there was a case immunopositive for H3K27M, with the loss of H3K27me3. 12 ETMRs were available to detect C19MC and Dicer1 gene mutation. 11 in 12 (88.9%) were found to have C19MC amplification, and one have Dicer1 mutation as well as H3K27M mutation. Among the 14 patients after surgery, All 10 patients received adjuvant radiotherapy/chemotherapy,Progression-free survival was 6.2 months, and overall survival was 11 months.

Conclusions: ETMRs have relatively distinguishing clinical and histopathological features. C19MC alteration and Dicer1 gene mutation, can be considered as useful biomarkers for the diagnosis and differential diagnosis, and provide a direction for targeted therapy in the future.

(IPO Lisboa), Lisbon, Portugal

Background: Midline gliomas H3K27-altered (GLM-H3K27) are a rare and very aggressive oncologic entity. Although the clinical, imaging, and prognostic characteristics are better characterized in childhood, studies of this pathology in the adult population are scarce.

Methods: Demographic, clinical, treatment, and survival characterization of adult patients with GLM-H3K27, followed at an Oncology Hospital between 2012-2022, through a retrospective review of clinical processes. The data cut-off was 31 December 2022.

Results: Cohort consisting of 17 patients, 53% male, mean age at diagnosis 38 years (18-63 years). The mean time from symptomatology to diagnosis was 3.9 months. The most common initial symptoms are related to cranial nerve dysfunction (6), headache (6) or motor defect (3). The most frequent anatomical locations were thalamus and trunk, 41% and 35%, respectively. Surgical samples were mostly obtained by biopsy (58%), the remainder by partial excision. The initial histological diagnosis varied, including grade 2 to 4 gliomas. In 88% of the cases (N=15) it was possible to identify the presence of the H3F3A K27M mutation by immunohistochemistry and/or mutational analysis of the gene, with 2 of the cases the diagnosis was made only by the loss of expression of H3K27me3. Most patients (82%) were treated with radiotherapy and chemotherapy; in 11.7%, isolated radiotherapy was performed, and only palliative care was given in one case. So far, 14 patients (70.1%) have died; 3 are alive and 1 patient was lost to follow-up. The median disease-free survival was 11 months (95%CI 8.6-13.4 months) and the median overall survival was 20 months (95%CI 12-28 months).

Conclusions: Our study highlights the clinical, anatomical and histological heterogeneity of this new and rare entity, particularly in adulthood. We emphasize the importance of the integrated diagnosis of this population, with the expectation that in the future an effective therapeutic approach can be implemented.

Background: Adagrasib (ada) is a $KRAS^{G12C}$ inhibitor with favorable properties including 23 hr half-life, dose-dependent PK, and CNS penetration. $KRAS^{G12C}$ inhibitor resistance may occur in CRC via EGFR reactivation, and a dual EGFR/$KRAS^{G12C}$ blockade may be necessary to effectively treat $KRAS^{G12C}$-mutated CRC. In phase 1/2 cohorts of KRYSTAL-1 (NCT03785249), ada was well tolerated as monotherapy (mono) and in combination with cetuximab (cetux) in patients (pts) with $KRAS^{G12C}$-mutated CRC who were previously treated with chemotherapy, with a higher response (46%) and longer median progression-free survival (6.9 months) for ada + cetux.

Methods: Pts with previously treated $KRAS^{G12C}$-mutated CRC received ada mono (600 mg BID) or ada (600 mg BID) + cetux (400 mg/m^2 then 250 mg/m^2 QW or 500 mg/m^2 Q2W). Exploratory analyses in both cohorts included mechanisms of acquired $KRAS^{G12C}$ resistance and correlation of plasma ctDNA clearance and baseline tumor IHC-assessed EGFR expression with response. Plasma was collected at baseline, cycle (C) 2 day (D) 1, C4D1, and end of treatment (EOT). Acquired genomic alterations were characterized for pathogenicity and defined as absent at baseline and present at EOT.

Results: At data cutoff (16 June 2022), 44 pts had received ada and 32 ada + cetux. A total of 27 pts in the ada cohort and 11 in the ada + cetux cohort had paired plasma samples at baseline and EOT. Acquired genomic alterations were observed in 81% (22/27) and 73% (8/11) of pts on ada and ada + cetux, respectively, and included mutations, copy number changes, and fusions. Mutant allele frequency clearance of >95% by C2 occurred in 55% (16/29) and 88% (14/16) of pts on ada and ada + cetux, respectively. Preliminary data suggest a relationship between tumor EGFR expression and response to ada + cetux.

Conclusions: Exploratory analyses suggest diverse mechanisms of acquired resistance in pts treated with ada mono and in combination with cetux, and a greater depth of ctDNA response in pts treated with ada + cetux. Ada + cetux is being investigated in 2L CRC in the phase 3 KRYSTAL-10 trial (NCT04793958).

Clinical trial identification: NCT03785249.

Background: As a highly selective and potent $KRAS^{G12C}$ inhibitor, D-1553 has shown encouraging antitumor activity in patients (pts) with KRAS G12C mutated CRC. Targeting KRAS and EGFR pathways at the same time may enhance the antitumor activity of D-1553. An ongoing multi-country phase II study (NCT04585035) is evaluating the safety and efficacy of D-1553 combined with cetuximab, an EGFR antibody, in KRAS G12C mutated CRC.

Methods: Pts with metastatic CRC progressed after standard treatment were enrolled. Pts were required to have KRAS G12C mutations, and no prior KRAS G12C directed treatment. Enrolled pts received D-1553 600 mg BID combined with

cetuximab (standard dose). Study endpoints included efficacy (RECIST, v1.1), safety, and pharmacokinetics (PK).

Results: As of April 17, 2023, 29 pts (37.9% female, median age 56.0 [range 32-76] years, 65.5% with ≥3 prior therapies [median 3; range 1-6], 100% stage IV disease at baseline, and 24.1%/75.9% ECOG PS 0/1) were enrolled. At data cutoff, 20 (69.0%) pts remained on treatment. The median treatment duration was 5.95 (range 1.35-9.13) months with a median follow-up of 6.24 (range 2.33-9.13) months. A preliminary overall response rate of 51.7% (15/29) was observed and 9 out of 15 responders had confirmed response, with 5 still on treatment and their responses to be confirmed. The disease control rate was 93.1% (27/29). Median progression-free survival (PFS) was 7.56 months (95% CI: 5.49, NA). Treatment-related adverse events (TRAEs) of any grade occurred in 29 (100%) pts, with the most common (≥ 20%) being rash, increased AST, increased ALT, and paronychia, predominantly ≤ grade 2. Grade 3-4 TRAEs occurred in 3 (10.3%) pts, all of which were related to cetuximab. No grade 5 TRAEs were reported. TRAEs led to D-1553 dose interruption in 2/29 (6.9%) pts, to cetuximab dose reduction and interruption in 1/29 (3.4%) and 5/29 (17.2%) pts respectively, and cetuximab discontinuation in 1/29 (3.4%) pt.

Conclusions: Combination of D-1553 and cetuximab showed an acceptable safety profile and achieved a higher response rate than D-1553 monotherapy and a promising PFS in heavily pretreated pts with KRAS G12C mutated CRC. More data will be presented at the meeting.

Clinical trial identification: NCT04585035.

Background: HER2 is an actionable biomarker for mCRC, though the impact of concomitant genomic alterations is unknown. On the basis of the MOUNTAINEER study, TUC + Tras was approved by the FDA for use in pts with chemo-refractory HER2+, RAS-WT mCRC. Here we present the impact of concomitant baseline genomic alterations on the clinical activity of TUC + Tras.

Methods: MOUNTAINEER enrolled pts w/ locally assessed HER2+ mCRC by tissue immunohistochemistry (IHC), in situ hybridization (ISH), and/or next-generation sequencing (NGS). Baseline tissue and blood samples were retrospectively analyzed by IHC/FISH, PGDx tissue NGS and Guardant 360 blood NGS. cORRs (proportion of pts w/ CR or PR per RECIST v1.1 by BICR) and DoR were calculated for selected genomic alterations (SNVs and CNVs) occurring in ≥5 pts treated with TUC + Tras. This analysis was descriptive; no statistical comparisons were made.

Results: From 84 pts treated with TUC+Tras, 65 samples were available for FISH testing. cORR was numerically higher w/ greater HER2 amplification as measured by either HER2/CEP17 ratio (>5, n=50: cORR [95%CI] = 44.0% [30.0, 58.7]; ≤5, n=15: cORR [95%CI] = 26.7% [7.8, 55.1]) or HER2 copy number (>9.45, n=57: cORR [95%CI] = 42.1% [29.1, 55.9]; ≤9.45, n=8: cORR [95%CI] = 25.0% [3.2, 65.1]). NGS testing of tissue (n=45) and blood (n=66) samples from pts w/ a central HER2+ test result identified concomitant mutations and/or genomic amplifications in key genes including ERBB2, PIK3CA, APC, and TP53. In these pts, cORR and DOR were generally similar to those observed overall (Table).

Conclusions: This exploratory analysis of the MOUNTAINEER trial found generally consistent clinical efficacy of TUC + Tras to the primary analysis across subsets of pts w/ HER2+ RAS-WT mCRC and other clinically relevant genomic alterations.

Table: 551O

552O FOxTROT: Results of embedded phase II evaluating the addition of panitumumab (pan) to neo-adjuvant FOLFOX for patients (pts) with KRAS-wt colon cancer (CC) with extended biomarker panel

J. Seligmann[1], D. Morton[2], M. Seymour[3], F. Elliott[3], K. Handley[4], B. Glimelius[5], C. Williams[6], G. Hemmings[7], D. Bottomley[8], R. Gray[9], P. Quirke[10], L. Magill[4], A.D. Beggs[11], N. West[12]

[1]Oncology, University of Leeds, Leeds, UK; [2]Surgery, The University of Birmingham - Medical School, Leeds, UK; [3]Oncology, UL - University of Leeds, Leeds, UK; [4]Surgery, The University of Birmingham - Institute for Cancer Studies, Leeds, UK; [5]Oncology, Akademiska Sjukhuset Uppsala, Leeds, UK; [6]Medical Research Department, UL - University of Leeds, Leeds, UK; [7]Pathology and data analytics, University of Leeds - Institute of Cancer and Pathology (LICAP), Leeds, UK; [8]Pathology and data analytics, UL - University of Leeds, Leeds, UK; [9]Medical Research Department, University of Oxford, Leeds, UK; [10]Pathology, UL - University of Leeds, Leeds, UK; [11]Institute of Cancer & Genomic Science, The University of Birmingham - Medical School, Leeds, UK; [12]Pathology and Data Analytics Department, St. James's University Hospital - Leeds Teaching Hospitals NHS Trust, Leeds, UK

Background: The FOxTROT trial has reported advantages of neoadjuvant chemotherapy (NAC) in locally advanced CC and also reported the embedded phase II which tested the addition of panitumumab (pan) to NAC in KRAS-wt pts. Here we present detailed results of neoadjuvant FOLFOX +/- pan with extended hypothesis-led biomarker testing, to reflect current pan use.

Methods: Pts had operable CC; CT-predicted stage T3-4, N0-2, M0, and KRAS-wt. *KRAS*-wt pts who had been allocated to NAC could optionally be sub-randomized 1:1 to 6 weeks FOLFOX ± pan during the NAC phase. All pts received FOLFOX post-op. RAS/RAF were tested by NGS; EREG/AREG (EGFR receptor ligands) by RNAseq. Primary endpoint of this exploratory analysis is RFS in RAS/BRAF-wt pts; secondary endpoints include safety, histological downstaging, DFS, CC specific survival, and test impact of primary tumor location (PTL) and EREG/AREG expression on pan effect.

Results: Biomarker data was available for 232(83%) pts randomised; 22(9.5%) were RAS mut; 41/210(19.5%) BRAF-mut. In 169 RAS/BRAF-wt pts with a median 42 month follow up, RFS was 88.1% in pts treated with FOLFOX+pan compared with 79.2% with FOLFOX (HR=0.51,p=0.09). Effect size was stronger in pts with high EREG/AREG (RFS HR=0.29,p=0.04), and for CC-specific survival (see table). Pan did not result in greater pathological response (TRG 1-3 16.4% vs 22.4%,p=0.27) or downstaging compared with FOLFOX. Pan was associated with higher rates of grade 3 diarrhoea (8% vs 3%) and rash (22% vs 2%), and trend towards more post-operative complications than FOLFOX alone.

Table: 552O

RAS/BRAF-wt population		Events	FOLFOX + pan vs FOLFOX HR	p-value
RFS	Overall	27/169	0.51 (0.24-1.10)	0.09
	Left PTL	16/102	0.45 (0.16-1.23)	0.12
	Right PTL	11/67	0.67 (0.20-2.21)	0.51
	High EREG/AREG	13/74	0.29 (0.09-0.99)	0.04
	Low EREG/AREG	13/83	0.75 (0.25-2.22)	0.60
DFS	Overall	39/169	0.51(0.27-0.97)	0.04
CC-specific death	Overall	13/169	0.23 (0.06-0.83)	0.03

Conclusions: In this exploratory analysis, neoadjuvant FOLFOX+ pan showed promising activity in RAS/BRAF-wt pts compared with FOLFOX alone in pts with operable CC. Further pt selection with EREG/AREG appears beneficial. No impact on tumour regression was seen with pan. Further testing and safety assessment is warranted.

Background: Whether *KRAS* and *BRAFV600E* mutations are prognostic in stage III CC remains controversial and has never been clearly analyzed in the subgroup of MSI-H patients (pts) due to sample size limitations. The prognostic value of individual KRAS mutations has also not been widely studied.

Methods: We studied the prognostic impact of individual *KRAS* exon 2 and *BRAFV600E* mutations in pts with surgically resected stage III CC who participated in 7 clinical trials from the ACCENT/IDEA databases. Associations between mutations and time to recurrence (TTR), overall survival (OS) and survival after recurrence (SAR) were assessed by Cox model, stratified by study and adjusted for sex, age, performance status, T and N stage, disease grade, and primary tumor location. The prognostic value of individual KRAS exon 2 submutations (G12A, G12C, G12D, G12R, G12S, G12V, G13D and others) was also analyzed.

Results: 8286 pts were included, 11.6% were MSI-H (N=967) with 5 yr recurrence rates of 24.1% for MSI-H and 30.3% for MSS subgroups. *BRAFV600E*, *KRAS* exon 2 mutants or double wild type represented 40.6%, 18.1% and 41.3% of the MSI-H group and 7.8%, 38.6% and 53.7% of the MSS group, respectively. In the MSS group, 5y TTR rates of 61.7%, 66.4% and 73.2% emerged in pts with *BRAFV600E, KRAS* exon 2 mutants and in double wild-type pts, respectively, (adjHR: 1.34 and 1.32, both $p<0.001$), while in the MSI group shorter TTR in mutated subgroups was not seen with 5y TTR rates of 76.1%, 75.8% and 75.6%, respectively (adjHR: 1.01 and 0.98, both $p>0.05$). Similar results were found for OS. However, SAR was significantly shorter for pts with tumors harboring a *KRAS* exon 2 or *BRAFV600E* mutation in both MSS (adjHR: 1.16 and 2.05; both $p<0.0001$) and MSI (adjHR: 1.76 and 2.00; both $p<0.05$) pts. No major differences were noted in the prognostic value of *KRAS* exon 2 submutations.

Conclusions: In the largest analysis of the association of *KRAS* exon 2 and *BRAFV600E* mutations and disease outcome in resected stage III CC, either mutation was associated with significantly shorter DFS, OS and SAR in MSS tumors, but only with shorter SAR in MSI-H tumors. In addition, all *KRAS* codon 12 and 13 mutations had similar prognostic value.

554MO Cetuximab plus FOLFOXIRI versus cetuximab plus FOLFOX in *RAS* wild-type patients with initially unresectable colorectal liver metastases: The TRICE randomized clinical trial

Y. Li[1], D. Wang[1], C. Ren[1], S-S. Li[2], W. Pat Fong[1], X. Wu[3], J. Xiao[2], Y. Yuan[4], B-K. Li[4], P-R. Ding[3], Z. Wang[1], F. Wang[1], Z. Pan[3], G. Chen[3], X-Z. Wang[5], L-Y. Wang[6], T. Chen[6], T. Liu[7], Y. Yuan[8], R-H. Xu[1]

[1]Department of Medical Oncology, Sun Yat-sen University Cancer Center, Guangzhou, China; [2]Department of Internal Medicine, The 6th Affiliated Hospital of Sun Yat-sen University, Guangzhou, China; [3]Department of Colorectal Surgery, Sun Yat-sen University Cancer Center, Guangzhou, China; [4]Department of Liver Surgery, Sun Yat-sen University Cancer Center, Guangzhou, China; [5]Department of Medical Oncology, Shantou Central Hospital, Shantou, China; [6]Department of Internal Medicine, Sun Yat-sen Memorial Hospital, Sun Yat-sen University, Guangzhou, China; [7]Department of Medical Oncology, Zhongshan Hospital Affiliated to Fudan University, Shanghai, China; [8]Department of Medical Oncology, The Second Affiliated Hospital, Zhejiang University School of Medicine, Hangzhou, Zhejiang, China

Background: The TRICE study was designed to determine whether intensifying the chemotherapy backbone in cetuximab-containing regimens could confer additional clinical benefits to RAS wild-type colorectal cancer (CRC) patients with initially unresectable liver metastases.

Methods: Patients were randomly assigned to receive either cetuximab plus FOLFOXIRI (triplet arm) or cetuximab plus FOLFOX (doublet arm) every 2 weeks. Primary efficacy analyses were conducted based on the intention-to-treat population, while

safety analyses were performed on patients who received at least one line of chemotherapy. The primary end point was the objective response rate (ORR). Secondary end points included the median depth of tumor response (DpR), early tumor shrinkage (ETS), R0 resection rate, progression-free survival (PFS), overall survival (OS), and treatment-related adverse events.

Results: From January 2018 to December 2022, 146 patients were randomized to the cetuximab plus FOLFOXIRI (n = 72) or the cetuximab plus FOLFOX (n = 74) treatment arms. The ORR was comparable with 84.7% versus 79.7% in the triplet and doublet arms, respectively (OR = 0.71, 95% CI 0.30 to 1.67; P = .43). Although intensifying the chemotherapy backbone led to a higher median DpR (59.6% vs. 55.0%; P = .039), other secondary outcomes remained comparable between the two arms. At a median follow-up of 26.2 months, the median PFS was 11.7 months in the triplet arm vs. 13.4 months in the doublet arm (HR = 1.37, 95% CI 0.91 to 2.07; P = .13). Additionally, the triplet arm was associated with a higher incidence of grade 3-4 neutropenia (44.1% vs. 27.0%; P = .03) and diarrhea (5.9% vs. 0%; P = .03).

Conclusions: Although intensifying upfront systemic chemotherapy in RAS wild-type metastatic CRC patients offered a better depth of tumor response, there was an increase in neutropenia and diarrhea incidence with no significant difference in ORR, PFS, and R0 resection rate.

Clinical trial identification: NCT03493048.

Background: The DEEPER trial, which evaluated m-FOLFOXIRI (irinotecan 150 mg/m^2, oxaliplatin 85 mg/m^2, 5-FU 2400 mg/m^2) plus cetuximab (cet) vs. bevacizumab (bev) as initial treatment in terms of depth of response (DpR) as the primary endpoint in *RAS* wild-type mCRC, has demonstrated a significantly better DpR of the cet arm (Tsuji A, et al. ASCO 2021). Moreover, longer PFS and OS in the cet arm were observed in *RAS*/*BRAF* wild-type and left-sided tumors although *BRAF* status was available for only half of the patients (pts) (JSMO 2023). An updated survival analysis was performed using *BRAF* status added by tumor tissue biomarker analysis.

Methods: The DpR and other clinical outcomes were evaluated in per protocol set (PPS) consisted of pts evaluable for the DpR at external review board. Survival analysis was performed according to clinical factors including primary tumor sidedness which was one of the stratification factors using a log-rank test. In 359 enrolled pts, *BRAF* status was available in 255 pts with biomarker analysis for 71 pts. All statistical tests were two-sided, and *P* values $\leq$ 0.05 were deemed significant.

Results: 321 pts were defined as PPS (median age 65y, 64% male, PS0/1: 91%/9%, left/right primary: 84%/16%). In 178 pts with *RAS*/*BRAF* wild-type and left-sided tumors, DpR and PFS both were significantly better in the cet compared to the bev arm (DpR, median 59.2% vs. 47.5%, *P*=0.0017; PFS, median 14.5 vs. 11.9 months, HR 0.71, *P*=0.032). A sub-group analysis by clinical factors showed that PFS was better in the cet arm among pts without surgical resection of R0/1 (HR 0.66, *P*=0.029), and it was significantly longer in pts with extra-hepatic metastases (HR 0.63, *P*=0.015) but not liver-limited disease. In addition, in the cet arm, male had a better PFS compared to female. Median PFS was longer in the cet compared to the bev arm among male (18.0 vs. 13.1 months, HR 0.72, *P*=0.096) but not female.

Conclusions: m-FOLFOXIRI plus cet regimen could be a good option for upfront chemotherapy with high DpR and longer PFS in mCRC pts with *RAS*/*BRAF* wild-type and left-sided tumors. The benefit may be relevant for pts with extra-hepatic metastases or male.

Clinical trial identification: NCT02515734.

556MO A phase II clinical trial of sintilimab plus chidamide combined with or without bevacizumab in patients with MSS/pMMR metastatic colorectal cancer

F. Wang[1], Y. Jin[1], H-Y. Luo[1], W-L. Guan[1], Y. Li[1], F. Wang[1], M. Qiu[1], L-L. Liu[2], X. Hu[3], Y. Zhang[4], W. Fang[2], Z-X. Wang[1], C. Ren[1], D. Wang[1], R-H. Xu[1]

[1]Department of Medical Oncology, Sun Yat-sen University Cancer Center, State Key Laboratory of Oncology in South China, Collaborative Innovation Center of Cancer Medicine, Guangzhou, China; [2]Internal Medicine-Oncology, The First Affiliated Hospital, Zhejiang University School of Medicine, Hangzhou, China; [3]Internal Medicine - Oncology, The First Affiliated Hospital of Guangxi Medical University, Nanning, China; [4]Department of Internal Medicine, Cancer Hospital Affiliated to Harbin Medical University, Harbin, China

Background: Immune checkpoint inhibitors(ICI) have shown significant clinical benefit for MSI-H/dMMR metastatic colorectal cancer (mCRC) patients. However, the majority of MSS/pMMR mCRC patients show no response to immunotherapy and better combinations are currently lacking. Based on our preclinical research, we designed a study to explore whether an ICI sintilimab combined with an HDAC inhibitor chidamide, with or without bevacizumab would show efficacy in MSS/pMMR mCRC patients.

Methods: This open-label, multicenter trial (NCT04724239) recruited patients with MSS/pMMR mCRC that had failed or were intolerant to at least two lines of systemic therapies. The patients were randomly assigned to two arms, sintilimab plus chidamide (doublet) group, and sintilimab plus chidamide combined with bevacizumab (triplet) group. Patients in the doublet group received sintilimab 200 mg IV q3w plus chidamide 30 mg PO biw. Patients in the triplet group received sintilimab 200 mg IV q3w plus chidamide 30 mg PO biw and bevacizumab 7.5 mg/kg IV q3w. The primary endpoint was progression-free survival rate achieved at 18 weeks (18wPFS). The secondary endpoints included objective response rate (ORR), progression-free survival (PFS), overall survival (OS), disease control rate (DCR), and safety.

Results: Between March 2021 and April 2022, 23 and 25 patients were randomly allocated to the doublets group and triplets group. 18wPFS was 17.4% in the doublets group and 66.7% in the triplets group (P = 0.0012). ORR was 13.0% and 44.0%, and DCR was 39.1% and 72.0% in the doublets and triplets group. The median PFS was 1.5 months with doublets and 7.3 months with triplets (P = 0.008). The median OS for the triplet arm had not been reached, while the median overall survival for the doublet arm was 18.9 months (P = 0.41). The most common treatment-emergent adverse events (TEAEs) were proteinuria (60.9%), thrombocytopenia (43.5%), and animea (39.1%) with doublets and thrombocytopenia (72.0%), proteinuria (72.0%), and neutropenia (60.0%) with triplets. Grade 3 and above TEAEs occurred in 7 (30.4%) patients in the doublet arm and 13 (42.0%) patients in the triplet arm.

Conclusions: Sintilimab combined with chidamide and bevacizumab had promising efficacy and tolerable toxicity in MSS mCRC patients.

Clinical trial identification: NCT04724239.

Background: No standard therapies beyond first line are established for advanced squamous cell anal carcinoma (SCAC). Although PD-1 blockade demonstrated activity in patients (pts) with advanced SCAC, response rate is modest. Preclinical data suggests that vorinostat (V), an HDAC inhibitor, might improve immunotherapy efficacy by modulating the epigenome.

Methods: PEVOsq is an open-label, non-randomized, multi-center, basket phase II trial, evaluating the efficacy of pembrolizumab (P) in combination with V in pts with recurrent and/or metastatic squamous carcinomas. Pts had to be PD1/PD-L1 antagonist-naïve with no restriction in terms of prior lines of treatments. P dose was 200 mg Q3W IV, and V 400 mg QD PO. Sample size was determined using an A'Hern design with the following hypotheses (alpha=5%, power=90%, p0=15%, p1=40%). Primary endpoint was objective response rate (ORR) according to RECIST 1.1. Secondary endpoints included safety, progression-free survival (PFS), overall survival (OS), and duration of response (DOR).

Results: Among 112 included pts, 29pts with SCAC were evaluable for safety and efficacy. Median age was 63 years old [range: 49-84], 23 were female and the median number of prior lines of therapies was 2 [range: 0-4]. Nine pts (31.0%) had an objective response [95%CI: 17.2; 47.9] and median DOR was not reached [95%CI: 5.6-NR]. Median PFS and OS were 5.8 [95%CI: 2.7-11.0] and 18.8 months [12.8-NR] respectively. Among the 22 pts with p16 evaluated, all were positive. Eighteen (62.1%) pts developed G3/4 treatment related adverse events. P and V were stopped for toxicity in 13.0% and 44.4% of pts, respectively. 79.3% of pts had a dose-reduced of V for toxicity including hematotoxicity, gastrointestinal disorders, asthenia and creatinine increase. Results according to PDL1, MSI, TMB and HPV will be presented at the meeting.

Conclusions: PEVOsq study met its primary endpoint, documenting promising antitumoral activity of the association of P+V in heavily pretreated SCAC pts. However, the high rate of toxicities requires a special attention in future trials.

Background: Postoperative ctDNA-based molecular residual disease (MRD) is reported to be associated with a high risk of recurrence. Here, we present an updated analysis on the prospective, observational GALAXY study.

Methods: Serial ctDNA was analyzed using tumor-informed assay (Signatera™) at 1 (4-week (wk)), 3, 6, 9, 12, 18, and 24 mos after surgery until recurrence in pts with resectable CRC. The primary endpoint was disease-free survival (DFS).

Results: Among 3,034 pts with clinical stage II-IV CRC enrolled between May 2020 and Nov 2022, 2,280 pts were included in this study. The median follow-up period was 16.5 mos (range: 0.1 - 31.9). Pts with ctDNA-positivity at 4-wk timepoint demonstrated a significantly inferior DFS compared to ctDNA-negative pts (HR: 16.9, $p<0.0001$). We further explored the benefit of adjuvant chemotherapy (ACT) amongst pts with stage II-III (N=1,555), in MRD-negative pts (N=1,333), 24-mo DFS was 95% in ACT group and 92.5% in no ACT group with no significant difference (HR: 1.4, p=0.2), whereas MRD-positive pts (N=222) showed significant benefit from ACT (HR: 0.4, $p<0.0001$) with a 24-mo DFS of 51.9% vs Not Reached. Additionally, within all stage pts who received ACT for either 3 mos or 6 mos, MRD-negative pts (N=606, HR: 1.1, p=0.89) showed no significant survival difference between the 2 cohorts while MRD-positive pts showed a significant benefit from 6 mos of ACT (N=154, HR: 0.4, p=0.002). On ctDNA dynamics analysis between 4 -12 wks, compared to pts who remained ctDNA-negative (N=941), a significantly shorter DFS was observed for pts who converted (N=22, HR: 11, $p<0.001$) or remained positive (N=81, HR: 20, $p<0.001$), respectively. Multivariate analysis in pts with stage II-III for DFS revealed that ctDNA-positivity was the most prognostic factor associated with poor outcomes (HR: 11.33, $p<0.001$).

Conclusions: Here we present an updated analysis on the GALAXY cohort with >2,000 pts analyzed. Our results indicate that pts with MRD-positivity showed benefit from ACT, possibly 6-mos ACT. Overall ctDNA status remains the most significant prognostic factor and predictive of pt outcomes.

Clinical trial identification: UMIN000039205.

Background: Rechallenge with anti-EGFR inhibitors demonstrated clinical activity in patients (pts) with refractory circulating tumor DNA (ctDNA) *RAS/BRAF* wild type (wt) metastatic colorectal cancer (mCRC) and it is included as an option in clinical guidelines. However, the available evidence (III C) is derived from small retrospective/prospective studies.

Methods: We conducted an individualized patients' data pooled analysis of pts enrolled in the CAVE, VELO, CRICKET and CHRONOS trials treated with anti-EGFR rechallenge with *RAS/BRAF* wt ctDNA. Overall survival (OS), progression free survival (PFS), overall response rate (ORR) and disease control rate (DCR) were calculated. Safety was reported.

Results: Overall, 114/194 pts that received anti-EGFR rechallenge as experimental therapy (48 cetuximab plus avelumab, 26 trifluridine/tipiracil plus panitumumab, 13 irinotecan plus cetuximab and 27 panitumumab) had *RAS/BRAF* wt baseline plasma ctDNA and were included in the current analysis. The study population included heavily pre-treated pts: 83/114 (72.8%) and 31/114 (27.2%) pts received rechallenge with EGFR inhibitors as third- or later lines of treatment, respectively. Median PFS (mPFS) and median OS (mOS) were 4.0 months (95% CI, 3.2-4.7) and 13.1 months (95% CI, 9.5-16.7). One patient achieved complete response (CR), 19 pts displayed partial response (PR), while 65 and 29 had stable disease (SD) and progressive disease as best response, respectively. The ORR (CR+PR) was 17.5% (20/114); DCR (CR+PR+SD) was 74.6% (85/114). Almost one of three pts significantly benefited from anti-EGFR rechallenge therapy (6-months PFS rate, 32.5%; 18-months OS rate, 31.6%). Treatments showed manageable toxicity, in lines with previous findings.

Conclusions: Results of this individual patients' pooled analysis demonstrate promising clinical activity of rechallenge with EGFR inhibitors with nearly one-third of the pts experiencing long PFS that lead to prolonged survival. Thus, rechallenge with anti-EGFR-based strategies might be considered as a therapeutic option in the continuum of care of pts with refractory ctDNA *RAS/BRAF* wt mCRC.

Background: FOLFIRI-Aflibercept (A) is one of the 2nd-line standard treatments for mCRC. We evaluated the efficacy and safety of induction with FOLFIRI-A (6 cycles) followed by maintenance with 5FU/LV-A or FOLFIRI-A until progression in older pts with mCRC.

Methods: This was a multicenter, randomized, open-label, non-inferiority phase II trial. Pts aged $\geq$70 years who failed a prior oxaliplatin-based regimen, were randomly assigned (1:1) to induction with 6 cycles FOLFIRI-A followed by maintenance with 5FU/LV-A until progression (arm A, experimental) or FOLFIRI-A until progression (arm B, control). Primary endpoint was progression-free survival (PFS). Secondary endpoints included overall survival (OS), overall response rate (ORR), and safety. To claim non inferiority with 95% CI, the upper limit of the boundary could not exceed HR=1.5, with one-sided α=0.075 and 80% power.

Results: Between November 2017 and February 2022, 170 pts were randomized to arm A (n=85) or arm B (n=85). Both arms were comparable at baseline (median age 74 years). Over a median follow-up time of 12.2 months (m) in arm A vs 10.9 m in arm B, most pts had died (arm A 83.5%, arm B 88.2%) mainly from disease progression. Arm A was non inferior to arm B in terms of PFS (HR=0.781 [95% CI 0.566-1.076]). There were also no significant differences in OS and ORR between arms (Table). Grade $\geq$3 adverse events related to treatment occurred in 58.8% of pts in arm A vs 62.4% in arm B (p=0.754). Severe asthenia was significantly higher in arm B during the maintenance phase (4.5% vs 21.6%, p=0.038).

Conclusions: Primary endpoint was met: induction with 6 cycles FOLIRI-A followed by maintenance with 5FU/LV-A was non-inferior to FOLFIRI-A until progression, in terms of PFS. OS and ORR did not either differ between arms. In older pts, severe asthenia was significantly reduced with 5FU/LV-A maintenance.

Table: 560MO

Efficacy	Arm A Experimental	Arm B Control	p-value
	FOLFIRI q2w + A 4 mg/kg IV 6 cycles 5FU/LV q2w + A 4mg/kg IV	FOLFIRI q2w + A 4 mg/kg IV	
PFS (m), median (95%CI)	6.1 (5.3-6.9)	5.5 (4.8-6.2)	0.128[a]
OS (m), median (95%CI)	12.2 (10.6-13.9)	11.5 (8.7-14.4)	0.466[a]
ORR, % (95%CI)	20 (12.1-30.1)	9.4 (4.2-17.8)	0.082[b]

561P Risk of colorectal cancer and premalignant lesions after kidney transplantation

K. Zwart[1], R.C.M. van Kruijsdijk[2], V. Angerilli[3], M. Baas[2], M. Koopman[1], I.D. Nagtegaal[3], G.M. Bol[1]

[1]Medical Oncology Dept, UMC - University Medical Center Utrecht, Utrecht, Netherlands; [2]Nephrology, Radboud University Medical Center, Nijmegen, Netherlands; [3]Pathology, Radboud University Medical Center, Nijmegen, Netherlands

Background: Improved survival of kidney transplant recipients has led to an increased cancer risk, including colorectal cancer (CRC). We hypothesize that impaired immunosurveillance allows progression of sessile serrated lesions (SSL), leading to a higher incidence of immunogenic mismatch repair deficient (dMMR), but not mismatch repair proficient (pMMR) CRC.

Methods: The nationwide Dutch transplant, pathology, and cancer registries were linked by probabilistic matching to retrieve clinical data of all transplant patients between 2000-2022. A standardized incidence ratio (SIR) was calculated for CRC adjusted for age, sex, and incidence year. Mismatch repair (MMR) status was determined through immunohistochemistry and risk ratios (RR) were estimated. Premalignant lesions were identified within the Dutch CRC screening program. Kidney transplant patients were 1:4 matched to controls based on age, sex, and year of screening.

Results: 20 181 kidney transplant patients were identified between 2000-2022 (Table). The mean recipient age was 48 years and 60% were male. 218 tumors were observed, resulting in a SIR of 1.11 (95% CI: 0.96-1.26). In the 162 transplant patients in which MMR status was determined, dMMR occurred more frequently compared to the general population, RR 2.1 (95% CI: 1.6-2.7). Polyps were identified in 488 kidney transplant patients and matched to 1952 patients without kidney transplantation. SSL with dysplasia occurred more often in the transplantation cohort, RR 2.3 (95% CI: 1.3-3.9).

Table: 561P Incidence of CRC

	CRC	
	Transplantation cohort	Control
Total no. of people	20 181	Population (16.6 mln.)
Observed and expected tumors	218 (observed)	197 (expected)
dMMR/total tumors	45/162 (28%)	5640/42 982 (13%)
Stage I	9/37 (24%)	1214/9405 (13%)
Stage II	14/36 (39%)	2138/9635 (22%)
Stage III	10/35 (29%)	1839/15 370 (12%)
Stage IV	12/45 (27%)	449/8572 (5%)
Stage unknown	0/9	-
	Premalignant lesions (2015-2022)	
Total no. of people	488	1965
Total no. of findings	1336	5181
Adenoma	1099	4050
Serrated polyps	237	1131
Type of serrated polyps		
Hyperplastic	172 (73%)	748 (66%)
SSL	61 (26%)	351 (31%)
Traditional serrated adenoma	4 (1.6%)	32 (2.8%)
Dysplasia		
SSL with dysplasia	15 (25%)	38 (8%)
SSL without dysplasia	46 (75%)	313 (92%)

Conclusions: This population-wide study suggests an increased risk to develop dMMR CRC, in all stages, after kidney transplantation but not pMMR CRC. Furthermore, we show an increased incidence of dysplasia in SSL, in which dMMR frequently occurs. This illustrates that unchecked immunosurveillance in transplant patients is clinically apparent in precancerous and cancerous lesions. These findings could change the manner of CRC screening and management of kidney transplant patients.

562P Quantifying the effect of colonoscopy and polypectomy rates in stage shift of colorectal cancer and reduced need for adjuvant chemotherapy

M. Sarofim[1], A. Ashrafizadeh[1], A. Gill[2], K. De Silva[2], J. Evans[1], S. Clarke[3], N. Pavlakis[3], I. Norton[4], A. Engel[1]

[1]Dept of Colorectal Surgery, Royal North Shore Hospital, St Leonards, NSW, Australia; [2]Dept of Anatomical Pathology, Royal North Shore Hospital, St Leonards, NSW, Australia; [3]Dept of Medical Oncology, Northern Cancer Institute, St Leonards, NSW, Australia; [4]Dept of Gastroenterology, Royal North Shore Hospital, St Leonards, NSW, Australia

Background: Existing literature supports the principle of early detection of colorectal cancer (CRC) via screening but has not definitively demonstrated an association between colonoscopy or polypectomy rates and CRC stage over time.

Methods: A longitudinal study was performed using the Australian national health database to obtain colonoscopy and polypectomy rates between 1998-2017. A second prospective database of CRC resection specimens was analysed for this period. The cohort was divided into three based on time intervals related to the national bowel cancer screening program: pre-commencement 1998-2006 (Period A), immediately post-commencement 2007-2011 (Period B), and subsequent years 2012-2017 (Period C).

Results: Annual colonoscopy rates doubled, and polypectomy rates tripled during the study ($p<0.001$). A total of 4506 patients underwent colorectal cancer resections. Annual colonoscopy rate correlated to a lower T-stage ($p=0.038$) and lower N-stage ($p=0.026$) leading to a 7% absolute (13.4% relative) increase in early CRC (stage I-II) in Period C ($p<0.001$). Across the study there was also a significant increase in right-sided tumours, and concurrent MMR deficiency and BRAF mutation.

Conclusions: Polypectomy and colonoscopy rates increased after the introduction of a national screening program which correlated to a clinically relevant shift to earlier CRC stages, a reduction in CRC incidence which manifested five years after implementation, and a reduced need for adjuvant chemotherapy.

563P The impact of participation in colorectal cancer screening: A population-based results from Lithuania

T. Poskus[1], M. Jakubauskas[1], L. Jakubauskiene[2], C. William Thattakath[3], E. Jasiunas[4], K. Strupas[1]

[1]Clinic of Gastroenterology, Nephrourology and Surgery, Institute of Clinical Medicine, Vilnius University - Faculty of Medicine, Vilnius, Lithuania; [2]Clinic of Obstetrics and Gynecology, Institute of Clinical Medicine, Vilnius University - Faculty of Medicine, Vilnius, Lithuania; [3]Faculty of Medicine, Vilnius University - Faculty of Medicine, Vilnius, Lithuania; [4]Center of Informatics and Development, Vilnius University Hospital Santaros Klinikos, Vilnius, Lithuania

Background: Around 1.9 million new cancer cases and around 930,000 deaths were attributed to colorectal cancer (CRC) worldwide in 2020. The European Union recommends population-based CRC screening. Reported long'term results from various CRC screening programs are quite controversial as some of them report no survival gains. In June 2009 the CRC screening program was initiated in Lithuania. The aim of the study is to report the impact of CRC screening program on long-term mortality.

Methods: The anonymous data of the population aged 50-74 from the years 2013 to 2019, who participated in the CRC screening program were extracted from the statistical database of the National Health Insurance Fund, which provided both, the participation in different services of screening indicated by specific codes, and the mortality and survival marked in the database. For statistical analysis we divided patients in three groups: Negative fecal immunochemical test (FIT); positive FIT and screening colonoscopy performed; positive FIT and screening colonoscopy was not performed. The statistical analysis was performed using the R statistical software package v4.2.2.

Results: From the year 2013 to 2019 a total of 1,521551 people participated in the screening program. During the observation period 66920 (4.4%) patients died. The highest mortality was seen in patients that were diagnosed with cancer (19%). High mortality was seen in patients that did not proceed with further colonoscopy after a positive FIT. These patients had a significantly higher mortality rate: Negative FIT (4.2%) vs. Positive FIT + colonoscopy (4.9%) vs. Positive FIT - colonoscopy (8.6%); $p<0.001$. A univariate logistic regression analysis revealed that positive FIT + colonoscopy (OR 1.19 95% CI 1.15-1.24; $p<0.001$) and positive FIT - colonoscopy (OR 2.18 95% CI 2.12-2.24; $p<0.001$) groups had significantly increased mortality risks when compared to the negative FIT group.

Conclusions: Fully completed screening after a positive FIT result is associated with significantly reduced mortality.

564P A large-scale real-world study for colorectal cancer screening

S. Liu[1], Y. Wang[1], D. Zhuo[2], J. Peng[2], R. Jiang[2], C. Duan[1], F. Liu[1], H. Zhang[3], X. Tian[4], X. Ding[5], M. Zhang[1], D. Cao[1], Y. Liu[1], Y. Wang[2], Z. Shi[1]

[1]Gastroenterology, Wuhan Hospital of Integrated Traditional Chinese and Western Medicine, Wuhan, China; [2]Oncology, BGI Genomics Co., Ltd, Shenzhen, China; [3]Gastroenterology, Wuhan Central Hospital, Wuhan, China; [4]Gastroenterology, Wuhan Third Hospital, Wuhan, China; [5]Gastroenterology, Wuhan Fourth Hospital, Wuhan, China

Background: Colorectal cancer (CRC) is a major public health concern worldwide. CRC screening is recommended for average-risk population starting at age 45 to 50. However, the participation rate of CRC screening is often low due to lack of awareness or limited access to screening. Fecal DNA tests have shown promising performance in detecting CRC, but large-scale, prospective, population-based evidence for screening effectiveness has been lacking.

Methods: A community-based CRC screening program was implemented in Wuhan, Hubei Province, China, from 2021 to 2022. Residents aged between 45 and 60 were eligible. Stool samples were self-collected and returned to the community health centers. A fecal DNA test (ColoTect®) which detected methylation status of *SDC2*, *ADHFE1*, and *PPP2R5C* was used, with a sensitivity of 88% for detecting CRC and a sensitivity of 46% for detecting advanced adenoma, at a specificity of 92%. Participants who tested positive were advised to receive diagnostic colonoscopy. All participants provided written informed consent.

Results: 105,537 subjects were invited, 102,348 subjects returned stool samples and 101,217 passed quality control. 4,483 (4.4%) subjects tested positive for fecal DNA test, and 3,200 (71.3%) underwent colonoscopy. Among these, 2347 (73.3%) had abnormal colonoscopy findings, of which 1,330 (56.7%) subjects received pathological diagnosis. Positive predictive values (PPVs, number of cases/number of colonoscopies) for CRC, adenomas, polyps were 1.3%, 16.3%, and 21.6%, respectively; 28.0% of all colonoscopies showed colorectal neoplasm but lack pathological diagnosis. 6.1% showed other abnormalities such as enteritis. Compared to a national CRC program implemented in Hubei Province between 2018 and 2019 using fecal immunochemical tests and CRC risk assessment questionnaires, current program showed a lower initial positive rate (4.4% vs. 17.4%), higher PPVs for CRC (1.3% vs. 0.08%) in the age-matched group, and a higher adherence rate for colonoscopy (71.3% vs. 18.2%).

Conclusions: Preliminary prospective evidence suggested that fecal DNA tests had promising diagnostic yield in population-based CRC screening, outperforming FIT/risk assessment questionnaire-based screening strategy.

Medizinische Klinik, Coburg, Germany; [10]Institut für Pathologie, Georgius Agricola Stiftung Ruhr - Institut für Pathologie - Ruhr-Universität Bochum, Bochum, Germany

Background: The incidence of early-onset colon cancer (early-onset CC, age <50 years (yrs)) is rising with limited data on its clinical and molecular characteristics. We analyzed a real-world cohort of the AIO ColoPredict Plus (CPP) Registry.

Methods: CPP collects data and tissue from patients (pts) with CC UICC stage I-III. Clinical and molecular characteristics were assessed comparing pts <50yrs with pts 50+ using student's Test and Fishers exact test. Disease-free survival (DFS) rate at 3 yrs was reported. Comorbidity was assessed by Charlson comorbidity index (CCI). Median follow-up was 28.1 months.

Results: Out of 9215 pts 479 (5%) had early-onset CC (median age 44 yrs (22-49) vs. 72 yrs (50-100) in late-onset CC). There were no significant differences regarding sex or BMI. Younger pts had less comorbidities (CCI 0: 91%) than older pts. (CCI 0: 60%, p <0.001). Interestingly, younger patients had larger tumors (p=0.045), more often lymph node metastases (p=0.002) and thus higher UICC stages (p<0,001). Tumor localization was predominantly left-sided in early- (53%) and right-sided in late-onset CC (61%, p<0,001). Younger pts more often received adjuvant chemotherapy (p<0,001) and more frequently oxaliplatin combinations (p<0,001). Mutational analysis was available in 5045 pts, 5% (264 pts) with early-onset CC. No significant difference in K- or N-RAS mutations or MSI were detected. The KRAS subtype p.G12C and BRAF mutations were significantly less prevalent in early-onset compared to late-onset CC (p=0,03 and p<0,01). Younger pts had a better 3 yrs DFS rate.

Conclusions: Pts with early-onset CC in our unique real-world cohort are more often UICC stage III with left primary tumors and better DFS. They also display distinct molecular features which should be considered when making treatment decisions.

566P Long-term survivorship outcomes of adolescents and young adults (AYA) with cancer of the lower gastrointestinal tract

K. Bolhuis[1], M. Chalabi[1], C. Vlooswijk[2], M. van Leerdam[1], N. Kok[3], W.T.A. Van Der Graaf[4], O. Husson[5]

[1]Department of Gastrointestinal Oncology, The Netherlands Cancer Institute, Amsterdam, Netherlands; [2]Research, Netherlands Comprehensive Cancer Organisation, Utrecht, Netherlands; [3]Surgical Oncology, Netherlands Cancer Institute, Amsterdam, Netherlands; [4]Medical Oncology, Netherlands Cancer Institute/Antoni van Leeuwenhoek Hospital, Amsterdam, Netherlands; [5]Psychosocial Research And Epidemiology Department, Netherlands Cancer Institute/Antoni van Leeuwenhoek Hospital, Amsterdam, Netherlands

Background: The incidence of lower gastrointestinal tract (GI) cancers among adolescents and young adults (AYAs) is rising. A cancer diagnosis and treatment(s) can lead to long-term morbidity and disrupt physical, cognitive, and psychosocial development, which can result in a reduced health-related quality of life (HRQOL) in this young population. The aim of this study was to describe the long-term survivorship outcomes of AYA with lower GI cancer.

Methods: The Netherlands Cancer Registry identified AYA cancer survivors (aged 18-39 years at initial cancer diagnosis, 5-20 years past diagnosis). They were invited to participate in a population-based, cross-sectional questionnaire study (SURVAYA). Survivorship issues (EORTC QLQ-SURV111) and HRQOL (EORTC QLQ-C30) were assessed. For this secondary analysis, we used data of all participating AYA colorectal and anal cancer patients.

Results: 82 SURVAYA participants were selected (43% colon, 47% rectal and 8% anal cancer; 59% male sex; mean age 34 years at study participation; 11.3 years after diagnosis). Primary treatment consisted of surgery (18%); surgery and chemotherapy (23%); surgery and radiotherapy (10%); radiotherapy and chemotherapy (10%); surgery, radiotherapy and chemotherapy (39%); 35% of patients had a stoma. AYA cancer survivors reported to some extent issues related to body image (41%), sexual intimacy (41%), fertility (49%), social isolation (43%), uncertainty about future (71%), reduced career opportunities (55%), reduced income (41%), and getting a mortgage/insurance (49%). Compared to the normative population, AYA cancer survivors experienced higher levels of fatigue (31.9 vs. 19.4), pain (15.4 vs. 11.4), insomnia (22.4 vs 17.3) and diarrhea (16.2 vs. 5.5); and reported lower physical (89.7 vs. 94.8), role (81.1 vs. 91.7), emotional (77.7 vs. 85.4), cognitive (80.0 vs. 92.0) and social functioning (85.3 vs. 93.6). Overall HRQOL was lower for AYAs compared to the norm (72.1 vs. 75.9; all p<0.05).

Conclusions: A substantial proportion of AYA lower GI cancer survivors reports long-term psychosocial and physical survivorship issues. Access to tailored age-specific healthcare resources is needed to maximize their HRQOL.

567P Impact of concomitant medication on recurrence, survival and tolerability of chemotherapy in early colon cancer patients: Results from the PETACC 8 study

E.S. Bergen[1], C. Canton[2], M. Boulin[2], K. Le Malicot[3], J. Bennouna[4], D. Gonzalez[5], L. Mineur[6], R. Coriat[7], O. Bouche[8], C. Lepage[9], J. Taieb[10]

[1]Division of Oncology, Department of Medicine I, Medical University of Vienna, Vienna, Austria; [2]EPICAD LNC-UMR1231, Burgundy Franche Comté University, Dijon, France; [3]Biostatistics, Fédération Francophone de Cancérologie Digestive, Dijon, France; [4]Medical Oncology Department, Hopital Foch, Suresnes, France; [5]U1231, Faculty of Health Sciences, Dijon, France; [6]Department of Medical Oncology, Cancer Avignon Provence Institute, Avignon, France; [7]Department of Gastroenterology, Hopital Cochin AP-HP, Paris, France; [8]Department of Digestive Oncology, CHU de Reims - Hôpital Robert Debré, Reims, France; [9]Department of Hepato-Gastroenterology, CHU Dijon, Dijon, France; [10]Gastroenterology and Digestive Oncology Department, Hopital European George Pompidou, Paris, France

Background: Few information is available about the impact of concomitant medication (CM) on the tolerability of chemotherapy as well as on the outcome of cancer patients. Therefore, we evaluated the impact of CM on disease-free survival (DFS), overall survival (OS) as well as side effects under adjuvant chemotherapy in a large cohort of early colon cancer (CC) patients.

Methods: Patients of the phase III randomized trial PETACC8 had resection with curative intent of a stage II or III CC and were treated with standard adjuvant fluoropyrimidine and oxaliplatin (+/- cetuximab) over 6 months.Information on CM intake has been gathered by study visits at inclusion and during chemotherapy. We investigated the association between number of CM as well as the 5 most frequently applied CM categories according to the WHO ATC classification system (gastroesophageal reflux disease (GERD) treatment, anticoagulants, aggregation inhibitors, cardiovascular sphere (CVS) treatment and antidiabetic drugs) with DFS, OS and grade 3/4 adverse events (AEs).

Results: Within 2537 patients eligible for this analysis, median number of CM intake was 8 (range 0 to 25), with only 22 patients (0.9%) without any CM. 1328 (51.9%) reported a GERD treatment, 452 (17.7%) an anticoagulant, 279 (10.9%) an anti-aggregant therapy, 1028 (40.2%) a CVS treatment and 236 (9.2%) an antidiabetic drug. Anticoagulation was the only CM category significantly and independently associated with a shorter DFS (HR 1.29, 95%CI 1.07-1.56, *p=0.009*) as well as OS (HR 1.29, 95%CI 1.03-1.61, *p=0.027*). No association of number of CM (<5, 5-10, >10) has been observed neither with DFS (ref.; HR 0.98; HR 1.17) nor OS (ref.; HR 0.98; HR 1.15) (*p>0.05*). Grade 3/4 AEs directly correlated with number of CM (*p<0.001*) and occurred significantly more frequently in patients with GERD treatment (78.8 vs 66.6%, *p<0.001*), anticoagulation (81.4 vs 71.1%, *p<0.001*) and anti-aggregants (79.2 vs 72.1%, *p=0.001*).

Conclusions: Early CC patients with a high CM intake did not generally exhibit an impaired outcome, even though tolerability of adjuvant chemotherapy was reduced. Anticoagulation was the only CM category associated with a shorter DFS and OS.

Background: Testing for DNA mismatch repair deficiency (MMRd) is recommended for all colorectal cancers (CRC). Automation of this would facilitate precision medicine, particularly if it provided information on likely aetiology.

Methods: We developed AIMMer, an AI-based method for determination of MMR protein expression at single cell level from IHC-stained routine pathology samples. We applied it to over 2,000 cases from the SCOT clinical trial, which compared 3 vs 6 months of oxaliplatin-based adjuvant chemotherapy (mFOLFOX6 or CAPOX) for stage II/III CRC. AIMMer performance was evaluated against ground truth established by blinded review by two expert pathologists, and MMRd prognostic and predictive value was determined by Cox proportional hazards models.

Results: Benchmarking of AIMMeR against pathologist ground truth MMR calls revealed AUROC of 0.98 (bootstrap 95% CI = 0.97−0.99) and Youden index (sensitivity plus specificity) of 1.87 at cutpoint of 10.7% MMR positive cells. This cutpoint gave positive predictive value (PPV) of >95% for both the commonest pattern of somatic MMRd (MLH1 and PMS2 loss) and for MMR proficient (MMRp) status, and agreement with pathologist calls approaching that between individual pathologists (k = 0.79−0.82 vs 0.88). Analysis of CRC recurrence-free interval (RFI) confirmed MMRd prognostic value in oxaliplatin-treated patients (multivariable-adjusted HR (aHR) = 0.62, 95% CI = 0.44−0.88, P=0.007), with effect size larger in those <70 years and those with right-sided tumours. MMRd did not predict differential benefit from chemotherapy duration. Patients with MMRp tumors had similar RFI whether treated with CAPOX or FOLFOX (aHR = 0.95, 95% CI= 0.77-1.16, P=0.6), while those with MMRd tumours treated with FOLFOX had shorter RFI (aHR = 2.08, 95% CI= 1.09-3.97, P=0.027, $P_{\text{INTERACTION}}$=0.04).

Conclusions: AIMMeR holds promise to reduce pathologist workflow and streamline clinical diagnostics in CRC. The possible predictive value of MMRd for chemotherapy regimen should be investigated in additional cohorts.

569P Artificial intelligence for detection of mismatch repair deficiency in colon carcinomas (alliance)

F.A. Sinicrope[1], G. Nelson[2], B. Saberzadeh Ardestani[3], G. Park[4], Y. Lim[5], D. Yan[6], K. Shanmugam[7], S. Alberts[8], Q. Shi[9], C-Y. Ock[10], R. Pai[11], D. Segovia[2]

[1]Oncology, Mayo Clinic, Rochester, MN, USA; [2]Clinical Trials and Biostatistics, Mayo Clinic - Rochester, Rochester, MN, USA; [3]Gastroenterology, Mayo Clinic - Rochester, Rochester, MN, USA; [4]Oncology, Lunit Inc., Seoul, Republic of Korea; [5]Oncology, SNUH - Seoul National University Hospital, Seoul, Republic of Korea; [6]R&D, Roche Diagnostics - Research and Development, Informatics, Belmont, MA, USA; [7]CDMA, Roche Diagnostics - Research and Development, Informatics, Belmont, AZ, USA; [8]Oncology, Mayo Clinic - Rochester, Rochester, MN, USA; [9]HSR Department, Mayo Clinic, Rochester, MN, USA; [10]Oncology Group, Medical Affairs, Lunit Inc., Seoul, Republic of Korea; [11]Pathology and Laboratory Medicine, Mayo Clinic - Arizona, AZ, USA

Background: Artificial intelligence (AI) algorithms have been developed to distinguish MMR-D from MMR-P (proficient) tumors, yet they lack biological interpretability. To address this shortcoming, we used validated AI algorithms to detect and quantify well described morphological features in colon cancers from whole slide images.

Methods: Digital images of stage III colon carcinomas from participants in a phase III trial of FOLFOX-based adjuvant chemotherapy (NCCTG N0147; Alliance) were utilized. Available MMR-D (n=191) and randomly selected MMR-P (n=188) cancers were analyzed. QuantCRC quantifies the amount of stroma and stromal subtypes (immature, mature, inflammatory) and tumor/stroma ratio in addition to grade, mucin, signet ring cells, budding/poorly differentiated clusters (TB/PDC) and tumor-infiltrating lymphocytes (TILs). We also distinguished TILs in epithelium vs stromal using another AI algorithm (Lunit SCOPE IO). Area under the curve (AUC), i.e., discrimination threshold, was measured for each feature to predict MMR status.

Results: Among AI-derived morphological features, significant differences were found by MMR status whereby dMMR cancers had lower immature stroma but higher inflammatory stroma, higher tumor grade, and increased mucin, signet ring cells, tumor size, TB/PDCs, and TILs (all Kruskal-Wallis p<0.05). Univariately, AUC (95% CI) values for prediction of MMR status above 0.6 were as follows: TILs 0.72 (0.67-0.77), immature stroma 0.67 (0.62-0.73); inflammatory stroma 0.67 (0.62-0.73); tumor grade 0.65 (0.60-0.71); signet ring cells 0.65 (0.60-0.71); mucin 0.64 (0.59-0.70). Given that TILs in the overall tumor was most discriminant, we then utilized a TIL-specific AI algorithm measuring TILs in epithelium and stroma and found that epithelial TILs had a significantly higher AUC [0.79 (0.74-0.84) compared to stromal TILs 0.58 (0.52-0.63) p<0.0001].

Conclusions: Among morphological tumor features quantified by AI, tumor immature desmoplastic stroma and TILs, particularly epithelial TIL densities, were best able to distinguish MMR-D from MMR-P tumors. These findings have implications for prognosis and subtype-based interventions and can guide spatial molecular interrogation.

570P Subclasses of microsatellite-instability colorectal cancer with unique molecular features and immune cell infiltration patterns

K. Wu[1], M. Wu[2], T. Luo[2], F. Li[2], L. Nunes[3], K. Hammarström[3], E. Lundin[3], I. Ljuslinder[4], A. Mezheyeuski[3], P-H. Edqvist[3], A. Löfgren-Burström[5], C. Zingmark[5], S. Edin[5], F. Ponten[3], R. Palmqvist[5], C. Lin[2], B. Glimelius[3], T. Sjöblom[3]

[1]Hangzhou Institute of Medicine (HIM), Chinese Academy of Sciences, Hangzhou, China; [2]BGI-Research, BGI-shenzhen, Shenzhen, China; [3]Department of Immunology, Genetics and Pathology, Uppsala University, Uppsala, Sweden; [4]Dept. of Radiation Science, Umea University, Umea, Sweden; [5]Dept. of Medical Biosciences, Umea University, Umea, Sweden

Background: Mismatch repair deficient or microsatellite instable (MSI) tumors are often characterized by high mutational burdens and strong immune infiltration and have shown higher sensitivity to immune checkpoint inhibitors (ICIs) compared to microsatellite stable (MSS) tumors. However, only a portion of the patients with MSI colorectal cancer (CRC) gain survival benefits from ICIs treatment, suggesting unclear heterogeneity in MSI tumors.

Methods: We analyzed the whole-genomes and transcriptomes of 223 ICIs treatment-naïve MSI CRC tumors from U-CAN project. Immune cell infiltration and cancer-relevant pathways were evaluated by CIBERSORT and PROGENy, respectively. An MSI subtyping model was developed based on ResNet50.

Results: Unsupervised classification based on gene expression data divided MSI tumors into two distinct classes (class1 and 2), with MSI class1 characterized by a lower level of chromosomal instability, a higher level of hypoxia, and more activated EGFR, JAK-STAT, TNFa, and NFkB pathways than class2. However, two MSI classes showed no differences in 5-year survival. Further investigation of the immune cell population showed that class1 had considerably higher immune cell infiltration compared to class2, specifically in M0, M1 and M2 macrophages, CD4 and CD8 T-cells, naïve B-cells, resting NK-cells, and neutrophiles. Class2 exhibited significantly higher loss in 10q23.31 (containing *PTEN*) and reduced expression of *PTEN*, which may lead to an immunosuppressive tumor microenvironment and partially explain the higher activation in PI3K and VEGF pathways in class2 compared to class1. Importantly, ICIs targets, such as *CTLA4, PD-1,* and *PD-L1* all had higher expressions in calss1. We further developed an MSI subtyping model based on refined pathway features of normal tissue, tumors with MSS, class1 or 2. Ongoing analyses include validation of MSI classification in the TCGA dataset.

Conclusions: We illustrated the heterogeneity in MSI CRCs and revealed two subclasses of MSI with distinct molecular features, which may be informative for immune-based treatments. The MSI subtyping model may further facilitate precision immunotherapy and allow patients to derive clinical benefits.

571P Artificial intelligence-powered analysis of tumor lymphocytes infiltration: A translational analysis of AtezoTRIBE trial

M. Carullo[1], C. Antoniotti[1], C. Ahn[2], T. Lee[2], V. Angerilli[3], M. Ambrosini[4], D. Rossini[1], F. Schietroma[5], S. Lonardi[6], S. Tamberi[7], F. Ghelardi[4], M. Seo[2], A. Righetto[3], V. Conca[1], G. Vetere[1], S. Shin[2], C. Ugolini[8], C-Y. Ock[2], M. fassan[3], C. Cremolini[1]

[1]Department of Translational Research and New Technologies in Medicine and Surgery/Unit of Medical Oncology 2, University of Pisa/AOUP, Pisa, Italy; [2]Oncology Group, Lunit Inc., Seoul, Republic of Korea; [3]Department of Medicine, University of Padua - School of Medicine, Padua, Italy; [4]Medical Oncology Department, De, Milan, Italy; [5]Dipartimento di Oncologia, Fondazione Policlinico Universitario Agostino Gemelli IRCCS, Rome, Italy; [6]Oncology department, IOV - Istituto Oncologico Veneto IRCCS, Padua, Italy; [7]Oncology Unit, Ospedale degli Infermi - AUSL Romagna, Faenza, Ravenna, Italy; [8]Unit of Pathology 3, AOU Pisana - Stabilimento di Santa Chiara, Pisa, Italy

Background: Adding atezolizumab (atezo) to FOLFOXIRI/bev prolongs PFS of mCRC patients (pts) in AtezoTRIBE trial. We explored the predictive role of immune phenotypes (IPs) and Inflamed Score (IS), as assessed by means of Lunit SCOPE IO, an artificial intelligence (AI)-powered whole-slide images (WSI) analyzer of tumor infiltrating lymphocytes (TILs).

Methods: In AtezoTRIBE study mCRC pts were randomized 1:2 to upfront FOLFOXIRI/bev -/+ atezo. AI-powered spatial and quantitative analyses of TILs were conducted on pre-treatment hematoxylin & eosin-stained WSI from 173 (79%) enrolled pts. Three IPs (inflamed, excluded, desert) were defined according to TILs density in tumor epithelium and stroma, and IS was calculated as the proportion of grids classified as inflamed within a WSI. IPs and IS were correlated with immune-related biomarkers (MMR, TMB, Immunoscore IC, Immunoscore, TPS PD-L1, TILs by optical microscope) and clinical outcome.

Results: AI-powered analyses were successfully performed in 154 (84%) cases. 67 (44%) and 87 (56%) cases were classified as excluded and desert, respectively, while no inflamed cases (IS $\geq$ 33.3%) were detected. Pts with excluded and desert tumors had similar baseline features, except for a higher percentage of pts with Immunoscore IC-high (p= .006), Immunoscore-high (p= .008), and TILs-high (p= .006) tumors in the excluded *vs* desert group. A similar PFS benefit from adding atezo was reported in the excluded (HR 0.70, 95% CI 0.40-1.23) and desert (HR 0.73, 95% CI 0.45-1.17) groups (p_{int}=0.817). Tumors with high ($\geq$3rd quartile, 1.01%) IS (n=39) were more frequently dMMR (p= .031) and TMB-high (p= .020) than those with low (<3rd quartile) IS (n=115). The PFS benefit from adding atezo was homogeneous between tumors with high IS (HR 0.80, 95% CI 0.38-1.67) and low IS (HR 0.69, 95% CI 0.44-1.07) (p_{int}=0.791). Similar results were found in the pMMR cohort.

Conclusions: IPs and IS by Lunit SCOPE IO provide a characterization of tumor microenvironment, being associated with Immunoscore, Immunoscore IC and TILs. Further development of AI-powered TILs analyses taking into account their densities may help identifying biomarkers of immunogenicity in mCRC.

Background: Colorectal cancer (CRC) is a heterogeneous disease with multiple subtypes that differ in their clinical and molecular features. The presence of neoantigens derived from somatic mutations is a promising avenue for immunotherapy in CRC. However, the heterogeneity of the neoantigen landscape among CRC subtypes remains unclear.

Methods: We analyzed the whole-genomes and transcriptomes of 1063 CRC patients from a Swedish large cohort. HLA alleles were called by at least two HLA callers including HLA-HD, HLA-LA, Kourami, OptiType, PHLAT, Polysolver, xHLA for each patient. Neoantigens were predicted by pVACseq pipeline using the default settings.

Results: In total, 83,630 MHC class I neoantigens derived from 29,106 mutations (511,159 mutations were inputted) were predicted in 979 patients. Average 6.1 neoantigens were from 4,480 frameshift INDELs while only average 2.3 neoantigens were from 24,276 SNVs. Patients older than 80 years carried more neoantigens than those under 65 years, and women tended to have more neoantigens than men (Wilcoxon test, P<0.01). Tumor neoantigen burden was significantly higher in right-colon, stage II, and hypermutated (HM) tumors (P<0.0001). In total, 850 mutations were predicted to generate neoantigens in at least two patients, including *KRAS* G12D (6.3%), *RNF43* G659X (6.1%), *KRAS* G12V (5.2%), *TBC1D23* K647X (2.9%), and *MSH3* K381X (2.8%). Neoantigen numbers from *PODXL2* and *CRAT* mutations were significantly higher in consensus molecular subtype (CMS) 3 tumors, whereas neoantigens from *JAG2* mutations were more common in CMS2 (chi-square test, P <0.05). Neoantigens derived from *DNAH3*, *KRAS* and *ERBB2* mutations (37%, 47% and 52% respectively) in non-HM patients were significantly more than those (5%, 14% and 13% respectively) in HM patients. Furthermore, in stage I-III, nHM patients (n=11) with *DNAH3* neoantigens have significantly longer overall survival than patients (n=24) with only *DNAH3* mutations.

Conclusions: Our study constitutes the largest neoantigen dataset from integrated genome and transcriptome of CRC to date and illustrates the heterogeneity of the neoantigen landscape among CRC subtypes. The identified neoantigens may contribute to future individualized CRC immunotherapies.

Background: Tumour infiltrating CD8$^+$ cytotoxic T cells confer favourable prognosis in colorectal cancer (CRC). The added prognostic value of other immune cells is unclear.

Methods: We used multiparameter co-immunofluorescence to determine the density of CD8$^+$, CD20$^+$, FoxP3$^+$ and CD68$^+$ cells in the intraepithelial (IE) and intrastromal (IS) compartments in stage II/III CRCs from the SCOT and QUASAR2 trials. We determined

marker prognostic and predictive value by Cox regression of SCOT cases, with validation in the QUASAR2 cohort.

Results: Our study included 2,340 SCOT and 1,069 QUASAR2 cases. Univariable analysis of recurrence-free interval (RFI) in SCOT revealed expected prognostic value of intraepithelial CD8 ($CD8^{IE}$) (continuous variable: HR for cases at 75th vs 25th percentile (HR^{75vs25})= 0.73, 95% CI=0.68-0.79, P=2.5e-16) and, less expectedly FoxP3 within tumour stroma ($FoxP3^{IS}$) (HR^{75vs25})= 0.71, 95% CI=0.64-0.78, P=1.5e-13), but not epithelium. $CD8^{IE}$ and $FoxP3^{IS}$ were independently prognostic in multivariable analysis, and a composite marker including both ($CD8^{IE}$-$Foxp3^{IS}$) was superior to either alone as a continuous variable ($adjHR^{75vs25}$= 0.70; 95%CI=0.63−0.78; P=5.1e-11), and when categorised into three groups (Low/Int/High) using sample medians (Int vs High HR = 1.60, 95%CI=1.24−2.05, P=2.5e-04; Low vs High HR = 2.30, 95%CI=1.80−2.95; P=3.6e-11). These results were validated in the QUASAR2 trial. Pooled analysis of both studies revealed interactions between $CD8^{IE}$-$FoxP3^{IS}$ and tumour sidedness ($adjP_{INT}$=0.010), stromal proportion ($adjP_{INT}$=0.018), and MMR status ($adjP_{INT}$=0.079). $CD8^{IE}$-$FoxP3^{IS}$ refined stage III risk groups, with clinical low risk (T1-3, N1), $CD8^{IE}$-$FoxP3^{IS}$ low cases demonstrating similar 3-year recurrence-free probability to clinical high risk (T4 and/or N2), $CD8^{IE}$-$FoxP3^{IS}$ high cases (79.2 vs 76.4%, adj log-rank P=0.16).

Conclusions: Combined evaluation of $CD8^{IE}$ and $FoxP3^{IS}$ is superior to single markers and refines CRC risk stratification. $FoxP3^{IS}$ prognostic value is inconsistent with an immunosuppressive role; further investigation of these cells as an immunotherapy target is merited.

574P Comparative analysis of the tumor immune microenvironment (TIME) in primary and metastatic sites of microsatellite stable (MSS) and microsatellite instability-high (MSI) colorectal cancer

M. Fakih[1], J. Ye[2], C. Wang[1], C. Egelston[2], M. Huang[3], J. Mercer[4], M.A. Thompson[5], J. Gong[6]

[1]Medical Oncology & Therapeutics Research, City of Hope Comprehensive Cancer Center, Duarte, CA, USA; [2]Departement of Immuno-Oncology, City of Hope Comprehensive Cancer Center, Duarte, CA, USA; [3]RWDA-MA, Tempus Labs, Inc., Chicago, IL, USA; [4]Medical Affairs Department, Tempus Labs, Chicago, IL, USA; [5]Medical Affairs, Tempus Labs, Chicago, IL, USA; [6]Medical Oncology, Cedars-Sinai Medical Center, Los Angeles, CA, USA

Background: We have previously reported significant differences between the tumor immune microenvironment (TIME) of primary colorectal cancer (CRC-P) and different metastatic sites. Increased immune cell infiltration, B-cells, and CD8 cells and decreased macrophages were noted in CRC-P and lung metastatic (LuM) lesions compared to liver (LM) and peritoneum (PM) metastases. We expanded our work to MSI CRC and compared their TIME to respective MSS tumor sites.

Methods: De-identified cases of MSS and MSI metastatic CRC that underwent next-generation sequencing with the Tempus xT assay were selected from the Tempus Database. Gene expression patterns of immune cells, including B, T (CD4+, CD8+), NK cells, and macrophages, were used to predict relative intra-tumor abundance. MSI and MSS cohorts included CRC-P, LM, and PM. LuM was analyzed only in MSS tumors due to the limited number of MSI LuM. Tumor mutational burden (TMB), neoantigen burden, and proportion of immune cells in CRC-P, LM, and PM were compared across MSI and MSS patients. Chi-squared/Fischer's exact tests or Kruskal-Wallis tests were used to assess statistical significance.

Results: A total of 208 MSI and 6,732 MSS tumors were subject of analysis. No differences were noted in TMB, neoantigen load, or PD-L1 expression between MSI CRC-P, LM, or PM. Across the 3 tissue groups, the median TMB and neoantigen tumor burden were significantly higher in MSI cohorts when compared to MSS cohorts ($p<0.001$). Compared to MSS LM, MSI LM exhibited a higher percentage of CD8 cells ($p=0.002$) and NK cells ($p<0.001$), with a trend towards a lower percentage of macrophages ($p=0.14$). Similar differences were noted for MSI PM compared to MSS PM (CD8 cells $p=0.018$, NK cells $p=0.044$ and macrophages $p=0.023$). The TIME of MSS LuM lesions shared more similarities with that of MSI LM/PM than MSS LM/PM.

Conclusions: MSI LM and PM have a more favorable TIME than respective MSS metastases, explaining the discordance in response to checkpoint inhibitors (CPI) and reported CPI benefits in MSI cases across all metastatic sites. MSS LuM have a comparable TIME to MSI metastatic sites, explaining the recently reported benefits from CPI therapy in this group.

Background: Preoperative chemoradiotherapy (CRT) may enhance antitumor immunity by increasing T-cell activation and tumor infiltration. These effects could possibly sensitize tumour cells to immunecheckpoint inhibitors and other immunotherapies. We investigated the immunologic alterations occurring after preoperative CRT for locally advanced rectal cancer (LARC).

Methods: The multicenter randomized STAR-01 study compared the preoperative CRT regimen with 50.4 Gy in 28 daily fractions with concomitant infused fluorouracil at the dose of 225 $mg/m^2/d$ with the same regimen plus oxaliplatin given weekly at the dose of 60 mg/m^2 in patients with LARC. Pre- and/or postoperative specimens were available for 305 patients from this trial (109 paired pre- and post-treatment samples). The immunoistochemical evaluation was performed with a panel of immune cells and associated factors such as CD3, CD20, CD4/CD8, PD-1. The pattern of tumor infiltrating lymphocytes (TILs) and related infiltrating lymphocytes (RILs) were also assessed. Microsatellite instability (MSI)/mismatch repair deficiency (dMMR) was evaluated on pre-treatment tumour biopsies.

Results: After therapy we observed a decreased CD4/CD8 ratio ($P<.0001$) and reduced expression levels of CD20 ($P<.0001$). The expression level of CD3+ and PD-1+ cells after therapy did not change significantly. The relative increase of lymphocytes CD8+ within the CD4/CD8 ratio evaluated on post-operative samples was significantly associated with pathological complete response after CRT ($P<.0001$), event-free survival (EFS) [hazard ratio (HR)=1.77, 95% confidence interval (CI)=1.08 to 2.89, $P=.0227$] and overall survival (OS) [HR=2.01, 95% CI=1.19 to 3.4, $P=.0087$] adjusted for treatment arm and adjuvant chemotherapy.

Conclusions: Our data indicate that CRT may induce an enrichment of CD8+ T lymphocytes and this translates in a better response to CRT and survival. Data on MSI status will be presented at the meeting.

576P Prognostic values of a modified diagnostic biopsy-adapted immunoscore based on double immunohistochemical staining in patients with locally advanced rectal cancer

Q. Zeng[1], W. Liu[1], S-M. Zou[2], Y. Tang[1], J. Jin[3]

[1]Radiation Oncology Department, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Beijing, China; [2]Department of Pathology, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Beijing, China; [3]Department of Radiation Oncology, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital and Shenzhen Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Shenzhen, China

Background: Tumor immune contexture plays a crucial role in the outcome of cancer patients. The aim of this study was to evaluate the prognostic value of the modified diagnostic biopsy-adapted immunoscore (mIS_b) for patients with locally advanced rectal cancer (LARC).

Methods: We included 181 LARC patients from a single sub-center of a prospective study (NCT02533271), with 151 (83.4%) receiving surgical treatment and 30 (16.6%) following a watch-and-wait (W&W) strategy. Tumor biopsy tissues were stained using dual immunohistochemistry for CD8+ and CD3+ T cell densities, and the CD8/CD3 ratio was calculated. mISb was developed using mean percentile values of CD8+ T cell density and CD8/CD3 ratio, and patients were classified into low (0%-25%), intermediate (>25%-70%), and high (>70%-100%) mIS_b groups. Spearman correlation analysis was performed. Kaplan-Meier survival analysis, multivariate Cox regression models were used to assess the prognostic value of mIS_b for disease-free survival (DFS), and the role of mIS_b in the W&W strategy was further investigated.

Results: A strong correlation was found between CD8+ and CD3+ T cell densities (R=0.86, $P<0.001$), and a weaker correlation with the CD8/CD3 ratio (R=0.45). In the low, intermediate, and high mIS_b groups, there were 35 (23.2%), 84 (55.6%), and 32 (21.2%) patients, respectively. The respective 3-year DFS rates for these groups were 59.0%, 69.5%, and 80.1% (P=0.01). Multivariate analysis in surgically treated patients revealed mIS_b as an independent prognostic factor for DFS (intermediate vs. high: HR=2.38, 95% CI: 0.92-6.16, P=0.08; low vs. high: HR=3.69, 95% CI: 1.35-10.07, P=0.01). Among W&W patients, 6 (37.5%) in the $mIS_b \leq 50\%$ group experienced local-region or distant metastases, while only 1 (7.1%) in the $mIS_b > 50\%$ group had local-region recurrence.

Conclusions: mIS_b, as a potentially valuable prognostic indicator, demonstrates significant importance in assessing the prognosis of LARC patients. Future research is needed to further investigate the clinical application of mIS_b in rectal cancer prognosis, particularly in the context of the W&W strategy.

577P Systematically assessing the intratissue microbiota in 937 patients with colorectal cancer

H. Zhong[1], Z. Shi[1], H. Ren[1], F. Li[1], L. Nunes[2], K. Hammarström[2], R. Palmqvist[3], K. Wu[1], B. Glimelius[2], T. Sjöblom[2], C. Lin[1]

[1]BGI-Research, BGI-Shenzhen, Shenzhen, China; [2]Department of Immunology, Genetics and Pathology, Uppsala University, Uppsala, Sweden; [3]Dept. of Medical Biosciences, Umea University, Umea, Sweden

Background: Dysbiosis of the fecal microbiota has been closely related to colorectal cancer (CRC) and has increasingly proven to be associated with CRC prognosis. However, a significant knowledge gap still exists regarding intestinal tissue-resident microbes and their associations with host genetic alterations, gene expressions and prognosis in CRC.

Methods: We undertook a comprehensive analysis of the tissue-resident microbes in CRC patients from the U-CAN cohort, a large prospective longitudinal study of adult cancer patients in Sweden, using treatment-naïve whole-genome (average 53x coverage) and whole-transcriptome sequencing data of tumors (n=937) and their adjacent normal tissues (n=475).

Results: In total, 301 genera and 420 species were identified as common tissue-resident taxa. We showed for the first-time distinct enrichment patterns of tissue-resident microbiome in the right- and left-sided colons. Importantly, these patterns were highly consistent between tumor and normal tissues, with right-sided colons enriched with *Clostridium spp* and left-sided colons enriched with *Akkermansia muciniphila* and *Bifidobacterium spp*. We identified 94 tumor-enriched bacteria, and 38 were significantly associated with host hypermutation (HM) status. Previously known CRC-enriched bacteria, such as *Fusobacterium* groups and *Campylobacter*, were more prevalent in right-sided and HM tumors, and strongly correlated with mutations in host drivers and DNA damage repair genes. CRC driver genes that correlated with identified intratissue bacteria including *CASP8, TP53* and *SMAD2,* with *CASP8* significantly associated with multiple CRC-enriched taxa in all and in HM samples. Finally, risk scores derived from tumor or normal-resident taxa could both predict CRC prognosis and significantly improve the prognosis performance of the consensus molecular subtypes (CMS).

Conclusions: Our study provides new insights into the interactions between tumor-enriched microbiota with CRC and identifies potential bacteria markers that could improve the accuracy of CRC prognosis prediction. These findings can guide future efforts to exploit the performance of intratissue bacteria on CRC prognosis prediction.

Background: Early evidence suggested a role of tissue-resident microbiota (TRM) in the development of colorectal cancer. However, its presence in colorectal cancer metastases (CRCM) is poorly reported. Here, we aim to explore and characterize the TRM in CRCM.

Methods: From several biobanks in Belgium, we retrospectively collected 237 frozen samples, including 104 CRC primary tumor (PT) and 133 patient-matched CRCM (liver CRCM=98). Hepatocellular carcinoma (HCC, n=50), cholangiocarcinoma (CGC, n=23) and breast liver metastases (BLM, n = 16) were also collected. 82 CRCM were collected prospectively. The V4 region 16S rRNA gene was amplified and sequenced. We strictly applied sterile conditions from sample collection to sequencing, with the integration of negative controls (n=253). Additionally, 257 duplicated random samples were processed twice by independent experimenters. Sequencing results were processed with DADA2 to identify bacterial amplicon sequence variants (ASVs).

Results: ASVs were identified in all tissues. Microbial composition was significantly different between tumor samples and negative controls (PERMANOVA, p=0.0001). PT presented the highest bacterial biomass. ASV sharing frequency between PT and CRCM was significantly higher within than between patients (Wilcoxon test, p=0.007), suggesting potential bacterial translocation from PT to CRCM. The most prevalent PT bacteria were also the most shared in matched CRCM. No difference was observed between CRCM locations (liver, others). TRM of HCC, CGC and BLM were characterized by an ultra-low bacterial biomass, and distinct phyla compared to CRCM. In CRCM, the presence of Ruminoccocus gnavus (Rg) was associated with overall survival after CRCM resection (median 83.6 vs 41.6 months, HR: 0.35 IC95:0.13-0.90, p=0.024).

Conclusions: We observe a specific TRM in CRCM, shared with matched PT and suggesting bacterial translocation from PT to CRCM. In this cohort, the presence of Rg in CRCM seems prognostic after CRCM resection. Further experiments are needed to confirm and detail these results.

Background: Up to 35% of patients with localized colon cancer (CC) have a relapse, even after receiving optimal initial treatment. New prognostic biomarkers are required to more accurately identify patients who benefit from receiving adjuvant treatment and more personalized care. We propose an artificial intelligence (AI) model combining clinical data with fractals, radiomics and deep features extracted from baseline computed tomography (CT) exams for the prediction of CC relapse.

Methods: This multi-center retrospective observational study includes real-world clinical data from CC patients and CT examinations from 2015 to 2021. Manual segmentation of the tumor was performed by an experienced abdominal radiologist. A total of 2158 radiomics, deep features and fractal dimension features were extracted using Quibim Precision® software (Quibim, Valencia, ES). Harmonization techniques were applied to address image quality variability. ResNet152V2 deep convolutional network was applied as a transfer learning framework for deep features extraction and logistic regression model to estimate probability of relapse. 80% of the cases (136 studies) were used to train and validate the model following a nested cross-validation strategy to handle overfitting problem while 20% (34) were used for independent test set to analyze model generalization.

Results: Baseline CT exams from 170 localized CC patients (69 relapsed and 101 non-relapsed patients) with stages I (4%), II (20%) and III (76%) were included. Ten features were finally selected (2 radiomics, 8 deep features) by mRMR algorithm, providing an increased area under the curve (AUC) of 0.70 (95% CI: 0.52-0.88) in the independent set higher than that obtained with the model trained with clinical variables alone (0.50, 95% CI: 0.35-0.65). Using the DeLong test to probe the difference between the AUC of models, it can be conclude that model including radiomic information has a statistically different AUC from model with only clinical features with p-value < 0.05 ($p = 0.023$).

Conclusions: This AI approach, by identifying a panel of imaging biomarkers and in combination with clinicopathological features, will help improve clinical decision-making and patient outcomes using standard-of-care data.

580P Prognosis in stage II colorectal cancer: The effect of the primary tumor location and biomarkers

V. Liégeois[1], J. Colebunders[1], B. Mullebrouck[1], G. Vanhoutte[2], N. Van Damme[3], M. Peeters[4], K. Janssens[5]

[1]Antwerpen, University of Antwerp, Antwerpen, Belgium; [2]Oncology, UZA - University Hospital Antwerp, Edegem, Belgium; [3]Belgian Cancer Registry, Brussels, Belgium; [4]Medical Oncology, UZA - University Hospital Antwerp, Edegem, Belgium; [5]Clinical genetics, Antwerp University Hospital - Center for Oncological Research (CORE), Edegem, Belgium

Background: Primary tumor location (PTL) is a well-established prognostic factor in stage III and IV colorectal cancer (CRC), with right-sided CRC (RSCC) showing a worse prognosis compared to left-sided CRC (LSCC). However, the impact of PTL on stage II CRC remains uncertain. One explanation for these inconsistencies is the potential confounding effect of molecular biomarkers, such as MMR status. Therefore, there is a need to elucidate the prognostic value of PTL, as well as the role of biomarkers in this effect.

Methods: This study utilized observational data from a retrospective cohort obtained from the Belgian Cancer Registry (BCR). The study population comprised all patients diagnosed with pathologically confirmed stage II CRC in Belgium from January 1st, 2015, to December 31st, 2016 (n= 3,278). Information on PTL, demographics, pathologic T category (pT category), and molecular biomarkers (including MMR status, BRAF and KRAS mutations) was collected from the registry, along with vital status to calculate overall survival (OS). The primary aim of this study was to investigate the independent prognostic value of PTL in stage II CRC. Additionally, we assessed whether potential confounding factors, such as biomarkers and demographics, influenced the prognostic effect of PTL.

Results: In the univariate analysis, patients with stage II RSCC had a significantly worse OS compared to those with LSCC (including rectal cancer; p-value=0.0055 and excluding rectal cancer; p-value=0.0035). Higher age and pT4 were also significantly associated with worse OS. However, in the multivariable analysis, only gender, age, and pathologic T-stage were found to be significant predictors of OS. PTL was not a significant factor in multivariable analysis. Furthermore, biomarkers such as MMR-status, BRAF-, and KRAS mutations did not show a significant effect on OS in either analysis.

Conclusions: Our analysis led us to the conclusion that PTL is not an independent prognostic factor in stage II. Notably, we observed confounding effects between patient characteristics and the prognostic impact of PTL, such as older age at diagnosis and shorter OS in patients with RSCC. Furthermore, molecular biomarkers did not have a statistically significant effect on OS in stage II CRC.

581P The effect of exercise intervention on defecation related symptoms of colorectal cancer patients a randomized controlled trial

J. Jeon, D-H. Park, Y.J. LEE, T.H. Lee, E. Kim, C. Oh, R. Park, J.W. Kang, S. Jun, K. Chiho, S. Yeon

Sports Industry Studies, Yonsei University, Seoul, Republic of Korea

Background: Although colorectal cancer (CRC) survivors often suffer from defecation related symptoms (DRS), there are very few treatment options to improve DRS. Strengthening of abdominal muscles to increase intra-abdominal pressure and pelvic floor exercises to improve pelvic floor dyssynergia may improve DRS in colorectal cancer patients. However, the effects of exercise on DRS have not been studied fully. Therefore, the purpose of this study is to investigate the efficacy of exercise on DRS in CRC.

Methods: A total of 120 CRC who completed surgery and adjuvants therapy were recruited out of 441 approached. 120 participants were randomly assigned to either exercise (EG) or usual care group (CG). The combined weekly supervised and home-based exercise program (12 weeks) includes increase in physical activity (PA) levels to meet the ACSM guideline as well as daily calisthenics exercises. Calisthenics exercises include a total of 12 movements aimed to increase whole body muscle strengths which focused on core and pelvic floor muscles. The primary outcome was DRS score assessed the sum of blood and mucus in stool, stool frequency, abdominal pain, buttock pain, bloating, flatulence, fecal incontinence and embarrassment in EOTRC-QLQ-CR29. A two-way ANOVA repeated measures were used determine group and time interaction.

Table: 581P Effects of exercise on defecatory symptoms

	Control		Exercise		*p*-value
	Pre	Post	Pre	Post	
Blood in stool	4.7 ± 9.7	4.4 ± 9.1	7.2 ± 15.5	3.1 ± 8.9	0.05
Stool frequency	26.3 ± 27.0	20.1 ± 20.5	28.7 ± 25.1	23.4 ± 23.8	0.91
Abdominal pain	14.4 ± 22.4	11.7 ± 19.2	18.3 ± 24.9	10.0 ± 16.6	0.21
Buttock pain	12.2 ± 21.2	12.8 ± 25.4	18.9 ± 30.3	12.8 ± 26.1	0.08
Bloating	22.8 ± 22.5	25.0 ± 25.8	34.4 ± 30.7	22.8 ± 27.1	0.01
Flatulence	21.0 ± 26.0	17.7 ± 23.3	28.3 ± 33.5	21.5 ± 25.1	0.42
Fecal incontinence	13.5 ± 20.5	13.1 ± 20.5	16.9 ± 24.8	12.9 ± 25.3	0.26
Embarrassment	20.4 ± 26.8	16.7 ± 20.8	27.6 ± 32.0	18.0 ± 25.5	0.16

Bolds were statistically significant different between pre and post (p<.05), *p*= Difference between control vs. exercise

Results: Among the 120 participants enrolled, 100 (96.6%) completed the trial with supervised exercise compliance rate of 95%. PA levels increased and fitness levels improved only in the exercise group. Exercise significantly decreased DRS score (6 week - 0 week: CG= -14.0 ± 54.7 vs. EG= - 56.1 ± 99.5, *p* for group and time interaction = 0.02). Symptom scores in EG include blood and mucus in stool, abdominal pain, buttock pain, bloating, flatulence and embarrassment were improved.

Conclusions: It is concluded that both combined supervised and home-based exercise significantly reduced bowel and defecatory problems in colorectal cancer patients.

Clinical trial identification: This study was approved by The Institutional Review Board of Severance Hospital (IRB No. 4-2018-0841).

582P High accuracy of a blood-based multimodal ctDNA test to detect advanced neoplasms in a FIT-positive screening population

J. Vidal Barrull[1], A. Gómez-Alderete[1], J.C. Balboa[2], V.M. Raymond[3], I. Faull[4], B. Bellosillo Paricio[5], X. Bessa[2], C. Montagut Viladot[1]

[1]Medical Oncology Department, Hospital del Mar - Parc de Salut Mar, Barcelona, Spain; [2]Gastroenterology Department, Hospital del Mar - Parc de Salut Mar, Barcelona, Spain; [3]Medical Affairs, Guardant Health, Inc., Redwood City, CA, USA; [4]Vice-president Medical Affairs International, Guardant Health, Barcelona, Spain; [5]Molecular Biology Department, Hospital del Mar - Parc de Salut Mar, Barcelona, Spain

Background: Current colorectal cancer (CRC) screening assays decrease CRC-related incidence and mortality. However, effectiveness of screening programs is limited by the very low adherence of the population to screening recommendations. Development of less invasive, more accessible, and more convenient tests is an unmet clinical need.

Methods: A circulating tumor (ct)DNA blood-based assay that integrates genomics, epigenomics and fragmentomics was tested in blood samples from two cohorts: (1) consecutive FIT-positive individuals from the CRC Barcelona stool-based screening program; (2) patients diagnosed with CRC. Colonoscopy was performed in all individuals. Primary endpoint was to establish the accuracy of the assay to detect CRC and advanced adenomas (AA) compared to colonoscopy. A secondary exploratory endpoint analyzed the accuracy of a refined version of the assay (including protein and updating bioinformatic thresholding) to detect AA in a cohort of random FIT-positive individuals from the CRC screening program.

Results: A total of 623 blood samples were analyzed in the primary analysis. Sensitivity and specificity of the assay to detect CRC was 93% and 90%, respectively. The sensitivity of CRC detection was high in all TNM stages (84% stage I, 94% stage II, 96% stage III, 100% stage IV). The test detected advanced neoplasms (AA or serrated lesion or CRC) with a sensitivity of 85% and a specificity of 90%. Sensitivity to detect AA was 23% when using a refined version of the test, with a specificity of 86%.

Conclusions: A blood-based multimodal ctDNA assay detected advanced neoplasms with high accuracy. This non-invasive, accessible, and convenient test is key to increase the population compliance to screening recommendations.

583P A rapid blood test for the earlier detection of colorectal cancer

J. Nobes[1], J.M. Cameron[2], A. Sala[2], G. Antoniou[3], J.J.A. Conn[3], R.G. McHardy[3], D.S. Palmer[3], M.J. Baker[4]

[1]Department of Blood Sciences, University of Dundee, Dundee, UK; [2]Research Dept., Dxcover Limited, Glasgow, UK; [3]Data Science, Dxcover Limited, Glasgow, UK; [4]Medicine & Dentistry, University of Central Lancashire, Preston, UK

Background: The detection of colorectal cancer (CRC) in early stages can enable the removal of pre-cancerous lesions and allow earlier treatment. Most CRCs develop from adenomas, with "advanced" adenoma (AA) considered to be clinically relevant precursor of CRC. Screening for CRC is recommended for average-risk adults using faecal immunochemical testing (FIT), but the performance of FIT is limited. FIT reportedly has false positive rate of ∼93%, and ∼10% of CRC diagnoses have a negative FIT result. Moreover, the sensitivity for detecting AA is only 24%, highlighting the need for alternative strategies.

Methods: The Dxcover® Colorectal Cancer Liquid Biopsy is a spectroscopic test that interrogates a blood sample with infrared light and generates a distinctive signature that represents the whole biomolecular profile of the sample. Patient samples (n=296) were retrospectively collected for this discovery study, and the full cohort consisted of 100 CRC, 99 adenoma (A) and 97 colonoscopy screening controls with a non-cancer (NC) diagnosis. Machine learning algorithms have been developed with the resultant spectral profiles to predict CRC and AA. Feature importance analysis has also been carried out to identify the spectral regions found to be most significant for each classification.

Results: The CRC v NC model achieved an area under the receiver operating characteristic curve (AUROC) of 0.93. At 90% specificity, the overall CRC sensitivity was 80%, and the detection rates were consistent across stages: 83% (I), 73% (II), 76% (III), and 100% (IV). The CRC+A v NC model reported an AUROC of 0.88, and at 90% specificity, the overall CRC sensitivity was 78%. The test successfully detected 83% of stage I, 73% of stage II, 76% of stage III and 87% of stage IV CRC. Furthermore, 59% of AA patients were identified with this classifier, which is greater than the current performance levels of FIT.

Conclusions: A rapid blood test that is sensitive to AA and early-stage CRC could substantially improve patient outcomes. This liquid biopsy can be fine-tuned to give a different balance of sensitivity and specificity depending on international healthcare markets. Current screening programmes have addressable shortcomings, and the emergence of new technologies is essential to support earlier CRC detection.

584P Two-year update of the prospective evaluation of ColonAiQ (PreC) study

Y. Ding[1], J. Liu[2], Y. Li[3], Q. Yuan[3], C. Wang[3], H. Luo[3], Y. Li[3], W. Pan[3], H. Yang[3], H. Jia[3], B. li[3], Y. Zhang[3], R. Liu[3]

[1]*Department of Gastroenterology, Affiliated Hospital of Yangzhou University (Yangzhou First People's Hospital), Yangzhou City, China;* [2]*Department of Endoscopic Center, Northern Jiangsu People's Hospital, Yangzhou, China;* [3]*PreC Study Group, Singlera Genomics Inc., Shanghai, China*

Background: PreC study supported ColonAiQ® (a blood-based assay targeting circulating tumor DNA methylation) as a robust noninvasive option for colorectal cancer (CRC) and advanced adenoma (AA) screening to efficiently stratify individuals with a higher risk based on the first year's real-world data reported in 2022 World Congress on Gastrointestinal Cancer (LBA SO-23). Here, the update CRC screening outcome was reported.

Methods: 105,285 participants living in the local community, aging from 40 to 80, were recruited from Jan 2021 to Dec 2022. ColonAiQ® test was used as the primary screening method for all participants and a follow-up colonoscopy was recommended after a positive primary test. Numbers of positive ColonAiQ® test, colonoscopy compliance rate and positive predictive values (PPV) for AA and/or CRC were determined.

Results: Overall, a total of 6,759 participants (6.42%) were tested positive via ColonAiQ® test. In the positive test population, 3,282 (48.56%) participants performed colonoscopy with pathological confirmation. Overall, there were 1,773 (54.02%) participants confirmed with colonoscopy findings, including 63 (1.92%) CRC, 441 (13.44%) AA, 754 (22.97%) non-advanced adenoma, 327 (9.96%) polyps, and 188 (5.73%) non-neoplastic GI disorders. Particularly, early colorectal neoplasm diagnosis rate reached 90.28%. Therefore, The predictive value (PPV) was 1.92% for CRC and 36.41% for adenoma (13.44% for AA).

Conclusions: The 2-year real world study confirms the initial findings that population compliance rate of colonoscopy is obviously higher than the average rate in Cancer Screening Program in Urban China (48.56% VS 17.25%). ColonAiQ® test could help to identify the asymptomatic patients with neoplasm who need endoscopic resection or surgery excision. These results warrant the cost-effectiveness of the two-step screening pattern in community populations from the ongoing PreC study.

Clinical trial identification: NCT05336539.

585P Fragmentomics early detection assay leading to potential clinical benefits in colorectal cancer

Y. Cao[1], N. Wang[1], C. Si[1], P. Shao[1], X. Wu[2], W. Tang[2], H. Tang[2], H. Bao[2], X. Wu[2], Y. Shao[2], L. Yang[1]

[1]*Colorectal surgery, Nanjing Medical University affiliated Cancer Hospital, Nanjing, China;* [2]*Geneseeq Research Institute, Nanjing Geneseeq Technology Inc., Nanjing, China*

Background: Colorectal adenocarcinoma (CRC) patients often experience delayed diagnosis, making liquid biopsy-based early detection a promising approach. Yet, its clinical usage has been restricted due to its insufficient sensitivity. We aimed to develop an integrated model using fragmentomic profiles of plasma cell-free DNA (cfDNA) for the accurately and cost-effectively detection of early-stage CRC.

Methods: 360 participants were enrolled as the training cohort, consisting of 176 CRC patients and 184 healthy controls. Plasma cfDNA were extracted and prepared for subsequent whole genome sequencing. To differentiate healthy controls from CRC patients, an ensemble stacked model was built upon five machine learning models couple with five cfDNA fragmentomic features. The model was subsequently validated in a cohort of 236 individuals, comprising 117 CRC patients and 119 healthy controls.

Results: The contracted ensemble stacked model demonstrated remarkable ability in distinguish between CRC patients and healthy controls as evidence in multiple facets. In the validation cohort, the ensemble stacked model demonstrated superior performance compared to all other base models constructed using feature-algorithm pairs, achieving a high AUC of 0.986. At 97% specificity, the sensitivity for detecting CRC patients in validation cohort reached 93%. Additionally, the sensitivity of our model increases alongside the progression of cancer stage. Our model consistently maintained high levels of accuracy during both within-run and between-run tests, successfully predicting cancer status at different clinical settings. Through a real-world simulation, the model's effectiveness was confirmed showing a potential increase of 17.47% in the 5-year survival rate.

Conclusions: Our ensemble stacked model, which leverages the multiplex nature of cfDNA, exhibited exceptional performance in terms of sensitivity and stability for detecting CRC risk. This model has the potential to facilitate early diagnosis and benefit a larger number of patients.

Background: Although ctDNA is associated with MRD and recurrence in curatively treated CRC, implementation in clinical practice remains to be optimised. We evaluated the utility of a tumour naive ctDNA assay using serial prospectively collected plasma samples from the ASpirin for Dukes C and high risk Dukes B COLorecTal cancer trial (ASCOLT, NCT00565708), a large randomised phase III study of adjuvant aspirin.

Methods: Plasma samples were collected at baseline, 6 and 12 m in the Australian/New Zealand cohort (n= 452). In a cohort of 118 pts matched by follow-up time (59 with recurrence [cases] and 59 non-recurrent [controls]), we used an ultra-sensitive ctDNA assay (SafeSEQ, Sysmex Inostics) for MRD detection. Cell pellets were analysed for mutations related to clonal haematopoiesis of indeterminate potential (CHIP). Results were correlated with recurrence and CEA.

Results: 291 plasma samples (median 4.0 mL, median DNA 71.0 gen equiv/uL) were analysed (54/118 F; median age 68; 48 high risk stage II, 70 stage III; all had adjuvant chemotherapy; median follow-up 53.1 m). 59 pts recurred at median 12.4 m, of whom 32 had detectable ctDNA (sens 54%, Table). CEA sensitivity for detecting recurrence was 26%. Of the 27 pts with recurrence but no detectable ctDNA, 13 (48%) recurred >12 m after final sample collection. 8 pts without recorded recurrence had plasma mutations (CHIP analysis not available n = 3, all TP53). In multivariate analysis adjusting for known risk factors, ctDNA positivity was independently associated with recurrence (OR, 6.5; 95% CI, 2.2 — 18.9; p<0.001). Median time from 1st positive ctDNA to imaging detected recurrence was 7.9 m (range 0.2 — 40.2). ctDNA change over time and correlation with tumour sequencing will be presented.

Table: 586P Summary of ctDNA Data

	Recurrence	No recurrence	Total
Positive ctDNA* at any time point	32	8	40
Negative ctDNA	27	51	78
Total	59	59	
	Sensitivity 54%	Specificity 86%	

*SafeSEQ 14 gene CRC MRD assay: AKT1, APC, BRAF, CTNNB1, ERBB3, FBXW7, KRAS, NRAS, PIK3CA, POLE, PPP2R1A, RNF43, SMAD4 and TP53

Conclusions: Tumour naïve, serial ctDNA detection within 1 year of adjuvant chemotherapy is independently associated with recurrence, noting limitations in sensitivity and specificity.

587P Short lead time and high rates of concomitant radiographic recurrences for ctDNA-based minimal residual disease assays colorectal cancer (CRC) during surveillance: Results from the MD Anderson INTERCEPT program

M. Eluri[1], N.A. Dasari[2], G. Maddalena[3], A. Bent[4], A.J. Pellatt[3], A. Balachandran Pillai[3], K. Alfaro-Munoz[5], R.J. Kell[3], T. Newhook[3], A. Uppal[6], T. Konishi[7], V. Morris[5], E.S. Kopetz[5]

[1]Oncology, MD Anderson Cancer Center, Houston, TX, USA; [2]Gastrointestinal Medical Oncology, Division of Cancer Medicine Dept., MD Anderson Cancer Center, Houston, TX, USA; [3]Department of Gastrointestinal Medical Oncology, MD Anderson Cancer Center, Houston, TX, USA; [4]Medical Oncology, MD Anderson Cancer Center, Houston, TX, USA; [5]Gastrointestinal Medical Oncology, University of Texas MD Anderson Cancer Center, Houston, TX, USA; [6]Colon & Rectal Surgery, University of Texas MD Anderson Cancer Center, Houston, TX, USA; [7]Colon & Rectal Surgery Department, MD Anderson Cancer Center, Houston, TX, USA

Background: Although observational cohorts have shown that detection of circulating tumor DNA (ctDNA)-defined minimal residual disease (MRD) following curative intent therapy has a lead time of over 9 months (m) prior to radiographic recurrence, real world data (RWD) where results are returned to patients and providers are lacking. This is especially important since these studies have not incorporated rigorous clinical evaluation for concomitant recurrence.

Methods: In the INTERECEPT program, pts with stages II-IV CRC treated with curative intent at MD Anderson Cancer Center between 1/1/2022 and 31/12/2022 were evaluated with a tumor-informed MRD assay (Signatera, Natera) with an overarching goal to generate RWD and to integrate MRD-based testing into CRC pt care. Surveillance evaluations were per established guidelines; ctDNA was recommended post-operatively and q3m with each surveillance visit. Pts and providers were informed of the results; subsequent clinical decisions and courses were tracked.

Results: Of 847 pts (median 57y, [21-93], 55% were male; stage% I-III/IV were 69/31; colon/rectum% were 61/39. 20.5% (n=174) of pts had a positive ctDNA assay during surveillance, prompting imaging tests in 99% of cases (CT scan in 157 pts, PET/CT in 13 pts, MRI in 3 pts). These radiological investigations demonstrated definitive disease in 48% of cases, indeterminate findings in 11% and no evidence of disease in 41% of cases. Of those with indeterminate findings, 17/19 had a recurrence confirmation with a 2nd imaging modality. The median time to radiologic recurrence after a positive ctDNA result was less than 2 months. For those patients without radiologic recurrence identify concurrently with ctDNA+, the median time to recurrence was 3 months.

Conclusions: CRC pts on surveillance who are ctDNA+ are likely to have radiographic recurrence identify upon further investigation. The potential clinical benefit of this earlier radiographic identification of recurrent disease remains to be determined. True MRD pts (ctDNA+ but radiographically -ve) have a lead time providing a potential opportunity for therapeutic intervention.

Background: Surgery followed by adjuvant chemotherapy (ACT) is standard of care in stage III colon cancer. However, only 15-20% of the patients truly benefit from ACT because 55% was cured by surgery alone and 25-30% develop recurrences despite ACT. Post-surgery circulating tumor DNA (ctDNA) is a biomarker for minimal residual disease, which may facilitate stratification of stage III colon cancer patients for ACT treatment decisions. The aim of this study is to determine the prognostic value and clinical validity of post-surgery ctDNA-testing in stage III colon cancer patients.

Methods: 236 stage III colon cancer patients treated with ACT were included in the PROVENC3 study. Blood was collected pre-surgery, post-surgery and post-ACT. Tumor-informed detection of plasma ctDNA was performed through integrated whole genome sequencing (WGS) analyses of formalin-fixed paraffin-embedded tumor tissue DNA (80x), germline DNA (40x), and plasma cell-free DNA (30x). Outcome measurement is time to recurrence (TTR).

Results: From 124 patients (median follow up: 31 months) show a worse TTR of ctDNA-positive patients [HR: 4.7, 95%CI: (2,37-9,3), $p<0.001$]. 64% of the ctDNA positive, and 21% of the ctDNA negative patients experienced a recurrence. 40% of the patients who experienced a recurrence were ctDNA positive post-surgery. TTR was significantly different per ctDNA status, with a shorter median TTR for ctDNA-positive compared to ctDNA-negative patients (7.7 vs 13.1 months). Final results from the complete cohort with median follow up of 41 months will be presented in October 2023.

Conclusions: Post-surgery ctDNA detection by WGS is a strong prognostic biomarker in stage III colon cancer patients. Importantly, part of the ctDNA-positive patients did not experience a recurrence and were likely cured by ACT. Approximately 60% of the recurrences were not detected by post-surgery ctDNA-testing. Ultimately, the results of this study will be used to model and design a ctDNA-guided interventional trial in stage III colon cancer patients, to reduce futile ACT and its associated negative side-effects.

589P Impact of landmark point selection on molecular residual disease detection in stage I-IV resectable colorectal cancer

D. Cao[1], C. Li[1], F. Wang[1], R. Zhang[1], X. Wu[1], L. Li[1], Z. Lu[1], Z. Pan[1], J-Z. Lin[1], M. Wu[1], Y. Liu[1], G. Lv[1], F. Qiu[2], Y. Liu[2], H. Xin[3], G. Chen[1]

[1]Colorectum Department, Sun Yat-sen University Cancer Center, Guangzhou, China; [2]R&D, Burning Rock Biotech, Shanghai, China; [3]Medical Affairs, Burning Rock Biotech, Shanghai, China

Background: Circulating tumor DNA (ctDNA) based molecular residual disease (MRD) detection has been shown to predict prognosis and guide individualized management of colorectal cancer (CRC). The landmark point is usually set at 4-12 weeks post resection in consideration of the disturbance to cell-free DNA (cfDNA) by surgery. This study aimed to evaluate the feasibility of moving the landmark point to 1-week post resection.

Methods: The study prospectively and consecutively enrolled stage I-IV CRC patients who received R0 resection. Blood samples at baseline, post-operative day (POD) 7, POD30 and subsequent every 3-6 months surveillance were collected. The MRD status of all the samples were evaluated by the Burning Rock Patient-specific pROgnostic and Potential tHErapeutic marker Tracking (brPROPHET™) approach. The cfDNA level, mean tumor mutant (MTM), positive predictive value (PPV) and negative predictive value (NPV) were compared between POD7 and POD30.

Results: In total, 164 eligible patients were enrolled. The median follow-up duration was 311 days (95% CI, 296-351) up to date. The brPROPHET displayed a high sensitivity of 95.1% (155/163) for detecting ctDNA preoperatively, with 88.5%, 96.1%, 96.2%, 100% in stage I to IV, respectively. Post-resection ctDNA positive rates were decreased to 15.2% (25/164) at POD7 and 12.8% (21/164) at POD30. The cfDNA levels of POD7 were significantly higher than those of baseline and POD30 ($P<0.001$). However, the MTMs were similar between POD7 and POD30 ($P = 0.55$). The accordance between POD7 and POD30 was 91.5% (150/164). For 6-month recurrence, the PPV was 13.6% vs 15.8% for POD7 and POD30, respectively, with NPV of 100% vs 98.2%. Of the 25 ctDNA positive patients at POD7, 9 turned negative at POD30 and had significantly lower ctDNA levels at POD7 than those who didn't ($P<0.001$). Patients with decreased ctDNA from POD7 to POD30 had a higher ctDNA clearance rate during surveillance than those without decreased ctDNA (100% vs 30%, $P = 0.02$).

Conclusions: The performance of ctDNA detection in POD7 and POD30 was similar. Shift of the landmark time to 1-week post resection may provide an easier way to evaluate MRD status for prognostic stratification.

Maria delle Croci" Hospital, Ravenna, Italy; [6]Department of Pathology, Bufalini Hospital, Cesena, Italy; [7]Medical Oncology Department, IRCCS Istituto Romagnolo per lo Studio dei Tumori (IRST) "Dino Amadori", Meldola, Forlì-Cesena, Italy; [8]Radiotherapy Unit, IRCCS Istituto Romagnolo per lo Studio dei Tumori (IRST) "Dino Amadori", Meldola, Italy

Background: Approximately 30% of colorectal cancers arise from the rectum with surgical resection being the mainstay of treatment. For rectal cancers with high-risk pathological features or cases of LARC, preoperative NAT followed by total mesorectal excision +/- adjuvant therapy is recommended. However, this paradigm is associated with questionable survival benefits and high morbidity. Post-NAT and post-surgical risk stratification using ctDNA may help predict outcomes in LARC pts.

Methods: Plasma samples (n=90) from pts with LARC (N=30, median age: 67 years) were analyzed retrospectively. A tumor-informed assay (Signatera™) was used to quantify ctDNA pre-NAT, post-NAT, and post-surgery. Neoadjuvant rectal (NAR) score was calculated and compared to ctDNA status to predict recurrence risk and survival outcomes.

Results: At the pre-NAT time point, ctDNA detection rate was 90% (27/30). Pts who were ctDNA-positive either post-NAT (N=5) or post-surgery (N=3) had worse recurrence-free survival (RFS) (HR 8.4, 95%CI: 2.3-30, $p<0.001$ and HR 14, 95%CI: 3.1-66, $p<0.001$, respectively), when compared to ctDNA-negative pts. Similarly, pts with a high NAR score exhibited an inferior RFS when compared to those with a low-risk score (HR: 21, 95%CI: 2.6-2731, $p=0.001$). When utilized in combination with ctDNA status in the post-NAT setting, ctDNA-positive with an intermediate-high NAR score exhibited an inferior RFS compared to ctDNA-negative pts with a low NAR score (HR 33.5, 95%CI: 3.7-4419, $p<0.001$) with 100% recurrence rate. Likewise, post-surgery, ctDNA-positive pts with an intermediate-high NAR score exhibited an inferior RFS, with a recurrence rate of 37.5%, when compared to ctDNA-negative pts with a low NAR score, none of whom recurred (HR 75, 95%CI: 2.6-4916, $p<0.001$). In multivariate analysis, ctDNA status post-surgery ($p=0.039$) and pathological nodal status ($p=0.033$) were the most significant risk factors associated with recurrence.

Conclusions: Post-treatment ctDNA status either as a sole surrogate outcome measure or as an adjunct to the NAR score may predict NAT response, improve risk stratification and potentially improve outcomes in LARC pts.

Background: The utility of ctDNA analysis in guiding personalized ACT for resectable CRM remains unclear.

Methods: Patients (pts) with previously untreated resectable CRM scheduled for curative resection were prospectively enrolled between March 2021 and October 2022. Pretreatment genomic alterations were detected using Guardant360, a 74-gene ctDNA profiling assay, while postoperative 4-week MRD was assessed using Guardant Reveal, a methylation-based ctDNA MRD assay.

Results: Of 118 eligible pts enrolled, pretreatment ctDNA was detected in 99 pts (84%), 62 (53%) of whom had poor genomic profile, predetermined to have at least one of BRAF, RAS, PIK3CA, or SMAD4 mutations. Of 110 pts who underwent surgery for CRM, postoperative 4-week MRD was detected in 26 (22%) pts. Eighteen patients (16%) had both pretreatment poor genomic profile and positive MRD. With a median follow-up time of 11.0 months (m), median recurrence-free survival (RFS) was 15.2 m. Poor genomic profile (hazard ratio [HR], 2.26 [95% CI, 1.00−5.10]) and MRD positivity (HR, 3.85 [95% CI, 1.79−8.30]) were significantly associated with shorter RFS in

multivariate analysis. Positive MRD was associated with shorter RFS (HR, 5.04 [95% CI, 2.30—11.05]) in the poor genomic profile group but not in those without poor genomic profile. Patients with poor genomic profile and positive MRD derived significant benefit from ACT (median RFS, 8.0 m vs. 2.0 m; HR, 0.25 [95% CI, 0.07—0.82]), while no significant benefit was observed in other groups.

Conclusions: Pretreatment genomic profile and postoperative MRD by ctDNA analysis accurately stratify the prognosis and may guide personalized ACT in pts with resectable CRM.

Clinical trial identification: UMIN000042490.

592P The role of early change in circulating tumor DNA as a potential predictor of response to chemotherapy in patients with metastatic colorectal cancer

J. Chang, W. Du, Z. Chen, W. Li, W. Zhang, X. Zhu, W. Guo

Department of Gastrointestinal Medical Oncology, Fudan University Shanghai Cancer Center, Shanghai, China

Background: There remains a need to improve the method to predict the therapeutic effect of metastatic colorectal cancer (mCRC). The aim of this study is to explore the value of early change in circulating tumor DNA (ctDNA) as a biomarker for prediction of the drug efficacy of chemotherapy in mCRC (NCT04555369).

Methods: Patients with mCRC treated with first-line chemotherapy (including clnical routine regimens such as XELOX, FOLFIRI, mFOLFOX6 with or without cetuximab or bevacizumab) were enrolled in this study. Plasma ctDNA was detected at baseline and before the second cycle of chemotherapy, and the mutation of 25 tumor-related genes in ctDNA were detected by next generation screen technology. The primary endpoint of this study is to evaluate the role of early change of ctDNA in predicting ORR (objective response rate).

Results: From Sep. 2020 to Sep.2022, 209 mCRC patients treated with first-line chemotherapy were enrolled in this study.The median follow-up time was 331 days. Among these 209 patients, the ctDNA mutations were detected in 84.21% of patients at baseline. The most frequently mutated genes were TP53 (60.29%), APC (56.94%) and KRAS (34.93%) gene. The value of MSAF (maximum somatic allele frequency) change after the first cycle of chemotherapy was significantly different between tumor remission and non-remission groups (P=0.001). The cut-off value of MSAF change for predicting tumor remission was 6.27% (AUC 0.637,95%CI:0.556-0.719, P=0.002). The ORR were 54.2% and 31.4% in patients with MSAF change $\geq$ 6.27% group and < 6.27% group (P=0.003), while DCR (disease control rate) were 95.3% and 91.4% (P = 0.347) in these two groups, respectively. In addition, the K-M survival curve and log-rank test showed that PFS (progression free survival) were significantly different in the two groups (median PFS of MSAF change $\geq$ 6.27% group vs. MSAF change < 6.27% group: 317 days vs. 217 days; HR:1.598, 95%CI:1.016-2.514, P=0.03).

Conclusions: The early changes in ctDNA levels after initiation of first-line chemotherapy in mCRC would enable early prediction of response prior to radiological assessment.

Clinical trial identification: NCT04555369.

Legal entity responsible for the study: Ethical Committees of Fudan University Shanghai Cancer Center.

593P Role of circulating tumor DNA (ctDNA) in assessing primary anti—epidermal growth factor receptor (EGFR) resistance in untreated RAS/BRAF wild-type (WT) metastatic colorectal cancer (mCRC) patients (pts)

J. Loh[1], J. Choo[2], K. Sooi[1], P. Low[1], C.S. Ang[1], R. Sundar[3], R.J. Walsh[4], S. Wijaya[1], J.L. Low[5], S. Hsing[6], S. Jain[6], C.E. Chee[1]

[1]Medical Oncology, NCIS - National University Cancer Institute Singapore, Singapore; [2]Haematology Oncology Department, NCIS - National University Cancer Institute Singapore, Singapore; [3]Haematology-Oncology, NUHS - National University Health System, Singapore; [4]University Medicine Cluster, NUS-National University of Singapore-National University Health System (NUHS), Singapore; [5]Cancer Institute, NUH - National University Hospital (S) Pte. Ltd., Singapore; [6]Guardant Health, Guardant Health Pte. Ltd., Singapore

Background: Current guidelines recommend anti-EGFR—based first-line therapy after evaluation of *RAS, BRAF* mutational status and primary tumor sidedness in mCRC pts. However, knowledge gaps about primary resistance to EGFR inhibition exist and more negative predictive biomarkers are required to identify pts who can be spared toxicities from anti-EGFR therapy and benefit from alternative biologic agents. With limited prospective data available, this study was conducted to explore the clinical utility of ctDNA NGS (Guardant360) in assessing alterations of primary EGFR resistance.

Methods: This is a prospective study looking to identify 40 newly-diagnosed, untreated mCRC pts who are RAS/BRAF WT by routine tumor profiling and planned for chemotherapy in combination with anti-EGFR therapy. Prior to treatment initiation, all pts underwent ctDNA testing to assess presence of at least one of the following alterations associated with resistance to anti-EGFR: mutations (mt) (*RAS*, *BRAF, PTEN, AKT, PI3KCA, SMAD4, EGFR)*, amplifications (amp) (*ERBB2, MET)*, and fusions (*NTRK/ROS1/ALK/RET)*. Pt characteristics, treatment information and outcomes were analyzed.

Results: With 21 pts consented thus far, sequencing success rate was 95.2% (20/21). Median age was 62 years, 100% left-sided tumors, 53% male and 90% (18/20) had at least 1 cycle of anti-EGFR therapy. Average turnaround time for ctDNA was 7.2 days. 6 pts (30%) had alterations of primary EGFR resistance including mt in *ERBB2* (N=1) and *SMAD4* (N=3); *ERBB2* amp (N=1) and *RAF* amp (N=1). Treatment response to anti-EGFR was observed in 10 of 13 pts (76.9%) without resistant alterations vs. 2 of 5 pts (40%) with alterations (odds ratio=1.92; p=0.27). With a median follow-up of 4.7 months(m), there was a trend towards improved median progression-free survival of pts without vs. with alterations (7.0 vs. 2.8m; HR=0.88; p=0.88).

Conclusions: ctDNA testing detects primary resistance to EGFR inhibition in a subgroup of untreated, RAS/BRAF WT mCRC pts, thus serving as a prognostic classifier and providing additional value above routine tumour profiling. Updated results will be presented.

594P The efficacy of anti-EGFR therapy for RAS mutant metastatic colorectal cancer (mCRC) patients with RAS mutation negative in circulating-tumor DNA (ctDNA) after 1st- or 2nd-line chemotherapy

Background: Liquid biopsy studies have shown the change of *RAS* status in ctDNA after chemotherapy in *RAS* wild-type mCRC. Our prospective observational study (RASMEX study) showed that the rate of *RAS* mutant mCRC patients (pts) with *RAS* mutations (mts) negative in ctDNA after standard chemotherapy was 22.8% (*Izawa*, et al, JSMO annual meeting 2023). Here, we present the efficacy of anti-epidermal growth factor receptor (EGFR) therapy for these pts.

Methods: *RAS* mutant mCRC pts with refractory or intolerable after response to prior fluoropyrimidine-containing regimen were enrolled. OncoBEAM™ RAS CRC kit was used to measure *RAS* mts in ctDNA just after 1st- or 2nd-line treatment. For pts with *RAS* mts negative in ctDNA who received anti-EGFR therapy after enrollment, the overall response rate (ORR), disease control rate (DCR), and progression-free survival (PFS) were prospectively evaluated. In *RAS* mts negative pts in ctDNA, blood samples were also collected before anti-EGFR therapy and *RAS/BRAF/PIK3CA* mts were measured by Plasma-SeqSensei ™ CRC RUO Kit.

Results: Of 55 (22.8%) had *RAS* mts negative in ctDNA among 241 pts who filled the eligibility criteria, 29 received chemotherapy including anti-EGFR antibody: median age, 66 years; left-sided primary tumor, 79.3%; 11 pts for 2nd-line setting and 18 pts for 3rd- or later-line setting. In 11 pts receiving 2nd-line combination chemotherapy, ORR and DCR were 0% and 54.5% (95% confidence interval [CI]: 25.1—84.0), respectively. The median PFS was 4.9 months (95%CI: 1.9—6.5). In 8 pts without any mts in ctDNA before treatment, DCR was 62.5% and median PFS was 5.6 months. While, ORR and DCR were 5.6% (95%CI: 0—16.1) and 55.6% (95%CI: 32.6—78.5), respectively, in 18 pts receiving 3rd- or later-line treatment with combo- or monotherapy. The median PFS was 3.3 months (95%CI: 1.6—4.8). In 12 pts without any mts in ctDNA before treatment, ORR and DCR both were better (8.3% and 58.3%, respectively).

Conclusions: Our prospective observational study revealed the efficacy of anti-EGFR therapy for *RAS* mutant mCRC pts with *RAS* mts negative in ctDNA after 1st- or 2nd-line treatment. Further prospective studies need to be conducted for these pts.

Background: Total neoadjuvant therapy (TNT) is a new standard of care for locally advanced rectal cancer (LARC). However, the activity of immunotherapy in combination with chemoradiotherapy (CRT) in microsatellite-stable (MSS) rectal cancer has been limited. We explored the efficacy and safety of TNT in combination with the anti-PD-L1 durvalumab (D) in LARC pts with MSS rectal adenocarcinoma.

Methods: The DUREC study is a multicenter, single-arm, phase II trial that recruited pts with stage II and III MSS rectal adenocarcinoma with MRI-defined high-risk T3 (extramural vascular invasion (EMVI), >5mm of perirectal fat infiltration, mesorectal fascia involvement), T4, N2, or distal third tumors (T3/4). Pts received 6 cycles of FOLFOX with D at 1500 mg q4W, followed by CRT with capecitabine and D, continuing D until surgery. The first 6 pts underwent a safety run-in phase. Primary endpoint was pathological complete response (pCR) rate. Assuming a minimum efficacy for pCR of 16% and an optimum of 30%, with an α error of 0.1 and a β error of 0.1 (90% power), the study aimed to recruit 58 pts.

Results: 61 pts were enrolled (median age, 61.3 years; 70% male). Clinical staging was T3/T4 tumors (78/22%), N2 (53%), and 60% had EMVI positivity. Mean number of administered cycles of mFOLFOX6 and durvalumab were 5.8 and 6.2, respectively, with 41 patients (67.2%) receiving 7 cycles of durvalumab before surgery. Among the 56 (92%) pts who underwent surgery, 22 (39%) achieved a pCR and 18 (32%) achieved a major response (71% of major pathological responses). pCR rate for the intention-to-treat population was 36% (95% CI 24.2%-49.4%). Reasons for not performing surgery were metastatic disease progression during therapy (n=3), toxicity (n=1) and major protocol deviation (n=1). Eight pts (13%) had treatment-related serious adverse events, with diarrhea being the most common (3.3%).

Conclusions: The DUREC trial is the first prospective clinical study evaluating the combination of immunotherapy throughout the TNT process for treating MSS LARC. The study met its primary endpoint, demonstrating promising activity and safety, and deserving further development in a phase III study.

Background: The benefit of adding oxaliplatin to neoadjuvant chemoradiotherapy (nCRT) for locally advanced rectal cancer (LARC) remains controversial. We conducted a multicenter randomized trial aimed at evaluating the value of adding oxaliplatin to nCRT in high-risk LARC patients.

Methods: LARC patients with high-risk factors (cT4 or cN2, high pathological grade, neurovascular invasion, or anal sphincter involvement) were randomized in a 1:1 ratio to receive long-course radiotherapy plus three cycles of concurrent CAPEOX or single-agent capecitabine. The primary endpoint was 3-year disease-free survival (3y-DFS). Secondary endpoints included pathological complete response (pCR) rate, CAP tumor regression grade, and treatment-related adverse reactions.

Results: From August 2017 to April 2022, 505 patients were randomized to the CAPEOX group (n=248) or the Capecitabine group (n=257). 91.5% of the CAPEOX group and 92.2% of the Capecitabine group underwent radical surgery after nCRT. Pathological examination showed no significant difference in pCR rate between the two groups (25.6% for the CAPEOX and 25.3% for the Capecitabine group, $P > 0.05$). However, compared with the single-agent group, a higher proportion of patients in the CAPEOX group achieved significant tumor regression (CAP 0-1) (59.0% *vs*. 46.8%, $P=0.009$). There was no significant difference in the incidence of grade 3-4 treatment-related toxicity between the CAPEOX and the Capecitabine group (46.5% *vs*. 39.9%, $P > 0.05$). After a median follow-up of 37 months, there was no significant difference in 3y-DFS between the two groups (81.7% in the CAPEOX *vs*. 83.5% in the Capecitabine group, $P > 0.05$). In the overall analysis, patients achieving CAP 0-1 had significantly better 3y-DFS than those achieving CAP 2-3 (89.0% *vs*. 80.9%, $P=0.018$).

Conclusions: We showed that adding oxaliplatin to nCRT in high-risk LARC patients may improve tumor regression with acceptable toxicities, although this may not translate into long-term oncological benefits.

Clinical trial identification: NCT 03042000.

Background: Radiation with sensitizing fluoropyrimidine (5FUCRT) is a standard curative intent treatment for LARC. The PROSPECT trial compared FOLFOX chemotherapy with selective use of 5FUCRT (intervention) to 5FUCRT (control) for neoadjuvant treatment prior to total mesorectal excision (TME) for LARC and the primary endpoint of non-inferiority disease-free survival was met. Analyzing quality of surgery is key to interpreting the results of PROSPECT.

Methods: Trial eligibility included cT2N+, cT3N-, cT3N+ rectal cancers deemed appropriate for neoadjuvant therapy prior to TME. Exclusions included tumors not amenable to sphincter preservation, T4 disease, threatened radial margins, or $\geq$ 4 enlarged lymph nodes. Pts were randomized 1:1 to 5FUCRT with 5040 cGy over 5.5 weeks with capecitabine or 5FU (control) or 6 cycles of mFOLFOX6 (intervention) followed by restaging. Secondary and post hoc surgical quality endpoints included: rate of sphincter preservation, completeness of TME, number of lymph nodes examined, radial margin status, length of hospital stay, reoperation, readmission, and rate of ostomy formation.

Results: From 6/2012 to 12/2018, 1194 pts were randomized, 1128 initiated protocol-assigned treatment, and 1045 completed surgery. Median age was 57 years, 34.4% were women, 61.9% had clinically positive nodes, 78.9% of tumors were <10 cm from the anal verge with a median tumor height of 8 cm. The table shows surgical quality outcomes.

Table: 597P

Surgical Quality	5FUCRT n(%)	FOLFOX with selective 5FUCRT n(%)	p-value
Completed Surgery	510	535	
Minimally invasive surgery	399 (78.2)	428 (80.0)	0.483[1]
Low anterior resection	485 (95.1)	508 (95.0)	0.914[1]
Ostomy performed	465 (91.2)	416 (77.8)	<0.0001[1]
Lymph nodes examined (median)	16	20	<0.0001[2]
Positive radial margin (≤1mm)	7 (1.4)	6 (1.1)	0.669[1]
Complete/near complete TME	499 (97.7)	527 (98.5)	0.718[1]
Length of hospital stay (median)	5.0	5.0	0.625[2]
Reoperation within 30 days	44 (8.6)	35 (6.5)	0.202[1]
Readmission within 30 days	99 (19.4)	77 (14.4)	0.030[1]

[1]Chi-Square; [2]Kruskal-Wallis

Conclusions: Low rate of positive radial margin along with high rate of complete/near complete TME and number of lymph nodes examined demonstrate a high quality of surgery in this multicenter trial. More pts treated with 5FUCRT (relative to the FOLFOX arm) required an ostomy and readmission within 30 days of surgery.

598P Influence of the early stoma closure after low rectal cancer resection on completeness of adjuvant chemotherapy (CoCStom): A randomized, controlled multicentre trial of the AIO (AIO KRK 0113)

F. Sandra-Petrescu[1], F. Herrle[1], C. Reissfelder[2], P. Kienle[3], H. Suelberg[4], A. Hinke[5], S. Tenckhoff[6], R.D. Hofheinz[7]

[1]Surgery, Medizinische Fakultät Mannheim der Universität Heidelberg, Mannheim, Germany; [2]Surgery, UMM - Universitaetsklinikum Mannheim, Mannheim, Germany; [3]Surgery, Theresienkrankenhaus, Mannheim, Germany; [4]Statistics, X-act Cologne Clinical Research GmbH, Koeln, Germany; [5]Statistics, CCRC - Cancer Clinical Research Consulting, Düsseldorf, Germany; [6]Clinical Research, Study Center of the German Surgical Society, Heidelberg, Germany; [7]Interdisciplinary Tumor Center, UMM - Universitaetsklinikum Mannheim, Mannheim, Germany

Background: There is uncertainty whether early closure (EC) of a defunctioning stoma influences the complete administration of the adjuvant chemotherapy (CoC) after low anterior rectal resection (LAR) for rectal cancer. CoC was previously shown in retrospective analyses to improve the five-year OS and DFS.

Methods: CoCStom trial was a prospective randomized multicenter investigator-initiated study. Patients undergoing neoadjuvant therapy (chemoradiation or 5x5 Gy radiotherapy) followed by LAR for locally advanced rectal cancer were randomized in two arms. Experimental - EC, 8 to 10 days after LAR; and control - late closure of the stoma (LC), after completion of the adjuvant chemotherapy (26 weeks) which included both 5-FU- and oxaliplatin-based regimens according to local practice and tumor stage. The primary endpoint was CoC. The study was designed to show an CoC improvement of 20 % (power 80%, alpha-value 0.05). Secondary endpoints: oncological and surgical outcomes as well as quality of life.

Results: A total of 257 patients with comparable baseline characteristics and pathohistological (UICC) stages were randomized between 2013 and 2018. Of these, 233 (EC: 116 vs. LC: 117) were eligible for analysis. Median follow up was 24 months. Surgical morbidity after stoma closure was comparable (Clavien Dindo III-IV: EC vs. LC: 15.8 vs. 18.9%). The median hospitalization after LAR was 17 days in both groups. CoC was similar EC [62.9% (95% CI: 53.5 - 71.7%] and LC [65.8% (56.5 -74.3%]. Patients in the EC group started adjuvant chemotherapy (median 38 vs. 27 days after randomization) significantly later and received less oxaliplatin-based regimens (8.5 vs. 15%). DFS was numerically better in the EC group (HR 1.6; 95% CI: 0.83 − 3.06).

Conclusions: EC of the stoma was feasible and did not lead to increased surgical morbidity. CoC was not improved, however, a trend towards better DFS was observed within the EC group despite similar CoC, a later start of adjuvant therapy as well as less use of oxaliplatin-based regimens. Thus, EC of the stoma appears to be a valid option for patients undergoing LAR.

Clinical trial identification: DRKS00005113.

Background: There is a strong rationale to combine radiotherapy with immune checkpoint inhibitors (ICIs). This study evaluates this combination before surgery in locally advanced rectal cancer (LARC).

Methods: R-IMMUNE, a multicentric phase Ib/II trial, included patients with stage II/III LARC treated with a preoperative combination of radio-chemotherapy (45-50 Gy/25 fractions, 5FU 225 mg/m2/d, 5d/w from week 1 to 5) + atezolizumab 1200 mg/infusion (ATZ). The phase Ib evaluated a single infusion of ATZ at week 3. Phase II evaluated 4 infusions of ATZ at weeks 3, 6, 9 and 12. Surgery was planned for week 15. Safety and efficacy based on the pathological complete response (pCR) rate are primary objectives. Based on a two-stage Simon design, 33 patients (+3 for the replacement of non-evaluable patients) were required in phase II to detect an increase in pCR rate from 15% to 35% ($\alpha = 0.1$, $\beta = 0.1$), with at least 8 pCRs to reject the null hypothesis.

Results: Six patients were included in phase Ib and 34 in phase II. This analysis covered 39 patients (median age 63 years, 56% male, 82% stage III, 12% MSI-H), excluding 1 phase II patient who is still undergoing treatment. A total of 193 adverse events (AEs) were reported, of which 29 (15%) were grade 3-4 and involved 19/39 (49%) of patients. Among gade 3-4 AEs, most frequent were urinary tract infections (6/29), blood disorders (5/29), post-operative anastomotic leaks/infections (4/29) and gastrointestinal disorders (4/29). Five patients presented immune-related AEs: 1 immune thrombocytopenia (grade 4), 2 endocrine disorders (grade 2) and 2 skin disorders (grade 1). So far, efficacy was assessed in 6 phase Ib patients and in 31 patients from the phase II (2 were excluded for protocol deviation). Respectively, 2/6 and 8/31 patients had a pCR. Overall, 10/37 (27%) patients had a pCR (including 2 MSI-H).

Conclusions: An analysis of the nearly complete R-immune cohort confirmed an acceptable safety profile and met study efficacy objectives. The results warrant further investigations of ICIs combined with radiotherapy in LARC eventually within a total neoadjuvant treatment and organ preservation based strategies.

Clinical trial identification: NCT03127007.

600P Effectiveness and safety of rectal arterial infusion chemotherapy combined with anti-PD1 antibody for microsatellite stable locally advanced rectal cancer: Early outcome report of a two-stage, single armed, phase II study (RAIC)

Y. Jiao[1], J. Li[1], X. Kong[1], C. Liu[1], S. Han[2], L. Wang[2], Y. Hu[1], H. Hu[3], Y. Song[1], Z. Wang[1], J. He[1], Q. Deng[1], H. Cao[1], K. Ding[1]

[1]Colorectal Surgery and Oncology, The Second Affiliated Hospital of Zhejiang University School of Medicine - East Gate 1, Hangzhou, China; [2]Department of Radiology, The Second Affiliated Hospital of Zhejiang University School of Medicine - East Gate 1, Hangzhou, China; [3]Medical Oncology Dept., The Second Affiliated Hospital of Zhejiang University School of Medicine - East Gate 1, Hangzhou, China

Background: The standard neoadjuvant therapy for locally advanced rectal cancer (LARC) is chemoradiotherapy (CRT) which increases perioperative complications. Chemotherapy alone has approximately 60% objective response rate and lower pathological complete response pCR rate compare with CRT. We propose a new strategy (induction chemotherapy followed by arterial infusion chemotherapy and anti-PD1 antibody) to achieve high pCR rate for microsatellite stable (MSS) LARC without radiotherapy.

Methods: Two cycles of Capox were given to eligible LARC patients (tumor located 5-12cm from anal verge). Patients who achieved more than 20% regression of maximum tumor diameter receive 2 cycles of rectal arterial infusion oxaliplatin (50mg, D1) + intravenous anti-PD1 inhibitor (Sintilimab, 200mg, D2) + capecitabine (1000mg/m2, po, twice daily, D1-D14) with 6 weeks before operation. Patients with tumor regression less than 20% were suggested to receive CRT. The primary endpoint is pCR rate. A total of 38 patients (10 in the first stage, 28 in the second) stage are planned to be recruited by Simon's two-stage design. The second stage will be conducted if more than 2 patients achieve pCR in the first stage, otherwise the trial will be terminated.

Results: A total of 20 patients had been enrolled and 13/20 reached 20% regression criterion after induction chemotherapy and received arterial infusion chemotherapy combined with intravenous anti-PD1 antibody. One patient achieved clinical complete response and refused surgery. Other 12 patients received operation and 4/12 (33.3%) achieved pCR (3/10 in the first stage). According to the tumor regression grading TRGstandard of the eighth edition of AJCC, the patients number of TRG0/1/2/3 was 4/4/2/2, respectively. Among the 12 patients 5 had grade 3 adverse event (abdominal pain and readmission), including one grade 3 immune-related adverse event (dermatitis).

Conclusions: Rectal arterial infusion chemotherapy combined with intravenous anti-PD1 antibody for MSS LARC achieved high pCR rate. The RAIC trial is now progressed to the second stage.

Clinical trial identification: NCT05307198.

Legal entity responsible for the study: The Second Affiliated Hospital Zhejiang University School of Medicine.

Funding: Has not received any funding.

601P Short-course radiotherapy based total neoadjuvant therapy combined with PD-1 inhibitor for locally advanced rectal cancer: Preliminary findings of TORCH

Y. Wang[1], L. Shen[1], J. Wan[1], H. Zhang[1], R. Wu[1], X. Wu[1], Y. Xu[2], S. Cai[2], Y. Zhao[3], Z. Xiang[4], H. Zhang[5], H. Wang[6], F. Xia[1], Z. Zhang[1]

[1]Department of Radiation Oncology, Fudan University Shanghai Cancer Center, Shanghai, China; [2]Department of Colorectal Surgery, Fudan University Shanghai Cancer Center, Shanghai, China; [3]Department of Medical Oncology, Affiliated Hospital of Jiangnan University, Wuxi, China; [4]Department of Radiation Oncology, Shanghai East/Oriental Hospital Affiliated to Tongji University - Headquarters/Northern Division, Shanghai, China; [5]Department of Radiation Oncology, The First Affiliated Hospital of Naval Medical University/Changhai Hospital of Shanghai, Shanghai, China; [6]Department of Oncology, Tianjin Union Medicine Center, Tianjin, China

Background: For locally advanced rectal cancer (LARC), total neoadjuvant therapy (TNT) increases the rates of complete response and organ preservation. Hypofractionated radiotherapy shows better synergistic effects in combination with PD-1 inhibitor. The combination of short-course radiotherapy (SCRT) based TNT and PD-1 inhibitor is likely to improve tumor response and prognosis.

Methods: TORCH is a prospective, multicentre, randomized phase II trial. 130 LARC (T3-4/N+M0, distance from anal verge $\leq$10cm) patients will be treated with TNT and assigned to consolidation arm (A) and induction arm (B). Arm A receives SCRT (25Gy/5Fx) followed by 6 cycles of Toripalimab combined with CAPOX (ToriCAPOX). Arm B receives 2 cycles of ToriCAPOX followed by SCRT and 4 cycles of ToriCAPOX. TME surgery is scheduled 2 weeks after TNT while a watch and wait (W&W) option can be applied to patients achieving clinical complete response (cCR). The primary endpoint is complete response (CR, pathological complete response [pCR] plus cCR) rate. The secondary endpoints include the grade 3-4 acute adverse effects (AE) rate, 3-year DFS rate, etc.

Results: Up to 2023/4/1, 130 patients were recruited and 104 patients have completed the treatment (Arm A 54, Arm B 50). The median age was 55 and 91 patients were stage III. 82.7% (86/104) of them showed one of the following features: lower location ($\leq$5cm), cT4, cN2, MRF+ and EMVI+. 59 patients underwent TME, of which 29 cases achieved pCR (49.2%, 29/59), and the major pathologic response rate (TRG0-1) was 62.7% (37/59). 29 patients achieved cCR and adopted W&W. The total CR rate was 55.8% (58/104), with 57.4% (31/54) in Arm A and 54.0% (27/50) in Arm B. The remaining 16 non-cCR patients refused surgery and went on with close follow-up. Among 53 patients who were assessed N+ on baseline MR and underwent surgery, 48 were pathologically confirmed N0 (90.6%, 48/53). The main grade 3-4 AE was thrombocytopenia (42.3%, 44/104), with 4 cases of grade 4 thrombocytopenia.

Conclusions: For LARC, SCRT based TNT combined with PD-1 inhibitor has achieved a high CR rate, which could provide new choice to achieve organ preservation for MSS and low rectal cancer patients and worth to be further validated in phase III trial.

Background: Neoadjuvant radiation and oxaliplatin-based systemic therapy (Total Neoadjuvant Therapy — TNT) has been shown to increase response and organ-preservation rates in localized rectal cancer. However, trials have been heterogeneous regarding treatment protocols and few have used a watch-and-wait (WW) approach for complete responders. This trial evaluates if conventional long-term chemoradiation followed by consolidation FOLFIRINOX increases complete response rates and number of patients managed by WW.

Methods: Thiswas apragmatic randomized phase II trial conducted in 2 Cancer Centers in Brazil that included patients with T3+ or N+ rectal adenocarcioma. After completing long-course 54Gy chemoradiation with capecitabine patients were randomized 1:1 to observation or 4 cycles of mFOLFIRINOX (Oxaliplatin 85, irinotecan 135, 5-FU 2400). All patients were re-staged with dedicated pelvic MRI and sigmoidoscopy 12 weeks after the end of radiation. Patients with a clinical complete response were followed using a WW protocol. Primary enpoint was complete response: complete clinical response (cCR) or pathological response(pCR).

Results: Between Feb 2020 and April 2023, 46 patients were randomized to TNT and 42 to standard of care. Median age was 59 and 64% were male. Tumors were 68% stage 3, median distance from anal verge was 5cm, 43% had at-risk circumferential margin and 21% involved sphincter. The rates of cCR+pCR were 9/46 (19%) for TNT vs 5/42 (11%) for controls (OR 1.79, CI95% 0.54-6.3 p=0.16) and rates of WW were 5/46 (10.8%) and 2/45 (4%) (ns). Median follow-up was 16.9 months and recurrence rates were 8/46 (17%) and 11/42 (26%) for TNT and controls (ns).

Conclusions: TNT with consolidation FOLFIRINOX is feasible and has high response rates. Complete data from 96 patients will be presented at the meeting. This trial was supported by a grant from the Brazilian Ministry of Health (PROADI-SUS) - NUP 25000.164382/2020-81.

Clinical trial identification: NCT05081687.

Background: Advances in metastatic colorectal cancer (mCRC) treatment have improved overall survival (OS) in clinical trials, but real-world survival data, in particular in later lines of treatment, are scarce. PROMETCO (NCT03935763) is the first international, prospective, real-world study to investigate the continuum of care in all patients (pts) with mCRC after two disease progressions since diagnosis.

Methods: Adult mCRC pts who were willing to receive subsequent treatment were included. Endpoint data presented include OS, progression-free survival (PFS; defined as start of treatment until progressive disease, death or start of new treatment), patient characteristics and treatment patterns.

Results: As of April 2023, 738 pts from 18 countries were enrolled (Table). 49% of pts were RAS mutant; 32% RAS/BRAF wild type; 5% BRAF mutant. 40% of pts had unknown microsatellite instability (MSI) status; 2% were MSI high; 3% were MSI low; 55% were microsatellite stable. Median time from mCRC diagnosis to PROMETCO inclusion was 22.0 mo. During the course of their disease, most pts had received fluoropyrimidine (99%), oxaliplatin (88%), irinotecan (96%), an anti-VEGF (79%) or an anti-EGFR antibody (40%), FTD/TPI (75%) or regorafenib (25%). 64% and 23% of pts had colorectal or liver surgery, respectively. For 628 pts who completed the study, mOS from mCRC diagnosis was 35.4 mo; mOS from inclusion in PROMETCO (i.e., after second disease progression) was 6.8 mo; and mOS from start of third-line treatment was 6.4 mo. Median PFS was 9.5 mo in first-; 4.8 mo in second-; 2.6 mo in third- and 2.4 mo in fourth-line.

Conclusions: These data provide key insights on pts characteristics, survival (which reflects observations from clinical trials) and treatment patterns in the real-world, which are generally consistent with ESMO guidelines. Table: Patient characteristics at enrollment.

Background: First-line randomized clinical trials in metastatic colorectal cancer (mCRC) comparing chemotherapy with doublets (CT) plus targeted therapies (bevacizumab, cetuximab and panitumumab) (TT), have shown substantial benefit in progression free survival but modest benefit in overall survival over CT alone. In addition, elderly patients (pts) and pts with ECOG performance status (PS) of 2 are usually under-represented. GEMCAD 1401 is a prospective observational, multicenter study (GEMCAD 1401. ClinicalTrials.gov identifier: NCT02254941), that compared overall survival benefit in treatment naïve mCRC pts, treated with or without first-line TT.

Methods: Between June 2014 and June 2018, 1107, mCRC pts were included and 1020 were eligible (640 pts treated with CT plus TT and 380 pts treated with CT alone). Baseline pts characteristics that would influence initial treatment strategy decision and efficacy (age, gender, tumor stage at diagnoses, primary tumor side, surgery of primary tumor, *RAS* and *BRAF* status, ECOG PS, Charlson score, number and type of affected organs, leucocyte, alkaline phosphatase, lactate dehydrogenase and CEA level) and postbaseline variables (time-varying covariates; ECOG PS, Charlson score, lactate dehydrogenase and grade 3-4 toxicities), were balanced using Inverse Probability Treatment Weighting (IPTW).

Results: After IPTW application, standardized differences of all basal variables between groups were $<$10%. The median overall survival was 21.2 months 95% confidence interval (CI) (18.9-23.6) in the CT plus TT group and 21.4 months (95% CI 18.2-25.3) in the CT group (hazard ratio (HR) for death, 0.93; 95% CI 0.8-1.08). The median progression free survival was 9.9 months (95% CI 9.3-10.7) in the CT plus TT and 8.9 months in the CT alone (95% CI 8.1-9.7). HR 0.87 (95% CI 0.76- 0.99).

Conclusions: First-line treatment with CT alone compared with CT plus TT, show no detrimental effect in overall survival.

Clinical trial identification: NCT02254941.

Background: Regional lymph node metastases are negative prognostic factors in localized disease and after liver resection, but little is known in metastatic colorectal cancer (mCRC). We studied demographics, treatments, and outcomes for mCRC with (N+) and without (N0) regional lymph node metastases in population-based and real-world settings.

Methods: Patients from three Nordic mCRC cohorts were combined; the population based PRCRC-study, the likewise Uppsala Region cohort and the real-world RAXO study. The dataset included 1764 patients with resected primary tumours, of which 1710 had pathologic N-stage reported. Characteristics and treatments were compared using Chi-square. Overall survival (OS) was estimated with Kaplan-Meier and compared using log-rank.

Results: N+ were seen in 1242 (73%) and N0 in 468 (27%). N+ patients associated with female sex, right-sided primaries, higher tumour grade, synchronous metastases, more metastatic sites, more liver, distant lymph node, and peritoneal metastases, and fewer lung metastases compared with N0 (Table). No differences were seen for ECOG and age $>$70 years. *BRAF*-V600E mutations (mt) were more common in N+, as was deficient mismatch repair, whereas *RAS*mt were seen less often.

Table: 606P

		N0		N+		p-value
Age (years)	</=70	241	51%	689	55%	0.141
	>70	227	49%	553	45%	
Sex	Male	276	59%	662	53%	0.036
	Female	192	41%	580	47%	
Primary sidedness	Right	131	28%	473	39%	<0.001
(15 unknown/multiple)	Left	334	72%	757	62%	
Tumour stage	1-2	87	19%	52	4%	<0.001
(11 missing)	3	284	62%	777	63%	
	4	91	20%	408	33%	
Tumour grade	Low	359	90%	829	77%	<0.001
(23 missing)	High	41	10%	254	23%	
Presentation of metastases	Synchronous	167	36%	682	55%	<0.001
	Metachronous	301	64%	560	45%	
Metastatic sites	Liver	285	61%	823	66%	0.038
	Lung	154	33%	323	26%	0.005
	Distant nodes	62	13%	350	28%	<0.001
	Peritoneum	73	16%	269	22%	0.005
Mutation groups	RAS&BRAFwt	116	31%	311	32%	0.001
(357 not adequately tested)	RASmt	224	60%	503	51%	
	BRAF-V600Emt	34	9%	165	17%	

N+ patients had less metastasectomies (31% vs 39%, p=0.001) and more systemic therapy only (51% vs 43 %, p=0.001), with no difference for best supportive care. Median OS was shorter in the N+ vs N0 group (23 vs 34 months, p <0.001); likewise for metastasectomy patients (64 vs 96 months, p=0.001), and systemic therapy only (20 vs 27 months, p=0.001). N+ did worse than N0 with non-liver metastasectomy (77 vs 45 months, p=0.018), with similar trends for synchronous (77 vs 39 months, p=0.060) and metachronous presentation (not reached vs 58 months, p=0.172) subgroups.

Conclusions: Regional lymph node metastases (N+) were associated with several other negative prognostic factors. This resulted in fewer metastasectomies and impaired outcome in all and non-liver metastasectomy and systemic therapy only.

Clinical trial identification: NCT01531595; EudraCT 2011-003137-33.

Legal entity responsible for the study: The authors.

Funding: The PRCRC-study was supported by The Norwegian, Danish, and Swedish Cancer Societies. Amgen partly supported the NGS analysis performed in patients included in the Uppsala region cohort. The RAXO-study was supported by Finska Läkaresällskapet, Cancer Foundation Finland, Relander's Foundation , the Competitive State Research Financing of the Expert Responsibility Area of Tampere, Helsinki and Turku, Tampere University Hospital Funds, the Research Fund of Helsinki University Hospital. The infrastructure with database and study nurses were partly supported by pharmaceutical companies (Amgen unrestricted grant 2012—2020, Eli Lilly 2012—2017, Merck KGaA 2012—2020, Roche Oy 2012—2020, Sanofi 2012—2017 and Servier unrestricted grant 2016—2020). The funding sources had no role in the design and conduct of the study, collection, analysis and interpretation of the data, or decision to submit the manuscript for publication.

Background: Primary tumour sidedness (PTS) in mCRC is prognostic and predictive for anti-EGFR efficacy, progression-free (PFS) and overall survival (OS). We aimed to investigate the impact of (PTS) on demographics, resectability, and outcomes of metastasectomy, local ablative therapy (LAT) and systemic therapy.

Methods: The prospective Finnish real-life RAXO study (NCT01531621) included 1086 patients 2012-2018 (Osterlund, TLRHE 2021). Bonferroni corrected $\chi 2$ <0.05, Kaplan-Meier estimates, and Cox regression were analysed. P-value <0.05 denoted with*.

Results: PTS was right in 310 (29%) and left (colon/rectum) in 770 (61%), with multiple primaries excluded. Patients with right-sided tumours more often had female sex, age >70 years, unresectable metastases upfront, mucinous & signet cell histology, high-grade differentiation, *RAS* and *BRAF* mutations, dMMR, regional and distant lymph node metastases, peritoneal and less typical metastases. Patients with left-sided tumours had more liver and lung metastases. There was no difference in ECOG, synchronous presentation, T-stage, or number of metastatic sites. Right vs left PTS was associated with less upfront resectable (26% vs 30%*) and borderline resectable (14% vs 18%*) metastases. Final resectability (upfront + converted resectable) was also lower (32% vs 45%*), and fewer patients had metastasectomy/LAT (33% vs 41%*). Median OS from mCRC diagnosis for right and left was 21 vs 35 months (HR 0.59, CI95% 0.51-0.69); after R0-1 metastasectomy 80 vs 86 months, after R2/LAT 24 vs 50* months, and 18 vs 23* months for systemic therapy only., PFS in systemic therapy only was 8.9 vs 10.0* months (HR 0.82, 0.69-0.94). In multivariable analysis for OS right PTS, *RAS* and *BRAF* status, N-stage, and unresectable metastases upfront remained significant but not female sex, age >70 or dMMR status.

Conclusions: Right-sided PTS associates with several negative prognostic and predictive factors but is an independent negative prognostic factor in multivariable analysis. Resectability and metastasectomy/LAT rates are slightly lower in right primaries and outcomes slightly worse but still "excellent".

Clinical trial identification: NCT01531621; EudraCT 2011-003158-24.

Background: Liver resection is the only treatment offering a chance of long-term overall survival (OS) to patients (pts) with CLM.This prospective cohort evaluates the R0/R1 resection rate in pts with predominant CLM who were treated with aflibercept (AFL)+FOLFIRI after failure of an oxaliplatin-based regimen.

Methods: All pts with predominant CLM initiating AFL (4 mg/kg q2w) + FOLFIRI per physician choice were eligible. Primary endpoint was R0/R1 resection rate. Secondary endpoints included overall response rate (ORR), progression-free survival (PFS), OS and safety. Assuming a resection rate of 10-20% and 10% of follow-up loss, 140 patients were needed to determine R0/R1 resection rate with good precision.

Results: From July 2017 to July 2020, 136 consecutive pts with CLM [median age 65 years; 64.7% males; 28.7% right-sided; 55.1/8.1% RAS/BRAFmt; 80.1% synchronous; 46.3% extrahepatic sites and median of 4 CLM] were enrolled at 21 French sites. All pts received a prior oxaliplatin-based regimen, 77.4% prior anti-VEGF and 19.0% prior anti-EGFR agents. A median of 7 cycles of AFL+FOLFIRI was given. Overall, 16.2% of pts had R0/R1 liver resections (19.2% for liver only disease): 4/11 (36.4%) after failure of adjuvant oxaliplatin, 17/99 (17.2%) in 2nd line and 1/26 (3.8%) in 3rd line mCRC. Of 22 pts resected, 4 were judged resectable upfront, 15 potentially resectable and 3 unresectable before treatment by the investigator. Median duration of follow-up was 10.7 months (Table). Four pts (18.2%) had post-operative complications (all Dindo-Clavien grade I-II); 34.3% had grade $\geq$3 adverse events with AFL+FOLFIRI, mainly general health deterioration (8.0%) and diarrhoea (3.6%).

Table: 608P Secondary efficacy endpoints

	All (n=136)	Resected (n=22)	Not resected (n=114)
Best ORR*, %	30.1%	68.2%	22.8%
Median PFS, mo [95% CI]	5.4 [4.4-5.9]	11.1 [5.9-13.8]	5.1 [3.7-5.7]
Median OS from AFL initiation, mo [95% CI]	11.2 [9.4-14.1]	NR [20.4-NR]	9.4 [8.2-11.2]
Median OS from mCRC diagnosis, mo [95% CI]	28.1 [24.1-30.8]	55.0 [54.4-NR]	26.5 [21.7-29.0]
2-year OS rate from AFL initiation	19.9%	62.6%	11.1%

*Complete + partial responses; mCRC: metastatic colorectal cancer; CI: confidence interval; mo: months; NR, not reported

Conclusions: This prospective cohort suggests that AFL+FOLFIRI allows a clinically relevant rate of conversion from potentially resectable/unresectable to resectable CLM.

Clinical trial identification: NCT00454220.

Background: In JCOG0603, the addition of mFOLFOX6 to hepatectomy provided no clear survival benefit over hepatectomy alone in patients with colorectal liver metastasis (CLM). Therefore, this study examined the impact of surgical invasiveness on the tolerability of chemotherapy and survival.

Methods: Among patients registered in JCOG0603, those who received mFOLFOX6 after hepatectomy were analyzed in this subgroup analysis. The associations of factors related to surgical invasion (e.g., extent of hepatectomy, operative time, blood loss, postoperative complications) with factors related to the tolerability to mFOLFOX6 (completion of nine cycles, dose intensity, and adverse events) and disease-free survival (DFS) were assessed. The Hx ratio (resected liver weight/body weight) was calculated to evaluate the relative resected liver wight for each patient.

Results: One hundred forty-one patients treated with mFOLFOX6 were analyzed. The Hx ratio was identified as a predictor of the completion of nine cycles of mFOLFOX6 (≥median vs. <median: 50.8% vs. 74.2%, p = 0.0096), oxaliplatin dose intensity (72.9% vs. 86.1%, p = 0.0002), and occurrence of grade 2–4 hematological adverse events (90.5% vs. 75.8%, p = 0.0033). The Hx ratio [≥median/<median: hazard ratio (HR) = 1.94, 95% CI = 1.16–3.22], resected liver weight (≥300 g/<300 g: HR = 2.27. 95% CI = 1.36–3.78), and operative time (≥median/<median: HR = 1.71, 95% CI = 1.06–2.75) were identified as poor prognostic factors for DFS in univariate analysis. There were some interactions of the effect of mFOLFOX6 compared to hepatectomy alone with these factors.

Table: 609P

Surgical invasiveness		mFOLFOX6 vs. hepatectomy alone	
		HR (95% CI)	p
Hx ratio	≥Median	0.73 (0.48–1.10)	0.12
	<Median	0.55 (0.31–0.950)	0.03
Extent of hepatectomy	Major hepatectomy	0.93 (0.45–1.90),	0.84
	Minor hepatectomy	0.65 (0.46–0.92)	0.015
Liver weight	≥300 g	0.81 (0.47–1.40)	0.44
	<300 g	0.55 (0.37–0.83)	0.038

Conclusions: Surgical invasiveness, especially the relative resected liver weight, might affect both the tolerability and cytotoxic effect of mFOLFOX6. Adjuvant mFOLFOX6 should be cautiously administered when the extent of hepatectomy is large.

610P Predicting benefit from FOLFOXIRI plus bevacizumab versus FOLFOX/FOLFIRI plus bevacizumab in patients with metastatic colorectal cancer

M.J.G. Bond[1], M. van Smeden[1], K. Degeling[2], C. Cremolini[3], H.J.E-V. Schmoll[4], D. Rossini[3], S. Ibach[5], M. Koopman[6], C.J.A. Punt[1], A.M. May[1], J.J. Kwakman[7]

[1]Department of Epidemiology, Julius Center for Health Sciences and Primary Care, University Medical Center Utrecht, Utrecht, Netherlands; [2]Cancer Health Services Research, The University of Melbourne, Parkville, VIC, Australia; [3]Department of Translational Research and New Technologies in Medicine and Surgery, University Hospital of Pisa, Pisa, Italy; [4]Department of Clinical Hematology-Oncology, University Clinic Halle, Halle (Saale), Germany; [5]Research, X-act Cologne Clinical Research GmbH, Cologne, Germany; [6]Department of Medical Oncology, University Medical Center Utrecht, Utrecht, Netherlands; [7]Department of Medical Oncology, Amsterdam UMC, Amsterdam, Netherlands

Background: Individual patient outcomes may substantially differ from average treatment effects obtained in randomised controlled trials (RCT) due to patient heterogeneity. We aimed to predict which patients with metastatic colorectal cancer (mCRC) will benefit from first-line FOLFOXIRI versus FOLFOX/FOLFIRI, both plus bevacizumab.

Methods: Data from 639 patients (434 deaths) included in the phase III TRIBE2 RCT were used for developing a Cox regression model based on prespecified clinical, molecular, and laboratory variables for predicting 2-year mortality. Data from 232 patients (199 deaths) included in the phase II CHARTA RCT were used for external validation and heterogeneity in treatment effects analysis. Missing data was handled by multiple imputation. The C-index and calibration plots were used for performance assessment. C-for-benefit was calculated to assess evidence for treatment heterogeneity. The hazard ratio and absolute risk reduction were plotted as a function of the predicted mortality risk to explore treatment heterogeneity.

Results: In TRIBE2, the C-index was 0.68 (95%CI 0.65 – 0.71). At external validation, the C-index was 0.70 (95%CI 0.64 – 0.75), and the calibration plot indicated slight underestimation of mortality in high-risk patients. The c-for-benefit was 0.56 (95%CI 0.47 – 0.65). On the relative scale, there was no evidence of treatment heterogeneity (p for interaction = 0.16). On the absolute scale, the risk reduction in the lowest risk to highest risk quarter was 18% (95%CI 0 – 37%), 24% (95%CI 2 – 45%), -4% (95%CI -3 – 18%) and 0% (95%CI -16 – 16%), respectively.

Conclusions: Although our data suggest that patients with a low mortality risk have greater benefit of intensified treatment on an absolute scale, the predictions lack sufficient certainty to be used in clinical practice for individualised decision making. Larger samples are required to draw final conclusions on whether benefit from FOLFOXIRI could be predicted in patients with mCRC.

Background: The standard 1L therapies for mCRC involve a fluoropyrimidine with oxaliplatin and/or irinotecan, and a biologic agent. SHR-1701, a novel bifunctional fusion protein targeting PD-L1 and TGFβ, may enhance antitumor activity in combination with 1L standard therapies in mCRC pts. This phase 2/3 trial was designed to evaluate the safety and efficacy of SHR-1701 in combination with BP102 (a biosimilar of bevacizumab) and XELOX as 1L treatment in this pt population.

Methods: In the phase 2 part, eligible pts with previously untreated, unresectable mCRC were given SHR-1701 (30 mg/kg, iv, d1, q3w) + BP102 (7.5 mg/kg, iv, d1, q3w) + XELOX (capecitabine 1000 mg/m^2, po bid, d1-14, and oxaliplatin 130 mg/m^2, iv, d1) of 21-day cycles. Primary endpoints were safety and objective response rate (ORR) per investigator according to RECIST v1.1. Secondary endpoints were duration of response (DoR), disease control rate (DCR), progression-free survival (PFS), and overall survival (OS).

Results: From June 22 2021 to February 28 2023, 62 pts were enrolled. Median age was 56 years (range, 23-73). The main characteristics of the pts were as follows: 22 (35.5%) right-sided mCRC, 43 (69.4%) had liver metastases, 62 (100.0%) had MSS/pMMR, 36 (58.1%) had *RAS* mutation, and 4 (6.5%) had *BRAF* mutations. As of February 28, 2023, the median follow up time was 12.5 months (range, 1.4-18.8). Grade $\geq$3 TRAEs were reported in 37 (59.7%) pts, with the most common being anemia (8.1%), decreased neutrophil count (6.5%), and anaphylactic reaction (4.8%). TRAEs led to discontinuation of any study agent in 12 (19.4%) pts; of these, 6 (9.7%) discontinued SHR-1701 due to TRAEs (1 in grade 1, 3 in grade 3 and 2 in grade 4). This combination regimen resulted in an ORR of 59.7% and a DCR of 83.9%. Median DoR was 10.7 months (95% CI, 8.4-13.0). Median PFS was 10.3 months (95% CI, 8.3-13.7), and median OS was immature.

Conclusions: SHR-1701 in combination with BP102 and XELOX as 1L treatment provided a manageable safety profile and potent antitumor activity in pts with unresectable mCRC.

Clinical trial identification: NCT04856787.

612P Updated results from the multicenter phase II study of fruquintinib plus mFOLFOX6/FOLFIRI as first-line therapy in advanced metastatic colorectal cancer (mCRC)

F. Zhou[1], W. Wang[2], L. Xia[2], J. Dai[2], H. Wu[1], L. Yang[1], J. Gong[3], X. Chen[4], Z. Xiong[5], X. Liang[6]

[1]Hepatobiliary pancreas (abdominal tumor), Radiochemotherapy Department, Zhongnan Hospital of Wuhan University, Wuhan, China; [2]Gastrointestinal tumor, Radiochemotherapy Department, Zhongnan Hospital of Wuhan University, Wuhan, China; [3]Medical Oncology, Huangshi Central Hospital, Huangshi, China; [4]Medical Oncology, Henan Cancer Hospital, Zhengzhou, China; [5]Gastrointestinal Surgery, HuBei Cancer Hospital, Wuhan, China; [6]Medicine Department, HuBei Cancer Hospital, Wuhan, China

Background: The fruquintinib (a highly selective, and potent oral inhibitor of VEGF receptor 1, 2, 3) plus mFOLFOX6/FOLFIRI (standard chemotherapy) in patients (pts) with advanced mCRC study was a prospective, open-label, multi-center, single-arm phase 2 study (NCT05004441). The results of this study have been previously reported at the 2023 ASCO GI (152 Poster Session) and here we updated the efficacy and safety results with more enrolled pts and longer follow-up duration.

Methods: Pts aged 18-75 years with unresectable or metastatic CRC, without prior systemic threatment were recruited. RAS/BRAF status should be detected to exclude BRAF mutations before enrollment. Pts received fruquintinib (3mg, QD, PO, Q4W) in combination with mFOLFOX6/FOLFIRI (Q2W) for up to 8 cycles. Pts with SD or above were followed by maintenance therapy (fruquintinib 3mg, QD, PO, Q4W, capecitabine 850mg/m^2, BID, PO, D1-7, D15-21, Q4W) until disease progression or intolerable toxicity. The primary endpoint was ORR, secondary endpoints included DCR, PFS, OS and safety.

Results: At updated analysis (cutoff: April 20, 2023), 37 pts were enrolled (median age 56, 18 males, 6 with right half colon cancer, 15 harboring RAS mutations, 18 with liver metastases). For 30 pts who were in efficacy analysis, 23 achieved PR (76.67%), 6 achieved SD (20%), resulting in an ORR of 76.67% and a DCR of 96.67%. At a median follow-up of 7.49 mo, 2 pts underwent surgical resection, 21 pts were still in treatment, and median PFS had not yet reached. Safety profile exhibited that the regimen was tolerable and mainly grade 1/2. Grade 3 TRAEs were neutrophil count decreased (23.33%), leukopenia (10%), GGT increased and hypertension accounted for 6.67% respectively, AST increased (3.33%). No pts have serious adverse events.

Conclusions: Updated analysis of this study data further support current combination therapy with fruquintinib plus mFOLFOX6/FOLFIRI as the first-line therapy followed by fruquintinib plus capecitabine maintenance for advanced mCRC pts, which shows durable response and a favorable long-term safety profile. The study is still ongoing.

Background: SUNLIGHT, an international, open-label, randomized, phase 3 study comparing trifluridine/tipiracil (FTD/TPI) + bevacizumab (FTD/TPI + bev) vs FTD/TPI monotherapy in patients (pts) with metastatic colorectal cancer (mCRC), demonstrated a 3.3-month increase in overall survival (OS) from 7.5 months with FTD/TPI monotherapy to 10.8 months with FTD/TPI + bev (HR, 0.61; 95% CI: 0.49 - 0.77; P$<$0.001). Here discussed are data on the effects of prior anti-VEGF use on OS.

Methods: A post-hoc analysis of SUNLIGHT was conducted in ptns with anti-VEGF treatment during prior regimens to assess the effect of prior anti-VEGF use on OS in a subgroup analysis and evaluate the treatment benefit associated with FTD/TPI + bev vs FTD/TPI monotherapy in each subgroup. Of note, the trial was not powered to detect statistical significance in this analysis.

Results: In the subgroup analysis (no anti-VEGF [group 1], anti-VEGF in first regimen only [group 2], anti-VEGF in second regimen only [group 3], and anti-VEGF in both first and second regimens [group 4]), ptns treated with FTD/TPI + bev had a higher OS than those treated with FTD/TPI monotherapy in each prespecified subgroup. In group 1, mOS was 16.36 months (95% CI: 11.86 - NA) with FTD/TPI + bev vs 7.39 months (95% CI: 5.52 - 9.3) with FTD/TPI monotherapy (HR, 0.42; 95% CI: 0.25 - 0.69).

In group 2, mOS was 10.41 months (95% CI: 8.54 - 15.31) with FTD/TPI + bev vs 7.23 months (95% CI: 5.55 - 12.52) with FTD/TPI monotherapy (HR, 0.65; 95% CI: 0.38 - 1.1). In group 3, mOS was 9 months (95% CI: 8.15 - 15.14) with FTD/TPI + bev vs 8.15 months (95% CI: 6.21 - 10.18) with FTD/TPI monotherapy (HR, 0.66; 95% CI: 0.44 - 1). In group 4, mOS was 9.36 months (95% CI: 7.49 - 10.97) with FTD/TPI + bev vs 6.9 months (95% CI: 5.98 - 8.51) with FTD/TPI monotherapy (HR, 0.76; 95% CI: 0.52 - 1.1). In group 2, the OS was similar to the other subgroups, suggesting that an anti-VEGF break did not have any impact on the efficacy.

Conclusions: All subgroups showed a comparable OS benefit. The benefit of FTD/TPI + bev vs FTD/TPI on OS is observed independently of the use or not of anti-VEGF during prior regimens. For ptns who had prior anti-VEGF, this benefit is observed independently of whether they had anti-VEGF breaks or not.

Clinical trial identification: NCT04737187.

Background: SUNLIGHT, a randomized phase 3 study comparing trifluridine/tipiracil (FTD/TPI) + bevacizumab (FTD/TPI + bev) vs FTD/TPI monotherapy in patients (pts) with metastatic colorectal cancer (mCRC), demonstrated a 3.3-month increase in overall survival (OS) from 7.5 months with FTD/TPI monotherapy to 10.8 months with FTD/TPI + bev (HR, 0.61; 95% CI, 0.49 — 0.77; $P<0.001$). Here reported are data on the effects of $KRAS^{G12}$ mutational status on OS.

Methods: A post-hoc analysis of the SUNLIGHT trial was conducted in pts with a $KRAS^{G12}$ mutation to assess the effect of the mutation on OS in the overall population treated with FTD/TPI monotherapy and FTD/TPI + bev. In addition, a subgroup analysis according to the $KRAS^{G12}$ mutational status was conducted to assess the treatment benefit associated with FTD/TPI + bev vs FTD/TPI monotherapy on OS.

Results: In the overall population, a similar OS trend was observed regardless of $KRAS^{G12}$ mutational status. In pts with a $KRAS^{G12}$ mutation, mOS was 8.34 months (95% CI: 7.49 — 9.59); whereas, in pts with no $KRAS^{G12}$ mutation, mOS was 9.17 months (95% CI: 8.15 — 10.94). A non-detrimental effect on OS was observed in pts with a $KRAS^{G12}$ mutation vs in pts with no $KRAS^{G12}$ mutation (HR, 1.09; 95% CI: 0.87 — 1.36) in the overall population treated with both FTD/TPI monotherapy and FTD/TPI + bev. Similar results were observed when the analysis was restricted to the RAS mutant subgroup. In the subgroup analysis, pts treated with FTD/TPI + bev were more likely to benefit with a higher OS than those treated with FTD/TPI monotherapy in

each subgroup ($KRAS^{G12}$ mutated or not). In the $KRAS^{G12}$ mutant subgroup, mOS was 9.36 months (95% CI: 8.15 − 10.94) with FTD/TPI + bev vs 7.23 months (95% CI: 6.31 − 9.13) with FTD/TPI monotherapy (HR, 0.67; 95% CI: 0.48 − 0.93). In the subgroup with no $KRAS^{G12}$ mutation, mOS was 11.27 months (95% CI: 9.56 − 14.19) with FTD/TPI + bev vs 7.13 months (95% CI: 5.88 − 8.87) with FTD/TPI monotherapy (HR, 0.59; 95% CI: 0.43 − 0.81).

Conclusions: The presence of a $KRAS^{G12}$ mutation had no detrimental effect on OS, with a similar OS trend regardless of whether the pts had a $KRAS^{G12}$ mutation or not. The benefit of FTD/TPI + bev vs FTD/TPI on OS was confirmed independently of the $KRAS^{G12}$ mutational status.

Clinical trial identification: NCT04737187.

615P The impacts of starting regorafenib dose on treatment outcomes in metastatic colorectal cancer

S. Yuki[1], K. Harada[1], T. Kawakami[2], T. Ogata[3], Q. Hu[4], K. FUSHIKI[2], K. Oshima[2], S. Kadowaki[3], H. Taniguchi[5], K. Muro[5], R. Nakanishi[4], K. Ando[4], S. Nambara[4], T. Nakamura[6], Y. Kawamoto[7], Y. Komatsu[7], E. Oki[4], T. Masuishi[5], K. Yamazaki[8]

[1]Department of Gastroenterology and Hepatology, Hokkaido University Hospital, Sapporo, Japan; [2]Division of Gastrointestinal Oncology, Shizuoka Cancer Center, Nagaizumi, Japan; [3]Department of Clinical Oncology, Aichi Cancer Center Hospital, Nagoya, Japan; [4]Department of Surgery and Science, Kyushu University - Graduate School of Medical Sciences - Faculty of Medical Sciences, Fukuoka, Japan; [5]Department of Clinical Oncology, Aichi Cancer Center Hospital, Nagoya, Aichi, Japan; [6]Division of Cancer Center, Hokkaido University Hospital, Sapporo, Japan; [7]Division of Cancer Center, Hokkaido University Hospital, Sapporo, Hokkaido, Japan; [8]Division of Gastrointestinal Oncology, Shizuoka Cancer Center, Nagaizumi, Shizuoka, Japan

Background: Based on the results of the ReDOS study, starting a reduced dose of regorafenib (REG) is considered a treatment option for patients with metastatic colorectal cancer (mCRC). However, the effect of starting REG at a reduced dose on treatment outcomes in a real-world setting has not been fully investigated.

Methods: Clinical data ofpatients who received REG for mCRC between May 2013 and December 2020 were retrospectively collected from four institutions in Japan. These patients were divided into two groups: those who received a standard starting dose of REG (Group S) and those who received a reduced starting dose of REG (Group R). Treatment outcomes were compared between the two groups using Cox proportional hazards models based on propensity score adjustment for baseline characteristics.

Results: A total of 573 patients were enrolled (299 in Group S and 274 in Group R). After propensity score matching, 151 patients each in Group S and R were analyzed. The median overall survival was 6.4 months [95% C.I. 5.5-7.4] in Group S, and 6.1 month [95% C.I. 5.1-7.1] in Group R, respectively (HR 1.018, p=0.882). The median progression free survival was 2.1 months [95% C.I. 1.8-2.4] in Group S and 2.1 months [95%C.I. 1.8-2.3] in Group R, respectively (HR 1.077, p=0.522). The median time to the first dose reduction was 33.0 days [95% C.I. 29.1-36.9] in Group S and 74.0 days [95% C.I. 30.6-117.4] in Group R (HR 0.613, p=0.002). The median time to the first dose interruption was 14.0 days [95% C.I. 13.3-14.7] in Group S and 16.0 days [95% C.I. 11.9-20.1] in Group R (HR 0.757, p=0.033). Both any grades and ≥grade 3 proteinuria were significantly less frequent in Group R than in Group S (any grades: 68.7% vs 53.8%, p=0.027, ≥grade 3: 11.3% vs. 3.8%, p=0.045). The median time to onset of any grades and ≥grade 3 proteinuria was significantly longer in Group R (any grades: HR 0.711, p=0.042, ≥grade 3: HR 0.338, p=0.045). No significant difference was observed in the frequency of hand foot skin reaction and hypertension between the two groups.

Conclusions: Our results suggest that starting a reduced dose of REG contributes to a reduction in the frequency and delay in the onset of proteinuria without any impact on efficacy.

616P Sequential treatment with regorafenib (REG) and trifluridine/tipiracil (TAS) +/- bevacizumab (Bev) in refractory metastatic colorectal cancer (mCRC) in community clinical practice in the USA

T. Bekaii-Saab[1], D. Ahn[2], C. Yuan[3], X. Jiao[4], M. Kurtinecz[4], X. Pan[5], Z. Vassilev[3], H. Ostojic[7]

[1]Medical Oncology Department, Mayo Clinic Cancer Center, Phoenix, AZ, USA; [2]Hematology/Medical Oncology Department, Mayo Clinic Cancer Center, Phoenix, AZ, USA; [3]Oncology RWE, Bayer HealthCare Pharmaceuticals Inc., Whippany, NJ, USA; [4]Real-World Evidence, Bayer HealthCare Pharmaceuticals Inc., Whippany, NJ, USA; [5]Global Outcomes Research Department, Bayer HealthCare Pharmaceuticals Inc., Whippany, NJ, USA; [7]Medical Affairs, Bayer Consumer Care AG, Basel, Switzerland

Background: REG and TAS are approved for the treatment of refractory mCRC. However, data on their sequential use in any setting is limited. The aim of this study was to describe the characteristics and clinical outcomes of patients (pts) with mCRC treated sequentially in community clinical practice in the USA.

Methods: This was a retrospective cohort study using the nationwide de-identified Flatiron Health electronic health record-derived database. Pts aged ≥18 years at mCRC diagnosis treated sequentially with REG and TAS±Bev from Jan 2015 to Sep 2022 were divided into two cohorts: R-T (REG followed by TAS±Bev) and T-R (TAS±Bev followed by REG). Index date was the initiation of the first therapy in a sequence. Minimum follow up was 3 months (mos). Clinical outcomes included overall survival (OS), time to treatment discontinuation (TTD), neutropenia, and use of granulocyte-colony stimulating factor (G-CSF).

Results: A total of 818 pts were included (n=393 R-T; n=425 T-R). Most pts received index therapy in 3L (41.9%) or 4L (23.7%). Baseline characteristics were similar between cohorts (Table). Median OS improved with R-T vs T-R in both 3L and 4L (13.1 vs 11.5 mos in 3L; 11.6 vs 10.3 mos in 4L), though the differences were not statistically significant (HR [95% CI]: 0.94 [0.74, 1.19] 3L; 0.86 [0.63, 1.18] 4L). TTD was slightly longer with R-T vs T-R in 3L (8.7 vs 8.1 mos, HR 0.91 [0.73, 1.14]) and 4L (8.5 vs 7.9 mos, HR 0.86 [0.63, 1.16]). Frequency of neutropenia and use of G-CSF were lower with R-T vs T-R (38.9% vs 48.0% neutropenia; 14.0% vs 17.9% G-CSF).

Table: 616P

n (%)	R-T n = 393	T-R n = 425
Median age (IQR), years	63 (56, 70)	63 (56, 72)
Male gender	233 (59.3)	227 (53.4)
Race White Black or African American Asian	241 (61.3) 64 (16.3) 19 (4.8)	270 (63.5) 54 (12.7) 16 (3.8)
Stage IV mCRC at diagnosis	217 (55.2)	237 (55.8)
ECOG PS 0/1	278 (70.7)	300 (70.6)
KRAS mut	183 (46.6)	194 (45.6)
BRAF mut	5 (1.3)	19 (4.5)
Line of index treatment 1 2 3 4 ≥5	26 (6.6) 67 (17.0) 167 (42.5) 87 (22.1) 46 (11.7)	27 (6.4) 67 (15.8) 176 (41.4) 107 (25.2) 48 (11.3)
Median months since mCRC diagnosis (IQR)	24.6 (16.6, 35.7)	24.5 (17.3, 36.0)
Prior anti-EGFR	131 (33.3)	153 (36.0)
Prior bevacizumab	308 (78.4)	337 (79.3)
TAS+Bev	45 (11.5)	63 (14.8)
Neutropenia	15 (3.8)	9 (2.1)
Prior G-CSF	198 (50.4)	227 (53.4)

Conclusions: This real-world study showed that pts treated with sequential R-T vs T-R appeared to have longer OS and TTD, and less neutropenia and G-CSF use. Sequential therapy starting with REG may provide a chemotherapy break to improve tolerability and reduce myelosuppression in pts with refractory mCRC.

Background: Primary tumor location (PTL) has a confirmed prognostic and predictive effect in colorectal cancer first-line therapy, but its effect during the refractory stage is uncertain.

Methods: Clinical data of patients diagnosed with mCRC who received regorafenib (R) and/or trifluridine/tipiracil (T) between July 2012 and March 2022, were collected from 13 Italian cancer institutes retrospectively. Patients were divided into two groups based on whether they presented right (RCC) or left colon cancer (LCC). Our aim was to evaluate the impact of PTL on overall survival (OS), progression-free survival (PFS), and disease control rate (DCR) in R or T treatment groups in a real-world setting.

Results: 866 patients were included. Of these, 146 (16.8%) received T followed by R (T/R), 116 (13.3%) the reverse sequence (R/T), 325 (37.5%) received T alone, and 279 (32.5%) R alone. M/F=504/362; median age was 68 (30-87); median duration of follow-up was 7.2 months. We focused on patients who were sequentially treated with T and R and with the reverse sequence. Among 262 patients, we identified 52 RCC and 94 LCC in the T/R group, compared to 34 RCC and 82 LCC of the reverse sequence. In LCC patients, we found an OS advantage, with a median of 16.8 months in the R/T group vs. 14.7 months in the T/R group (p=0,0569). PFS was statistically significantly longer for the LCC patients who received the R/T sequence (11.7 vs. 9.1 months of the reverse sequence) (p=0,0022). PTL had no effect on disease control rate: we identified the best DCR (34.8%) in LCC patients in both T/R and R/T sequences (p=0.4904).

Conclusions: In our real-world analysis, PTL appears to have a prognostic impact in patients with refractory metastatic colorectal cancer who have received R and T in a sequential way. In fact, treatment with the sequence R/T seemed to us significantly correlated with better outcomes in terms of OS and PFS in patients with left-sided primary cancer. In terms of DCR, we cannot state that PTL is a predictive factor. We advise conducting additional research with sequential R and T treatment. Prospective clinical investigations, we believe, are required in this context.

Background: Vactosertib (TEW-7197), a highly selective and potent inhibitor of TGF-β receptor type 1, combined with PD-1 inhibition could induce immune restoration and enhance anti-tumor responses in patients with microsatellite stable metastatic colorectal cancer (mCRC). MP-VAC-204 is a phase 1b/2a study evaluating the combination of vactosertib with pembrolizumab in previously treated MSS mCRC. Here we report the updated safety and efficacy data of this phase 1b/2a study (NCT03724851).

Methods: Eligible patients were >18 years old with ECOG performance status 0-1 and who had disease progression after treatment with all available therapies including fluoropyrimidine and oxaliplatin or irinotecan. The MSI testing was conducted by local or central tests. Tumor biomarkers including granzyme B+ CD8+T cells were measured in serial tumor samples by multiplex immunofluorescence staining and deconvolution-based immune cell analysis. Circulating proteins, TGF-b, CTGF, PAI-1 and PDGF-AB were evaluated from serial blood samples.

Results: A total of 105 patients (36 in 200mg BID, 30 in 200mg QD, 7 in 200mg TID and 32 in 300mg BID) were enrolled. In all patients (N=105), the overall objective response rate was 13.3% [95% confidence interval (CI), 7.5- 21.4] and median duration of response was 6.0 months (95% CI, 2.9-Not Reached [NR]). Median PFS and OS were 1.3 months (95% CI, 1.2-1.4) and 15.8 months (95% CI, 7.9-NR) respectively. Overall PFS rate at 6 months was 17.1% (95% CI, 10.5-25.7) and overall survival rate at 12 months was 61.0% (95% CI, 51.0-70.3). Rash, headache and decreased appetite were the most frequent treatment emergent adverse events (TEAEs), but all were manageable. No fatal serious TEAEs were observed in any cohort. The levels of TGF-β signaling related circulating cytokines, TGF-b, CTGF, PAI-1, and PDGF-AB/BB were significantly decreased after treatment. Tumor-infiltrating and microenvironmental granzyme B secretion by CD8+ cells were significantly increased after treatment.

Conclusions: Vactosertib combined with pembrolizumab showed anti-tumor activity, prolonged overall survival and manageable safety profiles in patients with MSS mCRC. The phase 2 part is still ongoing.

Clinical trial identification: NCT03724851.

619P Pelareorep + atezolizumab and chemotherapy in third-line (3L) metastatic colorectal cancer (mCRC) patients: Interim results from the GOBLET study

G. Ungerechts[1], D. Arnold[2], E. Goekkurt[3], A. Stein[4], J. Chater[5], U.M. Martens[6], H. Loghmani[7], M. Coffey[7], R. Trauger[8], T.C. Heineman[9]

[1]Medical Oncology Department, NCT - Nationales Zentrum für Tumorerkrankungen, Heidelberg, Germany; [2]Oncology, Haematology, Palliative Care Dept., Asklepios Tumorzentrum Hamburg AK Altona, Hamburg, Germany; [3]Medical Oncology Department, Hämatologisch-Onkologische Praxis Eppendorf HOPE, Hamburg, Germany; [4]Oncology Hematology Department, Hematology Oncology Practice Hamburg, Hamburg, Germany; [5]Medical Oncology Department, Klinikum Chemnitz gGmbH, Chemnitz, Saxony, Germany; [6]Klinik für Innere Medizin III, SLK-Kliniken Heilbronn GmbH, Heilbronn, Germany; [7]Translational Research, Oncolytics Biotech Inc, Calgary, AB, Canada; [8]Translational Medicine, Oncolytics Biotech, Inc. La Jolla, CA, USA; [9]Clinical Development Department, Oncolytics Biotech, Inc. La Jolla, CA, USA

Background: Pelareorep (pela) is an intravenously administered, non-genetically modified oncolytic reovirus that selectively kills tumor cells and activates innate and adaptive immune responses. Pela primes tumors for checkpoint inhibition by enhancing tumor infiltrating lymphocytes and PD-L1 expression. The GOBLET study is assessing safety and efficacy of pela + atezolizumab (atezo) +/- chemotherapy in multiple gastrointestinal cancers. Here we report the interim results for 3L mCRC with microsatellite stable (MSS) disease.

Methods: GOBLET is a phase 1/2 Simon two-stage basket study. Eligible patients must have mCRC failing 2 prior lines of chemotherapy. Patients receive pela, atezo and trifluridine/tipiracil. The first stage enrolled 15 evaluable patients (patients with at least one post-baseline tumor assessment). Primary objectives are safety and efficacy (per tumor response/disease stabilization). The Stage 1 success criterion for 3L CRC is $\geq$4 patients with stable disease at Week 16. Blood samples were collected for T cell receptor sequencing (TCR-seq) to assess treatment effects on the T cell repertoire.

Results: No safety signals were observed in treated patients. Five of 15 evaluable patients had stable disease (SD) as their best response, including 4 with SD at week 16. 10 patients had progressive disease (PD). The overall clinical benefit rate was 33%. Translational research, including TCR-seq, supported findings: an expansion of new and preexisting T-cell clones was demonstrated. Updated efficacy (PFS and OS) and TCR-seq results will be presented.

Conclusions: Consistent with previous clinical trials of pela, the investigational combination therapy was well-tolerated. The primary efficacy success criterion was met. Given pela's immunologic mechanism of action and the significant changes seen in the T cell repertoire by C2D1, we hypothesize that potentially protective immune responses may have been initiated. However, these heavily pretreated patients may have been too immunocompromised or have insufficient time before progressing to benefit fully from the immunotherapy.

Background: Angiogenesis is a crucial mechanism in colorectal cancer (CRC) development and progression, and anti-angiogenic drugs are a mainstay of CRC systemic treatment.

Methods: We conducted, according to Simon's "minimax" two stage design, an open-label, single arm phase II trial to evaluate the antitumor activity of cabozantinib in pretreated metastatic CRC (mCRC) patients (pts), that progressed after at least 2 lines of prior therapy for metastatic disease. The primary endpoint was the Progression Free Survival (PFS) rate at 16 weeks; secondary endpoints include PFS, Overall Survival (OS), Response Rate (RR), Disease Control Rate, safety. Here we present the initial exploratory biomarkers analysis.

Results: From October 2019 to January 2023 a total of 33 (19 male and 14 female) pts, median age of 58 years (30-79), were treated with cabozantinib 60 mg/daily per os. A comprehensive genomic profiling by next generation sequencing (NGS) was performed with FoundationOne CDx and FoundationOne Liquid CDx (324 genes) on tumor tissue (20/33) and plasma circulating tumor DNA (ctDNA) (15/33) both in 8/33 pts. 11 out of 33 patients were free of progression at 16 weeks and were considered responders and among these the NGS analysis was available at the time of abstract submission in 10 pts. No specific genetic feature was identified in responders, only 1 patient had *AXL* amplification (that represents a potential target of cabozantinib). Of note *MET* amplification found in 2/25 pts did not correlate with response to cabozantinib. In not responding pts *SMAD4* mutation as well as genetic alteration defying a "BRCAness" phenotype were most reported. RNASeq analysis is currently ongoing in 26/33 (78.8%) patient samples.

Conclusions: The ABACO study showed clinical activity of cabozantinib in a subset of refractory mCRC, to the date of the analysis no predictive markers were identified so far. Further analysis are ongoing.

Clinical trial identification: EudraCT 2019-000674-28.

Background: Consensus molecular subtypes (CMSs) are used to classify metastatic colorectal cancer (mCRC) based on gene expression patterns and may provide insights into the biology of the disease and guide treatment decisions. Here, we describe the systemic proteome of CMSs from patients with *RAS* wild-type (wt) mCRC receiving fluorouracil and folinic acid with or without panitumumab (Pmab) after Pmab + mFOLFOX6 induction within the randomized phase II PanaMa trial.

Methods: Serum samples were collected at baseline (prior to first cycle of chemotherapy) from 271 *RAS* wt mCRC patients within the PanaMa trial, and the CMS classification was determined by RNA sequencing of the primary tumor. The systemic proteome was analyzed from serum using liquid chromatography-mass spectrometry. Differential protein abundance analysis was performed to identify potential biomarkers and pathways associated with CMSs.

Results: A total of 6 differentially abundant proteins (DAPs) were identified among CMS subtypes. For CMS1, no significant DAPs were detected. CMS2 showed significant downregulation of C-reactive protein (CRP, 1.47-fold decrease; $P=0.011$). CMS3 showed significant upregulation of immunoglobulin-related proteins. In contrast to CMS2, CMS4 presented significant downregulation of peptidoglycan recognition protein 2 (PGLYRP2, 0.72-fold decrease; $P=0.027$) and upregulation of CRP (1.46-fold increase; $P=0.027$) and SERPINA1 (0.65-fold increase; $P=0.048$) and SERPINA3 (0.66-fold increase; $P=0.048$).

Conclusions: The identification of CMS-specific proteomic signatures helps elucidate the systemic setting of CMS-based tumor classification and ultimately may help inform the development of personalized treatment strategies for patients with mCRC.

Clinical trial identification: NCT01991873.

Background: The modified mCCS intends to predict overall survival (OS) of mCRC patients (pts) at start of 1L therapy. Five clinical routine parameters assign pts into three prognostic risk groups from low to intermediate and high risk: tumor stage, tumor grading, lymph node ratio, primary tumor resection status and number of metastatic sites at start of 1L treatment (Marschner N, et al. Colorectal Dis. 2019). VALIDATE (NCT03043950) prospectively validates the mCCS in a large patient cohort with RAS WT mCRC.

Methods: VALIDATE is a multicenter, non-interventional study evaluating real-world effectiveness, safety and quality of life in pts with RAS WT mCRC receiving 1L PAN plus FOLFIRI/FOLFOX. Pts were allocated to three mCCS risk groups. This second interim analysis (IA2) was performed 24 months after last patient in. Data were analyzed descriptively for effectiveness, response rates and secondary resection rates.

Results: At data-base cut (Nov 17, 2022), 611 pts from 108 German and 5 Austrian sites were evaluable. Median age was 66.1 years, 68.9% of pts were male and 83.3% had an ECOG performance status 0/1. 59.4% of pts were diagnosed with a colon tumor. 84.3% of these pts had a left-sided tumor.

Table: 622P

	Total N=611	mCCS		
		Low risk N=202	Intermediate risk N=198	High risk N=211
Overall response rate n (%)	381 (62.4%)	121 (59.9%)	128 (64.6%)	132 (62.6%)
Secondary resections n (%)	115 (18.8%)	43 (21.3%)	47 (23.7%)	25 (11.8%)
24-month OS rate [95%-CI]	54.2% [50.0, 58.3]	60.0% [52.4, 66.8]	61.3% [53.8, 67.9]	42.3% [35.3, 49.0]

Most common grade 3/4 (MedDRA v20.0) treatment-emergent adverse drug reactions (TEADR) were dermatitis acneiform (5.8%), rash (2.9%) and diarrhea (3.2%). One investigator assessed fatal TEADR (arterial embolism) occurred.

Conclusions: The IA2 showed favorable effectiveness for PAN plus FOLFIRI/FOLFOX in the total population and in all mCCS risk groups in clinical routine in Germany and Austria. Interestingly, rates of secondary resections were >20% for low and intermediate risk pts. mCCS predicting OS will be validated in the final analysis. No new safety signals emerged.

Clinical trial identification: NCT03043950.

623P VIC regimen (vemurafenib/irinotecan/cetuximab) versus bevacizumab plus chemotherapy as first-line treatment for BRAF V600E-mutated advanced colorectal cancer

Y. Chen[1], D. Zhu[2], J. Xu[1]

[1]Colorectal Cancer Center, Zhongshan Hospital Affiliated to Fudan University, Shanghai, China; [2]Colorectal Cancer Center, Zhongshan Hospital, Fudan University, Shanghai, China,

Background: The need for safe and effective therapies for untreated, BRAF *V600E*-mutated, unresectable locally advanced or metastatic colorectal cancer remains unmet. The purpose of this study was to compare the efficacy and safety of the VIC (Vemurafenib/Irinotecan/Cetuximab) regimen versus bevacizumab plus chemotherapy as first-line setting in Asian patients.

Methods: In the single-center prospective cohort study, 78 untreated, BRAF V600E-mutant, locally advanced or metastatic CRC patients were enrolled. Every two weeks, the VIC regimen and bevacizumab plus doublet or triplet chemotherapy are administered. We evaluated the objective response rate (ORR), the disease control rate (DCR), and the conversion resection rate. In progression-free survival (PFS) and overall survival, the Kaplan-Meier method was utilized (OS).

Results: In the evaluable population, 32 patients received VIC regimen and 35 patients received bevacizumab plus chemotherapy. The ORR and DCR in the VIC group were significantly higher than in the bevacizumab-therapy group (ORR: 68.8% versus 40.0%, P=0.018; DCR: 100.0% versus 80.0%, P=0.023). The VIC regimen was significantly superior to bevacizumab plus chemotherapy for PFS (median, 11.9 vs 7.9 months; hazard ratio [HR]=0.48, 95% CI, 0.27-0.87; P=0.012) and OS (median, 24.5 vs 14.4 months; HR=0.36, 95% CI, 0.16-0.78; P=0.007). In the VIC group, the conversion resection rate for liver metastases was 42.1% (8 of 19 patients), and for local CRC it was 66.7% (6 of 9 patients with initially unresectable local CRC). Rates of treatment-related adverse events of Grade 3 to 4 were 32.4% and 31.1% for the VIC regimen and bevacizumab plus chemotherapy, respectively.

Conclusions: Among Asian patients with BRAF *V600E*-mutated advanced CRC, the VIC regimen was superior to bevacizumab plus chemotherapy in terms of tumor response and oncological survival, with a tolerable and manageable toxicity profile in the first-line setting.

Clinical trial identification: NCT05540951.

624P Tolerability and safety of vemurafenib, cetuximab combined with camrelizumab for BRAF V600E-mutated /MSS metastatic colorectal cancer

M. Qiu, G. Wei, W. Leng, P. Cao

Department of colorectal cancer center, West China School of Medicine/West China Hospital of Sichuan University, Chengdu, China

Background: The doublet combination of the BRAF inhibitor and the EGFR antibody showed unsatisfactory effect for patients with BRAF V600E-mutated metastatic colorectal cancer (mCRC). Furthermore, multiple immune escape mechanisms exist in BARF V600E mutated/MSS tumors. Combining targeted therapy with PD-1 antibody is a promising treatment option.

Methods: We enrolled previously treated patients with BRAF V600E-mutated/MSS mCRC. Eligible patients had received at least one systemic treatment for metastatic disease, not include EGFR inhibitor, BRAF inhibitor, and PD-1 inhibitor (ECOG PS 0-1) and had at least one measurable disease according to RECIST 1.1. All enrolled patients received cetuximab (500mg/m2, iv, q14 days), camrelizumab (200mg, iv, q14 days) and vemurafenib (two dose levels of 960mg, po, daily or twice daily). The primary endpoints were safety, tolerability per CTCAE.5 The second endpoints included ORR, DCR, PFS per RECIST1.1 and OS.

Results: 12 patients were enrolled and received trial regimen. Median age is 51 years, and 50% were male. Because of the high incidence of AEs in first 3 patients, all patients finally treated with lower dose of vemurafenib (960mg, po, daily). With a median follow-up of 13.68 months, grade 1-2 treatment-related AEs occurred in 12 patients (100.0%). Grade 1-2 AEs included drug-related rash (75.0%), articular pain (75.0%), reactive capillary proliferation disease (66.7%), anemia (53.3%), muscular pain (41.7%), mucosal hemorrhage (41.7%), fatigue (25.0%), and mouth ulcers (16.7%).6 patients (50.0%) had grade 3 treatment-related AEs, included fever (25%), drug-related rash (16.7%), mucosal hemorrhage (8.3%), diarrhea (8.3%), immune myocarditis (8.3%), anemia (8.3%), thrombocytopenia (8.3%), mucosal hemorrhage (8.3%), and immunological myocarditis (8.3%). Finally, 10 patients received response evaluation. ORR is 40.0%, and DCR is 80.0%. 1 patient achieved CR with duration of response of 24.83 months. 3 patients achieved PR and 4 patients were evaluated as SD. Median PFS is 3.37 months (95%CI, 1.28-5.26). Median OS is 11.47 months (95% CI, 4.67-18.27).

Conclusions: The VCC regimen is effective and moderate-tolerated for patients with BRAF V600E-mutated /MSS mCRC.

Clinical trial identification: NCT05019534.

Background: The combination of encorafenib with cetuximab has become the standard of care in patients with *BRAF* V600E mutated metastatic colorectal cancer (mCRC), after a prior systemic therapy. This retrospective study aims to describe the efficacy and safety of encorafenib with cetuximab combination in the real-world setting.

Methods: All consecutive patients with *BRAF* V600E-mutated mCRC who received the combination encorafenib + cetuximab +/- binimetinib (e/c+/-b) from January 2020 to June 2022 in 24 French centers and 8 non-French centers were included.

Results: Overall, 201 patients were included, with 55% of women, a median age of 62 years and an ECOG-PS $\geq$2 in 20% of cases. Other main patients' tumor characteristics were 60% of right-sided primary tumor, 11% of MSI/dMMR phenotype and liver and peritoneum being the 2 main metastatic sites (57% and 51%). The e/c+/-b combination was prescribed in 1st line (L1) for 8 patients (4%), in 2nd line (L2) for 113 patients (56%), in 3rd line (L3) for 58 patients (29%), beyond L3 for 22 patients (11.3%), with an addition of binimetinib for 21 patients (10%). With e/c treatment, 21% of patients experienced grade $\geq$3 adverse events (AEs), with each type of grade $\geq$3 AE observed in less than 5% of patients The most frequent grade 1-2 AEs were acneiform dermatitis/rash (43%), dry skin (29%), arthralgia (21%), and anemia (22%). The objective response rate under e/c+/-b was 32% and the disease control rate was 71%, all lines combined. Median PFS under e/c+/-b was 4.4 months (95% CI 3.9-5.6) and median OS was 9.1 months (95% CI 7.8-10.8). In multivariate analysis, the factors associated with a shorter PFS under e/c+/-b were the presence of liver metastases (HR: 1.6, p=0.02) and ECOG-PS$\geq$2 (HR: 1.9, p=0.002) but not the line of treatment.

Conclusions: This real-world study showed that in patients with *BRAF* V600E mutated mCRC treated with encorafenib + cetuximab +/- binimetinib, efficacy data are very similar to those reported in the BEACON CRC registration trial. In this series, the main prognostic factors for this treatment are ECOG-PS$\geq$2 and liver metastases. The safety profile was favorable with only 21% of patients experiencing a grade 3 or more AE.

626P Mucinous differentiation (MD) as predictor of response in BRAF-V600E mutated metastatic colorectal cancer (mCRC) treated with BRAF inhibitors (BRAFi) combinations

F.J. Ros Montana[1], V. Navarro[2], R. Comas[2], S. Landolfi[3], L. Ramirez[4], H.G. Palmer[1], A. Garcia Rodriguez[1], N. Saoudi Gonzalez[1], I. Baraibar Argota[1], M. Rodriguez Castells[5], F. Salvà Ballabrera[6], J. Tabernero[7], M.E. Elez Fernandez[1]

[1]Medical Oncology Dept., Vall d'Hebron University Hospital, Barcelona, Spain; [2]Oncology Data Science (ODysSey) Group, Vall d'Hebron Institute of Oncology (VHIO)-Cellex Center, Barcelona, Spain; [3]Pathology Department, Vall d'Hebron University Hospital, Barcelona, Spain; [4]Stem Cells Lab, Vall d'Hebron Institute of Oncology (VHIO)-Cellex Center, Barcelona, Spain; [5]Medical Oncology Dept., Vall d'Hebron Institute of Oncology (VHIO)-Cellex Center, Barcelona, Spain; [6]Medical Oncology (Gastrointestinal Unit), Vall d'Hebron University Hospital, Barcelona, Spain; [7]Medical Oncology Dept., Vall d'Hebron University Hospital, Barcelona, Spain

Background: In *BRAF*-V600E mutated metastatic colorectal cancer (mCRC), 40% of tumors present with MD. This feature has been associated with poor prognostic and resistance to chemotherapy. However, the clinical impact of the presence of MD in patients treated with BRAFi remains unclear. Aim: The aim of this study is to evaluate the clinical impact of MD in a cohort of patients with *BRAF*-V600E mutated mCRC treated with BRAFi.

Methods: Patients with *BRAF*-V600E mCRC treated at Vall d'Hebron Hospital from 2019 to 2021 were included. MD was determined baseline based on the percentage of neoplasic mucinous component (FFPE). Data were collected prospectively. Survival analysis were calculated using K-M curves.

Results: A total of 54 patients were included, with a median age of 62 years, and 61% were females. Of these patients, 65% had right-sided tumors, 11% had MSI. 68% of patients received BRAFi-antiEGFR, while 32% received BRAFi-antiEGFR-MEKi. Initially, a dichotomic MD was established based on the presence or absence of tumoral mucin, with 36 and 17 patients, respectively. ORR was 41% and 25% for mucinous and non-mucinous tumors, respectively. PFS was 8.43 months (HR 0.49, 95%CI 4.83-11.1, p 0.02) for mucinous tumors, compared to 3.84 months for non-mucinous tumors. Mucinous tumors tended to have better overall survival (OS) (14 vs 10.2 months, HR 1.3, 95%CI 0.4-1.4, p 0.4). Then, we evaluated whether the percentage of tumor mucin impacted outcomes. Three groups were established based on an arbitrary cut-off of 20%: high-mucin -HM- (>20% of mucin, n:17), low-mucin -LM- (<20% of mucin, n:11), and non-mucinous -NM- (n:17). ORR was 68%, 33%, and 25%, respectively. Patients with high-mucin had better PFS compared to non-mucinous tumors, 9.4 months vs 3.84 months (HR 0.87, 95%CI 0.17-0.9, p 0.02). Patients with low-mucin tended to have better PFS than non-mucinous tumors (5.62 months, HR 1.2, 95%CI 4.60-12.9, p 0.08). Tumors with MD tended to have better OS in both groups (15 months in the HM group, 16.6 months in the LM group vs 10.2 months in the NM group).

Conclusions: Tumor mucin may be a potential predictive biomarker in *BRAF*-V600E mutated mCRC patients treated with BRAF inhibitors. Further validation is required.

628P Immunotherapy in mismatch repair-deficient metastatic colorectal cancer: Long-term outcome and novel predictive markers

A. Stemmer[1], O. Margalit[1], V. Serpas[2], G.Z. Strauss[2], J. Thomas[2], P. Shash[2], K. Levanon[1], E. Shacham Shmueli[1], E.S. Kopetz[3], M.J. Overman[3], B. Boursi[1]

[1]Oncology, Sheba Medical Center, Ramat Gan, Israel; [2]Oncology, MD Anderson Cancer Center, Houston, TX, USA; [3]GI Medical Oncology Department, The University of Texas MD Anderson Cancer Center, Houston, TX, USA

Background: PD-1 with or without CTLA-4 blockade is the treatment of choice in dMMR/MSI-H metastatic colorectal cancer (mCRC) patients. However, there are currently no validated predictors for treatment response, and there is a paucity of real-world data on treatment efficacy. Our aim was to assess predictive markers for response to immunotherapy in this patient population.

Methods: A study using two prospective cohorts from the University of Texas MD Anderson Cancer Center and Sheba Medical Center of consecutive patients with dMMR/MSI-H mCRC that were treated with immunotherapy between 2014-2022. Primary outcomes were progression-free survival (PFS) and overall response rate (ORR). Evaluated predictors included ECOG-PS score, *RAS*/*BRAF* status, single-agent versus nivolumab plus ipilimumab immunotherapy, metastatic sites, disease burden, and CEA levels prior to treatment initiation. Kaplan-Meier analysis and univariate Cox proportional hazard regression model were used to analyze the effect of all exposure variables on PFS.

Results: The study cohort included 153 patients with a median age of 60 (IQR 45-71), of them 51.6% (n=79) were males. First-line immunotherapy with anti-PD-1 or anti-PD-1 plus anti-CTLA-4 was used in 77.8% (n=119) and 22.2% (n=34) of patients, respectively. Median follow-up time was 26 months (IQR 11-48). Median PFS was 51.6 months (95%CI 38.1-NR) and ORR was 58.1% (n=89). ECOG-PS score ≥2 and ≥3 metastatic sites were associated with worse PFS with a HR of 2.09 (95%CI 0.98-4.47) and 3.11 (95%CI 1.61-6.03), respectively. The presence of liver or lung metastasis, either solitary or mixed sites, were associated with worse PFS with HRs of 2.35 (95%CI 1.43-3.88) and 2.30 (95%CI 1.31-4.04), respectively. Right-sided tumors were associated with improved PFS with a HR of 0.56 (95% CI 0.32-0.97). CEA levels >5 μg/L prior to treatment initiation were associated with worse PFS with a HR of 2.23 (95%CI 1.30-3.81).

Conclusions: Liver or lung metastasis, and high CEA levels predict poor response to immunotherapy in dMMR/MSI-H mCRC. Conversely, right-sided tumor predicts improved response.

Background: Colorectal cancers with microsatellite instability/deficient mismatch repair (dMMR/MSI CRC) are associated with particular outcome and treatment, especially in the recent context of immune checkpoint inhibitors (ICI). There is no large prospective real-life cohort evaluating outcome and prognostic factors in dMMR/MSI CRC.

Methods: COLOMIN2 is a prospective, multicenter cohort designed to assess treatment and prognosis of dMMR/MSI CRC. Key eligibility criteria included histologically proven CRC with a MSI (molecular biology) and/or dMMR (immunohistochemistry, IHC) status. The primary endpoint is time to recurrence (TTR) for non-metastatic tumors and progression-free survival (PFS) for metastatic tumors.

Results: Between January 2016 and December 2021, 637 patients were included by 37 centers with stage I (8.2%), II (36.4%), III (35.5%) or IV (18.7%) dMMR/MSI CRC. The mean age was 69.6 years, 59.8% were women and 62.6% were ECOG PS 0 or 1. Most tumors had a MMR IHC (76.1%) and 23.9% a MSI test alone. *BRAF* and *RAS* mutations were identified in 44.9% and 25.0%, respectively; with no difference according to tumor stage. One third of patients had a Lynch syndrome with proven MMR gene mutation (32.5%). Most tumors are located in ascending colon (69.5%) and well/moderately differentiated (55.3%). Among stage II and stage III CRC patients 16.9% and 61.7% had adjuvant chemotherapy (CT), respectively; mostly with oxaliplatin-based CT (82.6%) whatever the tumor stage. After a median follow-up of 23 months, TTR at 3 years were 97.0% in stage I, 88.6% in stage II and 68.9% in stage III. Most patients with stage IV disease had one metastatic site (74.5%), mostly in liver (48.1%) and peritoneum (36.8%). Most patients were treated by first-line CT +/- targeted therapy (79.8%) and few by ICI (12.9%). Median PFS were 11.8 [95%CI: 7.1-28.0] months and 28.0 [95%CI: 2.1-NA] months for patients treated with CT and IO, respectively.

Conclusions: This real-life cohort confirms the good prognosis of non-metastatic dMMR/MSI CRC by contrast to metastatic patients treated by chemotherapy +/- targeted therapy. Clinical and biological prognostic factors are currently explored, and will be presented during ESMO meeting.

Clinical trial identification: NCT05511688.

Background: The aim is to determine, using quantitative imaging features from baseline CT-scans and clinical factors, the response to mono vs combo immunotherapy for metastatic patients with mCRC MSI.

Methods: This retrospective study included 105 patients treated either with a single anti-PD1 (mono) or a combination of anti-PD1 and anti-CLA4 (combo). Baseline scanners were annotated manually in 2D on the axial plane slice with the largest diameter for each visible lesion by 6 expert radiologists. Tumor volume was computed by summing the volume of each lesion, and reproducibility was assessed using Intercorrelation coefficient (ICC2k). Cox models were used to predict overall survival (OS) on bootstrap samples, and the concordance index was used to assess its performance on out-of-bag samples. Progression free survival (PFS) was evaluated. Recursive feature elimination (RFE) was used to reduce the number of variables. Cutoffs were determined using maximally selected rank statistics and were used to binarize features, and a risk score was built using weights derived from the Hazard ratios. The final model was modified to exclude the type of treatment, and the cutoff was adjusted.

Results: In total, 1633 lesions were annotated. ICC2k was equal to 0.95 for total tumor volume. Of the 13 variables studied, 5 were selected after the RFE: age, type of treatment, presence of peritoneal carcinomatosis (PC), number of lesions and total tumor volume. The cutoffs for total tumor volume, number of lesions and age were 73 cm3, 20 lesions and 60 years old. The weights for total tumor volume, number of lesions, age and PC were 1.13, 0.96, 0.91 and 0.38 and the cutoff of the risk score was 1.51. Patients with a low risk score had similar OS and PFS independently of treatment, while those with a high score had significantly worse OS and PFS if treated with monotherapy ($p=0.004$ and $p=0.0001$).

Conclusions: Total tumor volume had the highest weight amongst other quantitative imaging measures and age, emphasizing the need to compute tumor burden before initiating treatment. This score could allow oncologists to identify mCRC MSI patients who need combo therapy, limiting its unnecessary side effects compared to monotherapy.

631P Using the unique somatic mutation profile of POLE loss of proof-reading mutation helps in selection of patients who may benefit from immunotherapy

G. Maddalena[1], F.A. Zeineddine[1], S. Chowdhury[2], M. Zeineddine[1], A. Yousef[2], M.J. Overman[1], E.S. Kopetz[1], J.P.Y-C. Shen[1]

[1]Department of Gastrointestinal Medical Oncology, MD Anderson Cancer Center, Houston, TX, USA; [2]Gastrointestinal Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX, USA

Background: It has been reported that POLE mutant tumors are likely to respond to immune therapy, however, most POLE mutations are passenger mutations and do not induce a hypermutated phenotype. Current methods to classify POLE mutations are limited in both accuracy and completeness complicating the selection of patients (pts) most likely to benefit from immunotherapy.

Methods: A curated list of 13 known loss of proof-reading (LOP) *POLE* mutations was used to identify 66 tumors with *POLE* LOP mutation from which we extracted somatic mutation signatures, these averaged together defined a positive control *POLE* LOP signature. POLE mutant tumors with mutational signatures highly correlated with the positive control (> 0.7) were determined to be LOP.

Results: A total of 1467 *POLE* mutations (mut) were identified from 50962 tumors accessed from cBioPortal. Correlation with the positive control *POLE* LOP signature was sensitive (all tumors with known *POLE* LOP mutation from literature were recovered) and specific ($92/97 = 94.8\%$ had high TMB, a hallmark feature of *POLE* LOP). In addition to recovering known LOP mut found in the exonuclease region, several new LOP were discovered including R705W mut, which is in the DNA

polymerase domain and positioned to interface with the binding to DNA. To evaluate *POLE* LOP as a predictive biomarker a cohort of pts with *POLE* mutant mCRC treated with immunotherapy (IO) (n=29) was identified from institutional databases. All 7 pts with *POLE* LOP achieved clinical benefit (3 CR, 3 PR, 1 SD) and remain on immunotherapy at the time of submission (median follow up time = 36 months). In contrast, none of the 7 MSS pts with Non-LOP *POLE* mut achieved an objective response to IO therapy (2 SD, 5 PD), and had disease progression with median PFS of 3.6 months (log-rank p<0.0003). For the other 15 pts with Non-LOP *POLE* mut response was supported by MSI-H status.

Conclusions: Identifying of the subset of *POLE* mut that cause LOP is critical in order to correctly identify pts most likely to benefit from immune therapy. CRC tumors with LOP *POLE* mutation were found to have deep, sustained response to IO therapy, in contrast to those with non-LOP *POLE* mutations.

632P Predictive value of C-reactive protein (CRP) in microsatellite-stable (MSS) metastatic colorectal cancer (mCRC) patients given first-line alternating short-course oxaliplatin-based chemotherapy (FLOX) and nivolumab

S. Meltzer[1], J.P. Berg[2], H.M. Hamre[3], C. Kersten[4], E. Hofsli[5], M.G. Guren[6], H. Sorbye[7], K. Flatmark[8], A.H. Ree[3]

[1]Department of Oncology, Akershus universitetssykehus HF, Lorenskog, Norway; [2]Institute of Clinical Medicine, University of Oslo, Oslo, Norway; [3]Department of Oncology, Akershus University Hospital HF, Lorenskog, Norway; [4]Department of Research, Sorlandet Hospital, Kristiansand, Norway; [5]Department of Oncology, St. Olavs Hospital HF, Trondheim, Norway; [6]Department of Oncology, Oslo University Hospital, Oslo, Norway; [7]Department of Oncology, Haukeland Universitetssykehus, Bergen, Norway; [8]Department of Gastroenterological Surgery, Oslo University Hospital - Radiumhospitalet, Oslo, Norway

Background: Tumour-associated systemic inflammation impedes immune checkpoint blockade (ICB) efficacy. We explored whether the initial two FLOX cycles of alternating short-course FLOX and nivolumab may affect circulating CRP and outcome (progression-free survival; PFS) in first-line treatment of MSS-mCRC.

Methods: In the METIMMOX randomised trial, patients were assigned to FLOX (oxaliplatin 85 mg/m^2 day 1, bolus 5-fluorouracil 500 mg/m^2 and folinic acid 100 mg day 1-2) Q2W (control arm) or alternating two cycles each of FLOX and nivolumab (240 mg) Q2W (experimental arm) with PFS as the primary endpoint. CRP was measured at baseline and every treatment visit. In this *post hoc* analysis, patients were categorised based on CRP ≥5.0 mg/L and <5.0 mg/L after the initial two FLOX cycles, immediately before the third FLOX (control arm) or first nivolumab (experimental arm) cycle was started.

Results: Patients were randomly assigned 2018/05-2021/10. At censoring 2023/01, median PFS was 9.3 months in both study arms. For the entire cohort, CRP was median 13.0 mg/L (range 0.70-112) at baseline (n=76) and 6.0 mg/L (range 0.50-60.0) after two FLOX cycles (n=73); p=0.014 (Mann-Whitney U-test). For experimental-arm patients, CRP <5.0 mg/L immediately before commencing nivolumab (n=17) was associated with significantly improved median PFS 15.7 months (range 2.6-41.6) compared to patients with CRP ≥5.0 mg/L (n=19) with median PFS 4.4 months (range 1.9-17.1); p=0.0004 (log-rank). No such difference was seen in the control arm; p=0.82 (log-rank). Experimental-arm patients with CRP <5.0 mg/L after the first two FLOX cycles had longer PFS compared to the corresponding control group; p=0.0082 (log-rank).

Conclusions: In MSS-mCRC patients receiving first-line therapy, CRP <5.0 mg/L after initial two FLOX cycles identified patients responding to sequential nivolumab with improved PFS compared to patients continuing FLOX. As a rapid, cost-effective analysis, and if early oxaliplatin-based chemotherapy counteracts tumour-associated systemic inflammation, CRP may predict ICB efficacy in MSS-mCRC.

Clinical trial identification: NCT03388190.

633P Genomic alterations in SPEN predict outcome of immune checkpoint therapy in gastrointestinal cancer

C. Wu[1], X. Qiao[1], D. Gong[1], S. Li[1], Z. Yu[1], Y. Liu[2], Q. Zhang[2], D. Chen[2]

[1]Hepatic-biliary-pancreatic Surgery, Hainan General Hospital, Haikou, China; [2]The Medical Department, Jiangsu Simcere Diagnostics Co., Ltd., Nanjing, China

Background: Application of Immune Checkpoint Inhibitors (ICIs) has become important therapy for gastrointestinal cancer (GC). *SPEN* gene encodes Msx2-interacting protein which can block the differentiation of precursor B-cells into marginal zone B-cells and represses transcription. However, the correlation between *SPEN* mutation and immune efficacy is unclear.

Methods: We retrospectively analyzed the genomic and survival data from 236 patients with GC derived from MSKCC cohort (Nat Genet 2019) to evaluate the relationship between *SPEN* mutation status and efficacy of immunotherapy. Then we explored the prognostic value of *SPEN* mutation in 914 GC patients from The Cancer Genome Atlas (TCGA) database. TMB was calculated as the total count of non-synonymous mutations in coding sequence. The CIBERSORT analysis relied on RNA-seq data in TCGA database to evaluate 22 types immune cell infiltration status.

Results: The TMB level of *SPEN*-mutant patients was higher than *SPEN*-wildtype patients in both MSKCC (Median [IQR]: 64.94[2.63-203.64] vs 6.14[0.00-153.47], P < 0.001) and TCGA (Median [IQR]: 31.20[0.96-296.91] vs 2.70[0.05-194.70], P < 0.001) cohort. In MSKCC cohort, compared to *SPEN*-wildtype patients, *SPEN*-mutant patients achieved prolonged OS (median OS: 34 vs 13 months, P=0.009). Moreover, a multivariable analysis across the MSKCC cohort demonstrated that *SPEN*-mutant was associated with better OS (HR=0.30; 95%CI, 0.11-0.82; P=0.019), after adjusting for age, gender, metastasis and treatment. In TCGA cohort, there was no significant difference in OS between *SPEN*-wildtype group and *SPEN*-mutant group (median OS: 67.3 vs 60.8 months, P = 0.33). The CIBERSORT analysis revealed that CD8+ T cell infiltration and activated CD4 memory T cell were significantly higher in *SPEN*-mutant group than *SPEN*-wildtype group (p < 0.05).

Conclusions: *SPEN* mutation is associated with higher TMB in ICI-treated gastrointestinal cancer patients. Survival analysis suggests that *SPEN* mutation may serve as a novel predictive biomarker in GC patients with ICIs, but not a prognostic factor. The significantly higher CD8+ T cell infiltration and activated CD4 memory T cell in *SPEN*-mutant group may be the potential mechanism.

Background: Long course chemoradiotherapy (LCCRT) for locally advanced rectal cancer (LARC) results in a complete pathological CR in 10-30% of patients (pts). Radiotherapy (RT) is immuno-stimulatory by enhancing tumour cell death, but also immunosuppressive stimulating PDL1 production and myeloid-derived suppressor cells. PDL1 inhibition may be required to enhance RT immuno-stimulatory effects. *Hypothesis:* In pts with resectable LARC, Avelumab given post LCCRT may enhance tumour response rates whilst reducing relapses.

Methods: Phase II single arm trial. Pts had LCCRT (50.4Gy + 5FU [225mg/m^2/day/CI] or Capecitabine [825mg/m^2 BID]/5.5 weeks). Post LCCRT pts received 4 cycles Avelumab (AV) (10mg/kg, q2 weeks), then resection 10-12 weeks post LCCRT. Fresh tumour biopsy/ctDNA sampling taken at pre LCCRT, pre AV and at surgery. Response by FDG PET and pelvic MRI. *Inclusion Criteria*: pts with MRI stage T3b-4/N1-2/M0 LARC , tumoural lower border <12cm from anal verge, measurable disease, ECOG 0-1, adequate organ function. *Endpoints:* (a) *Primary*; Complete pathological response rate (Target $\geq$ 35%) reported centrally, (b) *Secondary*; Imaging responses, Toxicity. (c) *Exploratory;* Tumoural immune cell subsets/checkpoint expression and ctDNA analysis, Distant relapse-free survival and the sites of relapse.

Results: 37 pts entered. Baseline TNM: T3b-d 75%, T4a-b 25%. 33 pts completed LCCRT, 31 pts (83%) had all 4 cycles of AV and 32 pts (86%) had surgery. ORR Pelvic MRI (N=33): 2 CR, 14 PR, 31 DCR. FDG PET: 10 CMR, 18 PMR.. 10 pts Grade 3 AEs, 3 pts with treatment-related G3 and no G4 AEs. No immune-related G3 AEs. Post-operative complications as expected. Pathological response (Modified Ryan Score) (N=32): Complete pathCR (18.7%), near CR (15.7%), in MSI-H (N=4), 50% and 25% resp. Median followup 3.1 yrs: 3 yr est. time to progression 82%, distant relapse free survival 80%, disease free survival 80%.

Conclusions: The Ave-Rec phase II study has shown Avelumab post LCCRT is safe with significant imaging responses and complete/near-complete path response rate of 34.3% in pts with ESMO high risk rectal cancers. Parallel translational studies are ongoing. The addition of immune checkpoint inhibitors warrants further evaluation in LARC.

Clinical trial identification: NCT03299660.

Background: Cetuximab could mediate, independently from RAS mutation, an immunogenic tumor cell death and antitumor immune response. This trial explores the efficacy and safety of AVE, CET and IRI for the treatment of refractory MSS mCRC.

Methods: Chemo-refractory (+anti-EGFR refractory if RAS wt) MSS, mCRC patients (pts) were enrolled in 3 cohorts (A: RAS wt, B & C: RAS mut) and treated with CET (500 mg/m^2/Q2W), IRI (150 mg/m^2/Q2W) and AVE (10 mg/kg/Q2W). Primary endpoints were safety, overall response rate (ORR) (cohorts A-B) and 6 months progression-free survival rate (6m-PFSR) (cohort C). Secondary and exploratory endpoints included disease control rate (DCR), PFS, OS and immunoscore (IS) biomarker. Based on a Simon 2-stage design (α=0.1; β=0.2) for ORR (cohorts A: P0/P1=0.15/0.33 – B: P0/P1=0.09/0.25) and 6m-PFSR (cohort C: P0/P1=0.15/0.31), 10+18 (A); 13+15 (B) and 14+25 (C) pts were needed. At least 2+5 (A); 2+3 (B) and 3+6 (C) pts must reach ORR (A-B) or 6m-PFSR (C) for efficacy objectives. Immunofluorescence (CD3, CD8 densities) was performed on baseline metastasis biopsies to generate IS.

Results: 57 pts (median 62 yrs, 73.7% male, 84.2% left-sided, 86.0% synchr. mCRC) were included and 55 pts treated. Any treatment-emergent adverse event (AE) grade >=3 occurred in 35 pts (63.6%; diarrhea in 11 pts, 20.0%). Immune-related AEs grade >=3 appeared in 2 pts (3.6%; 1 acute kidney injury, 1 cholangitis). Efficacy results are summarized.

Table: 635P

Characteristics	Cohort A (n=28)	Cohort B (n=13)	Cohort C (n=14)
ORR, % (pts)	21.4% (6/28)	0.0% (0/13)	0.0% (0/14)
DCR, % (pts)	50.0% (14/28)	61.5% (8/13)	42.9% (6/14)
6m-PFSR, % (pts)	25.0% (7/28)	38.5% (5/13)	7.1% (1/14)
Median PFS, months (95%CI)	3.6 (2.5-5.6)	3.7 (2.7-6.4)	2.8 (2.4-3.8)
Median OS, months (95%CI)	11.4 (5.3-15.6)	10.1 (6.0-22.8)	6.8 (5.3-9.7)

Independently of RAS mutation, high IS was associated with greater tumor shrinkage (OR=8.3, p<0.01), DCR (OR=8.0, p=0.05), PFS (median 7.1 vs 3.1 months; HR=0.29, p<0.01) and OS (median 12.9 vs 7.2 months; HR=0.62, p=0.19).

Conclusions: Despite good tolerability, AVETUXIRI trial did not reach its efficacy endpoint. IS could be a predictive biomarker for selecting patients with potential treatment benefits.

Clinical trial identification: NCT03608046.

636P Combination therapy of envafolimab, suvemcitug, and FOLFIRI in patients with metastatic microsatellite stable (MSS) or mismatch-repair proficient (pMMR) colorectal cancer: Results from a phase II clinical trial

Y. Liu[1], J. Wang[2], Y. Fang[3], Y. Deng[4], C. Hu[5], Q. Fan[6], K. Gu[7], Y. Zhang[8], C. Yang[9], J. Tian[9], Z. Liu[9], X. Sun[10], S. Sun[11], Y. Cheng[1]

[1]Internal Medicine, Jilin Cancer Hospital, Changchun, China; [2]Gastroenterology Department, Henan Cancer Hospital Affiliated Cancer Hospital of Zhengzhou University, Zhengzhou, China; [3]Medical Oncology Dept., Sir Run Run Run Shaw Hospital, Zhejiang University School of Medicine, Hangzhou, China; [4]Medical Oncology, The Sixth Affiliated Hospital, Sun Yat-sen University, Guangzhou, China; [5]Tumor Chemotherapy Department, Anhui Provincial Cancer Hospital, Hefei, China; [6]Oncology Department, The First Affiliated Hospital of Zhengzhou University, Zhengzhou, China; [7]Medical Oncology, The First Affiliated Hospital of Anhui Medical University, Hefei, China; [8]Oncology, Mianyang Central Hospital, Mianyang, China; [9]Clinical Science, Shandong Simcere Biopharmaceutical Co., Ltd., Shandong, China; [10]Clinical Pharmacology, Shandong Simcere Biopharmaceutical Co., Ltd., Shandong, China; [11]Clinical statistics, Shandong Simcere Biopharmaceutical Co., Ltd., Shandong, China

Background: Envafolimab is a humanized single-domain anti- PD-L1 antibody which is administered subcutaneously (SC). Suvemcitug is a humanized monoclonal antibody against vascular endothelial growth factor (VEGF). This study aims to assess the efficacy and safety of the combination of envafolimab and suvemcitug with chemotherapy as second-line or later therapy in patients (pts) with advanced or recurrent MSS/ pMMR mCRC.

Methods: This was an open-label, multi-cohort, multicenter, phase II trial conducted in China. Eligible pts had received at least one prior line of treatment for MSS/pMMR mCRC and were treated with envafolimab plus suvemcitug and FOLFIRI (Irinotecan, Leucovorin, and 5-Fluorouracil). The primary endpoint was objective response rate (ORR). Secondary endpoints included duration of overall response (DoR), disease control rate (DCR), and progression-free survival (PFS) and safety.

Results: As of March 31,2023, 20 pts with MSS/pMMR mCRC were enrolled. 25.0% pts (5/20) received two prior therapies and 50.0% pts (10/20) were prior treated with antiangiogenic agents. The confirmed ORR was 25.0% (95% CI 8.7%-49.1%). DCR was 90.0% (95% CI 68.3%-98.8%). With a median follow-up time of 8.0 months (IQR 6.9-9.8), the median PFS was 5.6 months (95% CI 4.01-7.59) and DoR was 4.1 months (95% CI 3.02-NE). The most common grade $\geq$ 3 TRAEs were neutrophil count decreased (60.0%) and leucopenia (25.0%). No death was reported. Both envafolimab and suvemcitug showed similar pharmacokinetic profile to monotherapy. Biomarker analysis suggested APC wild type or TP53 mutation were associated with poor efficacy, while KRAS, PI3KCA, BRAC2, SMAD4 and AR mutations, which reported with poor response to immunotherapies, had no effect on the response.

Conclusions: To the best of our knowledge, this is the first study demonstrated promising antitumor activity and a manageable safety profile of immunotherapy plus anti-angiogenic agent and chemotherapy in pts with MSS/ pMMR mCRC who had failed at least one line of therapy. The results support further evaluation of the therapy in a larger population.

637P A phase II study to evaluate the efficacy and safety of fruquintinib combined with tislelizumab and Hepatic Artery Infusion Chemotherapy (HAIC) for advanced Colorectal Cancer Liver Metastases (CRLM)

L. Wang, T. Zhang, Y. zhao, Q. Pan, A. mao, W. Zhu, Y. Feng, J. Zhou

Liver surgery department, Fudan University Shanghai Cancer Center, Shanghai, China

Background: Metastases to the liver remain the primary driver of disease-specific mortality for colorectal cancer (CRC). The FRESCO study has shown that fruquintinib significantly prolongs the survival of CRLM patients (pts). Meanwhile the combination of fruquintinib and PD-1 inhibitors has shown promising efficacy in advanced CRC. HAIC is an unique and effective option for CRLM pts. So we carried out a study to assess the efficacy and safety of fruquintinib combined with tislelizumab and HAIC for advanced CRLM pts.

Methods: We enrolled CRLM pts who had failed standard therapy in this phase II study (NCT05435313). Eligible pts received fruquintinib (3mg, qd, po, D2-21, Q3W) in combination with tislelizumab (200mg, ivgtt, D2,Q3W) and HAIC (TOMOX: raltitrexed 2mg/m^2, D1, oxaliplatin 85mg/m^2, D1, Q3W; or TOMIRI: raltitrexed 2mg/m^2, D1, irinotecan 120mg/m^2, D1, Q3W) for 4-6 cycles, followed by maintenance therapy with fruquintinib and tislelizumab until disease progression, death or unacceptable toxicity. The primary endpoint was ORR. The secondary endpoints were DCR, PFS, 6mo-PFS%, OS and safety.

Results: Between July 17, 2022 and April 27, 2022, 38 pts were enrolled. Median age was 59 (range: 35-73) years and 24 were male, MSS accounted for 37 pts and 18 pts harboring RAS mutation. 22 and 4 pts had previously received bevacizumab and regorafenib, respectively. At data cut off, 29 pts with MSS had efficacy evaluation data, the combination therapy provided an ORR of 27.59% (1 CR, 7 PR) and a DCR of 93.10% (19 SD). ORRs of RAS mutation and wild type were 14.29% (2/14) and 40% (4/10), respectively. 19 (65.52%) of 29 pts showed evidence of a reduction in tumour volume. Neither median PFS nor median OS were reached. TEAEs were mainly grade 1/2, Grade 3/4 TEAEs occurred in 5 pts, including hypertension, hand-foot-skin reactions, GGT increased, neutrophil decreased and AST increased. No treatment related death.

Conclusions: Fruquintinib combined with tislelizumab and HAIC showed promising efficacy and acceptable safety for CRLM pts who had failed standard therapy in this interim analysis. Updated data will be presented in the future.

Clinical trial identification: NCT05435313.

Legal entity responsible for the study: The authors.

Funding: Has not received any funding.

638P Stereotactic ablative radiotherapy combined with fruquintinib and tislelizumab in metastatic colorectal cancer: Preliminary findings from a single-arm, prospective phase II trial (RIFLE)

Y. Chen[1], K. Wang[1], Z. Zhiyuan[2], H. Zhang[1], W. Yang[1], R. Wu[1], M. Zhou[1], Z. Zhang[1], F. Xia[1]

[1]Department of Radiation Oncology, Fudan University Shanghai Cancer Center, Shanghai, China; [2]Department of Radiation Therapy, Fudan University Shanghai Cancer Center, Shanghai, China

Background: Stereotactic ablative radiotherapy (SABR) has been shown to sensitize immunotherapy through inducing immunogenic death and remodeling the tumor immune microenvironment. Anti-angiogenic therapy exhibits synergistic antitumor effects with PD-1/PD-L1 antibodies through its immunomodulatory effects for $\geq$ 3L metastatic colorectal cancer (mCRC) patients. Here, we report the preliminary results from RIFLE trial: the efficacy and safety of the combination of fruquintinib, PD-1 inhibitor tislelizumab and SABR in mCRC patients.

Methods: This is a single-center, single-arm, prospective phase II clinical trial (NCT04948034). mCRC patients with at least 2 measurable lesions who have failed $\geq$ 1L standard therapy will receive SABR followed by fruquintinib (5 mg, d1-14, qd) and tislelizumab (200 mg, d1, q3w) within two weeks from completion of radiation. The primary endpoint is the objective response rate (ORR). The secondary endpoints include disease control rate (DCR), duration of response (DoR), progression-free survival (PFS) rate, overall survival (OS) rate and toxicity.

Results: From August 2021 to April 2023, 27 patients were included in the trial and 24 in the efficacy analysis. Median age was 64 years, 17 (70.8%) patients were male, 21(87.5%) had $\geq$ 3 metastases, and 12(50%) had received $\geq$ 3 prior lines of systemic therapy. The biological effective dose (BED) for irradiated lesions ranged from 37.5 to 105 Gy. Median study follow-up was 12.6 months, 20 patients were alive and 11 remained on treatment. 7 patients achieved partial response (PR) for target lesions, 10 stable disease (SD), illustrating an ORR of 29.2% and a DCR of 70.8%. Median PFS was not reached. The most common treatment-related adverse events (TRAEs) were proteinuria (45.8%), hypertension (25%) and rash (16.7%). Grade 3-4 AEs occurred in 8 patients, including proteinuria and hypertension, and there were no treatment-related deaths.

Conclusions: SABR combined with tislelizumab and fruquintinib shows promising effects and good safety in the treatment of metastatic colorectal cancer, which is expected to provide new therapeutic strategies and improve the prognosis for mCRC patients.

Clinical trial identification: NCT04948034.

639P First report of the safety/tolerability and preliminary antitumor activity of fruquintinib plus capecitabine versus capecitabine as maintenance treatment for metastatic colorectal cancer: An open-label, randomized phase Ib/II study

W. Li[1], J. Chang[1], C. Wang[1], J. Peng[2]

[1]Department of Gastrointestinal Medical Oncology, Fudan University Shanghai Cancer Center, Shanghai, China; [2]Department of Colorectal Surgery, Fudan University Shanghai Cancer Center, Shanghai, China

Background: Maintenance therapy with fluoropyrimidines (such as capecitabine [Cap]) following induction therapy is wildly recommended to unresectable mCRC patients. Fruquintinib (Fru) is a highly selective inhibitor of VEGFR1/2/3 with conspicuous safety and efficacy in mCRC. We sought to evaluate and compare the therapeutic potential of Fru plus Cap (FC) versus Cap as maintenance therapy for mCRC.

Methods: Eligibility criteria included: histologically confirmed mCRC (stage IV), age $\geq$ 18 years, ECOG PS 0-2, achieved disease control (including CR/PR and SD) after $\geq$ 6 cycles of first-line standard chemotherapy and still unresectable. In safety lead-in phase (SP), patients (pts) were orally administered with Fru (4 mg, QD, d1-21, Q4W) plus Cap (850 mg/m^2, BID, d1-7 and d15-21, Q4W). In expansion phase, pts were randomized in a 1:1 ratio between FC (Arm A) and Cap (Arm B) only. The primary objectives were to characterize safety, confirm the recommended phase 2 dose (RP2D; in phase SP), and evaluate the efficacy (in phase EP).

Results: As of April 24, 2023, 22 pts were enrolled (SP: n = 6; EP: Arm A/B n/n = 7/7). In phase SP, 1 pt experienced DLT of grade 3 oral mucositis. The treatment emergent AEs (TEAEs, Grade $\geq$3) were hypertension (1/6), oral mucositis (1/6), voice alteration (1/6), small intestinal obstruction (1/6) and blood bilirubin increased (1/6). After full consideration about patient's tolerance and safety, the RP2D of Fru was adjusted from 4mg to 3mg through charrette. In Arm A, the most common TEAEs (Grade $\geq$3) were merely hypertension and leukopenia. Intriguingly, these results provided further evidence that reducing RP2D from 4 mg to 3mg can ensure the safety and tolerance. In 6 evaluable pts of phase SP, the DCR was 100% while the mPFS was immaturity, but 3 pts showed the PFS of $\geq$ 6 months (7.5, 8.6, 8.9 mon, respectively).

Conclusions: The combination of fruquintinib plus capecitabine demonstrated an acceptable tolerability profile. Preliminary antitumor activity was observed in pts with mCRC that revealed promising efficacy and safety as a first-line maintenance therapy. Dose expansion is ongoing at the RP2D in dedicated mCRC.

Clinical trial identification: NCT05451719.

640P A phase II, multicenter, open-label study of PolyPEPI1018 in combination with atezolizumab in participants with relapsed or refractory microsatellite-stable metastatic colorectal (MSS mCRC) cancer (Oberto-301): Initial results

J. Hubbard[1], D. Ahn[2], J.C. Jones[3], Z. Jin[4], M. Zhu[5], H. Xie[5], E. Novo[5], R. Graham[6], K. Wittenberger[5], M. Kremlitzka[7], Z. Csiszovszki[8], E. Somogyi[8], O. Lorincz[8], L. Molnar[9], J. Toth[8], H. Youssoufian[10], E.R. Toke[11]

[1]Oncology Department, Mayo Clinic, Rochester, MN, USA; [2]Hematology/Medical Oncology Department, Mayo Clinic Cancer Center, Phoenix, AZ, USA; [3]Oncology Department, Mayo Clinic - Florida, Jacksonville, FL, USA; [4]Medical Oncology Department, Mayo Clinic, Rochester, MN, USA; [5]Oncology Department, Mayo Clinic - Rochester, Rochester, MN, USA; [6]Pathology, Mayo Clinic - Rochester, Rochester, MN, USA; [7]Treos Bio Co. Ltd., Veszprém, Hungary; [8]Product Development, Treos Bio Zrt., Veszprem, Hungary; [9]Medical Department, Roche (Hungary) Ltd., Budaors, Hungary; [10]Medical Strategy and Medical Monitor, Youssoufian Hagop, Boston, MA, USA; [11]Product Development, Treos Bio Limited, London, UK

Background: The efficacy of checkpoint inhibitor immunotherapy in MSI-H mCRC has not been replicated in MSS mCRC. Therefore, additional interventions are needed to convert immunologically "cold" MSS CRC to "hot" tumors resembling MSI-H tumors. PolyPEPI1018 is an off-the-shelf, multi-peptide vaccine containing 12 immunogenic epitopes derived from 7 cancer testis antigens which demonstrated early evidence of clinical activity, in first-line MSS mCRC.

Methods: Patients with MSS mCRC who have progressed on 2-3 lines of prior chemotherapy regimen received PolyPEPI1018 (1.2 mg, sc) and atezolizumab (1,200 mg, iv) Q3W. The primary endpoint was safety. A Simon 2-stage design was applied; data from the stage 1 of the study will be presented.

Results: 18 patients (77% female) were enrolled for stage 1 of the study. At baseline, median age was 55 years (range 38—79), 50% had liver metastases and 61% received at least 3 lines of prior therapies. PD-L1 expression was <1% for 85% of patients. The median number of doses received was 4 (range 2-10). A formal review of safety was performed after the initial 6 participants received 2 cycles of study therapy. The combination was well-tolerated; most common side effect related to treatment was Grade (Gr) 1-2 local skin reaction (n=12). Gr 3 events (n=2) at least possibly related to treatment were nausea and vomiting. There were no Gr 4-5 events or study discontinuation due to treatment AE. The ORR was 0% and the DCR was 68% (n=18). Post-treatment, vaccine-specific T cell responses were detected in the PBMC of 3/4 subjects tested and 3/5 patients had increased density of CD3+ and CD8+ TILs by up to 10-fold. The average PD-L1 expression (IC %) increased significantly after treatment (n=5; p=0.04), consequently 2/5 patients' tumor converted to high Immunoscore (Veracyte).

Conclusions: PolyPEPI1018 in combination with atezolizumab has a manageable safety profile. PolyPEPI1018 induced immunological responses at both peripheral and tumor level, converted "cold" tumor into "hot", although to date no responses per RECIST have been noted. The study is on-going.

641P Phase I/II study of the EP4 antagonist CR6086 combined with the anti-PD-1 balstilimab in mismatch-repair-proficient and microsatellite stable (pMMR/MSS) chemorefractory metastatic colorectal cancer (mCRC)

F. Pietrantonio[1], F. Morano[1], M. Niger[1], F. Ghelardi[1], C. Chiodoni[2], M. Palazzo[1], N. Brambilla[3], E. Benincasa[3], G. Giacovelli[3], C. Vitalini[3], F. Girolami[3], L.C. Rovati[4]

[1]Medical Oncology Department, Fondazione IRCCS - Istituto Nazionale dei Tumori, Milan, Italy; [2]Molecular Immunology Unit, Department of Research, Fondazione IRCCS - Istituto Nazionale dei Tumori, Milan, Italy; [3]Clinical Research, Rottapharm Biotech, Monza, Italy; [4]Clinical Research, Rottapharm Biotech - University of Milano-Bicocca School of Medicine, Monza, Italy

Background: Approved immune checkpoint inhibitors (ICI) have little to no benefit in patients (pts) with pMMR/MSS mCRC. Several combination strategies to overcome intrinsic resistance have failed. Prostaglandin E2, through its receptor 4 (EP4), is a major contributor to immunosuppression in the tumor microenvironment and blockade of this pathway may sensitize cold tumors to ICI. In preclinical models, the EP4 antagonist CR6086 significantly enhanced the activity of PD-1 blockade, prompting this ongoing phase I/II study of CR6086 added to the anti-PD-1 balstilimab in pMMR/MSS chemorefractory mCRC.

Methods: Adult pts with pMMR/MSS mCRC, ECOG PS $\leq$1 and previous exposure to fluoropyrimidines, oxaliplatin and irinotecan, received oral CR6086 (30, 90 or 180 mg twice daily) plus balstilimab (3 mg/kg every 2 weeks) until disease progression, unacceptable toxicity or death. Primary endpoints are safety and disease control rate (DCR) per RECIST 1.1. Secondary endpoints include objective response rate (ORR), duration of response, progression-free and overall survival (PFS, OS). Exploratory endpoints include tissue and blood biomarkers.

Results: Twenty-eight pts were treated and 8 are still ongoing. Median age was 59 (interquartile range [IQR]: 54-68) years and 54% were men; median prior treatment lines was 4 (IQR: 3-5). No dose-limiting toxicities were observed. CR6086-related AEs were grade 1 (G1), except for a serious G4 duodenal ulcer which led to consideration of proton pump inhibitors prophylaxis in all pts. Balstilimab-related AEs were $\leq$G2 and one was serious (pneumonitis). Three pts had partial response (all ongoing at 15, 8, and 6 months) and 11 had stable disease, with an ORR of 11% and a DCR of 50% (8% and 25% in the 12 pts with liver metastases). At a median follow-up of 6.4 months (IQR 5.3-8.4), median PFS and OS were 2 (95% CI, 1.7—3.6) and 11.3 (95% CI, 8.8—not reached) months, respectively. Translational analyses are ongoing.

Conclusions: CR6086 combined with balstilimab was well tolerated and achieved durable responses in pMMR/MSS mCRC. Expansion in other gastrointestinal tumours and further clinical development in pMMR/MSS mCRC are ongoing.

Clinical trial identification: NCT05205330.

Background: GCC19CART, the first clinical candidate from the CoupledCAR® solid tumor platform, targets guanylate cyclase-C (GCC) which is expressed in colorectal cancers. CoupledCAR utilizes multiple vectors to make both solid tumor targeting CAR-T and CD19 CAR-T in a single manufacturing step. An investigator-initiated dose escalation trial in China for patients with relapsed or refractory metastatic colorectal cancer (R/R mCRC) is reported here.

Methods: Based on a data cutoff of October 20, 2022, 21 subjects have been enrolled and treated, with all subjects completing $\geq$1 evaluation of response and being evaluable. Eligible subjects undergo leukapheresis, a single dose of lymphodepleting chemotherapy (fludarabine 30mg/m^2 and cyclophosphamide 300mg/m^2) 3 days prior to infusion, and then administration of a single infusion of GCC19CART at one of two preassigned doses: Dose 1 (1x10^6) or Dose 2 (2x10^6) CAR T-cells/kg. Endpoints are safety and preliminary evidence of efficacy.

Results: 13 subjects have been enrolled to dose level 1 (1x10^6 cells/kg) and 8 subjects have been enrolled to dose level 2 (2x10^6 cells/kg). The most common adverse events were cytokine release syndrome (CRS) in 21/21 subjects (Grade 1 19/21 (90.48%) or Grade 2 2/21 (9.52%)) and diarrhea in 21/21 subjects (Grade 1 6/21 (28.57%) Grade 2 5/21 (23.81%) Grade 3 9/21 (42.86%) or Grade 4 1/21 (4.76%)). All patients with grade 3 and higher side effects were well managed. Immune effector cell-associated neurotoxicity syndrome (ICANS) was observed in 2/21 (9.52%) subjects at Grade 3 or 4 and resolved with corticosteroids. For dose level 1, the overall response rate (ORR) per RECIST 1.1 was 15.4% (2/13). The median PFS was 2.0 months and the median overall survival was also 13.3 months. For dose level 2, The ORR per RECIST 1.1 was 50% (4/8). The median PFS was 6.3 months and the median follow-up was also 21.3 months.

Conclusions: Preliminary results demonstrate that GCC19CART has meaningful dose-dependent clinical activity and an acceptable safety profile in relapsed or refractory metastatic colorectal cancer. This trial is ongoing and updated data will be presented. A phase 1 trial of GCC19CART in the US has opened for accrual and is expected to enroll patients in mid-2022.

643P A phase Ib/IIa study to assess the safety, tolerability, pharmacokinetics, and antitumor activity of YYB101, hepatocyte growth factor neutralizing humanized monoclonal antibody, in combination with irinotecan in metastatic or recurrent colorectal cancer patients (NOV110501-201)

Y. Cha[1], S-W. Song[2], J.Y. Choi[2], Y.W. Park[3], H. Lee[3], S. Lee[4], M.A. Lee[5], J. Lee[6]

[1]Division of Medical Oncology, Center For Colorectal Cancer, National Cancer Center - Graduate School of Cancer Science and Policy, Goyang, Republic of Korea; [2]Clinical Development Team, CellabMED Co., Ltd., Seoul, Republic of Korea; [3]Oncology Drug Development & Business Development, National OncoVenture, Goyang, Republic of Korea; [4]Department of Clinical Pharmacology and Therapeutics, Seoul National University Hospital, Seoul, Republic of Korea; [5]Division of Medical Oncology, Department of Internal Medicine, Cancer Research Institute, College of Medicine, Seoul St. Mary's Hospital, The Catholic University of Korea, Seoul, Republic of Korea; [6]Division of Hematology/Oncology, Department of Internal Medicine, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Republic of Korea

Background: The hepatocyte growth factor (HGF)/MET pathway is implicated in tumorigenesis and treatment resistance of colorectal cancer (CRC). This report presents final results of a multi-center phase Ib/IIa study investigating biweekly YYB101, an anti-HGF monoclonal antibody, combined with irinotecan in refractory metastatic/recurrent CRC.

Methods: Eligible patients had metastatic/recurrent CRC with disease progression <6 months from the last irinotecan dose. phase Ib determined the recommended phase II dose (RP2D) of YYB101 with irinotecan (150 mg/m2), starting at 20 mg/kg, focusing on dose-limiting toxicities (DLT) incidence. Phase IIa assessed objective response rate (ORR) as the primary endpoint, with secondary endpoints including progression-free survival (PFS), overall survival (OS), disease control rate (DCR), safety, and pharmacokinetics. Archival tissue specimens and serial blood samples were collected for exploratory analysis.

Results: Thirty-five patients, aged 42-73 (median: 56), were enrolled. All had received $\geq$3 prior therapy lines (42.9% $\geq$4 lines). No DLTs were reported in phase Ib, with 20 mg/kg YYB101 selected as RP2D. In phase IIa, ORR was 5.7% (2/35) [95% confidence interval (CI), 0.70—19.16], and DCR was 82.9% (95% CI, 66.4—99.4). Median PFS was 4.80 months (95% CI, 3.15-8.84), and median OS was 14.9 months (95% CI, 9.30—not reached). Adverse events were generally manageable, mostly grades 1-2. During the COVID-19 pandemic, 54.3% of patients skipped one or two YYB101 doses but maintained serum concentrations above the predicted minimum effective concentration (100 μg/ml).

Conclusions: The YYB101 and irinotecan combination showed modest efficacy and tolerable adverse events in refractory metastatic/recurrent CRC. Ongoing biomarker analyses aim to identify genomic and transcriptomic variables associated with long-term disease control.

Clinical trial identification: NCT04368507.

644P Phase Ib/II open-label study to evaluate the safety, tolerability, and efficacy of rivoceranib plus trifluridine/tipiracil in patients with previously treated metastatic colorectal cancer

C. Eng[1], C.H. Park[2], X. Meng[2], S.H. Jang[2]

[1]Hematology/Oncology Department, Vanderbilt Ingram Cancer Center, Nashville, TX, USA; [2]Elevar Therapeutics, Fort Lee, NJ, USA

Background: Rivoceranib (Rivo) is a novel oral TKI that potently and selectively inhibits vascular endothelial growth factor receptor-2 (VEGFR2). Selective inhibition of VEGFR2 has been shown to enhance the efficacy of chemotherapy. Herein, we present safety and efficacy results of the phase 1b portion of this study evaluating Rivo in patients (pts) with previously treated metastatic colorectal cancer.

Methods: In phase 1b of the study, a 3+3+3 dose-escalation was conducted to identify the recommended phase 2 dose (RP2D) of Rivo to be used in combination

trifluridine/tipiracil. The phase 2 portion will evaluate the RP2D of Rivo PO QD (Days 1-28) in combination with trifluridine/tipiracil 35 mg/m^2 PO BID (Days 1-5, 8-12 Q28 days).

Results: As of September 2022, 29 pts received treatment with Rivo. The median age was 54 yrs (range, 30-80), most pts were male (55.2%) and White (86.2%), ECOG PS was 0 (55.2%) or 1 (44.8%), and most pts received 3 (24.1%) or 4 (24.1%) prior lines of systemic therapy. Efficacy results at each dose level are summarized in the table. Dose limiting toxicities included myelosuppression, nausea, diarrhea, fatigue, asthenia, anorexia, proteinuria and arrythmia. No treatment-related deaths occurred. The patient who received the longest duration of treatment (>26 cycles) continues to receive treatment with rivoceranib.

Table: 644P Efficacy Results (Intent-to-Treat Population)

	300 mg (n=7)	400 mg (n=7)	500 mg (n=8)	600 mg (n=7)
ORR, n (%)	0	0	1 (12.5)	0
BOR per RECIST v1.1				
PR, n (%)	0	0	1 (12.5)	0
SD, n (%)	4 (57.1)	5 (71.4)	4 (50.0)	1 (14.3)
PD, n (%)	2 (28.6)	1 (14.3)	3 (37.5)	4 (57.1)
NE, n (%)	1 (14.3)	1 (14.3)	0	2 (28.6)
mPFS, mo (95% CI)	3.9 (0.9,8.3)	4.2 (1.8,NE)	3.6 (1.8,14.6)	2.1 (1.2, NE)
mOS, mo (95% CI)	13.4 (1.9, 26.9)	6.7 (3.1, NE)	11.3 (3.3, NE)	7.6 (5.2, NE)
OS at 12 mo (95% CI)	57.1 (17.2,83.7)	42.9 (9.8,73.4)	50.0 (15.2,77.5)	33.3 (4.6,67.6)

Conclusions: Rivo 400 mg PO QD is the RP2D to be used in combination with trifluridine/tipiracil 35 mg/m^2 PO BID.

Clinical trial identification: NCT04073615.

645P A phase Ib dose escalation study of binimetinib plus mFOLFIRI in patients with metastatic RAS mutated colorectal cancer

V. Florou[1], H. Lee[2], C.D. Nevala-plagemann[1], H.P. Soares[1], G.W. Gilcrease[1], J. Whisenant[1], K. Barber[1], K. Boucher[2], I. Garrido-Laguna[1]

[1]Internal Medicine, University of Utah Health- Huntsman Cancer Institute, Salt Lake City, UT, USA; [2]Population Health Sciences, University of Utah, Salt Lake City, UT, USA

Background: MEK inhibition (MEKi) may act synergistically when combined with cytotoxics in RAS mutated (mt) metastatic colorectal tumours (mCRC). We investigated the safety and clinical activity of MEKi, binimetinib, and mFOLFIRI in patients (pts) with *RAS* mt mCRC.

Methods: Eligibility criteria: Pts >18 years with *RAS* mt mCRC, ECOG 0-1, acceptable organ function, measurable disease, and progression or ineligibility to oxaliplatin. Pts received binimetinib plus mFOLFIRI, in a dose-escalated standard 3+3 design, to determine the maximum tolerated dose (MTD) and dose-limiting toxicities (DLTs). A 6-day lead-in period with binimetinib alone was required prior to combination therapy. Two levels of binimetinib were evaluated - 30mg BID and 45mg BID - and given on days 1-12/14-day cycle po with mFOLFIRI every 14 days iv. An additional 12 patients enrolled in the dose expansion phase to assess preliminary efficacy. The study completed accrual and herein we report the updated results.

Results: 13 pts enrolled in the dose escalation phase (7 pts on the first binimetinib dose level and 6 on the second) and 12 pts in the expansion phase. Median age was 49 yrs (35-71), and 13 were male. All pts in expansion and 9 in escalation, had received irinotecan prior. All pts in the expansion cohort had irinotecan refractory disease. The MTD of binimetinib was 45mg BID. The most common grade 1-2 adverse effects (AEs) (%) were diarrhoea (64), fatigue (64), nausea (48), vomiting (44), rash (24). Grade 3-4 AEs included fatigue (12), rash (4), heart failure (4), and pneumonitis (4). 1 pt with pre-existing heart disease had a DLT of decreased cardiac ejection fraction on dose level 1. 17 pts discontinued therapy due to progression, 5 due to AEs and 3 for other reasons. The mean number of FOLFIRI and MEK cycles received was 6.7 (0-29) and 7.5 (1-30), respectively. Of the 25 pts, 24 were evaluable for response. Best response included 1 PR and 12 SD (all had received prior irinotecan and 10 had progressed on it). 4 pts remained on study for >6 months (7-15). The median PFS was 3.35 months (95% CI 2-8.61) and the median OS was 8.41 months (95% CI 4.7-12.8).

Conclusions: MEKi plus mFOLFIRI has acceptable toxicity and showed activity even in patients with prior progression on irinotecan.

Clinical trial identification: NCT02613650.

Sammons Cancer Center, Dallas, TX, USA; [17]Medical Oncology/Hematology, Texas Oncology, McAllen, TX, USA; [18]Medical Oncology/Hematology, Compass Oncology, Portland, OR, USA; [19]Clinical Development, Inspirna, New York, NY, USA; [20]Hematology-Oncology, Jonsson Comprehensive Cancer Center, University of California - Los Angeles, Los Angeles, CA, USA

Background: Creatine Kinase B (CKB) was identified as a driver of RASm mCRC. CKB generates ATP from phosphocreatine (PCr), which is imported by SLC6A8. Ompenaclid depletes PCr and ATP resulting in tumor cell apoptosis. In a phase 1a study, ompenaclid monotherapy showed objective anti-tumor activity in RASm mCRC without dose-limiting toxicities (DLTs).

Methods: Objectives of this ongoing phase 1b/2 study are evaluation of safety, PK/PD and efficacy of ompenaclid + FOLFIRI/BEV in 2L mCRC. Eligible pts had disease progression after a 1L oxaliplatin-containing regimen.

Results: Enrollment as of 28Apr2023, 35 pts (22 KRASm, 3 NRASm, 10 RAS-wt) in the Dose Escalation/Expansion cohorts receiving 2400mg BID (n=14) or 3000mg BID (n=21); all pts received FOLFIRI/BEV. No DLTs were observed in Dose Escalation and a MTD was not reached. Across safety-evaluable pts (n=33), the most common treatment emergent AEs Gr≤2 were nausea (50%), diarrhea (44%); Gr≥3 were neutropenia (15%), abdominal pain (11%), diarrhea (11%), fatigue (11%). The AE profile is similar to FOLFIRI/BEV alone, demonstrating good combinability. At both ompenaclid doses, systemic exposure was comparable and resulted in up to a 48X increase in urine creatine, suggesting robust target inhibition. The ORR in 17 RASm and 10 RAS-wt evaluable pts was 41% (6 confirmed PRs, 1 unconfirmed PR) and 20% (2 unconfirmed PRs), respectively. Five RASm pts are pending 1st scan and not yet evaluable. PRs were observed in pts with diverse KRASm (G13D [2 pts], G12V [2 pts], G12D, G12S and pG10dup). For RASm pts, mPFS was 11.8M and mOS was 19.1M, and for RAS-wt pts, mPFS was 7.5M and mOS was 14.5M.

Conclusions: At the evaluated dose levels, ompenaclid + FOLFIRI/BEV was well tolerated and induced potent inhibition of the target SLC6A8. Encouraging efficacy was observed in pts with RASm mCRC, with a response rate exceeding that expected with SOC. This preferential RASm activity is consistent with preclinical and phase 1a data. There is a high unmet need for a safe and combinable oral pan-RASm therapy in mCRC. Recruitment of RASm pts continues and a randomized controlled trial in 2L RASm mCRC is planned.

647P Patient-derived xenograft approach to explore differential responses to diet dependent on genotypic or phenotypic characteristics of colorectal cancer

G. Rizzo[1], S.E. Pineda Chavez[2], M. Wozny[2], C. Cappadona[2], A. Maroli[3], P. Spaggiari[4], M. Carvello[3], R. Asselta[2], E. Casiraghi[5], G. Valentini[5], A. Repici[2], A. Spinelli[2], A. Armuzzi[2], S. Vetrano[2]

[1]Laboratory of Gastrointestinal Immunopathology, Department of Gastroenterology, IRCCS Humanitas Research Hospital, Rozzano, Italy; [2]Department of Biomedical Sciences, Humanitas University, Pieve Emanuele, Italy; [3]Colon and Rectal Surgery Unit, IRCCS Humanitas Research Hospital, Rozzano, Italy; [4]Department of Pathology, IRCCS Humanitas Clinical and Research Center, Rozzano, Italy; [5]AnacletoLab, Dipartimento di Informatica, Università degli Studi di Milano, Milan, Italy

Background: Colorectal cancer (CRC) results from the combination of genetic alterations and environmental risk factors. Several evidences indicate that the diet may have a role in prevention and progression of CRC, but more research is needed to clarify the heterogeneity of dietary associations with CRC.

Methods: Patient-derived xenografts (PDXs) were generated implanting subcutaneously human CRCs at different staging into immunodeficient mice, and feeding with control normal diet (ND) and classical western diet (WD). Tumor phenotype, transcriptomic, genetic and metabolomic were analyzed.

Results: The response to WD was heterogeneous among all generated PDXs. Only one out of three showed a greater growth in mice fed with WD. Particularly, WD induced transcriptomic perturbations of several genes related to epigenetic regulations and tumor progression, remodeling tumor microenvironment, promoting mucin secretion, mitochondria dysfunction and metabolic reprogramming. Interestingly, the three PDXs responded to the same WD with a distinct metabolomic profile that was validated through the machine learning. With whole exome sequencing, PDXs did not share the same somatic cancer mutations that could play a key role in conditioning response to a specific diet. Consistently, the same heterogeneous response to WD in tumor growth was observed in xenografts generated with CRC cell lines. To strictly mimics human diet, we tested in comparison to classic WD, humanized WD diet that displayed a different tumor behavior. The analysis of patient derived organoids developed from PDX fed with humanized diets revealed that the altered metabolic reprogramming acquired *in vivo* is also maintained *in vitro* in absence of any stimulus, suggesting a metabolic memory of cancer cells.

Conclusions: Specific CRC somatic mutations, modifying several signaling pathway and tumor metabolism promote tumor growth and progression, and could be predictive of a response to a specific diet. In this scenario, PDX could be considered as a suitable approach to study the response to the diet and to provide a screening of different diets in order to create a dietary guidance for CRC patients.

Background: As extended analysis of the COVID-DELAY study, we aimed to assess COVID-19 impact on diagnosis, staging and treatment outcomes of CRC patients in 2021 and 2022 compared to 2019 and 2020.

Methods: All consecutive newly diagnosed CRC patients referred to 8 Italian Oncology Departments between March and December 2019, 2020, 2021, and 2022 were evaluated. Access rate (number of patients/year), demographic characteristics, diagnostic and therapeutic temporal intervals (between date of symptoms onset, radiological and cytohistological diagnosis, treatment start, and first radiological evaluation), as well as PFS and OS were assessed and compared.

Results: Compared to 2019 (n=485), a reduction in new CRC cases was found in 2020 (n=390, -19.6%). On the other hand, a progressive increase in new CRC diagnosis was found in 2021 (n= 461, +18.2%) and 2022 (n= 509, +30.5%), compared to 2020. A higher rate of stage IV tumours was diagnosed in 2020 (31.3%) and 2021 (29.6%) compared to 2019 (20.8%), with a normalization in 2022 (22.8%) ($p<0.001$); a lower number of patients has been discussed in multidisciplinary tumor boards in 2020 (22.1%) compared to 2019 (34.9%), 2021 (37.0%), and 2022 (47.6%) ($p<0.001$). A significant difference in terms of temporal interval between histological diagnosis and first oncological examination (median of 31 vs. 38 days, respectively, p=0.004), cytohistological diagnosis and systemic treatment start (median of 52 vs. 58 day, $p<0.001$), first oncological appointment and systemic treatment start (median of 52 compared to 58 days, p=0.034), was found between 2020 and 2021-2022 years, respectively. At multivariate analysis, the 2021-2022 years confirmed to be associated with a reduction in the risk of disease progression compared to 2020 (HR=0.71 (0.53-0-97); p=0.031).

Conclusions: A worsening drop in CRC diagnosis in 2020, with a progressive increase in 2021 and 2022, in parallel with a higher incidence of late-stage CRC diagnosed in 2020 and 2021. This might have affected some diagnostic-therapeutic time intervals in 2021-2022 years compared to 2020.

649P The genomic landscape of appendiceal adenocarcinoma (AA) revealed by 855 whole exome sequences (WES)

M.G. White[1], B. Helmink[2], S. Rivero-Hinojosa[3], N. Bhutiani[2], V. Aushev[3], S. Chowdhury[4], Y. Gu[4], A. Jurdi[5], M.C. Liu[6], K.F. Fournier[2], J.P.Y-C. Shen[4]

[1]Colon & Rectal Surgery, The University of Texas MD Anderson Cancer Center, Houston, TX, USA; [2]Surgical Oncology, The University of Texas MD Anderson Cancer Center, Hoo; [3]TMED, Natera, Inc., San Carlos, CA, USA; [4]Gastrointestinal Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX, USA; [5]Oncology, Natera, Inc., San Carlos, CA, USA; [6]Oncology Department, Natera, Inc., San Carlos, CA, USA

Background: AA is a rare malignancy with a predilection for peritoneal metastases without hematogenous or lymphatic metastases. Despite this, AA is treated with chemotherapy similar to colorectal cancer. Studies suggest inefficacy of these regimens for many AA patients supporting the likelihood of a unique genomic landscape.

Methods: WES of tumor tissue was performed as part of personalized circulating tumor DNA (ctDNA) testing (Signatera™) in 855 patients with AA. Tumor mutational burden (TMB) and microsatellite instability (MSI) were assessed; Kyoto Encyclopedia of Genes and Genomes (KEGG) network analysis was performed. WES data on stage-

matched colon (CC, N=833) and rectal cancer tissues (RC, N=841) were compared with AA.

Results: A total of 98,310 variants were identified from 855 AA tumor tissues (median 132.5 variants/tumor). AA had lower TMB (median: 2.14 Muts/Mb) than RC or CC (median: 3.55 and 4.31 Muts/Mb, respectively). Only 1.3% (11/855) of the AA were MSI-high, compared to RC (2.5%) and CC (16.76%). Comparison of frequently mutated genes highlighted that AA has much less frequent APC and TP53 and more frequent GNAS mutations. Despite differences in driver mutations and overall lower TMB, the mutational signatures for AA, CC, and RC were similar with SBS1 (clock-like) and SBS6 (MMR-deficient) being predominant in each tumor type. Co-mutation analysis identified a dense interaction network of 805 co-occurring or mutually exclusive interactions highlighted by connections between Wnt, Ras-MAPK, and DNA repair pathways. Copy number analysis identified that AA has less aneuploidy relative to CC or RC, however, within AA, TP53 mutation was associated with significantly higher aneuploidy relative to wildtype. Interestingly, TP53 mutations were also associated with detectable ctDNA in AA (44.6% vs. 24.9%, p<0.001), but not in CC or RC.

Conclusions: WES data on AA reveals important differences in driver somatic mutations, CNV, and co-mutational networks compared to CC and RC. This is the first large-scale genomic profiling of AA, establishing the genetic landscape of this rare and orphan disease. Future studies should focus on AA-specific treatments rather than the extrapolated CC/RC experience.

Background: Several genomic alterations have been described in small bowel adenocarcinoma (SBA) but the prognostic value of these alterations remains unclear. The aim of this multicentre study was to determine the genomic profile of SBA and its impact on the prognosis.

Methods: Three cohorts in France and Italy were pooled. A common dataset of genomic analysis have been performed on 35 genes of interest. MSI (MicroSatellite Instable) and MMR (MisMatch Repair) status were also assessed.

Results: A total of 188 tumour samples had conclusive results for mutation analysis. The patients (pts) were male (55.3%), with duodenum primary (58.5%), stage I-II (39.6%), III (40.6%) and IV (18.8%). with a predisposing disease (21%) mainly Lynch syndrome (LS) (n=19) and Crohn disease (CD) (n=11). The most frequent mutation were *KRAS* (42.0%) of which 7/79 G12C, *TP53* (40.4%), *APC* (19.1%), *PIK3CA* (18.6%), *SMAD4* (12.8%) and *ERBB2* (9.6%). *TP53* mutations were more frequent in CD (81.8%) but less frequent in LS (15.8%) than in no predisposing disease (39%). *ERBB2* mutations were more frequent in LS (26.3%) than in no predisposing disease (7.5%). No *APC* mutation was observed in CD. *KRAS* and *SMAD4* mutations were more frequent in tumour than in localized tumour (59.4% vs 37.7%, p=0.0164) and (24.3% vs 9.9%, p=0.0187). *ERBB2* mutations were less frequent in metastatic than in localized tumour (0% vs 11.9%, p=0.0272). For localized tumour univariate analysis revealed that: age ≥65 (p=0.0327), T4 (p=0.570), high grade (p=0.0028) stage III (p=0.0390) and wild type *APC* (p=0.395) were associated with a poor overall survival (OS). In multivariate analysis: high grade (p=0.023), age ≥65 (p=0.0123) and wild type *APC* (p=0.0254) were associated with a poor OS. For metastatic tumour a trend for a better OS was observed in case of a mutated *KRAS* tumour (HR=0.6 (0.34-1.06), p=0.0797) in univariate analysis. dMMR/MSI status was available in 238 pts. Overall, dMMR/MSI was reported in 29.8%, 31.8% in localized and 11.3% in metastatic tumour. dMMR/MSI was associated with a better OS (HR=0.61 [0.39-0.96], p=0.0333).

Conclusions: There is different genomic profile according to the predisposing disease. MSI/dMMR predict a better prognosis. *APC* mutation in localized and *KRAS* mutation in metastatic tumour are associate with a better prognosis.

Background: Triplet DCF (docetaxel, cisplatin and 5-fluorouracil) and doublet CP/CF (carboplatin and paclitaxel/cisplatin and 5-fluorouracil) regimens were prospectively evaluated in advanced squamous anal cell carcinoma (SCCA), and validated as standard treatments. Even though the high efficacy and good tolerance of DCF regimen were confirmed in 3 independent prospective trials, doublet CP regimen is still recommended in several guidelines based in its better safety profile with similar efficacy compared to CF regimen.

Methods: We performed a propensity score-adjusted method with inverse probability of treatment weighted (IPTW) and matched case control (MCC) comparison among patients with metastatic or non-resectable locally advanced recurrent SCCA, treated with chemotherapy as first-line regimen. The primary endpoint was the overall survival (OS), and the secondary endpoint was the progression-free survival (PFS).

Results: 247 patients were included for analysis. 154 patients received DCF and 93 patients received a doublet regimen. Patients' characteristics and outcomes in both groups were comparable to published data. The median OS was 32.3 months with DCF and 18.3 months with doublet regimens (HR 0.53, 95%CI 0.38-0.74; p=0.0001), and the median PFS was 11.2 months with DCF versus 7.6 months with doublet regimens (HR 0.53, 95%CI 0.39-0.73; p<0.0001). The hazard ratios by IPTW and MCC analyses were 0.411 and 0.406 for OS, and 0.466 and 0.438 for PFS (Table).

Table: 651P Multivariate Cox analyses for OS and PFS in propensity score matched population and with IPTW weighted method

	Matched analysis (n=154)			IPTW analysis (n=247)		
	HR	95%CI	P	HR	95%CI	P
OS	0.406	0.261-0.632	<0.0001	0.411	0.324-0.521	<0.0001
PFS	0.438	0.298-0.644	<0.0001	0.466	0.376-0.576	<0.0001

Conclusions: The triplet DCF regimen provides a high and significant benefit in OS and PFS over doublet regimens, and can be considered as upfront treatment for eligible patients with advanced SCCA.

[1]Medical Oncology, Memorial Sloan Kettering Cancer Center, New York, NY, USA; [2]Medical Oncology, New York University Medical Center, New York, NY, USA; [3]Internal Medicine Dept./Oncology Division, University of Utah Health-Huntsman Cancer Institute, Salt Lake City, UT, USA; [4]Investigational Cancer Therapeutics Department, The University of Texas MD Anderson Cancer Center, Houston, TX, USA; [5]Medical Oncology, Dana-Farber Cancer Institute, Boston, MA, USA; [6]Oncology, Sarah Cannon Research Institute, Nashville, TN, USA; [7]Medical Oncology, Mary Crowley Cancer Research Center, Dallas, TX, USA; [8]Medical Oncology, The Christ Hospital-Hematology&Oncology, Cincinnati, OH, USA; [9]Oncology, NEXT OncologyTM, San Antonio, TX, USA; [10]Nonclinical Development and Clinical Pharmacology, Revolution Medicines, Inc., Redwood City, CA, USA; [11]Clinical Development, Revolution Medicines, Inc., Redwood City, CA, USA; [12]Next Oncology Virginia, Virginia Cancer Specialists, Fairfax, VA, USA

Background: RMC-6236 is a novel, oral RAS^{MULTI}(ON) inhibitor that is selective for the active, GTP-bound state of both mutant and wild-type variants of the canonical RAS isoforms. Preclinical studies have demonstrated deep and sustained regressions across multiple RAS^{MUT} tumor types, particularly PDAC and NSCLC harboring KRAS glycine-12 substitutions ($KRAS^{G12X}$).

Methods: Patients with previously treated, advanced $KRAS^{G12X}$ mutant solid tumors were enrolled at escalating doses (10mg to 160mg once daily (QD)) of single agent RMC-6236. Additional patients with PDAC or NSCLC were enrolled at dose levels that cleared dose-limiting toxicity evaluation.

Results: As of April 24, 2023, 22 patients with $KRAS^{G12X}$ PDAC (13 G12D, 7 G12V, 2 G12R) and 11 with $KRAS^{G12X}$ NSCLC (5 G12D, 4 G12V, 2 G12A) were enrolled, and 14 patients with PDAC and 9 patients with NSCLC continue treatment with RMC-6236. Median prior therapies was 3 (range, 1-7). Treatment-related adverse events (TRAEs) occurring in $\geq$10% of patients were rash (52%), diarrhea (21%), nausea (21%), and vomiting (15%). The only Grade $\geq$3 TRAE was in a patient with PDAC who had a Grade 4 large intestine perforation at the site of an invasive tumor that reduced in size on treatment. Preclinical modeling predicts tumor regressions at 80mg QD or higher in humans. Preliminary clinical activity in PDAC and NSCLC was assessed at 80mg and 120mg QD. Among 14 patients (10 PDAC, 4 NSCLC) dosed at least 8 weeks prior to the data cut-off date, the objective response rate was 36% (2 confirmed and 3 unconfirmed; 2/10 PDAC and 3/4 NSCLC). Median time to onset of initial response was 6 weeks (range, 5-11). Disease control rate was 86% (12/14; 8/10 PDAC and 4/4 NSCLC). Tumor reduction was observed in 4 patients with stable disease (range, -2% to -21% by RECIST v1.1). Of the 12 patients with partial response or stable disease, 11 continue on treatment.

Conclusions: RMC-6236 exhibits promising anti-tumor activity in patients with $KRAS^{G12X}$ PDAC and NSCLC at doses that are well tolerated. Dose escalation is ongoing and data from additional patients will be available at the time of the meeting.

Clinical trial identification: NCT05379985.

Background: Glecirasib is a direct oral KRAS G12C inhibitor (KRAS G12Ci) with favorable tolerability and promising efficacy. JAB-3312 is a potent oral SHP2 inhibitor that may overcome KRAS G12Ci resistance. Together these compounds were shown to exert synergistic anti-tumor effect when combined with glecirasib in multiple animal models. Here we present the preliminary clinical data from the dose escalation phase.

Methods: The phase 1/2a study [NCT05288205] evaluated glecirasib plus JAB-3312 in patients (pts) with *KRAS p.G12C* mutated solid tumors. The primary endpoint of the dose escalation part was safety and tolerability. The secondary endpoints included objective response rate (ORR), disease control rate (DCR) per RECIST 1.1 and pharmacokinetics (PK) profile. Glecirasib 400 mg or 800 mg daily was combined with various JAB-3312 doses and schedules.

Results: As of April 7th, 2023, 60 pts (50 non-small cell lung cancer [NSCLC], 9 colorectal cancer, and 1 pancreatic cancer) were enrolled in six dose levels. About 40% had $\geq$ 2 prior lines of therapy, and 26.7% had received prior KRAS G12Ci treatment. Dose escalation concluded with one dose-limiting toxicity (grade 3 pneumonitis) at a higher dose level. The most common (>20%) treatment-related adverse events (TRAE) included anemia, ALT/AST increased, hypertriglyceridemia, bilirubin increased, neutropenia/leukopenia, creatine kinase increased, and edema. TRAE $\geq$ grade 3 occurred in 36.7% of pts. No TRAE led to discontinuation of both glecirasib and JAB-3312. PK of JAB-3312 of the combination was generally comparable with historical monotherapy, suggesting low risk of drug-drug interaction. Amongst the 50 pts with NSCLC, 35 were efficacy evaluable, 14 have not reached the first scan and one withdrew due to COVID-19. Out of 28 evaluable pts with KRAS G12Ci naïve NSCLC, ORR was 50% (14/28) and DCR was 100%. In pts with KRAS G12Ci treated NSCLC, ORR was 14.3% (1/7), and DCR was 57.1%. Additional safety, efficacy and PK data will be presented at this meeting.

Conclusions: Glecirasib plus JAB-3312 was well tolerated with promising efficacy in *KRAS p.G12C* NSCLC. Currently, dose expansion is underway to further evaluate efficacy and safety.

Clinical trial identification: NCT05288205.

Background: T-DXd is an antibody—drug conjugate targeting HER2 approved in HER2-expressing breast cancer (BC), HER2-positive gastric cancer (GC), and *HER2*-mutant non-small cell lung cancer (NSCLC) in the US. Treatment (Tx) options are limited for pts with other solid tumors harboring *HER2*m.

Methods: In an open-label, multicenter, phase 2 study (NCT04639219) in pts with advanced solid tumors harboring prespecified *HER2*m (excluding HER2-overexpressing BC and GC, and *HER2*-mutant NSCLC), and who failed previous systemic Tx received T-DXd 5.4 mg/kg q3w. The primary endpoint was confirmed objective response rate (ORR) by RECIST 1.1 according to independent central review (ICR). Secondary endpoints included duration of response (DoR), progression-free survival (PFS), and safety.

Results: 102 pts were assigned to T-DXd (data cutoff Jan 25 2023; median follow-up, 8.61 [range 1.5—22.1] months [mo]) with median 3 [range 1—13] prior lines of systemic therapy. The ORR was 29.4% (95% CI 20.8, 39.3); median DoR was not reached (54.2% of responders remained in response by ICR at 18 mo); median PFS was 5.4 mo (95% CI 2.7, 7.1). Responses were observed across HER2 expression levels, including HER2 IHC 0 tumors. The table shows ORR by tumor type and *HER2*m domain. Grade

Table: 654O

	N	ORR by ICR	
		n	%
All pts	102	30	29.4
Tumor type			
Breast	20	10	50.0
Colorectal	20	4	20.0
Biliary tract	19	2	10.5
Esophageal/esophagogastric	11	1	9.1

[a]By local testing;[b]L755S, D769H, Y772_A775dup/A775_G776insYVMA, V777L, G778_P780dup/P780_Y781insGSP, V842I, T862A; [c]S310F, S310Y; [d]R678Q

(G) ≥3 adverse events (AEs) occurred in 51.0% of pts; 9.8% discontinued Tx due to AEs. Adjudicated drug-related interstitial lung disease/pneumonitis occurred in 11 pts (10.8% [G3, n=1; G5, n=2]).

Conclusions: DPT-01 is the first tumor-agnostic global study of T-DXd in a range of solid tumors with prespecified *HER2*m. In heavily pretreated pts with limited Tx options, T-DXd demonstrated encouraging anticancer activity and long DoR across multiple tumor types with *HER2*m and a range of HER2 expression levels, with a known safety profile. Translational research will help characterize pts who may derive greatest benefit from T-DXd.

Clinical trial identification: NCT04639219.

Background: Cofetuzumab pelidotin (Cofe-P), a protein tyrosine kinase 7 (PTK7)–targeting antibody-drug conjugate, was tolerable and had preliminary antitumor activity in patients (pts) with advanced solid tumors (Phase 1; NCT02222922). Results are presented from an ongoing Phase 1b, open-label, single-arm, multicenter study (NCT04189614) of Cofe-P in pts with PTK7-expressing rNSCLC.

Methods: Eligible pts were ≥18 yrs with PTK7-expressing (central immunohistochemistry [IHC]) rNSCLC and prior platinum doublet and immune checkpoint inhibitor (tumors w/o actionable genetic alterations [AGA−]) or platinum doublet and targeted agent(s) (AGA+ tumors). Pts received 2.8 mg/kg Cofe-P IV Q3W until PD/unacceptable toxicity.

Results: As of August 9, 2022, 56 pts received Cofe-P (median age, 64 years; male, 63%; Asian, 50%, White, 46%); 27 pts (48%) were nonsquamous (NSQ) EGFR WT, 13 (23%) were NSQ EGFR mutant, and 16 (29%) were squamous (SQ). PTK7 IHC enrollment cutoff was refined during study; 42 pts (75%) had PTK7 expression above

Table: 655O

Parameter	NSQ EGFR WT, PTK7 ≥90%/≥2+ N=21	Overall N=56
ORR, % (95% CI)	30.0 (11.9, 54.3)[a]	19.6 (10.2, 32.4)
CBR (CR + PR + SD), % (95% CI)	90.0 (68.3, 98.8)[a]	78.6 (65.6, 88.4)
mDOR, mo (95% CI)	5.8 (2.8, −)	7.2 (2.8, 9.7)
mPFS, mo (95% CI)	5.5 (2.6, 8.5)	5.3 (3.6, 5.9)

[a]Response-evaluable pts (N=20) (≥1 postbaseline measurement).
CI, confidence intervals; CBR, clinical benefit rate; CR, complete response; EGFR, epidermal growth factor; mDOR, median duration of response; mPFS, median progression free survival; NSQ, nonsquamous; ORR, objective response rate; PR, partial response; PTK7, protein tyrosine kinase 7; pts, patients; SD, stable disease; WT, wild type.

final ≥90%/≥2+ cutoff; of these, 21 (50%) were NSQ EGFR WT. Enrollment of SQ and NSQ EGFR mutant pts was halted to prioritize NSQ EGFR WT accrual due to response rates in each subgroup. Efficacy results are shown in the table. TEAEs were reported in all pts, most common (≥30%): alopecia (52%), neutropenia (45%), headache (36%), pruritis (36%), and decreased appetite (30%). Grade ≥3 TEAEs were reported in 68% of pts, most common (≥5%): neutropenia (39%), leukopenia (9%), pneumonia (7%), anemia (5%), fatigue (5%). Peripheral neuropathy was reported in 18% of pts; 2% had Grade 3. No deaths related to Cofe-P were reported. PK was similar to previous phase 1 study with Cofe-P conjugate elimination half-life ∼3 days.

Conclusions: Cofe-P was well-tolerated with encouraging antitumor activity observed in rNSCLC and 30% ORR in the subpopulation with NSQ EGFR WT NSCLC and PTK7 ≥90%/≥2+.

Clinical trial identification: NCT02222922.

Editorial acknowledgement: Medical writing support was provided by Caryne Craige, PhD, of Fishawack Facilitate Ltd., and funded by AbbVie.

Legal entity responsible for the study: AbbVie.

Funding: AbbVie and Pfizer provided financial support for the Ph 1b study and an AbbVie/Pfizer Joint Steering Committee oversaw design and conduct of Ph 1b study. AbbVie provided support for analysis, data collection, interpretation of data, and the review and approval of the publication. All authors had access to relevant data and participated in the drafting, review, and approval of this publication. No honoraria or payments were made for authorship.

Background: SHR-A1811 is a novel ADC composed of trastuzumab (anti-HER2), a cleavable linker, and a topoisomerase I inhibitor payload, with optimized drug-antibody ratio of 6 and strong bystander killing effect. We initiated this global, dose escalation, PK expansion, and indication expansion phase 1 study in HER2-expressing/mutated advanced STs. The primary analysis showed that SHR-A1811 was well-tolerated and had promising antitumor activity, especially in HER2-positive or low-expressing breast cancer (AACR 2023 , CT175). Here we report the findings focusing on non-breast STs.

Methods: Patients (pts) with advanced, unresectable, or metastatic HER2-expressing/mutated STs that were refractory or intolerant to standard therapies were treated with SHR-A1811 at 1.0−8.0 mg/kg Q3W (IV).

Results: As of Feb 28, 2023, 98 pts with non-breast STs were enrolled. Pts had a median 2 prior lines of therapy (range 1−9), and 66.3% had ≥2. ORR was 45.9% (39/85 evaluable pts; 95% CI 35.0−57.0); DCR was 88.2% (75/85; 95% CI 79.4−94.2); and median TTR was 1.4 mo (range 0.7−5.8). ORR was 54.1% (20/37) in pts with HER2 IHC3+, 41.7% (10/24) with IHC2+, and 50.0% (7/14) with IHC1+. For individual tumor type, ORR was 56.3% (9/16) in BTC pts, 59.1% (13/22) in UC, 50.0% (6/12) in GC/GEJA, and 36.4% (4/11) in CRC (data by HER2 status for each tumor type are shown in table). Overall, 38 (38.8%) of 98 pts had disease progression or died; the 6-mo PFS rate was 52.1%. Grade ≥3 treatment-related adverse events (TRAEs) occurred in 50

Table: 656MO ORR by tumor type and HER2 status

	BTC (N=22)	UC (N=23)	GC/GEJA (N=13)	CRC (N=14)	Other tumors (N=26)
ORR*, n/N (%) (95% CI)	9/15 (60.0%) (32.3–83.7)	13/22 (59.1%) (36.4–79.3)	6/12 (50.0%) (21.1–78.9)	4/11 (36.4%) (10.9–69.2)	7/25 (28.0%) (12.1–49.4)
HER2 IHC 3+	7/10 (70.0%) (34.8–93.3)	2/6 (33.3%) (4.3–77.7)	4/10 (40.0%) (12.2–73.8)	3/3 (100.0%) (29.2–100.0)	4/8 (50.0%) (15.7–84.3)
HER2 IHC 2+	0/1	7/10 (70.0%) (34.8–93.3)	2/2 (100.0%) (15.8–100.0)	0/3	1/8 (12.5%) (0.3–52.7)
HER2 IHC 1+	1/2 (50.0%) (1.3–98.7)	4/5 (80.0%) (28.4–99.5)	0	0/1	2/6 (33.3%) (4.3–77.7)
HER2 mutation and/or amplification	1/2 (50.0%) (1.3–98.7)	0/1	0	1/4 (25.0%) (0.6–80.6)	0/3

*tumor response evaluable set.

(51.0%) of pts; the most common (≥10%) were decreased neutrophil count and anemia. Serious TRAEs were reported in 15 (15.3%) pts. Of note, only 1 (1.0%) pt had interstitial lung disease.

Conclusions: SHR-A1811 had favorable antitumor activity and acceptable safety profile in heavily pretreated HER2-expressing/mutated advanced non-breast STs, including BTC, UC, GC/GEJA, and CRC.

Clinical trial identification: NCT04446260, Release date: 24 June 2020.

Background: BDC-1001 is an ISAC consisting of a trastuzumab biosimilar conjugated to a proprietary cell membrane impermeable TLR7/8 agonist via a non-cleavable linker. It is designed to trigger the innate immune system and generate a durable tumor-targeted adaptive immune response. We present new results from the recently completed dose-escalation study (NCT04278144).

Methods: Pts with HER2+ (protein or gene) or HER2-low solid tumors progressing after standard therapies (Txs) were enrolled. BDC-1001 was given IV q3w, q2w, or q1w as monotherapy (mono; n=94) and q2w or q1w with nivolumab 240mg q2w (combo; n=37).

Results: As of 24 March 2023, 131 pts with 16 different tumor types received 0.15 to 20mg/kg of BDC-1001. Mean age 60 yrs, median 4 prior lines of Txs (range 0-13; prior anti-HER2 67%, immune 29%). The RP2D of 20mg/kg q2w (mono/combo) was determined based on safety, efficacy, pharmacokinetic, and PD data. BDC-1001 was well tolerated as mono/combo. Grade 1/2 infusion-related reactions were the most common adverse events (30%). Clinical activity observed in multiple tumor types and doses improved as targeted Cmin ≥10mg/mL was reached, particularly at the RP2D. 6 pts (3 mono) had partial response (PR), 11 pts (9 mono) achieved stable disease (SD) ≥24 wks. Clinical benefit rate in 15 pts with HER2+ tumors at the RP2D was 47% (27% confirmed PR, additional 20% SD ≥24wks), 60% tumor shrinkage and 33% pts still on active Tx. Comprehensive plasma and fresh biopsies (bx) studies performed. PD responses in plasma and paired tumor bx (protein/gene analyses) demonstrated immune activation with BDC-1001 (e.g., IFNg, antigen processing, macrophage activation), not observed by trastuzumab treatment, and subsequent T cell recruitment in tumor tissue.

Conclusions: Our novel ISAC BDC-1001 (mono/combo) led to tolerable, encouraging efficacy, translational biomarker data consistent with novel MOA in pts with pretreated HER2+ tumors, particularly at the 20mg/kg q2w RP2D. International phase 2 expansions in HER2+ colorectal, gastroesophageal, and endometrial cancers and a new phase 2 in breast cancer (BDC-1001 ± pertuzumab) have been initiated.

Clinical trial identification: NCT04278144.

Background: HER3 is widely expressed in solid tumors and associated with tumor growth/spread, drug resistance and poor prognosis. SHR-A2009 is a novel ADC composed of a fully human anti-HER3 IgG1 mAb, cleavable peptide linker and DNA topoisomerase I inhibitor. We report preliminary results from the first-in-human, multinational phase 1 trial of SHR-A2009 in patients (pts) with advanced solid tumors refractory to standard therapy.

Methods: SHR-A2009 was given at doses of 1.5-10.5 mg/kg (Q3W, iv) in an i3+3 dose escalation scheme, followed by cohort expansion at selected doses. The primary endpoints were MTD/MAD, RP2D and safety.

Results: At data cutoff (Apr 24, 2023), 42 pts were enrolled (ECOG 1, 83.3%; stage IV, 100%; NSCLC, 85.7%; brain metastasis, 31.0%); median prior lines of systemic therapy was 3 (range, 1-11). Among 36 NSCLC pts, 34 (94.4%) had *EGFR* mutations; all were resistant to EGFR-TKI, with 85.3% (29/34) previously treated with 3rd generation agents. Up to 10.5 mg/kg, no DLT was observed; dose-escalation is ongoing. Grade≥3 TRAEs were reported in 13 (31.0%) pts, with all occurring in ≥5% being hematotoxicities. TRAEs led to drug discontinuation in 3 (7.1%) pts. Interstitial lung disease occurred in 2 (4.8%) pts. In evaluable pts, ORR was 25.0% (9/36; 95% CI 12.1-42.2) across all tumor types and 30.0% (9/30; 95% CI 14.7-49.4) in NSCLC; median DoR was 7.0 mo (range, 2.8-8.5) in both pt sets. Tumor response by dose is shown in the table. 1. 6-mo PFS rate was 46.4% (95% CI 27.0-63.8) across all tumors and 49.8% (95% CI 28.8-67.8) in NSCLC. Systemic exposure of SHR-A2009, total antibody and free toxin increased approximately dose proportionally after single/multiple doses at 1.5-9.0 mg/kg; plasma toxin exposure was low across all levels (data not available for 10.5 mg/kg).

Conclusions: SHR-A2009 showed a tolerable safety profile and encouraging anti-tumor activity in pts with heavily pretreated advanced solid tumors. The trial is ongoing to assess SHR-A2009 at higher doses and in selected cancer types (NSCLC and other solid tumors).

Clinical trial identification: NCT05114759.

Background: Nectin-4 is an adhesion molecule that highly expressed in variety of solid tumors and could be a potent therapeutic target. 9MW2821 is a monoclonal antibody-drug conjugate (ADC) that delivers monomethyl auristatin E to cells expressing Nectin-4. Here we report the first-in-human, multicenter, phase I/II study designed to explore the safety, pharmacokinetics and efficacy of 9MW2821 in advanced solid tumors.

Methods: 9MW2821 was administered by intravenous infusion on days 1, 8 and 15 of each 28-day cycle. The study included dose escalation, dose expansion and cohort expansion period which included urothelial cancer (UC) and other Nectin-4 positive solid tumors. Primary objectives were assessment of safety and preliminary efficacy.

Results: As of April 27, 2023, 97 patients (pts) were enrolled with doses ranging from 0.33 to 1.5mg/kg. Median age was 57 years (range, 32-78). Only 1 dose limiting toxicity of grade 4 neutropenia lasted more than 5 days was observed at 1.5mg/kg group. Maximum tolerated dose was not yet reached. Treatment related adverse events (TRAEs) of any grade occurred in 64.9% pts. The most common TRAEs were white blood cell (WBC) count decreased (36.1%), neutropenia (35.1%), nausea (22.7%), aspartate aminotransferase increased (22.7%), rash (19.6%), alopecia (19.6%), fatigue (18.6%), decreased appetite (18.6%), anemia (17.5%), vomiting (16.5%), peripheral sensory neuropathy (16.5%). Grade 3/4 TRAEs occurred in 35.1% pts. The most common grade 3/4 TRAEs were WBC count decreased (18.6%) and neutropenia (18.6%). Treatment related death was not observed. Among 39 pts treated with 9MW2821 at 1.25mg/kg or above and evaluable for tumor assessment, objective response rate (ORR) and disease control rate (DCR) was 38.5% and 84.6%, respectively. In 18 pts with UC who progressed after platinum-based chemotherapy and immune checkpoint inhibitors and dosed at 1.25mg/kg, ORR and DCR was 55.6% and 94.4%, respectively. Objective responses were also observed in pts with breast cancer and cervical cancer.

Conclusions: The results showed that 9MW2821 had manageable safety profile and promising antitumor activity. Enrollment continues to determine efficacy of 9MW2821 in certain solid tumors.

Clinical trial identification: NCT05216965.

Background: B7-H4 is a B7 immune checkpoint ligand expressed at low levels in normal tissue and is upregulated in solid tumors, including breast, ovarian, and endometrial cancers. SGN-B7H4V is an investigational vedotin ADC comprising a B7-H4-directed monoclonal antibody conjugated to monomethyl auristatin E via a protease-cleavable linker. We report first results from dose escalation (Part A) of this ongoing phase 1 study.

Methods: SGNB7H4V-001 is a first-in-human, multicenter study evaluating the safety, tolerability, pharmacokinetics, and antitumor activity (objective response rate per RECIST v1.1) of SGN-B7H4V in patients with advanced solid tumors. Part A enrolled patients with histologically or cytologically confirmed locally advanced unresectable or metastatic solid tumors irrespective of B7-H4 expression. Patients received SGN-B7H4V on Days 1 and 8 of a 21-day cycle (2Q3W, 0.75, 1.0, 1.25, or 1.5 mg/kg), or on Days 1 and 15 of a 28-day cycle (2Q4W, 1.25, 1.5, 1.75, or 2.0 mg/kg).

Results: As of 10 March 2023, 75 patients were enrolled and received SGN-B7H4V. In 2Q3W (n=35), 3 patients (8.6%) had dose-limiting toxicities (DLTs) of hyperglycemia (1.25 mg/kg), arterial embolism (1.5 mg/kg), and neutropenia (1.5 mg/kg). The most common TEAEs across doses were fatigue (20.0%), peripheral sensory neuropathy (20.0%), and neutropenia (17.1%). The most common grade ≥3 TEAE was neutropenia (14.3%). In 2Q4W (n=40), 2 of 39 DLT-evaluable patients (5.1%) had DLTs of peripheral sensory neuropathy (1.5 mg/kg) and transaminitis (2.0 mg/kg). The most common TEAEs were fatigue (27.5%), peripheral sensory neuropathy (27.5%), and nausea (22.5%). The most common grade ≥3 TEAEs were anemia, dyspnea, hypotension, and pneumonia (5.0% each). Confirmed objective responses (starting at 0.75 mg/kg) were observed in evaluable patients with breast (7/25 patients), ovarian (2/15 patients), endometrial (1 [complete response]/16 patients), and biliary tract cancers (2/9 patients).

Conclusions: SGN-B7H4V showed a manageable safety profile in patients with advanced solid tumors. Responses were observed at all tested dose levels and across various tumor types. Dose expansion in select tumor types is planned.

Clinical trial identification: EudraCT 2021-002107-35, NCT05194072; Release date: 03 April 2023.

Background: Belvarafenib (Belva) is a type II selective RAF dimer inhibitor that, in combination with Cobimetinib (Cobi) has shown clinical activity in patients with NRAS-mutant melanoma (ASCO 2021 , ESMO 2021). One cohort in this phase I trial evaluated BRAF fusions (including indel/rearrangement) or class II/III point mutations, which are considered potential therapeutic targets for Belva +/- Cobi. Here, we present findings on activity and safety of Belva and Cobi in patients with BRAF fusion including indel/rearrangement.

Methods: A total of 23 patients harboring BRAF non-canonical aberration were enrolled and treated with Belva 300mg PO BID and Cobi 20mg PO TIW (3 times a week) in the HM-RAFI-103 study (NCT03284502). Sub-cohort A (SC-A) enrolled patients with BRAF fusions and sub-cohort B (SC-B) enrolled patients with BRAF class II/III point mutations. Safety results were updated based on 133 patients who were treated with Belva and Cobi as of Jan 31, 2023.

Results: In SC-A, a total of 15 patients harboring BRAF fusions (Melanoma (10), NSCLC (3), CRC (1), Pancreatic cancer (1)) and 8 patients with BRAF class II/III point mutation were in SC-B (Biliary tract cancer (3), CRC (3), SCLC (1), Glioblastoma (1)) were enrolled. The confirmed objective response rate (ORR), assessed by investigators' assessment, for SC-A was 60.0%, median progression-free survival (mPFS) was 13.7 months, and median duration of response was 12.0 months (95% CI: 7.43 to 22.34) with median follow-up time 12.9 months, while patients in SC-B showed best response of stable disease. As of cut-off date, the most common treatment related adverse events from 133 patients is dermatitis acneiform (54.1%), rash (28.6%), and blood creatine phosphokinase increased (24.1%). No new safety signals were found.

Table: 661MO

		SC-A: BRAF fusion (N=15)	SC-B: Point mutation (N=8)
Best overall response	CR	0	0
	PR	9 (60.0)	0
	SD	5 (33.3)	4 (50.0)
	PD	1 (6.7)	4 (50.0)
ORR	n (%)	9 (60.0)	0
	95% CI	32.29, 83.66	0, 36.94
Disease control rate (PR+SD)	n (%)	14 (93.3)	4 (50.0)
	95% CI	68.05, 99.83	13.70, 78.80
mPFS	month	13.7	2.1
	95% CI	7.36, 18.23	1.61, 7.16

Conclusions: The combination of Belva with Cobi showed promising anti-tumor activity as well as durable responses in patients with BRAF fusions regardless of cancer type.

Clinical trial identification: NCT03284502.

(Shanghai), Shanghai, China; [15]Development, IMPACT Therapeutics, Inc. (Shanghai), Shanghai, China; [16]Research, IMPACT Therapeutics, Inc. (Shanghai), Shanghai, China

Background: IMP7068 is a potent and highly selective WEE1 inhibitor. Ongoing phase 1 study showed preliminary antitumor activity with a manageable safety profile in patients (pts) with advanced solid tumors.

Methods: Eligible pts were enrolled in escalation cohorts starting with 30mg (administered orally, once [QD] or twice daily [BID] for 3 days, followed by 4 days off [3/4] every week for 21-day cycles).

Results: As of April 12, 2023, 50 pts were enrolled across 10 dose cohorts (Table). Additional schedules including 2 days of dosing followed by 5 days off (2/5) and 5 days of dosing followed by 2 days off (5/2) every week were suggested by SMC after the notice of grade 3 ECG QT prolongation. The most common (>10%) treatment related adverse events were QT prolongation (28%), vomiting (16%), diarrhea (14%) and nausea (14%). 9 dose-limiting toxicities (DLTs) of grade 3 QT prolongation and pulmonary embolism were observed in 8 pts (Table). The mean QT interval prolongation in 80mg BID is lower than that in 160mg QD in schedule 3/4. 35 pts were efficacy evaluable, 1 patient with uterine serous cancer in cohort 4 has maintained complete response for 30 weeks, 18 pts had stable disease (SD), of which 1 patient with ovarian cancer in cohort 7 has maintained SD for 24 weeks. 5 pts are still on treatment. The pharmacokinetic (PK) analysis showed the exposure of IMP7068 in cohort 7 was comparable to that in cohort 4. The phosphorylated cyclin-dependent kinase 1 level in cohorts 4, 7 and 9 was reduced by ≥50% after treatment. Based on safety, PK and pharmacodynamic data, 80mg BID can be considered as a recommended phase 2 dose (PR2D) of 3/4 schedule.

Table: 662MO DLT by escalating cohorts

Cohorts	Dose (mg)	Schedules	Subject number/DLT evaluable	DLT, Subject number
1	30 QD	3/4	1/1	No
2	60 QD	3/4	1/1	No
3	120 QD	3/4	3/3	No
4	160 QD	3/4	9/9	1
5	200 QD	3/4	10/9	2
6	300 QD	3/4	3/3	3
7	80 BID	3/4	9/9	1
8	240 QD	2/5	3/3	1
9	50 BID	5/2	8/7	No
10	60 BID	5/2	3/2	No

Conclusions: IMP7068 conferred promising antitumor activity and good tolerability as QT prolongation has been mitigated by altering schedule. 80mg was defined as a potential PR2D in 3/4 schedule, and a second potential RP2D is being explored in 5/2 schedule. RP2D for IMP7068 will be determined soon.

Background: We present preliminary results from a phase 1, open-label, global, dose-escalation study (NCT05067283) of MK-1084, a selective *KRAS* G12C inhibitor, as monotherapy in advanced solid tumors and in combination with pembrolizumab (pembro) for first-line metastatic NSCLC.

Methods: Eligible pts aged ≥18 y had locally advanced unresectable or metastatic solid tumors and ≥1 line of prior therapy (Arm 1), or previously untreated metastatic NSCLC with PD-L1 TPS ≥1% (Arm 2), with histologic or blood-based confirmation of *KRAS* G12C mutation, measurable disease per RECIST v1.1 and ECOG PS of 0 or 1. Pts received MK-1084 PO QD or BID (25—800 mg) as monotherapy (Arm 1) or with pembro 200 mg Q3W (Arm 2) using a modified toxicity probability dose-escalation design. Treatment continued until PD, unacceptable toxicity, withdrawal, or maximum permitted cycles (≤35 cycles for pembro; no limit for MK-1084). Primary endpoints were dose-limiting toxicities (DLTs), AEs and discontinuations due to AEs. AEs were graded per NCI CTCAE v5.0. ORR per RECIST v1.1 by investigator review was a secondary endpoint.

Results: As of Apr 5, 2023, 43 pts received MK-1084 in Arm 1 and 15 received MK-1084 plus pembro in Arm 2. Median (range) follow-up was 6.0 (0.03—14.47) mo in Arm 1 and 4.4 (0.07—10.17) mo in Arm 2. Arm 1 included 28 pts (65%) with CRC and 9 (21%) with NSCLC; 31 pts (72%) had ≥2 lines of prior therapy. No DLTs have been reported to date. AEs of any cause occurred in 36 pts (84%) in Arm 1 and 13 (87%) in

Arm 2; none led to discontinuation. Treatment-related AEs occurred in 22 pts (51%) in Arm 1 (all grade 1 or 2 except 1 pt [2%] with grade 3 increased blood alkaline phosphatase) and 11 (73%) in Arm 2 (all grade 1 or 2 except 2 pts [13%] with grade 3 pruritus, rash, and papular rash); none were grade 4 or 5. There were no grade ≥3 transaminases elevations. ORR was 19% (8/42 pts, all PR; 4 in CRC, 4 in NSCLC) in Arm 1 and 47% (7/15 pts, all PR) in Arm 2; 7 and 3 pts not yet assessed, respectively.

Conclusions: MK-1084 as monotherapy and in combination with pembro showed manageable safety and preliminary antitumor activity in pts with previously treated solid malignancies and previously untreated NSCLC whose tumors harbored *KRAS* G12C mutations. Study is ongoing; updated data will be presented.

Background: MEK inhibitors (MEKi) lack clinical monotherapy efficacy in most RAS-mutant cancers and typically produce only a cytostatic response in preclinical RAS-mutant cancer models. BCL-XL is an anti-apoptotic BCL2 family protein identified by a synthetic lethal shRNA screen as a key suppressor of apoptotic response to MEKi. Combined BCL-XL/MEK inhibition led to tumor regressions in mouse models of RAS-mutant cancers.

Methods: We conducted a dose escalation study (NCT02079740) of the BCL2, BCL-xL and BCL-w inhibitor navitoclax and the MEK inhibitor trametinib in patients with RAS-mutant tumors with dose expansion cohorts for (1) pancreatic cancer, (2) gynecologic (GYN) cancers, (3) non-small cell lung cancer (NSCLC), and (4) other cancers harboring NRAS mutation. Paired pre-treatment and day 15 tumor biopsies and serial cell-free (cf)DNA were analyzed.

Results: 91 patients initiated study treatment, 38 in dose escalation. Overall 58.2% had 3 or more prior therapies. 15 patients (16.5%) had colorectal cancer (CRC), 19 (10.9%) pancreatic, 15 (16.5% NSCLC, and 32 (35.2%) GYN cancers. The recommended phase 2 dose (RP2D) was established as trametinib 2mg daily days 1-14 and navitoclax 250mg daily days 1-28 of each cycle after a 7-day lead-in of navitoclax at 150 mg daily during cycle 1. The most common adverse events included diarrhea, thrombocytopenia, increased AST and ALT, and acneiform rash. At RP2D, 8/49 (16.3%) evaluable pts had a partial response (PR) with disease control rate (DCR) 59.2%. Disease-specific differences in efficacy were noted. In GYN patients at the RP2D, 7/21 (33.3%) achieved a confirmed PR, with DCR 85.7% and median duration of response of 8.2 months. By contrast, no PRs were observed in any CRC, NSCLC, or pancreatic patients. Evidence of MAPK pathway inhibition was observed in paired pre- and on-treatment tumor biopsies, and reductions in KRAS or NRAS mutation levels in cfDNA correlated with clinical benefit.

Conclusions: Navitoclax in combination with trametinib was tolerable, and the R2PD was established. Durable clinical responses were observed in patients with RAS-mutant GYN cancers, warranting further evaluation of combined BCL-XL/MEK inhibition in this population.

Clinical trial identification: NCT02079740.

665P First-in-human, phase Ia/b, dose-escalation/expansion study of KRAS G12C inhibitor BI 1823911, as monotherapy and combined with anticancer therapies, in patients (pts) with advanced or metastatic solid tumours harbouring a KRAS G12C mutation

J. Heymach[1], N. Kotecki[2], H. Prenen[3], G. Alonso[4], C.R. Lindsay[5], M. Barve[6], C. Thamer[7], S. Eigenbrod-Giese[8], M.A. Marotti[8], G. Van Lancker[9]

[1]MD Anderson Cancer Center, The University of Texas, Houston, TX, USA; [2]Medical Oncology Department, Institute Jules Bordet, Brussels, Belgium; [3]Oncology Department, University Hospital Antwerp, Edegem, Belgium; [4]Early Drug Development Unit, Vall d'Hebron University Hospital and Vall d'Hebron Institute of Oncology, Barcelona, Spain; [5]Medical Oncology Department, The Christie NHS Foundation Trust, Manchester, UK; [6]Research Oncology, Mary Crowley Cancer Research Center, Dallas, TX, USA; [7]TA Oncology Medicine, Boehringer Ingelheim International GmbH, Biberach, Germany; [8]TA Oncology Medicine, Boehringer Ingelheim International GmbH, Ingelheim am Rhein, Germany; [9]Drug Research Unit Ghent, Ghent University Hospital, Ghent, Belgium

Background: BI 1823911, a mutant-selective KRAS G12C inhibitor, covalently binds to G12C mutant KRAS, irreversibly locking it in its inactive GDP form, interfering with cell signalling, causing tumour cell apoptosis and blocking cell proliferation. NCT04973163 is assessing BI 1823911 monotherapy and is designed to evaluate combinations with other anticancer therapies in pts with locally advanced/metastatic solid tumours with a KRAS G12C mutation.

Methods: The study has two arms (monotherapy; combination with anticancer therapies) and three parts (dose escalation, A; confirmation, B; expansion, C). Primary endpoint in Part A is number of pts with dose-limiting toxicities (DLTs) during the maximum tolerated dose (MTD) evaluation period. Primary endpoint in Parts B and C is objective response (confirmed complete or partial response [PR]). Primary objective is to ascertain the MTD/recommended phase II dose of BI 1823911, alone and in combination.

Results: As of 23rd Jan 2023, 17 pts received monotherapy in Part A (50/100/200/400/600/900/1200 mg QD, n=1/1/1/3/3/3/5); 9 male, 8 female; median age 58 years. 8 discontinued treatment (progressive disease, n=4; adverse event [AE], n=2). 3 pts had DLTs in the MTD evaluation period: G3 gastrointestinal stoma complication (n=1; 900 mg) and G3 diarrhoea (n=2; 1200 mg; 1 serious AE [SAE]). All pts experienced AEs (G3, n=8), most commonly diarrhoea (n=14) and nausea (n=14). 16 had drug-related AEs (G3, n=3; G4, n=0), most commonly diarrhoea (n=12; G3, n=3), nausea (n=12; G3 n=0) and vomiting (n=10; G3 n=0). 1 had a DLT outside the MTD evaluation period (G3 diarrhoea; 600mg; SAE). 2 had AEs leading to discontinuation; 6 had AEs leading to dose reduction. During early dose escalation (≥100 mg), 11 pts had disease control, including 8 with stable disease and 3 with confirmed PR (600 mg, n=2, lung and unknown cancer, Day 53 and 55; 900 mg, n=1, small intestine, Day 50).

Conclusions: Preliminary data suggest BI 1823911 monotherapy is generally well tolerated and offers clinical activity. Recruitment is ongoing; updated data will be presented.

Clinical trial identification: NCT04973163.

Background: *NTRK* gene fusions are oncogenic drivers of various solid tumour types. Entrectinib, a potent CNS-active TRK inhibitor, yielded systemic and intracranial responses in pts with *NTRK*-fp solid tumours in previous integrated analyses of three phase I/II trials (ALKA-372-001 [EudraCT 2012-000148-88]; STARTRK-1 [NCT02097810]; STARTRK-2 [NCT02568267]). We present updated data with ∼30% more pts and longer follow-up (data cut-off: 2 Aug 2022).

Methods: Adults with measurable, locally advanced/metastatic *NTRK*-fp solid tumours and ≥12 months' follow-up from first on-study scan, who received ≥1 dose of entrectinib, were efficacy evaluable. The safety population comprised all pts who received ≥1 dose of entrectinib. Eligible pts from TAPISTRY (NCT04589845) were also included. Tumour responses were assessed by blinded independent central review per RECIST v1.1 at Week 4 and then every 8 weeks. Primary endpoints: objective response rate (ORR); duration of response (DoR). Key secondary endpoints: progression-free survival (PFS); overall survival (OS); safety.

Results: The efficacy-evaluable population comprised 194 pts with 17 types of solid tumours. Median age: 58 years (range 19−92); 63 (32.5%) pts received ≥2 prior lines of therapy. Median survival follow-up was 38.7 months. ORR was 62.4% (95% CI 55.2−69.2); the table shows responses in histologies with n>10. Median DoR was 29.4 months (95% CI 17.2−36.8). Median PFS and OS were 15.7 months (95% CI 13.7−22.9) and 38.2 months (95% CI 28.6−56.5), respectively. In the safety cohort (N=296), median treatment duration was 8.3 months (range 0.0−72.0). Of all pts with treatment-related adverse events (TRAEs; n=265), 57% had grade 1−2 TRAEs; dose reduction, interruption and discontinuation occurred in 24%, 34% and 6% of all pts, respectively.

Table: 666P

NTRK-fp tumour types* (n>10)	Objective response rate, n/N (%)
Total	121/194 (62.4)
CNS metastases at baseline	22/36 (61.1)
No CNS metastases at baseline	99/158 (62.7)
Non-small cell lung cancer	32/51 (62.7)
Sarcoma	23/38 (60.5)
Salivary (mammary analogue secretory carcinoma)	27/31 (87.1)
Thyroid	14/21 (66.7)
Breast	8/13 (61.5)
Colorectal cancer	4/13 (30.8)

*Other tumour types in the efficacy-evaluable cohort: neuroendocrine (n=7); head and neck (n=5); pancreatic (n=4); cancer of unknown primary (n=3); gynaecological (n=2); adrenal (n=1); cholangiocarcinoma (n=1); gastrointestinal (n=1); neuroblastoma (n=1); penile (n=1); prostate (n=1).

Conclusions: In this updated analysis, entrectinib was well tolerated and continued to induce clinically meaningful responses in pts with *NTRK*-fp solid tumours.

Clinical trial identification: EudraCT 2012-000148-88; NCT02097810; NCT02568267; NCT04589845.

KG, Essen, Germany; [10]Global Oncology, Bayer HealthCare Pharmaceuticals, Inc., Basel, Switzerland; [11]Division of Oncology, The Children's Hospital of Philadelphia, University of Pennsylvania, Philadelphia, PA, USA; [12]Department of Medicine, Memorial Sloan Kettering Cancer Center and Weill Cornell Medical College, New York, NY, USA

Background: Laro is a highly selective, central nervous system (CNS)-active TRK inhibitor approved for tumour-agnostic use in pts with TRK fusion cancer based on a rapid, robust and durable objective response rate (ORR) in both adult and paediatric pts. We report data on laro-treated pts without prior systemic therapy.

Methods: Pts with treatment-naïve non-primary CNS TRK fusion cancer from three laro clinical trials were included. Laro was administered at 100 mg twice daily in most pts. Responses were assessed per independent review committee (IRC) using RECIST v1.1.

Results: As of July 2022, 84 pts were eligible for efficacy analyses by IRC; three pts (all adults) had known brain metastases at baseline. There were 12 different tumour types; the most common were soft tissue sarcoma (n=24; 29%), infantile fibrosarcoma (n=18; 21%), thyroid (n=15; 18%) and salivary gland (n=14; 17%). Median age was 31.5 years (range 0–90). The gene fusions involved were *NTRK1* (n=30; 36%), *NTRK2* (n=3; 4%) and *NTRK3* (n=51; 61%). ORR was 80% (95% confidence interval [CI] 70–88): 42 (50%) complete response (CR; including six pathologic CR), 25 (30%) partial response, 10 (12%) stable disease, six (7%) progressive disease and one (1%) not evaluable. Median time to response was 1.8 months. Median duration of response was 44.5 months (95% CI 31.4–not estimable [NE]) at a median follow-up of 26.7 months. Medians for progression-free survival and overall survival (OS) were 46.2 months (95% CI 32.0–NE) and not reached, respectively, at median follow-ups of 30.4 and 41.3 months. The 48-month OS rate was 82% (95% CI 71–92). Treatment duration was 0–64+ months. Treatment-related adverse events (TRAEs) were mainly Grade 1/2. Grade 3/4 TRAEs occurred in 20 (24%) pts. Two pts discontinued due to a TRAE (malaise and hypoventilation occurred in one pt each).

Conclusions: Laro demonstrated rapid and durable responses, extended survival and a favourable safety profile in pts without prior systemic therapy. This supports the use of laro in a first-line setting and the wider adoption of next-generation sequencing panels that include *NTRK* gene fusions to identify pts who may benefit from treatment.

Clinical trial identification: NCT02576431, NCT02122913, NCT02637687.

Background: Neurotrophic tyrosine receptor kinase (*NTRK*) gene fusions are oncogenic drivers in a variety of tumour types. Larotrectinib is a highly selective, central nervous system-active TRK inhibitor, approved to treat pts with TRK fusion cancer. We report updated efficacy and safety data in an expanded dataset of pts with longer follow-up.

Methods: Data were pooled from 3 clinical trials (NCT02576431, NCT02122913, NCT02637687) of pts with TRK fusion cancer treated with larotrectinib. Responses were assessed by independent review committee (IRC) per RECIST v1.1.

Results: As of 20 July 2022, a total of 289 pts (median age 44 years [range 0—90]) were included. There were 26 different tumour types, including soft tissue sarcoma (24%), infantile fibrosarcoma (17%), thyroid (10%), and lung (10%). Pts received a median of 1 prior line of systemic therapy, with 124 (43%) pts receiving ≥2. Among 274 IRC-eligible pts, the objective response rate was 66% (95% CI 60—72): 75 (27%) complete response (CR), including 13 (5%) pathological CR (pCR); 107 (39%) partial response (PR); 49 (18%) stable disease; 26 (9%) progressive disease; and 17 (6%) not evaluable. Median duration of response was 43.3 months (mo; 95% CI 31.4—54.7) at a median follow-up of 31.5 mo. Median progression-free survival was 30.8 mo (95% CI 22.5—36.1) at a median follow-up of 31.3 mo. Median overall survival (OS) was not reached; 48-mo OS rate was 65%. Pts were treated for up to 75+ mo. At data cut-off, 108 pts had progressed; 46 continued treatment post-progression for ≥4 weeks due to continued clinical benefit. Treatment-related adverse events (TRAEs) were mainly Grade 1/2; 59 (20%) pts had Grade 3/4 TRAEs. Five (2%) pts discontinued due to TRAEs. In a 5-year long-term follow-up analysis of the original 55 pts from the July 2018 primary data cut-off, 8 pts had an improved best overall response from PR to CR (or pCR), with a total CR rate of 27%.

Conclusions: Larotrectinib continued to demonstrate rapid and durable responses, extended survival benefit, and a favourable safety profile. This supports the wider adoption of next-generation sequencing panels that include *NTRK* gene fusions to identify pts who may benefit from treatment.

Clinical trial identification: NCT02576431, NCT02122913, NCT02637687.

669P Patient-reported outcomes with selpercatinib in patients with RET-driven cancers in the phase I/II LIBRETTO-001 trial

H. Kang[1], L.E. Raez[2], Y. Ohe[3], M. Khanal[4], K. Wang[5], Y. Han[6], S. Szymczak[7], S. Barker[8], A.M. Gilligan[9]

[1]Medicine Department, University of California San Francisco, San Francisco, MD, USA; [2]Hematology-Oncology, Memorial West Cancer Institute, Pembroke Pines, FL, USA; [3]Department of Thoracic Oncology, National Cancer Center Hospital, Chuo-ku, Japan; [4]RWA-Oncology, Eli Lilly and Company, Indianapolis, IN, USA; [5]Statistics, Tigermed America LLC, Fort Collins, USA; [6]Statistics-RWE, Eli Lilly and Company, Indianapolis, IN, USA; [7]Eli Lilly and Company, Indianapolis, IN, USA; [8]Loxo Med Affairs, Eli Lilly and Company, New York, NY, USA; [9]Value Evidence Outcomes-Oncology, Eli Lilly and Company, Indianapolis, IN, USA

Background: Selpercatinib, a first-in-class highly selective and potent rearranged during transfection (*RET*)-inhibitor, demonstrated efficacy in treatment of *RET*-driven cancers in the phase 1/2 LIBRETTO-001 trial. We report patient-reported outcomes for non-small cell lung cancer (NSCLC), medullary thyroid cancer (MTC), non-MTC thyroid cancer (TC) (15 Jun 2021, data cut-off date) and tumor agnostic (TA) cohorts (24 Sep 2021, data cut-off date).

Methods: Patients completed the European Organization for Research and Treatment of Cancer Quality of Life Questionnaire-Core 30 (QLQ-C30) at baseline (BL), approximately every 8 weeks until cycle 13, and then every 12 weeks until end of treatment (EoT). Subscales were scored 0—100; higher scores indicate better functioning or more severe symptoms based on the subscale. Proportion of patients with improved, stable, or worsened status post-BL was assessed. For symptom subscales improved is 10-point decrease from BL, worsened is 10-point increase from BL, and stable is being within 10 points from BL. For other subscales improved is 10-point increase from BL, worsened is 10-point decrease from BL, and stable is being within 10 points from BL.

Results: For patients with NSCLC, MTC, TC, and TA, respectively, 200 (63%), 208 (71%), 32 (70%), and 28 (68%) patients completed BL assessment; compliance rate was 85%,

87%, 72%, and 86%. BL functional domain subscale scores were >65 points across cohorts. Mean (SD) BL global health status (GHS) scores were: NSCLC — 62 (24), MTC — 65 (24), TC — 73 (20), and TA — 59 (26). The highest BL symptom scores (mean [SD]) were: NSCLC — fatigue (37 [26]) and dyspnea (30 [29]), MTC — diarrhea (42 [38]) and fatigue (36 [27]), TC — insomnia (28 [27]) and fatigue (27 [24]), and TA — fatigue (40 [29]) and appetite loss (37 [36]). Change in post-BL status varied across cohorts (Table).

Table: 669P

		Proportion of patients with post-BL response (Cycle 3 to EoT), mean (SD)
NSCLC		
GHS	Improved	42 (9)
	Stable	42 (10)
	Worsened	17 (8)
Fatigue	Improved	44 (7)
	Stable	27 (5)
	Worsened	29 (9)
Dyspnea	Improved	34 (6)
	Stable	57 (5)
	Worsened	9 (4)
MTC		
GHS	Improved	37 (7)
	Stable	45 (4)
	Worsened	19 (7)
Fatigue	Improved	46 (6)
	Stable	28 (5)
	Worsened	26 (8)
Diarrhea	Improved	53 (5)
	Stable	35 (3)
	Worsened	12 (4)
TC		
GHS	Improved	21 (9)
	Stable	54 (8)
	Worsened	25 (6)
Fatigue	Improved	39 (10)
	Stable	32 (14)
	Worsened	30 (11)
Insomnia	Improved	24 (14)
	Stable	56 (7)
	Worsened	21 (13)
TA		
GHS	Improved	39 (10)
	Stable	44 (8)
	Worsened	17 (4)
Fatigue	Improved	49 (12)
	Stable	19 (9)
	Worsened	33 (11)
Appetite loss	Improved	44 (9)
	Stable	51 (13)
	Worsened	5 (6)

Conclusions: The majority of patients with *RET*-driven cancers remained stable or improved on most QLQ-C30 domains during treatment with selpercatinib.

Clinical trial identification: NCT03157128.

Background: Tinengotinib is a spectrum-selective multi-kinase inhibitor that targets cell proliferation, angiogenesis, and immune-oncology pathways by inhibiting Aurora kinases A/B, Janus kinases and receptor tyrosine kinases (FGFRs and VEGFRs). Tinengotinib has shown promising clinical signal in solid tumors from several studies globally. Here we present the interim data from a phase Ib/II trial in China.

Methods: Pts with advanced/metastatic solid tumors were enrolled and treated with tinengotinib in 21-day cycle. Monotherapy and combination therapy with dose escalation (phase Ib) and dose expansion (phase II) were designed.

Results: As of 5-Mar-2023, thirty-three (33) pts have received tinengotinib monotherapy. Median age was 58.0 years (29-81), 66.7% were male, 81.8% had ECOG of 1, 87.9% had stage IV disease, 69.7% had ≥3 lines of prior therapies. No DLT was observed in phase Ib (3 pts in each group of 8, 10, 12 mg QD). 10 mg QD was selected as RP2D. Treatment-related AEs (TRAEs) were reported in 30 (90.9%) pts, Gr 3 in 14 (42.4%), Gr 4 in 1 (3.0%), and no Gr 5. The most common TRAEs (≥30%) included abnormal laboratory parameters (blood thyroid stimulating hormone increased, white blood cell count decreased, neutrophil count decreased, aspartate aminotransferase increased, alanine aminotransferase increased), palmar-plantar erythrodysaesthesia syndrome and anaemia. Among 22 efficacy-evaluable pts, the median Progression-free survival (PFS) have reached 6.70 (95% CI, 3.22-NA) months. For 19 pts with measurable target lesions, the overall response rate (ORR) and disease control rate (DCR) were 15.8% and 89.5%, respectively. For 4 CCA pts harboring FGFR2 alteration, ORR was 50%, DCR was 100%. One responder with prior treatment of erdafitinib achieved tumor reduction of 44%, the other with no prior FGFR inhibitor treatment achieved 69% reduction.

Conclusions: Tinengotinib monotherapy was well-tolerated in Chinese pts and 10 mg QD was selected as RP2D. Promising efficacy has been observed, especially in CCA with FGFR2 alteration. The ongoing study is to further evaluate the safety and efficacy of monotherapy and combination therapy.

Servicio de Oncología Médica, University Hospital Puerta de Hierro Majadahonda, Madrid, Spain; [3]Early Phase Clinical Trial Unit, Hospital Madrid Norte San Chinarro-Centro Integral Oncologico Clara Campal, Madrid, Spain; [4]Medical Oncology Dept., Rutgers Cancer Institute of New Jersey, New Brunswick, NJ, USA; [5]Medical Oncology Department, University Hospital Puerta de Hierro Majadahonda, Madrid, Spain; [6]Internal Medicine, Montefiore-Einstein Center for Cancer Care, Bronx, NY, USA; [7]Medical Oncology Dept., Montefiore Einstein Center for Cancer Care, Bronx, NY, USA; [8]Clinical Development, PharmaMar, SA, Madrid, Spain

Background: PM060184 (PM) induces depolymerization of tubulin fibers with disorganization and fragmentation of the microtubule network leading to mitosis. PM combined with gemcitabine (GEM) showed synergistic antitumor activity in preclinical studies.

Methods: This dose-ranging, phase I trial evaluated the safety, pharmacokinetics (PK) and efficacy of PM 10-min infusion plus GEM 30-min infusion, both on Day 1 and 8 in 3-week cycles, in eligible patients (pts) with advanced pretreated solid tumors. Tumors were assessed every 6 weeks until Cycle 4, and every 9 weeks thereafter. Adverse events (AEs) were graded per NCI-CTCAE v.4.

Results: 57 pts were enrolled into 8 dose levels (DLs). 74% were females, 74% had ECOG PS1; median age was 62 years; median number of prior lines of therapy was 3 (range, 1-7). Dose-limiting toxicities in Cycle 1 were grade (G) 3 peripheral sensory neuropathy, G3 abdominal pain, G3 intestinal obstruction (at the MTD), and G4 thrombocytopenia (1 pt each). The highest DL (DL8: PM 10.5 mg/m^2 + GEM 1000 mg/m^2) was the MTD. Accrual into DL7 (PM 10.0 mg/m^2 + GEM 1000 mg/m^2) was stopped before it was formally defined as the RD. Most common treatment-related non-hematological AEs at all DLs were fatigue (56%), nausea (55%), diarrhea (31%), decreased appetite and vomiting (27% each). Most of these AEs were G1/2 and none reached G4; most common G3 AEs were fatigue (3 pts), nausea, vomiting and abdominal pain (2 pts each). G3/4 hematological toxicities comprised anemia (35%), neutropenia (27%) and thrombocytopenia (17%). No treatment-related deaths occurred. Mean PK parameters for PM at DL7 in Cycle 1 were maximum concentration 665 μg/L, area under curve 430 h*mg/L and half-life 4 h. PK parameters for GEM or dFdU at all DLs were in line with reference values from the literature. 6/46 evaluable pts were responders (overall response rate [ORR]: 13%) and 12/46 pts had stable disease (SD) >4 months (disease control rate: 39%) at all DLs and tumor types. Of note, 2 partial responses and 2 SD >4 months occurred among 13 pts with ovarian cancer.

Conclusions: The combination of PM and GEM is well tolerated. The MTD was PM 10.5 mg/m^2 + GEM 1000 mg/m^2. No PK drug-drug interaction was found. While ORR was modest overall, the most encouraging outcome occurred in ovarian cancer pts.

Marii Sklodowskiej-Curie, Panstwowy Instytut Badawczy, Warsaw, Poland; [3]Early Drug Development, Vall d' Hebron Institute of Oncology (VHIO), Barcelona, Spain; [4]Department of Medical Oncology, Vall d'Hebron Institute of Oncology (VHIO), Barcelona, Spain; [5]Translational Medicine, Ryvu Therapeutics, Krakow, Poland; [6]Medical and Safety, Ryvu Therapeutics, Krakow, Poland; [7]DMPK, Ryvu Therapeutics, Krakow, Poland; [8]Early Drug Development, NEXT Oncology, Hospital Universitario Quirónsalud, Madrid, Spain; [9]Medical Oncology, Vall d'Hebron University Hospital, Barcelona, Spain; [10]Early Clinical Drug Development, Vall d'Hebron University Hospital, Barcelona, Spain

Background: CDK8 and its paralog CDK19 are part of the mediator complex connecting enhancers and core promoters and regulating genes responsible for oncogenic transformation and differentiation. RVU120 is a selective CDK8/19 inhibitor, currently in phase 1 clinical development. RVU120 showed strong anticancer activity in non-clinical cancer models.

Methods: In the ongoing phase I/II study (NCT05052255), patients with metastatic or locally advanced solid tumors receive RVU120 until disease progression or unacceptable toxicity. Primary objectives are safety, tolerability, and determination of the recommended phase 2 dose. Secondary objectives include ORR, pharmacokinetic and pharmacodynamics. Molecular response to RVU120 is assessed by genetic profiling of tumor biopsies and ctDNA. NanoString technology is used for transcriptional profiling of tumor biopsies.

Results: As of 01 May 2023, there were 30 patients treated across 7 cohorts (75 - 375 mg). The most frequent AEs were nausea and vomiting, all were G1 or 2. No patient experienced a DLT, 10 SAEs were reported in 6 patients (worsening of tumoral pain, urinary tract infection, medullary compression, lower GI bleeding, worsening of basal ataxia/dizziness, renal calculi, stroke). One patient died following an SAE of general physical health deterioration due to PD. No SAE was considered IMP related. A total of 15 patients had at least 1 RECIST assessment: 2 PD (21% and 26% increase in TL size), 13 radiologic SD (between -4% and +11% change in TL size). Out of these, a patient with refractory pancreatic cancer achieved a reduction of CA19.9 on 3 consecutive time points and radiologic SD after cycle 3. Pharmacodynamic profiling of all patients revealed target engagement of >70% at doses up to 375 mg. Data from genetic and transcriptomic profiling will be presented.

Conclusions: After 7 dose levels with single agent RVU120 (up to 375 mg), a favorable safety profile was observed. Most TEAEs were mild/moderate, no DLTs nor IMP related SAEs were reported. RECIST assessments of 15 patients demonstrated radiologic SD in 13 patients. Dose escalation is currently ongoing with PK modeling indicating high target engagement.

Clinical trial identification: NCT05052255.

Background: BI 907828, a highly potent mouse double minute-2 (MDM2)-p53 antagonist, has shown potent preclinical antitumour activity. This phase I study is evaluating BI 907828 in pts with advanced solid tumours. Here we report safety and efficacy for all pts who received BI 907828 once every 3 weeks (Q3W).

Methods: During dose escalation (phase Ia), pts received escalating doses of BI 907828 on day 1 of 21-day cycles (Q3W) or days 1 and 8 of 28-day cycles; recommended dose for expansion (RDE) was 45 mg Q3W (Gounder et al, ESMO 2021). During dose expansion (phase Ib), pts were enrolled in Cohort 1 (*TP53*wt, *MDM2*-amplified liposarcoma) or Cohort 2 (other *TP53*wt, *MDM2*-amplified solid tumours). Primary endpoint was progression-free survival (PFS); secondary endpoints included objective response and the number of pts with grade ≥3 treatment-related adverse events (TRAEs).

Results: At data cut off (April 2023), 140 pts had been enrolled to receive BI 907828 Q3W (29 in phase Ia; 111 in phase Ib); 78 (55.7%) were male, 77/62 (55.0%/44.3%) had ECOG PS 0/1, the median number of prior systemic therapies was 2. Of the 140 pts who received BI 907828 Q3W, 130 (92.9%) and 65 (46.4%) had any-grade and grade ≥3 TRAEs, respectively. The most common any-grade TRAEs were nausea (73.6%) and fatigue (57.9%). The most common grade ≥3 TRAEs were neutropenia (26.4%), thrombocytopenia (22.9%) and anemia (12.1%). Forty pts had serious AEs; the most common were thrombocytopenia (n=5), nausea, pulmonary embolism and neutropenia (n=4 each). At data cut off, 16/140 pts (11.4%) had a confirmed partial response (PR), and 89 pts had stable disease (SD), giving a disease control rate (DCR; at least SD) of 75.0%. Preliminary median PFS was 7.8 months; 36 pts (25.7%) had PFS >6 months. A total of 10 pts with advanced biliary tract cancer (BTC) received BI 907828 Q3W; of these, 3 (30%) had a confirmed PR and 5 had SD (DCR 80%). Two pts with BTC achieved PFS >12 months.

Conclusions: BI 907828 demonstrated antitumour activity and a manageable safety profile in pts with advanced solid tumours, including those with BTC; dose expansion is ongoing. BI 907828 is being further assessed in pts with BTC in the phase IIa/IIb open-label Brightline-2 trial (NCT05512377).

Clinical trial identification: NCT03449381.

674P Response of thrombopoietin receptor agonists in MDM2 inhibitor induced thrombocytopenia

R. DeMatteo, E. Sgroe, M.B. Merrill, M. Gounder, D. Liu

Early Drug Development, MSKCC-Memorial Sloan Kettering Cancer Center, New York, NY, USA

Background: MDM2 targets p53 for proteasomal degradation and has been exploited as a therapeutic target. Clinical trials have evaluated the efficacy and safety of MDM2 inhibitors (MDM2i), with thrombocytopenia being recognized as a class effect. Thrombopoietin Receptor Agonists (TPO-RAs) have been shown to improve thrombocytopenia secondary to chemotherapy, but their role in thrombocytopenia induced by MDM2 inhibition remains unclear.

Methods: Patients who were enrolled in any MDM2i clinical trial were identified from February 2014 to March 2023 at MSKCC. Patient characteristics and safety outcomes were collected from medical record. Statistical analysis consisted of the Mann-Whitney test.

Results: 113 Patients treated with 4 MDM2i using 8 different dosing schedules were evaluated. The median age was 59 years (range 19-89) and patients received a median of 2 (range 0-12) prior lines of therapy. Forty eight percent of patients had liposarcoma, with the remaining 52% having other solid tumors. Thrombocytopenia of any grade were present in 50% of patients, and of these, 26% were grade 3-4. Thirteen patients who experienced grade 3-4 thrombocytopenia were evaluated for response to any TPO-RA. Among these patients, the median time to platelet recovery, defined as achieving a platelet count of 75 k/mcl or higher, was 36 days (95% CI: 11-37) in 11 patients who received a TPO-RA vs. 16 days (95% CI: 9-21) in 14 patients who did not receive a TPO-RA (p=0.085). Dose reductions occurred in approximately 45% of patients who experienced grade 3-4 thrombocytopenia, 24% of whom received a TPO-RA vs. 21% who did not receive a TPO-RA. Dose interruptions occurred in 97% of all patients who experienced grade 3-4 thrombocytopenia. Two patients in the TPO-RA cohort and one patient in the non-TPO-RA cohort never achieved a platelet count above 75 k/mcl. No reports of severe bleeding or thromboembolism were observed in the TPO-RA cohort.

Conclusions: In this retrospective study with a heterogenous patient population, no significant difference in days to resolution of grade 3-4 thrombocytopenia secondary to an MDM2i was observed in those who received TPO-RAs. The role of TPO-RAs in this setting warrants further investigation.

675P A phase I study of safety, pharmacokinetics, and pharmacodynamics of SCR-6920, a protein arginine methyltransferase 5 (PRMT5) inhibitor, in patients with advanced malignant tumors

J. Yu[1], Y. Sun[2], S. Guo[3], H.Q. Wang[4], J. Wu[5], X. Jiang[5], J. Chen[6], G. Yang[6], C. Yang[5]

[1]Radiotherapy Department, Shandong Cancer Hospital, Jinan, China; [2]Phase I Clinical Research Center, Shandong Cancer Hospital, Jinan, China; [3]Oncology Department, The First Affiliated Hospital of Henan University of Science and Technology, Luoyang, China; [4]Department of Oncology, Tianjin Union Medical Center, Tianjin, China; [5]Clinical Science, Shanghai Xianxiang Medical Technology Co., Ltd., Shanghai, China; [6]Clinical Pharmacology, Shanghai Xianxiang Medical Technology Co., Ltd., Shanghai, China

Background: SCR-6920, a highly potent and selective PRMT5 inhibitor, demonstrates anti-tumor effect in multiple tumor models. SCR-6920 observed a better anti-tumor effect and lower target-related hematological toxicity in pre-clinical studies. Evaluation on pharmacokinetics (PK), pharmacodynamics (PD) and safety in clinic were ongoing in the phase I study.

Methods: Patients with advanced malignant tumors were enrolled in this phase I study (NCT05528055) with the guidance of the Bayesian Optimal Interval (BOIN) design for dose escalation. Patients received oral SCR-6920 once daily (QD) on a 21-day cycle. Safety, PK, PD, and preliminary efficacy were evaluated to identify the recommended phase II doses (RP2D).

Results: As of 25 February 2023, twenty-one patients were enrolled and dosed from 10 to 160 mg QD. The most common tumor types were non-small cell lung cancer (NSCLC) (28.6%), ovarian cancer (OC) (23.8%), cervical cancer (23.8%). Seventeen patients (81%) experienced treatment-related adverse events (TRAEs). Most common ($\geq$10%) TRAEs included anaemia (47.6%), white blood cell count decreased (23.8%), hypoalbuminaemia (23.8%), and neutrophil count decreased (23.8%). Grade 3 TRAEs included anaemia (9.5%), alanine transaminas increased (4.8%), aspartate aminotransferase increased (4.8%), lymphocyte count decreased (4.8%), and chronic colitis (4.8%). No dose-limiting toxicity (DLT) and grade 4 or 5 TRAE were reported. Six patients had serious adverse events (SAEs), and only chronic colitis was treatment related. Available PK indicated fast absorption with median T_{max} less than 1 hour. Concentration-dependent blood-to-plasma partition was observed in clinical led to a non-linear blood and plasma PK from 10 to 160 mg QD. The terminal half-life was $<$1 day and $>$ 3 days in plasma and blood respectively. The major metabolite SCR-6959 accounted for 30$\sim$80% from SCR-6920. Plasma symmetric dimethyl arginine (SDMA), the enzymatic product of PRMT5 was significantly reduced (inhibitory rate: 52.8%$\sim$77.4%) at steady state.

Conclusions: SCR-6920 had a manageable safety profile and further assessments are ongoing to determine the RP2Ds.

Clinical trial identification: NCT05528055.

676P Preclinical characterization of novel peptide binders for EphA2-targeted radiopharmaceutical therapy

R. Clift[1], S. Richardson[2], T. Ehara[3], H. Yanagida[3], I. Hung[4], Z. Amso[5], K. Salvador[1], M. Guest[6], G. Han[7], A. Bhat[5], D. Cole[5], E. Bischoff[8], G. Li[7]

[1]Pharmacology, RayzeBio, Inc., San Diego, CA, USA; [2]DMPK, RayzeBio, Inc., San Diego, CA, USA; [3]Discovery, PeptiDream, Kanagawa, Japan; [4]Biology, RayzeBio, Inc., San Diego, CA, USA; [5]Chemistry, RayzeBio, Inc., San Diego, CA, USA; [6]Radiochemistry, RayzeBio, Inc., San Diego, CA, USA; [7]Translational Medicine, RayzeBio, Inc., San Diego, CA, USA; [8]Preclinical Development, RayzeBio, Inc., San Diego, CA, USA

Background: EphA2 is a transmembrane glycoprotein, primarily involved in tissue patterning during embryonic development, and its expression levels are low or absent in normal adult tissues. EphA2 overexpression has been observed in multiple cancers, and is often associated with poor prognosis. The broad overexpression in solid tumors and relatively low expression in normal adult tissues make EphA2 attractive for targeted radiopharmaceutical therapy.

Methods: RAYZ-6114 is comprised of a peptide binder to EphA2, a linker, and DOTA chelator that can be complexed with different isotopes. RAYZ-6283 differs from RAYZ-6114 only in the linker. The binding affinity, selectivity and cross-species reactivity to EphA2 and other Ephrin proteins were determined by SPR. Internalization was measured using flow cytometry. In vivo biodistribution and anti-tumor efficacy studies were performed in nude mice. For tumor type identification, EphA2 IHC was performed on tumor microarrays representing diverse tumor types.

Results: IHC analyses confirmed EphA2 expression in a multitude of tumors, with the highest positivity rates in cervical, pancreatic, bladder, colorectal, esophageal and lung cancers. RAYZ-6114 showed potent binding to human EphA2 (K_D=0.03 nM), which was conserved across mouse and cynomolgus monkey EphA2. No binding to other Ephrin type-A or Ephrin type-B proteins was detected. The binder internalized in EphA2+ H1299 cells, with $\sim$75% internalized by 1 hour. In PC3 xenograft mice, ^{177}Lu-RAYZ-6283 showed sustained tumor uptake ($\sim$25% ID/g) for up to 48 hours and tumor/kidney ratios of 2.7, 3.3, and 5.9 at 24h, 48h, and day 7, respectively. Low uptake was seen in other normal tissues. Both ^{177}Lu- and ^{225}Ac- labelled RAYZ-6114 significantly inhibited tumor growth. Particularly, durable tumor regression and survival benefit were achieved by a single dose of ^{225}Ac-RAYZ-6114 (3 uCi), out-performing ^{177}Lu-RAYZ-6114 dosed at 3 mCi. All treatments were well tolerated.

Conclusions: RAYZ-6114 and RAYZ-6283 are first-in-class, highly potent and selective macrocyclic peptide binders. Preclinical pharmacodynamic, pharmacokinetic, biodistribution and efficacy data demonstrated their potential for treatment of patients with EphA2-positive tumors.

677P Preliminary findings from a phase I, open-label, dose-finding study of SNB-101 in patients with advanced solid tumors

Y.B. Sang[1], Y. Kim[1], M.A. Lee[2], S.Y. Rha[3], M. Jung[3], C-K. Lee[3], Y.H. Park[4], D. Heo[4], A. Kim[4], J. Kim[4], J-H. Kim[1]

[1]Medical Oncology, CHA Bundang Medical Center, CHA University, Seongnam, Republic of Korea; [2]Medical Oncology, Seoul St. Mary's hospital, The Catholic University of Korea, Seoul, Republic of Korea; [3]Medical Oncology, Yonsei Cancer Center, Yonsei University Health System, Seoul, Republic of Korea; [4]Medical Oncology, SN BioScience, Seongnam, Republic of Korea

Background: SNB-101 is a nanoparticle lyophilized injection of SN-38 (active metabolite of irinotecan), using polymer micelle technology, that is being developed to treat advanced solid tumors. The aim of this phase 1, dose-escalation study (SNB-101 101; NCT04640480) is to determine maximum tolerated dose (MTD) and recommended phase 2 dose (RP2D) of SNB-101 in patients (pts) with advanced solid tumors.

Methods: SNB-101 101 is a 6-cohort, open-label, dose-escalation study with an estimated enrollment of up to 36 pts. Key eligibility criteria: age $\geq$18y; histologically/cytologically confirmed, locally advanced/metastatic disease progressing after standard systemic treatment; not suitable for complete surgical resection; measurable/evaluable disease (RECIST 1.1); ECOG PS 0/1. Pts receive SNB-101 i.v. (5/8 to 50/80 mg/m^2 SN-38/irinotecan HCl) d1&15 q28d, until progressive disease, unacceptable toxicity, death or consent withdrawal. An independent safety review committee determines dose escalation/de-escalation/modification and MTD/RP2D. Key efficacy outcomes: objective response rate (ORR); disease control rate (DCR); progression-free survival (PFS); overall survival (OS). Pharmacokinetic (PK) analysis of SN-38 and irinotecan is also performed.

Results: As of April 28, 2023, 21 pts have been enrolled/are evaluable. Most common treatment-related AEs: neutropenia (61.9%); white blood cell decreased (28.6%); nausea (23.8%); anemia (19.0%); platelet count decreased (19.0%). Most frequent grade 3/4 AEs: neutropenia (33.3%); white blood cell decreased (14.3%); platelet count decreased (9.5%). MTD was not reached after dose escalation at all planned doses. ORR is 14.3% and DCR is 42.9%, with 3 partial responses (SCLC, NSCLC, rectal) and 6 pts with stable disease (NSCLC, SCLC, tonsil, gastric x2, rectal). Median PFS and OS are 1.9 and 6.1 months, respectively. PK of SN-38 and irinotecan appears dose dependent.

Conclusions: SNB-101 was well tolerated; despite relatively high rates of hematological AEs, neutropenia was manageable. SNB-101 demonstrated antitumor efficacy, which appeared to be dose dependent. A phase 1b/2a trial combining SNB-101 with immunotherapy is planned.

Clinical trial identification: NCT04640480.

678P ExoDS: A bioengineered exosome-based capsule for targeted delivery of chemotherapy drugs to cancer cells and cancer stem cells

A. Dutta, S. Paul, S. Bhagat

R&D, Exsure, Bhubaneswar, India

Background: Cancer stem cells (CSCs) are the major cause of therapy failure. CSCs are responsible for cancer relapse, metastasis, chemo-resistance, and radiation resistance. Therefore, targeting CSCs is imperative for better therapy outcomes. To date, there is no therapy precisely targeting CSCs. To fill these lacunae we have developed ExoDS a bioengineered exosome-based platform to precisely deliver chemotherapy drugs directly to CSCs effectively eliminating them.

Methods: ExoDS is an exosome-based platform that has been isolated and purified from immune cells that have been treated with a patented bioformulation and the specific drug to be incorporated within exosomes. To test the efficacy of ExoDS in targeting CSCs, we first generated and isolated CSCs from breast cancer cell lines, MCF7, MDA-MB-231, and MDA-MB-468. We next isolated CSCs from chemo-naïve breast tumor tissue samples to test the efficacy of ExoDS in targeting breast CSCs. We extensively used flow cytometric dependent analysis of AnnexinV to determine apoptosis in CSCs.

Results: Our results have shown that ExoDS can specifically identify and target CSCs with a 12-fold higher efficiency as compared to free drugs. At a cellular level, we established that ExoDS gets internalized inside CSCs within 6hrs of treatment. ExoDS was also found to target CTCs isolated from patient blood (n=5). Further analysis revealed that ExoDS spared healthy PBMCs isolated from healthy donors (n=9) as well as breast cancer patients (n=7). Our data confirmed that ExoDS can reduce chemotoxicity by more than 30%. Broadly, our results highlight the benefits of using ExoDS as compared to free chemotherapy drugs. ExoDS is a potential chemotherapy alternative.

Conclusions: Collectively, ExoDS efficiently targeted CSC in-vitro and also ex-vivo. Its specificity towards CSCs was established by the inability of ExoDS to target PBMCs derived from healthy individuals as well as patients. ExoDS can potentially target CSCs in a clinical setting making it a first-of-its-kind therapy vehicle. Targeting CSCs will revolutionize cancer treatments and will lead to better therapy outcomes. Currently, we are testing ExoDS in murine models to test it's in vivo efficacy and efficiency.

679P Lurbinectedin (LRB) pharmacokinetics (PK) and safety when co-administered with itraconazole (ITZ) in patients with advanced solid tumor

I. Moreno[1], T. Hernandez[2], E. Calvo[1], S. Fudio[3], C. Kahatt[3], S. Martinez[3], J. Iglesias[3], R.O. Calafati[3], L. Pérez Ramos[3], L. Montilla[3], A. Zeaiter[3], R. Lubomirov[3]

[1]Oncology, START Madrid-CIOCC, Centro Integral Oncológico Clara Campal, Madrid, Spain; [2]Oncology, START Madrid-FJD, Hospital Universitario Fundación Jiménez Díaz, Madrid, Spain-Current address: START Barcelona-HM CIOCC Early Phase Program, Hospital HM Nou Delfos, Barcelona, Spain; [3]Clinical Development, PharmaMar, Colmenar Viejo, Madrid, Spain

Background: LRB is a highly selective inhibitor of oncogenic transcription primarily metabolized by CYP3A4. This study investigated whether the PK and safety profile of LRB is affected by co-administration with ITZ, a strong CYP3A4 inhibitor, in adult patients with advanced solid tumors.

Methods: This was a 2-part crossover, open-label, phase Ib drug-drug interaction study (NCT05063318). In Part A, 3 patients were assigned to sequence 1 (TR) receiving a cycle (C) 1 of LRB (0.8 mg/m^2, 1 hour [h], iv) co-administered with ITZ (200 mg/day oral; 12-days), followed by a C2 of LRB alone (3.2 mg/m^2, 1 h, iv). In Part B, 11 patients were randomized (1:1) to receive either sequence 1 (TR) or 2 (RT). Plasma samples for LRB and ITZ PK were collected.

Results: 11 patients were evaluable for the primary objective of the study: 3 patients in Part A and 8 patients in Part B (4 in each of sequences 1 and 2). The systemic exposure of LRB was increased [15% for C_{max}, 2.4-fold for AUC_{0-t} and 2.7-fold for $AUC_{0-\infty}$] with ITZ co-administration. This correlated with reduced clearance (CL) by 63% and prolonged elimination half-life ($t_{1/2}$) by 2.2-fold. Co-administration with ITZ produced statistically significant modifications in the unbound plasma LRB PK parameters of similar extent than in total plasma with a 2.2-fold and 2.4-fold increase in AUC_{0-t} and $AUC_{0-\infty}$, respectively compared to LRB alone. Unbound LRB CL decreased by 58% and $t_{1/2}$ was 2-fold longer. Consistent with previous studies, the most common treatment-related adverse events of LRB alone at dose of 3.2 mg/m^2 were neutropenia, nausea, vomiting and fatigue. Safety profile of LRB at a dose of 0.9 mg/m^2 when co-administered with ITZ was no worse than that of LRB administered alone at 3.2 mg/m^2.

Conclusions: In comparison with LRB alone, the co-administration with multiple doses of ITZ, significantly altered LRB systemic exposure reducing total plasma (by 63%) and unbound (by 58%) LRB CL. The magnitude of these changes showed a clinically relevant effect of ITZ co-administration on LRB PKs. To avoid LRB overexposure and a worst safety profile when co-administered with strong CYP3A4 inhibitors a LRB dose reduction proportional to CL reduction should be applied.

Background: Ataxia telangiectasia and Rad3-related (ATR) is a critical protein in sensing DNA damage and activating the DNA damage checkpoint. ART0380 is a potent and selective, orally administered ATR inhibitor. This is the first report of the ongoing phase I trial (NCT04657068).

Methods: Patients (pts) with advanced solid cancers received escalating doses of ART0380 on a continuous daily (QD) or intermittent (3 days on, 4 days off) schedule. Investigators were guided to enroll pts with cancers that harbored DNA damage response deficiencies as identified by the Artios DcoDeR platform. Key study objectives included evaluation of safety and tolerability, preliminary efficacy, pharmacokinetics (PK), and pharmacodynamics.

Results: 49 pts were dosed with ART0380 monotherapy: 39 pts on intermittent doses between 100mg and 1200mg, and 10 pts on QD doses of 200mg and 400mg. PK data show ART0380 is rapidly absorbed followed by immediate decline to a low level succeeded by a longer mean elimination half-life of 8.3 hours. ART0380 exposure is dose proportional with increasing dose from 100mg to 1200mg in terms of Cmax and AUC0-24ss. The recommended phase II doses have been established as 600mg intermittent and 200mg QD. Approximately 36% of pts experienced the only Grade 3 treatment-related adverse event of anemia. Pts on QD dosing experienced fewer unplanned dose interruptions due to adverse events compared to intermittent dosing. Confirmed partial responses were observed in 3 pts with endometrial adenocarcinoma and 1 pt with anal cancer. One pt with cholangiocarcinoma had a profound reduction in their tumor marker associated with a reduction in non-measurable disease. There was a 25% confirmed objective response rate in pts with measurable disease treated on the QD regimens. Target engagement was

demonstrated via γH2AX modulation in circulating tumor cells. Exploratory biomarker analysis is underway.

Conclusions: These early data demonstrate that ART0380 dosed both continuously and intermittently is well tolerated and clinically active. ART0380 has a PK profile conducive with both intermittent and continuous dosing. The DcoDeR platform enabled the successful identification of pts with cancers sensitive to ATR inhibition.

Clinical trial identification: NCT04657068.

(Shanghai), Shanghai, Taiwan, China; [10]Oncology, IMPACT Therapeutics, Inc. (Shanghai), Shanghai, China; [11]Medical, IQVIA RDS (Shanghai) Co., Ltd. Beijing Branch, Beijing, China

Background: IMP9064 is a potent oral ataxia telangiectasia and rad3-related (ATR) inhibitor with anti-tumor activity demonstrated in vitro and in vivo. This ongoing first-in-human study (NCT05269316) explores IMP9064 monotherapy and in combination with senaparib (IMP4297) in patients with advanced solid tumors.

Methods: This phase I/II, open-label study aims to evaluate the safety, pharmacokinetics, anti-tumor activity, maximum tolerated dose, recommended phase 2 dose for IMP9064 monotherapy and combination with senaparib. Here, we report the preliminary results in dose escalation of monotherapy stage. Patients received IMP9064 once daily, 3 days on and 4 days off per 21-day cycle using an i3+3 dose escalation design.

Results: As of Feb 14th,2023, 16 patients were enrolled: Cohort 1 (n=1, 7.5 mg); Cohort 2 (n=1,15 mg); Cohort 3 (n=4, 30 mg); Cohort 4 (n=3, 45 mg); Cohort 5 (n=4, 80 mg); Cohort 6 (n=3, 120 mg). No dose-limiting toxicities were observed in the dose range of 7.5 to 80 mg. 10 (62.5%) patients experienced at least one treatment emergent adverse event (TEAE). TEAEs reported in 3 or more patients included nausea (25.0%), diarrhea (18.8%), fatigue (18.8%). Grade $\geq$3 TEAEs occurred in 4 (25.0%) patients. The only grade $\geq$ 3 AE related to IMP9064 was grade 3 diarrhea, which led to dose interruption and resolved within 48 hours. No drug-related death was reported. 9 of 13 evaluable patients had stable disease as their best response. A patient with advanced renal tumor from cohort 4 experienced stable disease and remains on trial with more than 7 cycles to date. In Cohort 3, a non-small cell lung cancer patient displayed a 158% ctDNA increase on C2D1, followed by a 58.2% decrease on C4D1 and an 84% decrease on C6D1 relative to C2D1. In the dose range of 7.5 to 80 mg investigated, the IMP9064 exposure increased as the dose increased; the median Tmax ranged from 1 to 3 hours, the mean elimination half-life ranged from 4 to 6 hours, and with minimal accumulation.

Conclusions: These results indicate that IMP9064 monotherapy appears to be well-tolerated and support further dose escalation. More MRD and biomarker analyses are underway.

Clinical trial identification: NCT05269316.

682P Preclinical and ongoing phase I study data of the CHK1 inhibitor BBI-355 in development for patients with oncogene amplification on extrachromosomal DNA (ecDNA)

A. Drilon[1], I.I. Rodriguez Rivera[2], A.I. Spira[3], M.R. Sharma[4], R. Hansen[5], S. Chowdhry[5], S. Kasibhatla[5], A. Tewari[6], S. Weymer[7], K. Wagner[7], T.A. Yap[8]

[1]Medicine Department, Memorial Sloan Kettering Evelyn H. Lauder Breast Center, New York, NY, USA; [2]Oncology, NEXT OncologyTM, San Antonio, TX, USA; [3]Research Institute, Virginia Cancer Specialist, Fairfax, VA, USA; [4]Medical Oncology Department, START Midwest, Grand Rapids, MI, USA; [5]Drug Discovery, Boundless Bio, Inc., San Diego, CA, USA; [6]Medical Oncology Department, Dana-Farber Cancer Institute, Boston, MA, USA; [7]Clinical Development, Boundless Bio, Inc., San Diego, CA, USA; [8]Investigational Cancer Therapeutics Department (Phase I Program), The University of Texas MD Anderson Cancer Center, Houston, TX, USA

Background: Focal high-copy number gene amplifications of oncogenes (e.g., *MYC, EGFR*) frequently occur on extrachromosomal DNA (ecDNA), highly transcribed units of circular non-chromosomal DNA. While targeted therapies have improved survival for patients with oncogene mutations, they have limited activity in most oncogene amplified cancers. We validated several drug targets essential for ecDNA function; tumor cells with oncogene amplification on ecDNA exhibit increased DNA replication stress and are hypersensitive to inactivation of checkpoint kinase 1 (CHK1). Thus, we developed BBI-355, a potential best-in-class orally available, potent (IC50 16nM), selective small molecule inhibitor of CHK1, which is in phase 1 development.

Methods: BBI-355-101 is a first-in-human, dose-escalation and dose-expansion, phase 1/2 study of BBI-355 alone or in combination with targeted therapies directed against a relevant amplified oncogene (e.g., EGFR inhibitor targeting amplified wildtype EGFR) in patients with solid tumors with oncogene amplification on ecDNA (NCT05827614).

Results: *Preclinical: In-vivo* anti-tumor activity of single agent BBI-355 was demonstrated in multiple ecDNA+ tumor models. Applying targeted therapy pressure to tumors with oncogene amplification on ecDNA induced tumor cells to evade such pressure via ecDNA-based resistance mechanisms, further increasing reliance on CHK1. Synergistic anti-tumor activity of BBI-355 in combination with agents targeting the amplified oncogenes was demonstrated in multiple *in-vivo* tumor models including: FGFR inhibitors in ecDNA+ *FGFR2* amplified gastric cancer (TGI: ∼120%) and CDK4/6 inhibitors in ecDNA+ *CDK4* amplified sarcoma models (TGI: ∼80%). *Clinical:* Safety, pharmacokinetic, predicitive biomarker, and efficacy data of the first dose levels of single agent BBI-355 will be presented for the first time at the conference.

Conclusions: The first ecDNA directed therapy, BBI-355, demonstrated significant anti-tumor activity as a single agent and in combination with targeted therapies in multiple ecDNA+ oncogene amplified tumor models. Clinical testing in patients with oncogene amplification is ongoing.

Clinical trial identification: NCT05827614.

683P Preclinical evaluation of HLX42, a novel EGFR-targeting ADC, for cetuximab or TKI resistant cancer

Y. Shan[1], R. Liu[1], G. Song[1], H. Song[1], J. Jiang[1], C. Jia[1], X. Huang[1], X. Yuan[1], W-J. Yang[1], X. Wang[2], Q. Wang[2], C. Hu[2], C. Zhao[2], Q. Wang[2], J. Zhu[2]

[1]Shanghai Innovation Center, Shanghai Henlius Biotech, Inc., Shanghai, China; [2]Global Product Development, Shanghai Henlius Biotech, Inc., Shanghai, China

Background: EGFR is highly expressed in various tumour types and is a driving force in tumourigenesis and progression. Although anti-EGFR and EGFR TKIs have demonstrated success in cancer treatment, a considerable medical need remains for patients who do not respond to or experience relapse following standard care. EGFR ADCs in clinical evaluation displayed preliminary efficacy, but conventional EGFR ADCs could pose considerable toxicity risks due to the universal expression of EGFR in normal epithelial tissues.

Methods: HLX42, a next-generation EGFR ADC, is comprised of a highly specific humanized IgG1 anti-EGFR connected to a novel topoisomerase-I inhibitor payload, whose cleavage and release are tumour microenvironment dependent and do not necessitate internalisation of ADC. This distinct mechanism of payload release grants HLX42 a superior therapeutic index compared to its predecessors. HLX42 was examined in antigen binding, internalisation, and plasma stability assays; efficacy analyses were also performed in multiple CDX and PDX models.

Results: *In vitro* evaluations verified that HLX42 possessed a similar binding affinity and internalisation rate as its parental antibody. Additionally, the ADC remained stable in rat and cynomolgus monkey plasma. HLX42 exhibited robust tumour suppression in several CDX and PDX models that were resistant to anti-EGFR or TKIs. In comparison to conventional ADC technologies such as vc-MMAE and GGFG-Dxd, HLX42 displayed superior efficacy and elicited more durable antitumour responses. In the NCI-H1993 model, weekly administration of HLX42 at 8 mg/kg for three times resulted in a 91.5% TGI compared to 79.8% TGI induced by anti-EGFR-GGFG-Dxd. Furthermore, the combination of HLX42 and osimertinib exhibited strong synergy in the LU3075 PDX model which poorly responded to osimertinib alone. In our pilot toxicity studies, HLX42 was well tolerated in rats and non-human primates (severely

toxic dose in 10% of animals = 50 mpk in rats; highest non-severely toxic dose = 20 mpk in non-human primates).

Conclusions: Taken together, these preclinical data strongly suggest that HLX42 is a potential best-in-class EGFR-targeting ADC which is worth further clinical investigations.

Background: SHR-A1811 is a novel ADC consisting of a humanized, anti-HER2 IgG1 mAb bound to a DNA topoisomerase I inhibitor payload via a cleavable, tetrapeptide-based linker. We conducted a phase 1 trial to assess SHR-A1811 in HER2-expressing locally advanced or metastatic GC/GEJ and CRC.

Methods: Patient (pts) who had failed or had no available/applicable standard treatment were enrolled. Pts were given SHR-A1811 at 3.2, 4.8, 6.4 and 8.0 mg/kg (Q3W, iv) in an i3+3 dose-escalation (DE) scheme, followed by PK expansion at selected tolerable doses and then clinical expansion at RP2D. The primary endpoints were DLT, safety and RP2D.

Results: As of data cutoff (Apr. 21, 2023), 98 pts were enrolled, including 55 GC/GEJ and 43 CRC pts (HER2-positive, 72.7%/86.0%; ≥2 lines of prior therapy, 29.1%/67.4%). During DE, 1 DLT (grade 4 decreased platelet count) occurred at 8.0 mg/kg. Combined with dose-proportional systemic exposure of SHR-A1811, total antibody, and payload at 3.2-8.0 mg/kg, and general treatment tolerability and an ORR of 50.0% (6/12) at 6.4 mg/kg during DE and PK expansion, 6.4 mg/kg was established as RP2D. Overall, the respective ORR in GC/GEJ and in HER2-positve GC/GEJ at RP2D were 38.2% (21/55; 95% CI 25.4-52.3) and 43.8% (14/32; 95% CI 26.4-62.3); the corresponding ORR in CRC were 44.2% (19/43; 95% CI 29.1-60.1) and 46.9% (15/32; 95% CI 29.1-65.3). Additional tumor response data are shown in the table. The respective 6-mo PFS rates in GC/GEJ and in HER2-positve GC/GEJ at RP2D were 71.0% (95% CI 54.0-82.7) and 73.9% (95% CI 52.1-86.9); the corresponding rates in CRC were 75.6% (95% CI 57.9-86.6) and 85.5% (95% CI 65.6-94.3). Grade ≥3 TRAEs occurred in 67 of 98 pts (68.4%), with all events occurring in ≥10% being hematotoxicities. No interstitial lung disease was reported.

Conclusions: SHR-A1811 showed an acceptable safety profile and promising clinical activity in pts with HER2-expressing GC/GEJ and CRC. Further investigation was warranted.

Clinical trial identification: NCT04513223.

Background: BL-M07D1 is an anti-HER2 antibody drug conjugate (ADC). It consists of a humanized anti-HER2 antibody, a cathepsin B cleavable linker, and a novel topoisomerase I inhibitor (Ed-04).

Methods: This study included subjects with locally advanced or metastatic HER2 expressing (positive/low) breast cancer (BC) and other solid tumors. For dose escalation (D-ESC), BL-M07D1 is planned to be administered at doses of 1.0mg/kg D1D8 Q3W or 2.6, 3.2, 3.8, 4.4, 5.0, 5.6, 6.2 mg/kg D1 Q3W. A subset of subjects were enrolled in the dose-expansion phase (D-EXP) at D1 Q3W regimens.

Results: As of May 1st, D-ESC has reached a dose of 5.0 mg/kg, with no observed dose limiting toxicities (DLTs).The maximum tolerated dose (MTD) was not reached. A total of 50 pts were treated with at least one dose, 19 pts in D-ESC and 31 in the D-EXP phase. The dose levels for expansion included 3.8, 4.4 and 5.0 mg/kg D1 Q3W. Among 50 pts,one received BL-M07D1 at 1.0 mg/kg on Day 1 and Day 8 every 3 weeks (D1D8 Q3W), while the remaining 49 subjects were treated with the drug on a Day 1 every 3 weeks (D1Q3W) schedule. The study enrolled 41 BC, 5 gastric cancer, 2 rectal cancer and 2 non-small cell lung cancer patients. The most common TRAEs (>10%, all grade /≥G3) were leukopenia (60%/13%), neutropenia (58%/21%), nausea (44%/0%), anemia (44%/0%), vomiting (25%/2%), lymphocyte count decreased (23%/8%),

Table: 685P

	ALL (n=26)	BC (n=23)	HER2+BC (n=15)
Median prior treatment lines (range)	3 (1-13)	3 (1-13)	3 (1-13)
Best overall response			
PR (cPR)	11 (6)	10 (6)	9 (6)
SD (with shrinkage)	12 (8)	11 (8)	6 (4)
PD	3	2	0
ORR, % (95% CI)	42.3 (23-63.1)	43.5 (23.2-65.5)	60 (32.3-83.7)
DCR, % (95% CI)	88.5 (69.9-97.6)	91.3 (72-98.9)	100%

gamma-glutamyltransferase increased (21%/2%), asthenia (19%/0%), thrombocytopenia (19%/0%), decreased appetite (17%/0%), alopecia (17%/0%), aspartate aminotransferase increased (15%/0%). No ILD was observed. Twenty six subjects were evaluated for efficacy (i.e., at least one post-baseline tumor assessment). Updated efficacy and pharmacokinetic (PK) results will be presented at the conference.

Conclusions: BL-M07D1 demonstrated encouraging efficacy in heavily pretreated HER2 expressing cancers, especially in HER2-positive BC. The safety profile showed adequate safety and tolerability.

Clinical trial identification: NCT05461768.

686P Phase I study of HRS8807, an oral selective ER covalent antagonist (SERCA), in ER+/HER2- locally advanced (LA) or metastatic (M) breast cancer (BC)

J. Wu[1], J. Zhang[2], Y. Meng[2], Y. Du[2], X. Liu[2], Y. Mu[2], Y. Zhang[3], J. Wang[4], W. Xin[5], X. Zhu[5]

[1]Department of Breast Surgery, Fudan University Shanghai Cancer Center, Shanghai, China; [2]Phase I Clinical Trial Center, Fudan University Shanghai Cancer Center, Shanghai, China; [3]Statistics and Programming, Jiangsu Hengrui Pharmaceuticals Co., Ltd., Shanghai, China; [4]Clinical Pharmacology, Jiangsu Hengrui Pharmaceuticals Co., Ltd., Shanghai, China; [5]Medical Oncology, Jiangsu Hengrui Pharmaceuticals Co., Ltd., Shanghai, China

Background: HRS8807 exerts strong antitumor effect in wild-type and mutant ER+ BC cells and mouse xenograft models. Here we report the preliminary results of HRS8807, the second SERCA to enter clinical development, in patients (pts) with ER+/HER2- LA/M BC.

Methods: In this phase 1 study, eligible pts were women of any menopausal status who had received $\geq$1 line of endocrine therapy and/or $\leq$2 lines of chemo with radiologically confirmed disease progression from the most recent anticancer regimen. Dose escalation was started at 25 mg with 1 pt and then switched to i3+3 design at doses of 75 to 600 mg. 3 d after a single dose, HRS8807 was given continuously qd in 28-d cycles. Dose-limiting toxicities (DLTs) were observed from the first dose to end of the first cycle (ie, 31 d).

Results: As of Apr 12, 2023, 7 pts were recruited (1 at 25 mg, 3 at 75 mg, and 3 at 150 mg). Median age was 53 yr. All had ECOG PS of 1. 71.4% were PR+. Median time from diagnosis to enrollment was 44.6 mo. For the LA/M disease, 57.1% had $\geq$2 lines of prior anticancer therapies; 71.4% had prior selective ER modulator degrader (SERD) and 85.7% had prior CDK4/6i. No DLTs were observed. Treatment-related adverse events (TRAEs) were reported in all pts, with the most common being hypertriglyceridemia, increased AST, hyperuricemia, increased ALT, increased blood creatinine, and anemia. No grade $\geq$3 TRAEs occurred, and no TRAEs led to treatment discontinuation. 3 pts achieved PR (1 at 75 mg and 2 at 150 mg; in which 2 had prior SERD [fulvestrant] and all had prior CDK4/6i in the M setting; treatment duration was 8.4, 8.6+, and 7.0+ mo). Impressively, ORR reached 42.9% (95% CI 9.9-81.6) in overall population, and 66.6% (95% CI 9.4-99.2) at 150 mg and 33.3% (95% CI 0.8-90.6) at 75 mg. The active metabolite SHR180451, a reversible ER inhibitor slightly more potent than HRS8807 in prohibiting BC cell proliferation *in vitro*, had longer terminal elimination half-life than and comparable systemic exposure to the parent. ^{18}F-FES PET-CT SUV_{max} decreased significantly after treatment.

Conclusions: HRS8807 was well-tolerated and showed early signs of robust antitumor activity, favorable PK properties (both parent and active metabolite), and high ER occupancy in pretreated ER+/HER2- LA/M BC.

Clinical trial identification: NCT04993430, Release date: 6 August 2021.

Ltd-Temasek Lifescience Laboratories, Singapore; [13]Clinical Development, Hummingbird Bioscience, Singapore; [14]Research, Hummingbird Bioscience Pte. Ltd-Temasek Lifescience Laboratories, Singapore

Background: Human epidermal growth factor receptor (HER)3 is a HER family transmembrane protein. Overexpression of HER3 is observed in multiple solid tumour types and are associated with poor clinical outcome. HMBD-001 is an IgG1 humanized monoclonal antibody specifically targeting HER3 with a unique mechanism of action, inhibiting both ligand-dependent and independent activation.

Methods: HMBD-001 is being evaluated in a first in human, multi-centre, open-label, non-randomised phase 1/IIA trial: Part A dose-escalation, with an initial intra-patient dose escalation, followed by inter-patient dose escalation utilising a one-stage Bayesian continuous reassessment design in advanced solid tumours commonly overexpressing HER3; and Part B, a dose-expansion phase in combination in metastatic castration-resistant prostate cancer (mCRPC) (NCT05057013). The primary objectives of Part A are to determine safety and tolerability and the recommended dose and schedule for phase 2 evaluation (RP2D). The pharmacokinetic profile, clinical and pharmacodynamic activity of HMBD-001 as a single agent and potential predictive and pharmacodynamic biomarkers are being evaluated.

Results: As of 11 April 2023, 17 patients with advanced solid tumours have received weekly infusions of HMBD-001 monotherapy across 6 cohorts (150mg-3000mg). In total, 70 HMBD-001 treatment related adverse events (TRAEs) have been reported. 14 (82.4%) patients have had $\geq$1 TRAE. No grade $\geq$3 TRAEs nor DLTs have been observed. More TRAEs have been observed at higher doses. Gastrointestinal disorder TRAEs are the most frequently reported (45.7%, 32/70); 13 patients (76.5%) experienced grade $\leq$ 2 diarrhoea. 4 patients (23.6%) have experienced trial-specific events of special interest; grade $\leq$2 infusion related reactions. Stable disease has been recorded in 4/12 evaluable heavily pre-treated patients.

Conclusions: Preliminary data supports a highly tolerable safety profile, supporting combination therapy. HMBD-001 will next be evaluated in Part B in biomarker selected mCRPC with Enzalutamide. Trials of HMBD-001 in squamous NSCLC and NRG1 fusions are also planned for Q3/4 2023.

Clinical trial identification: NCT05057013.

688P Pharmacokinetics of HMBD-001, a human monoclonal antibody targeting HER3, a CRUK first-in-human phase I trial in patients with advanced solid tumours

O. Idowu[1], J. Craigen[2], S. Svetlik[2], G.J. Veal[1], D. Jamieson[1]

[1]Newcastle University Centre for Cancer, Newcastle University, Newcastle upon Tyne, UK; [2]Centre for Drug Development, Cancer Research UK, London, UK

Background: HMBD-001 is an IgG1 humanised monoclonal antibody that directly blocks the dimerisation of HER3 to HER2 and EGFR. The ongoing first-in-human trial is an open-label, multi-centre, phase I/IIa adaptive study design (CRUKD/22/002) of HMBD-001 in patients with tumour types known to overexpress HER3. We report the pharmacokinetic profile of HMBD-001 from the initial dose escalation cohorts.

Methods: Patients (n = 17) were allocated to dose-escalating cohorts and administered an IV once weekly infusion dose (150, 300, 600, 1200, 1800 and 3000 mg) over 2 hours. The pharmacokinetics of HMBD-001 were evaluated over 7 days following administration on days 1 and 15 of cycle one. Concentrations of HMBD-001 in serum samples were determined by a validated bridging enzyme-linked immunosorbent assay (ELISA) method with a lower limit of quantification of 250 ng/mL. Pharmacokinetic parameters, including maximum concentration (C_{max}), T_{max}, area under curve (AUC), terminal half-life ($t_{1/2}$), and clearance (CL), were calculated by non-compartmental analysis using Certara WinNonlin software (version 8.3). A population pharmacokinetic approach was explored using Lixsoft Monolix Suite (version 2023R1).

Results: HMBD-001 C_{max} and AUC values increased linearly with dose on days 1 and 15 of treatment and a $T_{1/2}$ of 12.2 +/- 3.4 days was calculated at a dose of 3000mg. Drug clearance values observed on day 15 (dose 3) were significantly lower than those on day 1 (dose 1) (p = 0.017). Preliminary population pharmacokinetic suggest that the data are best described by a one compartmental model, with sex and weight as covariates for clearance and volume of distribution, respectively.

Table: 688P Pharmacokinetics of HMBD-001 on day 1 of dosing

Cohort	n	Dose (mg)	C_{max} (µg/mL)	T_{max} (h)	C_{trough} (µg/mL)	CL (mL/h)	AUC (µg/mL.h)	$T_{1/2}$ (days)
1	1	150	33	2.7	11	33.3	4499	4.5
2	1	300	98.3	2.1	25.6	25.4	11822	5.8
3	3	600	137.0 ± 34.9	4.1 - 25.1	62.7 ± 17.7	21.8 ± 6.4	29251 ± 9062	6.4 ± 0.6
4	3	1200	296.2 ± 60.2	2.2 - 7.4	148.4 ± 6.4	15.6 ± 1.6	77099 ± 7548	8.6 ± 2.2
5	6	1800	412.1 ± 57.8	2.4 - 4.9	158.6 ± 41.2	23.7 ± 5.0	79966 ± 23210	6.5 ± 1.6
6	3	3000	841.2 ± 209.3	2.2 - 2.8	368.3 ± 92.4	13.4 ± 1.9	227419 ± 32461	12.2 ± 3.4

Conclusions: The pharmacokinetic data generated to date are consistent with dose-dependent increases in drug exposure for HMBD-001. A $T_{1/2}$ of approximately 12 days is predicted.

Clinical trial identification: NCT05057013.

Background: DB-1305 is a novel ADC composed of a humanized anti-trophoblast cell-surface antigen 2 (Trop-2) IgG1 monoclonal antibody attached to a DNA topoisomerase I inhibitor (P1021) via a cleavable linker. Here, we present the initial results of the first-in-human (FIH) study.

Methods: This multi-center, open-label Ph 1/2a study includes dose escalation and expansion. Pts with advanced solid tumors who had failed standard therapy were enrolled. In Ph1, DB-1305 was planned to be administered from 2 mg/kg to 8 mg/kg (Q3W, iv) in a 3+3 design with accelerated titration for the starting dose; additional pts were enrolled to determine the recommended phase 2 dose (RP2D). Ph 2a will enroll approximately 10-40 pts per cohort at the RP2D to assess efficacy.

Results: As of 07 Apr 2023, 44 pts (2 mg/kg, n=1; 4 mg/kg, n=20; 5 mg/kg, n=17; 6 mg/kg, n=6) were enrolled in the Ph1. The median treatment duration was 1.5 (range, 0.7-6.1) months with 25 pts (56.8%) remaining on treatment. Pts had 3 median prior lines of therapy (range, 1-6). Three patients dosed at 6 mg/kg experienced dose-limiting toxicities (i.e., stomatitis, febrile neutropenia, and white blood cell decreased), and the maximum tolerated dose was established as 5 mg/kg. The most common (≥30%) treatment-related adverse event (TRAE) was stomatitis (75.0%). The most common (≥10%) Gr≥3 TRAE was stomatitis (22.7%), while all other events were reported in ≤2 pts. No TRAE led to death. The initial PK results suggest that exposure of DB-1305 increased with dose. The half-life of DB-1305 is approximately 3-4.5 days at the dose range of 4-6 mg/kg. The average systemic ADC/payload molar ratio is approximately 80, indicating ADC stability in systemic circulation. As of cut-off date, 7 pts (non-small cell lung cancer [NSCLC], n=6; fallopian tube cancer, n=1) had partial responses, 4 confirmed, and 3 requiring further confirmation. The objective response rate (ORR) was 30.4% (7/23), and disease control rate (DCR) was 87.0% (20/23). Thirteen NSCLC pts had an ORR of 46.2% (6/13), with a DCR of 92.3% (12/13).

Conclusions: DB-1305 has a manageable toxicity profile. Encouraging efficacy signals were observed in the NSCLC. Study continues to identify dose(s) of DB-1305.

Clinical trial identification: NCT05438329, released on 29 June 2022.

Background: I-DXd is a novel B7-H3—directed antibody—drug conjugate that leverages the clinically validated deruxtecan (DXd) technology with a plasma-stable linker and potent topoisomerase I inhibitor payload. Here we present a follow-up analysis (7 mo since last report) of an ongoing phase 1/2 trial that includes heavily pretreated patients with castration-resistant prostate cancer (CRPC), esophageal squamous cell carcinoma (ESCC), squamous non-small cell lung cancer (sqNSCLC), and small cell lung cancer (SCLC). DOR, OS, and B7-H3 correlations with response are reported for the first time for CRPC, ESCC, and sqNSCLC.

Methods: Efficacy and safety were analyzed in patients treated with I-DXd at 4.8 to 16.0 mg/kg. Response was evaluated in patients with ≥2 postbaseline scans or discontinuation for any reason. Fourteen patients with CRPC lacked measurable target lesions at baseline (BL) and were excluded from ORR analysis. B7-H3 level was evaluated retrospectively as patients were not pre-selected by BL expression.

Results: As of 31 Jan 2023, 8 patients remained on treatment. Safety data were consistent with previous reports. I-DXd still demonstrated promising ORR results, including in an updated sample size for sqNSCLC (Table). Even in this heavily pretreated population, I-DXd exhibited durable response and encouraging early OS (Table), although further follow-up is needed. B7-H3 expression was moderate to high in most patients; no correlation was observed between response and B7-H3 level, and an update will be presented at the congress.

Table: 690P Efficacy

	CRPC	ESCC	sqNSCLC	SCLC
No. of prior lines, median (range)	6 (1 − 11)	4 (1 − 7)	3 (1 − 12)	2 (1 − 9)
ORR by RECIST v1.1 (confirmed)	n = 59	n = 28	n = 13	n = 21
n (%)	15 (25)	6 (21)	4 (31)	11 (52)
DOR by RECIST v1.1	n = 59	n = 28	n = 13	n = 21
Median, mo (95% CI)	6.4 (2.8 − 10.6)	3.5 (2.4 − NE)	4.1 (2.8 − NE)	5.9 (2.8 − 7.5)
PFS by RECIST v1.1	n = 73	n = 28	NR	n = 21
Median, mo (95% CI)	4.8 (3.9 − 5.9)	2.8 (1.6 − 4.2)		5.8 (3.9 − 8.1)
OS	n = 73	n = 28	NR	n = 21
Median, mo (95% CI)	13.5 (10.3 − 16.6)	7.0 (4.8 − 12.2)		9.9 (5.8 − NE)

DOR, duration of response; NE, not estimable; NR, not reported; ORR, objective response rate; OS, overall survival; PFS, progression-free survival; RECIST, Response Evaluation Criteria In Solid Tumors.

Conclusions: I-DXd continues to demonstrate a manageable safety profile and promising antitumor activity with encouraging DOR and OS in these heavily pretreated patients, which warrants further clinical evaluation across multiple indications.

Clinical trial identification: NCT04145622.

Background: Anti−c-Met (MET protein) antibody-drug conjugate ABBV-400 comprises monoclonal antibody telisotuzumab conjugated to a potent topoisomerase 1 inhibitor via a stable, cleavable linker. *MET* gene amplification (amp) occurs at low frequency in primary tumors (<5%) but has increased frequency in recurrent/refractory disease. ABBV-400 showed deep, durable responses in preclinical patient (pt)-derived xenograft models of *MET* amp, c-MET−overexpressing advanced solid tumors. A first-in-human phase I study (NCT05029882) is evaluating safety, pharmacokinetics, and preliminary efficacy of ABBV-400 in pts with advanced solid tumors; we present results of an ad hoc analysis of efficacy in pts with *MET* amp.

Methods: Analyzed pts had measurable disease per RECIST v1.1 and history of advanced solid tumors that progressed/were not amenable to any available therapies/surgery. Pts had *MET* amp per local NGS reports of tissue/blood samples from various approved labs. ABBV-400 administered intravenously once every 3 weeks.

Results: As of 3 Apr 2023, 11 pts with *MET* amp advanced solid tumors were treated with ABBV-400 at 2.4 (N=4), 3 (N=6), or 4 (N=1) mg/kg; median follow-up 6.7 months. Enrolled tumor types included NSCLC, intrahepatic cholangiocarcinoma, gastroesophageal, ovarian, urachal, colorectal, and breast cancers. Median age 65 (range 41−73) years, 64% male, 64% Asian, 27% White, 9% Black, 6 (55%)/5(45%) had ECOG PS 0/1; median prior lines of therapy 3 (range 1−6). Pts had MET IHC H-score range of 73−270 and 5−75% cells with 3+ staining (data available for 6/11 pts). Treatment-emergent AEs reported in 11 pts (100%; 55% grade ≥3); most commonly, neutropenia (55%), anemia (46%), nausea (46%), and leukopenia (46%). Confirmed partial response observed in 8 pts (ORR = 73%, 95% CI: 39, 94) per investigator review and RECIST v1.1; 6 pts had ongoing response. Median progression-free survival was 10.8 months (95% CI: 1.2, not reached [NR]), duration of response and overall survival NR; longest ongoing response was >9 months.

Conclusions: ABBV-400 monotherapy showed promising tolerability and efficacy in pts with various *MET* amp advanced solid tumors. Based on these results, *MET* amp cohort will be expanded to 60 more pts.

Clinical trial identification: NCT05029882.

Background: ELU001 is small nanoparticle drug conjugate (∼6 nm), designed to penetrate deep into solid tumors and be eliminated rapidly by the kidneys to reduce toxicity versus antibody drug conjugates. ELU001 has ∼13 folic acid targeting moieties and ∼21 cathepsin-B cleavable exatecans, a topoisomerase-1 inhibitor, covalently bound to short polyethylene glycol chains surrounding a silica core. ELU001 binds cancer cells expressing FRα releasing exatecan intracellularly. ELU001 demonstrated efficacy in preclinical models with low to high levels of FRα.

Methods: Phase 1 / 2 multicenter, open label clinical trial. Part 1, Dose Escalation, enrolled patients with cancers likely to overexpress FRα. Escalating doses of ELU001, administered once a week (QW) (0.58-1.94 mg/m^2 for 3 weeks, 1 week rest), every other week (Q2W) (1.5-2.25 mg/m^2), or every three weeks (Q3W) (2.75-3.5 mg/m^2). Primary objective of Part 1: identify the starting dose and regimen for Part 2, Tumor Group Expansion.

Results: As of May 8, 2023, 40 patients (18 ovarian, 7 endometrial, 10 colorectal, 3 non-small cell lung and 2 cholangiocarcinoma) enrolled in Part 1 (15 QW, 14 Q2W, 11 Q3W), median prior lines of therapy 5 (2-13). To date 23 were evaluable for first tumor assessment at ∼8 weeks after first dose (1 Partial Response,18 Stable Disease and 4 Progressive Disease). 7 patients continued treatment for >6 cycles (4 for >8, 3 for >11). Treatment-Emergent Adverse Events: Grade 3 and 4 (≥ 10%): QW/Q2W/Q3W: neutropenia (46.7%/28.6%/50%), anemia (46.7%/28.6%/30%), leukopenia (40.0%/14.3%/10.0%), and thrombocytopenia (20%/7%/40%). Grade 1 and 2, (All regimens ≥ 20%): anemia (38.5%), fatigue (23.1%), neutropenia (30.8%), diarrhea (20.5%) and vomiting (23.1%). No evidence of ocular, liver, renal or cardiac toxicities, interstitial lung disease or peripheral neuropathy. Preliminary half-life ∼22 hours. The Q2W regimen had a better hematological safety profile with no related discontinuations.

Conclusions: Safety and efficacy of ELU001 demonstrated expected, manageable safety profile based on the payload, exatecan, with promising activity in heavily pretreated patients across several cancer indications with low, moderate or high FRα expression.

Clinical trial identification: NCT05001282.

693P Preclinical activity of HLX43, a PD-L1-targeting ADC, in multiple PD-1/PD-L1 refractory/resistant models

Y. Shan[1], R. Liu[1], G. Song[1], H. Song[1], J. Jiang[1], C. Jia[1], Y. Chen[1], X. Yuan[1], Z. Hou[1], X. Wang[2], X. Hou[2], Y. Shen[2], C. Hu[2], H. Wei[2], Q. Wang[2], J. Zhu[2]

[1]Shanghai Innovation Center, Shanghai Henlius Biotech, Inc., Shanghai, China; [2]Global Product Development, Shanghai Henlius Biotech, Inc., Shanghai, China

Background: PD-1/PD-L1 monoclonal antibodies have revolutionised the landscape of cancer treatment. Nonetheless, some PD-L1+ patients do not respond to or become resistant to such therapy. The elevated expression of PD-L1 in tumours makes it an attractive target for ADC development, which could potentially alter the treatment for PD-1/PD-L1 inhibitor refractory/resistant (R/R) cancers.

Methods: HLX43 is a novel PD-L1-targeting ADC consisting of an engineered anti-PD-L1 humanised IgG1 antibody linked to a camptothecin-based toxin, with a drug to antibody ratio of 8. Our innovative linker-payload is activated preferentially in the tumour microenvironment, enabling its tumour-specific release of the toxin without needing internalisation of the ADC. Toxin release in PD-L1+ cancer cells is efficient and tumour-specific, minimizing damage to normal cells and reducing systemic toxicity from non-specific toxin release in periphery. HLX43 was examined in antigen binding, internalisation, and plasma stability assays; efficacy studies were performed in multiple CDX and PDX models.

Results: HLX43 has been shown to have similar affinity and internalisation rates as the parental antibody. It was stable in the plasma of rats and cynomolgus monkeys. In *in vivo* efficacy studies, HLX43 induced tumour regression in multiple PD-L+ CDX and PDX models, and was well tolerated across all dosing groups. Weekly administration of HLX43 8 mg/kg for three times significantly reduced tumours in the MDA-MB-231 model without causing weight loss. HLX43 exhibited superior anticancer efficacy compared to anti-PD-L1-GGFG-Dxd at equal doses in all models tested, including those with low PD-L1 levels, high heterogeneity, and non-responsiveness to PD-1/PD-L1 inhibitors. Preliminary toxicity assessments demonstrated good tolerability of HLX43 in rats and cynomolgus monkeys, with the maximum tolerated dose being 60 mg/kg in rats and 10 mg/kg in non-human primates. GLP toxicology studies will explore a higher dose at 20 mg/kg.

Conclusions: HLX43 showed promising efficacy and tolerability in preclinical assessments. It may offer a novel treatment for PD-1/PD-L1 inhibitor R/R cancers like NSCLC, HNSCC, ESCC, MEL, and OVC.

Background: Clever-1 is an immunosuppressive scavenger receptor expressed on tumor associated macrophages. Bexmarilimab (FP-1305) is a novel humanized anti-CLEVER-1 IgG4-antibody capable of switching tumor macrophage phenotype leading to T-cell mediated anti-tumor responses.

Methods: MATINS (Macrophage Antibody To INhibit immune Suppression) trial is a first-in-human phase I/II study (NCT03733990) to assess safety and preliminary efficacy of Bexmarilimab (Bex) in patients with refractory advanced solid tumours. Part I has been completed with initial adequate safety profile, preliminary signs of efficacy, and initial recommended dose of 1mg/kg Q3W for part II. In Part II, 10 patients with distinct solid tumour types and variable doses and dosing frequency of Bex were studied to investigate safety, tolerability and efficacy.

Results: At the data cut-off of Apr 17th 2023, 214 patients have been enrolled to the study. In the alternative dosing cohorts, 66 patients were exposed to Bex with 1-3mg/kg Q1W, 1-3mg/kg Q2W, or 3-30mg/kg Q3W dosing. Bex was well tolerated with fatigue (15.9%) and pyrexia (5.6%) being the most frequent treatment related adverse event (TRAE) and 7.9% of the patients experiencing grade 3-4 TRAE. Disease control rate (DCR) was 13.0% (n=28) overall. Highest disease control rates (DCR) were observed in hepatocellular cancer (36%), ER+ breast cancer (33%), cutaneous melanoma (22%), and cholangiocarcinoma (21%). DCR was associated with Bex-induced immune activation in blood and tumor. Median progression-free survival was 2.0 and overall survival 5.6 months. 18-month survival rates (landmark analysis) were 32.9% in patients achieving DCR while this was 5.5% in non-DCR patients. The PFS ratio (defined by the PFS on bex/duration of previous treatment line) was >1.3 in 46.4% of the DCR patients while this was 9.6% in non-DCR patients ($p<0.0001$). In the alternative dosing regimens, no dose-dependency was observed to adverse events or DCR rates.

Conclusions: Bexmarilimab demonstrates promising anti-tumour activity as a monotherapy in several refractory solid tumours. A dose of 1mg/kg Q3W is considered feasible for further monotherapy studies in solid tumors.

Clinical trial identification: NCT03733990.

Background: NIZ985, an investigational recombinant heterodimer of interleukin (IL)-15 and IL-15 receptor alpha, binds the IL-2/IL-15 receptor on immune cells. NIZ985 activates immune cells in pts with advanced cancer and may help overcome resistance to checkpoint inhibitors (CPIs).

Methods: This is a phase I/Ib, open-label, multicenter, dose-escalation (ESC)/-expansion (EXP) study (NCT04261439) of NIZ985 alone and with spartalizumab (SPA) in pts with advanced solid tumors or lymphoma. Eligible pts had previously responded and progressed on a CPI. ESC comprised two arms: (1) single-agent (SA), subcutaneous NIZ985 at 2−16 μg/kg weekly, 3 weeks on/1 week off and (2) in combination with SPA 400 mg (N+S) intravenously on Day 1 of each 28-day cycle. Study objectives were to evaluate safety, tolerability, preliminary antitumor activity and PK.

Results: Fifty-six pts have been treated in the ESC SA NIZ985 (n=27) and N+S (n=29) arms. Pts received a median 3 (1−7) and 4 (1−9) prior therapies, with a median 1 prior CPI-containing regimen (ranges 1−3 and 1−4), respectively. At data cut-off, 21 (77.8%) and 24 (82.8%) pts had discontinued treatment in each arm respectively, mainly due to progressive disease (66.7% and 48.3%). Three DLTs during the first cycle included grade (gr) 3 fatigue, gr 2 bullous dermatitis and gr 2 injection site reaction. Gr ≥3 treatment-related AEs (TRAEs) were reported in 4 (14.8%) pts in the SA arm (pyrexia, fatigue, increased ALT, cutaneous vasculitis, and linear IgA disease) and in 4 (13.8%) pts in the N+S arm (increased ALT, hyperprogression, soft tissue infection, and increased transaminases). Of the 42 pts evaluated, 2 had a PR and 16 had SD. PK were dose proportional up to 12 μg/kg NIZ985, and overlapping exposures were observed with 16 μg/kg NIZ985. Biomarker data showed strong peripheral immune activation; increased Ki67 expression in CD8+ and NK cells and increases in systemic pro-inflammatory cytokines were noted.

Conclusions: NIZ985 +/- SPA was generally well tolerated with evidence of immune activation. The RDE was declared as 12 μg/kg NIZ985 SA and in combination. Additional pts with NSCLC have enrolled in EXP with tislelizumab.

Clinical trial identification: EudraCT 2109-0040690-42.

696P SIM1811-03 (SIM0235), an anti-tumor necrosis factor receptor-2 (TNFR2) monoclonal antibody, in patients with advanced solid tumor and/or cutaneous T cell lymphomas (CTCL): Preliminary results from an on-going first-in-human phase I trial in China

F. Liu[1], N. Yang[2], J. Wang[3], R. Wang[4], Z. Han[5], C. Yang[6], J. Li[6], Z. Liu[6], Y. Li[6], J. Tang[7], A. Cui[8], R. Xu[9]

[1]Clinical Research, Sun Yat-sen University Cancer Center, Guangzhou, China; [2]Lung&Gastrointestinal Oncology Department, Hunan Cancer Hospital, Changsha, China; [3]Digestive Department, Henan Cancer Hospital Affiliated Cancer Hospital of Zhengzhou University, Zhengzhou, China; [4]Phase I Clinical Trial Laboratory, Anhui Chest Hospital, Hefei, China; [5]Oncology Department, The Affiliated Hospital of Xuzhou Medical University, Xuzhou, China; [6]Clinical Science, Shandong Simcere Biopharmaceutical Co., Ltd., Shandong, China; [7]Translational Medicine, Shandong Simcere Biopharmaceutical Co., Ltd., Shandong, China; [8]Clinical Pharmacology, Shandong Simcere Biopharmaceutical Co., Ltd., Shandong, China; [9]Medical Oncology Department, Sun Yat-sen University Cancer Center, Guangzhou, China

Background: TNFR2 drives immune escape and tumor proliferation, and is highly expressed on tumor cells, immunosuppressive cells in the tumor microenvironment. SIM1811-03 is a humanized IgG1 monoclonal antibody that targets TNFR2,which demonstrated antitumor active in non-clinical models as single agent. SIM1811-03 is being evaluated in the First-in-Human study in patients with advanced solid tumors.

Methods: The study enrolled patients with advanced tumors who were not eligible for standard of care treatment. Patients received one dose of SIM1811-03 in cycle 0 and subsequently once every 2 weeks in dose from 0.5mg/mg to 25mg/mg. Based on emerging data a once every 3 weeks schedule in 40mg/kg dose was tested. The primary objectives were to determine the maximum-tolerated dose or recommended dose and to evaluate preliminary anti-tumor activity using either RECIST v1.1 for solid tumors. Secondary objectives were to assess safety and tolerability and to characterize pharmacokinetics and pharmacodynamics profiles.

Results: As of April 18, 2023, 22 patients received SIM1811-03 at doses of 0.5 mg/kg (n=3), 1.5 mg/kg (n=4), 5 mg/kg (n=4), 15 mg/kg (n=4), 25 mg/kg (n=4) Q2W and 40 mg/kg Q3W (n=3). No dose-limiting toxicity was observed and the MTD was not been reached. Majority of adverse events were Grade 1 or 2.There were two subjects with Grade 3/4 treatment-related adverse event. Two patients experienced treatment-related serious adverse event. SIM1811-03 showed a non-linear PK profile at the lower dose levels and a linear PK profile at the higher dose levels (15 to 40 mg/kg) with a half-life of about 12 days. TNFR2 receptor occupancy increased with SIM1811-03 concentration, and reached sustained saturation in peripheral blood CD14+ and CD16+ cells with the concentrations higher than about 10 ug/mL.

Conclusions: SIM1811-03 was well tolerated without DLTs reported across all dose levels and MTD was not reached. The preliminary PK and PD results support every 3-week dosing at 40mg/kg as the recommended dose for expansion. The clinical development of SIM1811-03 in combination with immunotherapy is planned.

Clinical trial identification: NCT05781386.

Background: BI 770371, a pan-specific anti-signal regulatory protein alpha (SIRPα) monoclonal antibody (mAb), reactivates innate and adaptive anti-tumour immune responses. This phase I, non-randomised, open-label, multicentre trial (NCT05327946) aimed to determine the maximum-tolerated dose (MTD) and recommended dose for expansion of BI 770371 ± ezabenlimab.

Methods: BI 770371 was administered alone or in combination with ezabenlimab IV once every 3 weeks in patients with advanced solid tumours. Treatment continued until progressive disease, unacceptable toxicity or other withdrawal criteria. Dose escalation was guided by a Bayesian Logistic Regression Model with overdose control. Primary endpoint was dose-limiting toxicities (DLTs) in the MTD evaluation period. Secondary endpoints were adverse events (AEs) and DLTs in the on-treatment period.

Results: As of 31 March 2023, 18 patients (monotherapy, n=15; combination therapy, n=3) have been treated in Canada, Japan and the US. In the patients who received monotherapy, the most common tumour types were colorectal, ovarian and prostate cancer (n=2 patients with each). 53% of patients were male, 53% had ECOG PS 0 and all had received >2 prior lines of treatment. AEs were reported in 12 patients (80%) and grade 3 AEs were reported in one patient (peripheral oedema, atrial fibrillation). Treatment-related AEs were observed in 10 patients (67%; all grade 1/2); the most common were pruritus (n=5) and peripheral oedema (n=2). Serious AEs were reported in four patients (27%; atrial fibrillation, decreased appetite, encephalitis, hypoxia, disease progression). Only one patient had an AE leading to treatment discontinuation (encephalitis). In 14 evaluable patients, 11 (73%) achieved a best response of stable disease. In the MTD evaluable set (n=15 monotherapy, n=3 combination therapy), no DLTs were reported during the MTD evaluation period. The MTD has not been reached; dose escalation is ongoing.

Conclusions: BI 770371 showed manageable toxicity alone and in combination with ezabenlimab. The trial is ongoing.

Clinical trial identification: NCT05327946.

Chiles Research Institute, Providence Cancer Institute, Portland, OR, USA; [8]Division of Medical Oncology, University of Colorado Denver-Anschutz Medical Campus, Aurora, CO, USA; [9]Department of Hematology/Oncology, UCSF-University of California San Francisco, San Francisco, CA, USA; [10]Division of Medical Oncology, Department of Medicine, Samuel Oschin Comprehensive Cancer Institute, Los Angeles, CA, USA; [11]Department of Clinical Development, Harpoon Therapeutics, Inc., South San Francisco, CA, USA; [12]Department of Translational Medicine, Harpoon Therapeutics, Inc., South San Francisco, CA, USA; [13]Department of Medical Oncology, Dana-Farber Cancer Institute, Boston, MA, USA

Background: HPN328 is a delta-like canonical Notch ligand 3 (DLL3)-targeting T-cell engager (TCE). HPN328 has 3 binding domains including anti-DLL3 for target engagement, anti-albumin for half-life extension, and anti-CD3 for T cell engagement and activation.

Methods: Pts with relapsed/refractory, metastatic SCLC and other NEN associated with DLL3 expression are eligible. Primary objectives are safety, determination of the maximum tolerated dose (MTD), and pharmacokinetics (PK). Secondary objectives are immunogenicity and efficacy. HPN328 is administered IV once weekly with a priming dose preceding the target dose in higher dose cohorts. Adverse events (AEs) are graded (G) by CTCAE 5.0, and ASTCT for cytokine release syndrome (CRS).

Results: As of 18Apr23, 44 pts received HPN328 doses of 0.015-24 mg across 11 cohorts (SCLC [n=29;66%]; NE prostate cancer [NEPC, n=6;14%]; other NEN [n=9;20%]). Median number of prior regimens was 2 (1-5); 59% previously received a PD-1/PD-L1 blocker. Treatment is ongoing in 20 pts. Treatment-related AEs in >10% of pts included CRS (46%), fatigue (23%), dysgeusia (21%), nausea (18%), pyrexia and vomiting (16% each), and anemia (11%). The 27 CRS events were G1 (n=14); G2 (n=11); G3 (n=2). G3 CRS was a dose-limiting toxicity (DLT) in 2 pts at a priming dose of 2 mg; dose escalation continues with a reduced priming dose to 1 mg. Three pts (2 SCLC, 1 NEN) have had confirmed partial response and an additional pt with SCLC had an initial report of complete response following the data cut-off date. Three pts remained on therapy for >1 year. HPN328 exhibited linear PK with dose-proportional increases in exposure and a median $T_{1/2}$ of 71 hrs. Transient increases in cytokines up to 24 hrs post-dose and T-cell activation were observed.

Conclusions: HPN328 is well tolerated and clinically active. MTD determination and dose escalation are ongoing. Future planned cohorts include every other week dosing and HPN328 + atezolizumab. Updated safety and efficacy results including pts recently enrolled in backfill cohorts will be presented.

Clinical trial identification: NCT04471727.

699P Immunogenicity and reactogenicity of BNT162b2 COVID-19 mRNA vaccine in long-survivor (LS) patients with metastatic lung cancer (mLC) after primary immunization (PV) and booster (BD): COVALENCE study

E. Vita[1], F. Monaca[2], L. Mastrantoni[2], G. Piro[2], G. Moretti[3], I. Sparagna[2], A. Stefani[2], A. Vitale[2], G. Trovato[2], M. Di Salvatore[2], M. Sanguinetti[4], A. Urbani[3], L. Richeldi[5], C. Carbone[2], E. Bria[1], G. Tortora[2]

[1]UOSD Oncologia Toraco-Polmonare, Fondazione Policlinico Universitario Agostino Gemelli-IRCCS, Rome, Italy; [2]Oncologia Medica, Fondazione Policlinico Universitario Agostino Gemelli-IRCCS, Rome, Italy; [3]Chimica, Biochimica e Biologia Molecolare Clinica, Fondazione Policlinico Universitario Agostino Gemelli-IRCCS, Rome, Italy; [4]Microbiologia, Fondazione Policlinico Universitario Agostino Gemelli-IRCCS, Rome, Italy; [5]Pneumologia, Fondazione Policlinico Universitario Agostino Gemelli-IRCCS, Rome, Italy

Background: As COVID-19 will likely became an epidemic disease, vaccination planning will be crucial for LS-mLC receiving anti-cancer therapy (ACT) in order to prolong effective immunity

Methods: According to the timing of BD and Sars-Cov2 infection (Cov-I) during oncological history, LC pts were allocated in three cohorts: A) Cov-I before PV or third BD; B) uninfected who completed PV during ACT; C) uninfected LC who had completed PV before cancer diagnosis and will receive BD after stating of ACT. As control cohorts, we included other cancer patients (mOC pts) who had completed PV and were candidate to BD during myelosuppressive (cohort D) or not-myelosuppressive (cohort E) ACT. The primary endpoints were seroprevalence of IgG Anti-spike-RBD (anti-S IgG) at two pre-defined time-points (T1: +30-90 days after BD; T2: + 6 months +/- 4 weeks after BD). As exploratory endpoint, we compared median pre-vaccination value of four cytokines (IL-6, IL-2R, TNF-α, IL-10) with post-BD values in immunotherapy-treated pts (IT-pts)

Results: Between October 2021 and February 2022, 113 LS-mLC patients were assigned in cohort A (20 pts), in cohort B (61 pts) or in cohort C (32 pts); 55 LS-mOC patients were allocated in cohort D (25 pts) and in cohort E (30 pts). Throughout the Omicron variant spread, 40 pts (24%) experienced Cov-I before T2 evaluation. Anti-S IgG qualitative seropositivity rate was 100% at T1 and 98.8% at T2. After 6-months FU, hybrid immunization (Cov-I before or after BD), was associated with higher median anti-S IgG trier compared to vaccine alone-induced immunity ($p = <0.0001$). In uninfected pts, median anti-S IgG titre was significantly lower in IT-treated patients compared to non-IT treated patients ($p = 0.02$); no difference was found when comparing myelosuppressive or not ACT. Among 68 IT-pts, 5 pts (7.3%) showed significant increase ($\geq$ 1.5 fold) of at least two cytokines in post-BD samples, without reporting ir-AE

Conclusions: Administration BDs of COVID-19 mRNA vaccine in LS-mLC pts resulted effective and safe. In IT-pts without recent Cov-I, additional BDs should be considered to prolong serological immunity

700P First-in-human dose-escalating study of ABSK043, a novel and oral small-molecule inhibitor of PD-L1, in patients with advanced solid tumors

A. Cooper[1], V. Andelkovic[2], K. Wilkinson[1], V. Ganju[3], J. Lundy[3], M. Hong[1], S. Airey[2], L.L. Meng[4], B. Shen[5], H. Li[6], L. Yao[7], M. Zhang[8], J. Coward[2]

[1]Medical Oncology Department, Liverpool Hospital-South Western Sydney Local Health District, Liverpool, NSW, Australia; [2]Department of Gynaeoncology, ICON Cancer Centre-South Brisbane, Brisbane, QLD, Australia; [3]Oncology Department, Peninsula and Southeast Oncology, Frankston, VIC, Australia; [4]Clinical Medicine, Abbisko Therapeutics Co., Ltd., Shanghai, China; [5]Translational Medicine, Abbisko Therapeutics Co., Ltd., Shanghai, China; [6]Biometrics, Abbisko Therapeutics Co., Ltd., Shanghai, China; [7]Clinical Pharmacology, Abbisko Therapeutics Co., Ltd., Shanghai, China; [8]Clinical Development, Abbisko Therapeutics Co., Ltd., Shanghai, China

Background: Immunotherapies targeting the PD-1/PD-L1 pathway with therapeutic antibodies have shown remarkable anti-tumor effects. Comparing to antibodies, small molecules render lower immunogenic risk and convenience in administration. ABSK043 is an oral small molecule PD-L1 inhibitor that potently blocks PD-1 and PD-L1 interaction. Here, we report the preliminary results from the first-in-human (FIH) study of ABSK043.

Methods: The FIH study evaluated the safety, tolerability, PK, PD, and preliminary efficacy of ABSK043. Dose escalation adopted the BOIN design, and ABSK043 was given orally QD or BID in patients with advanced solid tumors. PD assessments included PD-L1 inhibition and T-cell function.

Results: As of February 2023, 19 pts were enrolled in 5 doses from 200mg QD to 800mg BID in Australia. No DLT was observed and MTD was not reached. The most common (≥10%) TRAEs were rash (10.5%) and decreased appetite (10.5%). No peripheral neuropathy was reported. A grade 3 treatment-related thyroiditis with hyperthyroidism was reported in one patient (400mg BID) who recovered after steroid therapy. No grade 4 or 5 AEs occurred. Among 7 response evaluable pts in BID dosing, two were genomic instability, one endometrial carcinoma with MSI-H/dMMR (600mg BID) and one breast cancer with Lynch syndrome (400mg BID), both achieved partial response and were IO-naïve. ABSK043 depleted over 90% of surface PD-L1 on ex vivo stimulated whole blood in a dose dependent manner. BID dosing enhanced PD-L1 inhibition. Furthermore, ABSK043 decreased soluble PD-L1 levels in serum. Increases in IL-2 with ex vivo stimulation, CXCL9, and IFN-γ levels were observed post-treatment, indicating the activation of T cells.

Conclusions: ABSK043 was well tolerated up to 800 mg BID with no DLT reported. On-target PD effects were consistent with PD-L1 inhibition and data reported by anti-PD-(L)1 mAbs. Preliminary anti-tumor activity was observed, and further studies are warranted to explore the efficacy in a larger number of patients.

Clinical trial identification: NCT04964375.

701P NCI10221: Phase II multicenter biomarker driven combination trial of copanlisib and nivolumab in patients with molecularly-selected advanced solid tumors (BaCoN)

T.A. Yap[1], S.A. Piha-Paul[1], D. Karp[1], E.E. Dumbrava[1], D.S. Hong[1], S. Fu[1], V. Subbiah[1], A.M. Tsimberidou[1], J. Rodon[1], J. Rhudy[1], C. Valladolid[1], Y. Yuan[2], B. Jana[3], P. Spiliopoulou[4], L. Randall[5], A. Poklepovic[6], K. Sehgal[7], G.I. Shapiro[7], R. Said[8], F. Meric-Bernstam[1]

[1]Department of Investigational Cancer Therapeutics, The University of Texas MD Anderson Cancer Center, Houston, TX, USA; [2]Department of Biostatistics, The University of Texas MD Anderson Cancer Center, Houston, TX, USA; [3]General Oncology, Internal Medicine, UTMB Health-University of Texas Medical Branch at Galveston, Galveston, TX, USA; [4]Medical Oncology Department, Princess Margaret Cancer Centre, Toronto, ON, Canada; [5]Gynecologic Oncology, Virginia Commonwealth University Medical College of Virginia Campus, Richmond, VA, USA; [6]School of Medicine Internal Medicine, Virginia Commonwealth University Medical College of Virginia Campus, Richmond, VA, USA; [7]Medical Oncology Department, Dana-Farber Cancer Institute, Boston, MA, USA; [8]CTEP, DCTD, NCI, NIH, Investigational Drug Branch, Rockville, MD, USA

Background: Preclinical data showed antitumor efficacy with PI3K and PD-1 combined blockade. We hypothesized that efficacy will be enriched in tumors with *PIK3CA* hotspot and *PTEN* mutations vs those without. This provided rationale for this 3-arm trial of copanlisib (pan-PI3K inhibitor) and nivolumab (PD-1 inhibitor) in patients (pts) with: (1) activating *PIK3CA* hotspot mutations, (2) inactivating *PTEN* mutations or *(3)* wildtype (WT) for *PIK3CA/PTEN* mutations (NCT04317105).

Methods: Copanlisib was started as monotherapy in cycle 1 at 60 mg IV D1, 8, 15, before nivolumab was added from cycle 2 at 480 mg IV every 28 days. Fresh tumor biopsies and ctDNA were mandated in all pts at baseline, copanlisib monotherapy, on combo and at progression. Prior PD-1/L1 or PI3K inhibitors (PD-1/L1i or PI3Ki) were allowed. Objectives were safety, antitumor activity and analyses of sequential tumors (WES; RNA-Seq; RPPA) and ctDNA.

Results: 50 pts (M:F 17:33; ECOG PS 0:1 18:32; mean age 58 years (27-79) with ovarian (n=12), breast (n=10), HNSCC (n=4), bile duct (n=3), NSCLC (n=3), prostate (n=3), colon (n=3), gallbladder (n=2), leiomyosarcoma (n=2), salivary gland (2), bladder, cervical, endometrial, liposarcoma, sarcoma, skin (n=1) cancers enrolled. Pts with *PIK3CA* hotspot (n=16), *PTEN* (n=18), and WT (n=16) tumors enrolled. 31/50 pts had ≥3 lines of prior therapy; 23 (46%)/50 pts had prior PD-1/L1i and 3 (6%)/50 prior mTOR inhibitors. Common toxicities: G1/2 nausea (35%), rash (24%), diarrhea (24%), mucositis (20%), anemia (20%), fatigue (18%), hyperglycemia (18%); ≥ G3 transient hypertension (24%). RECISTv1.1 CR/PR in *PIK3CA* and *PTEN* cohorts were achieved in 4 (27%)/15 (1 cPR; 3 uCR/PR) pts and 3 (20%)/15 (3 cPR) pts, vs 0/15 (0%) pts in WT cohort. Responses were deep (up to -100%) and durable (up to 15+ months). Clinical benefit rate (SD>4 months/CR/PR) was 29% across cohorts; 40% in *PIK3CA* hotspot cohort, 33% in *PTEN* cohort and 13% in WT cohort.

Conclusions: The combination of copanlisib and nivolumab is well tolerated with antitumor activity in pts with *PIK3CA* hotspot and *PTEN* mutations including PD-1/L1i-exposed pts. Translational analyses are ongoing.

Clinical trial identification: NCT04317105.

Background: Human leukocyte antigens (HLAs) are expressed in a variety of cells, including cancer cells and immune cells. Recent studies have shown that germline HLA gene zygosity, supertype and individual HLA genotypes may be associated with immunotherapy (IO) outcomes. We aimed to evaluate whether germline HLA-A gene haplotype and zygosity is associated with response to IO.

Methods: Pts enrolled in phase 1 clinical trials in the Vall dHebron Institute of Oncology Early Drug Development Unit with available HLA-A testing were reviewed. Median progression free survival (PFS) and overall survival (OS) were estimated using the Kaplan-Meier method.

Results: From 2021 to 2023 a total of 247 eligible pts were reviewed. Median age was 59y, 63% female, main types of tumor with positive HLA biomarker were colorectal/anal cancer 19% (47pts), gynecological tumors 14%(34pts); and breast cancer 14% (34pts). Alleles present at >5% samples: 02:01:01 25%, 01:01:01 11%, 03:01:01 11%, 24:02:01 9%, 29:02:01 8%. Twenty-five (10.20%) pts presented HLA-A homozygosis. Homozygosis occurred in the most common haplotypes: 02:01:01 (14pts), 01:01:01 (2pts), 03:01:01 (4pts%), 24:02:01 (2pts%) and 29:02:01 (2pts). Eighty-five (34.5%) pts received IO; main types of tumors that received IO were genitourinary tumors 67% (10pts), gynecological tumors 45% (16pts) and colorectal/anal tumors 27% (13pts). Pts treated with anti-PD1 were 17 (20%), anti-PDL1 17 (20%) and other combinations 20 (24%). Twelve patients (17%) had PR, and thirty eight (45%) SD. Overal PFS and OS was 6.1 months and 29.6 months respectively. Presence of 03:01:01 was associated with a higher likelihood of response. Six pts with HLA homozygosis received inmunotherapy, all of them achieved SD as best response (NS).

Conclusions: Prevalence of HLA 02:01:01 in our population is significantly lower than reported in other populations. Presence of Homozygoses was not significantly associated with lack of response to inmunotherapy.

703P Prognostic scores for immunotherapy-based phase one trials (P1T): To GRIm or not to GRIm?

P. Corbaux[1], L. Verlingue[2], H. Vanacker[3], M. Brahmi[3], A. Swalduz[3], C. Terret[3], P. Cassier[3], A. Vinceneux[3]

[1]Medical Oncology Department, Université Claude Bernard Lyon 1, Villeurbanne, France; [2]Phase 1 Clinical Unit, Centre Léon Bérard, Lyon, France; [3]Medical Oncology Department, Centre Léon Bérard, Lyon, France

Background: Prognostic scores are useful to better select patients (pts) who may benefit from P1T. The Royal Marsden Hospital (RMH) score (Lactate deshydrogenase (LDH), albumin, number of metastatic sites) was the first validated prognostic score in the area of chemotherapy and targeted agents (TA) P1T. More recently, GRIm-Score (LDH, albumin, neutrophil-to-lymphocyte ratio) was shown as a better prognostic score for patients treated with immune-checkpoint therapies. We aimed to compare RMH and GRIm scores in the area of new immunotherapy (IT) agents P1T, monotherapy or in combination.

Methods: We performed a retrospective analysis of adult pts enrolled into P1T evaluating at least one IT at the Centre Léon Bérard, between 2012 and 2022. Univariate and multivariate analyses were conducted to assess the prognostic value of RMH and GRIm scores at screening for overall survival (OS) and progression-free survival (PFS).

Results: We identified 411 pts from 36 P1T, of whom 119 (29.0%) received IT monotherapy, 240 (58.4%) bi-IT, 49 (11.9%) IT monotherapy associated with TA and 3 (0.7%) IT triplet. The median age was 62 years [20 - 83] and the median number of previous lines was 2 [0 - 11]. The most common tumor types were colorectal (n=69), pancreatic (n=52), breast, (n=45), lung cancers (n=45), melanoma (n=31) and urothelial carcinomas (n=27). The median OS was 8.8 months [95%CI 7.7 − 10.0] and the median PFS, based on iRECIST criteria, was 2.2 months [95%CI 2.0 − 2.7]. At screening, 77.1% of patients (n=317) had a favorable RMH score (<2) and 81.5% (n=326) had a favorable GRIm-score (<2), with a discordance of 14.8% between both scores. In multivariate analyses, a favorable GRIm-score was associated with better OS (HR 0.47 [95% CI 0.34-0.65, $p < 0.001$), together with Performans Status (PS) 0 vs 1 (HR 0.76 [95% CI 0.59-0.99], $p = 0.039$) whereas RMH was not (HR 0.75, 95%CI [0.53-1.05], $p = 0.091$). Similarly, GRIm-score and PS were associated with better PFS, with respective HR 0.65 [95%CI 0.50 − 0.85], $p = 0.002$ and 0.66 [95% CI 0.53-0.82], $p < 0.001$, contrary to RMH.

Conclusions: While our results confirm RMH as suboptimal to determine the prognosis of patients included in P1T trials evaluating IT, GRIm-score and PS at screening both appear as highly reliable prognostic factors.

704P Regional differences in drug-induced lung disease (DILD) caused by anticancer drugs between the US, EU and Japan: A large-scale data-based analysis using the FDA Adverse Event Reporting System (FAERS)

R. Sadachi[1], J. Sato[2], M.O. Okada[2], Y. Katsuya[2], T. Koyama[2], N. Yamamoto[2]

[1]National Cancer Center Hospital/Biostatistics Division, NCCH, Chuo-ku, Japan; [2]Experimental Therapeutics, National Cancer Center Hospital, Tokyo, Japan

Background: DILD is a significant adverse event with a high fatality rate, and risk factors related to DILD have not been determined. Previous reports indicated regional differences in DILD. However, no large-scale data-based analyses investigating regional differences in DILD have been reported.

Methods: Adverse events report from the FAERS between January 2010 and December 2020 were collected. Regional differences in DILD incidence were examined based on data from the United States (US), Europe (EU), and Japan (JP). Multivariable logistic regression analysis, including the type of agent (tyrosine kinase inhibitors: TKIs, immune checkpoint inhibitors: ICIs, antibody-drug conjugate: ADCs, and cytotoxic agents) as confounding factors, was performed to calculate the reporting odds ratios (RORs).

Results: We identified reports of DILD from the US, EU and JP (74548, 31009, and 23004). Results of univariate analysis showed significantly higher RORs of anticancer drugs for reports from JP and EU compared to those from the US (JP, ROR 4.432 [95% CI, 4.366-4.499], $p<0.001$; EU, ROR 1.291 [95%CI, 1.274-1.308], $p<0.001$). Results of multivariable analysis for each single agent regimen of anticancer drugs showed that, for all regimens, reports from JP had significantly higher RORs compared to those from the US (TKIs, ROR 3.274 [95%CI, 3.105-3.451], $p<0.001$; ICIs, ROR 2.170 [95%CI, 2.025-2.325], $p<0.001$; ADCs, ROR 2.335 [95%CI, 1.666-3.272], $p<0.001$; cytotoxic agents, ROR 3.989 [95%CI, 3.776-4.215], $p<0.001$). Reports from the EU showed higher RORs for TKIs and cytotoxic agents than the US, but no significant difference between ICIs and ADCs (TKIs, ROR 1.679 [95%CI, 1.594-1.769], $p=0.0034$; ICIs, ROR 1.041 [95%CI, 0.965-1.123], $p=0.2960$; ADCs, ROR 1.046 [95%CI, 0.763-1.434], $p=0.7804$; cytotoxic agents, ROR 1.418 [95%CI, 1.354-1.485], $p<0.001$).

Conclusions: Reports from JP had significantly higher RORs than those from the US for all anticancer drug regimens. Further, reports from the EU had higher RORs than the US for TKIs and cytotoxic agents, but no significant difference among ICIs and ADCs. Japanese patients may have a higher risk for DILD than US and EU patients.

705P TIMES: A ctDNA tumor fraction based and externally validated nomogram to predict survival in cancer patients referred for early phase trials

A. Italiano[1], L. Belcaid[2], S. Cousin[1], K. Trin[3], A. Bayle[4], I. Soubeyran[5], M. Alamé[6], L. Blouin[6], E. Rouleau[7], L. Lacroix[8], D. Vasseur[9], C. Bellera[10]

[1]Early Phase Trials, Institut Bergonié, Bordeaux, France; [2]Medical Oncology, Copenhagen University, Copenhagen, Denmark; [3]Clinical Research, INSERM U1219-Bordeaux Population Health-ISPED University of Bordeaux, Bordeaux, France; [4]DITEP, Gustave Roussy, Villejuif, France; [5]Biopathology, Institut Bergonié, Bordeaux, France; [6]Molecular Pathology, Institut Bergonié, Bordeaux, France; [7]Tumor Genetics, Gustave Roussy-Cancer Campus, Villejuif, France; [8]Molecular Pathology, Institute Gustave Roussy, Villejuif, France; [9]Molecular Biology, Gustave Roussy-Cancer Campus, Villejuif, France; [10]Clinical Research, Institut Bergonié, Bordeaux, France

Background: Typical entry criteria in early phase studies include expected life expectancy greater than 3 months. However, this evaluation is quite subjective and more objective and reproducible tools are needed to improve patient selection for phase I trials. The quantification of ctDNA shed by measuring tumor fraction (TF) has been associated with prognosis in patients with solid tumors. Our objective was to develop and validate a nomogram integrating TF to predict overall survival in cancer patients referred for early phase studies.

Methods: All consecutive adult patients with an advanced solid tumor included between December 2020 and December 2021 in two precision medicine studies (BIP, NCT02534649, sponsor: Institut Bergonié, Bordeaux, France) and STING (NCT04932525, sponsor: Institut Gustave Roussy, Villejuif, France). All patients underwent comprehensive genomic profiling with the 324-gene FoundationOne®. TF was analyzed as a binary variable, indicating whether a specimen had TF $\geq$10% or TF $<$10%. Other variables included previously validated prognostic scores such as the Royal Marsden (RMHs: albumin, LDH, number of metastatic sites) and the GRIm (LDH, neutrophil/lymphocyte ratio, albumin) scores as well as their individual components.

Results: TF $>$ 10, the GRIM score and the RMH score were independent prognostic factors in the training dataset (BIP study n= 965 patients). We generated a nomogram based on TF, number of metastatic sites, albumine level and neutrophil/lymphocyte ratio. To determine the clinical usefulness of our nomogram, we compared it with the RMH and GRIM scores. For our nomogram, the area under the receiver operating characteristic curve (AUC) was 0.79 as compared with 0.65 and 0.68 for the RMH and GRIM scores respectively. In the validation dataset (STING study, n= 947), the AUC was 0.76 as compared with 0.60 and 0.64 for for the RMH and GRIM scores respectively. The nomogram was well-calibrated in both the training and validation datasets.

Conclusions: This is the first prospective analysis confirming that TF is a strong prognostic factor in patients with advanced solid tumors. The TIMES nomogram represent an helpful tool in the process of patient selection for phase I trial entry.

Clinical trial identification: NCT02534649; NCT04932525.

Meltzer[8], P. Niehusmann[9], I.A. Oppedal[2], H.E.G. Russnes[9], K. Tasken[10], S. Smeland[7], A. Helland[1]

[1]Institute for Cancer Research, Oslo University Hospital, Oslo, Norway; [2]Dept. of Oncology, Haukeland University Hospital, Bergen, Norway; [3]Dept. of Oncology, University Hospital of North Norway, Tromsoe, Norway; [4]Research Support Services, Oslo University Hospital, Oslo, Norway; [5]Dept. of Oncology, St. Olavs Hospital, Trondheim, Norway; [6]Dept. of Obstetrics and Gynecology, Stavanger University Hospital, Stavanger, Norway; [7]Division of Cancer Medicine, Oslo University Hospital, Oslo, Norway; [8]Dept. of Oncology, Akershus University Hospital, Lorenskog, Norway; [9]Dept. of Pathology, Oslo University Hospital, Oslo, Norway; [10]Dept. of Cancer Immunology, Institute for Cancer Research, Oslo University Hospital, Oslo, Norway

Background: IMPRESS-Norway is a national, prospective, investigator-initiated, open-label, non-randomized combined basket and umbrella precision medicine trial. Patients with advanced malignancies with no further treatment options are included and treated in multiple treatment cohorts, defined by tumor type, molecular alteration and study drug.

Methods: The trial started recruitment in April 2021, and by February 2023, 126 patients were included in treatment cohorts. Patients were treated with: trametinib (n=28); pertuzumab+trastuzumab (n=25); atezolizumab (n=19); vemurafenib+cobimetinib (n=16); trametinib+dabrafenib (n=12); alpelisib (n=11); pemigatinib (n=6); atezolizumab+ bevacizumab (n=4); vismodegib (n=3); alectinib (n=1) and imatinib (n=1). Per protocol, adverse events (AEs) grade $\geq$ 3 and serious adverse events (SAEs) are collected, allowing us to perform a preliminary safety analysis of currently treated patients.

Results: In total, 172 AEs and 131 SAEs were reported by February 2023. 32% of all AEs, were considered as not related or unlikely related to treatment, 35% were classified as possibly related and 27% as related to treatment. Conversely, 60% of the SAEs we considered as not related or unlikely related to treatment, 28% as possibly related and 10% as related to treatment. Ten AEs and two SAEs were still not evaluated at the time of data collection. Six deaths were registered during the treatment period, one considered to be treatment related, and four suspected unexpected serious adverse reactions (SUSARs) were reported. Nine patients discontinued treatment permanently due to AE**.** Detailed analysis and updated results will be presented.

Conclusions: We report preliminary safety analysis of eleven drugs or drug combinations used in the IMPRESS-Norway trial. All drugs are used outside of their current indications. These first results show safety profiles consistent with toxicities reported in earlier trials.

Clinical trial identification: EudraCT 2020-004414-35; NCT04817956.

Background: Although oral targeted therapies used in oncology demonstrate high interpatient variability in pharmacokinetics (PK), resulting in overdosing (>15%) and underdosing (30%) of patients (pts), a standard fixed dose for all pts is still used. This could lead to unnecessary toxicity and decreased efficacy, considering the established exposure—response and —toxicity relationships for many of these drugs. Personalised dosing through therapeutic drug monitoring (TDM) — individual dose adjustments based on measured PK—levels — could improve treatment outcomes. Results of 600 pts were published last year (Groenland et al, Ann Oncol. 1071-82, 2022 Oct). We hereby provide results of additional enrolment up to a 1000 pts, longer follow—up and newly reviewed cohorts.

Methods: This ongoing prospective study focusses on the feasibility, efficacy and tolerability of TDM of multiple oral targeted therapies in oncology. PK—levels are measured at 4—8—12 weeks after start of treatment and every 12 weeks thereafter. Recommendations are given based on established efficacy targets. Recommended interventions include dose adjustments, intake with food, split of intake moments, emphasize compliance and adjustment of interacting medication. An intervention is considered successful if there is a PK—level above target after intervention and if there is no dose limiting toxicity observed within one month.

Results: As of May 1st 2023, this study includes 1006 pts from 14 hospitals using one of 24 different oral targeted therapies. The largest cohorts are abiraterone (n = 189), imatinib (n = 165), sunitinib (n = 112) and pazopanib (n = 106). Among 916 evaluable pts, 41.3% (n = 378) had all PK—levels above target, while 58.7% (n = 538) had ≥1 PK—level below target. A PK-guided intervention was possible in 55.4% (n = 298), and was successful in 69.1% of cases. Of all pts with a PK-level below target, intervention was successful in 38.3%. As a result, there was a 22.5% gain in pts with PK-levels above target, reaching a total of 63.8% (n = 584).

Conclusions: The results of this study support the feasibility of TDM of oral targeted therapies in oncology. Before implementation, efficacy of TDM still requires further evaluation. For the largest cohorts this evaluation will be performed.

Background: Next generation sequencing (NGS) has become widely available but molecular profiling guided therapy (MGT) has not been established in the real world

due to a lack of available therapies and expertise to interpret and match treatment in Korea.

Methods: Patients with advanced solid tumors without remaining standard treatment were enrolled. Virtual, central molecular tumor boards (cMTB) reviewed patients' NGS reports and recommended clinical trials or investigational medicinal products (IMPs) as previously described (https://doi.org/10.1016/j.esmoop.2022.100653). Primary variable was to assess the proportion of patients with actionable genomic alterations and patients receiving MGT as MTB recommendations. Other variables were duration of treatment (DoT), overall response rate (ORR), disease control rate (DCR) and safety.

Results: From Feb 2021 to Feb 2022, 198 patients were enrolled. Median time from case submission to MTB discussion was 7 days (range, 2-20) and concordance rate between pre-MTB physicians' choice and MTB recommendations were 60.1% (119/198). A total of 107 (54.0%) received IMPs based on MTB decision (32, TE; 21, AZ; 14, TP; 13, BE; 8, AP; 6, CA; 5, DT; 4, AL; 3, EL; 1, BV). ORR and DCR were 13.3% (1 CR, 9 PR, 45 SD, and 20 PD), and 73.3%. DoT was 3.6 months (95% CI, 2.8-5.0) and 4 months DoT rate (4MDoTR) was 45.5%. DoT>12 months were observed in 10 (9.3%). TE showed a durable DoT, regardless of ERBB2 amplification and mutation (5.8 and 4.0 months), previous exposure of anti-HER2 targeted agents (4.0(No) vs. 5.4 months (Yes)), and high (6>) vs. low (6<) copy number variation (4.0 and 8.0 months).

Table: 708P

IMPs	ORR	DCR	4MDoTR	DoT(months)
Alectinib (AL)	33.3%	33.3%	50.0%	3.4
Alpelisib (AP)	50.0%	50.0%	42.9%	1.4
Atezolizumab (AZ)	21.4%	57.1%	30.0%	1.9
Bevacizumab (BV)	0.0%	100.0%	100.0%	8.3
Bevacizumab + erlotinib (BE)	9.1%	54.5%	33.3%	3.4
Capecitabine (CA)	0.0%	100.0%	0.0%	1.6
Dabrafenib + trametinib (DT)	50.0%	100.0%	60.0%	6.9
Erlotinib (EL)	0.0%	100.0%	66.7%	6.5
Trastuzumab and pertuzumab (TP)	0.0%	100.0%	57.1%	4.6
Trastuzumab emtansine (TE)	8.3%	75.0%	56.7%	4.2
All	13.3%	73.3%	45.5%	3.6

Conclusions: KOSMOS suggested the feasibility of nationwide cMTB guided MGT and also showed modest ORR, and a promising DCR in heavily pre-treated patients. KOSMOS-II (NCT05525858) is currently underway to confirm this in larger number of patients.

709P Challenges and opportunities to the implementation of adaptive design in phase III oncology trials: Results from a cross-sectional analysis

A. Krendyukov, M. Lerchenmueller

Innovation & Management, University of Mannheim, Mannheim, Germany

Background: Adaptive design (AD) trials have been developed as an innovative alternative to conventional design (CD) trials with the aim of accelerating innovative medicinal products (InMP) clinical development. Despite AD concept adoption by major competent authorities the use and implementation of AD remains substantially lower than CD. There is an emerging need to better understand the operational characteristics contributing to the challenges and opportunities for wider implementation of AD into oncology InMP development.

Methods: Oncology InMPs approved by the FDA in 2018 were selected for cross-sectional analysis. The ClinicalTrial.gov (CT.gov) platform was used to identify phase III trials conducted with those InMPs between 2010-2021. Analysis was then accomplished by PubMed search for full manuscripts associated with these trials, as additional source to describe trial design and methodology.

Results: Of the 63 indentified phase III trials, 47 (75%) were CD and 16 (25%) were AD. Among the AD, 81% were conducted in solid tumours and 19% in haematological malignancies. AD was associated with several distinct operational characteristics vs CD: i) with comparable number of patients enrolled, median number of sites/trial was higher in AD (203 sites) vs CD (106 sites) leading to substantial differences in median number of patients per individual site observed in CD (35.9 patients) and AD (3.8 patients); ii) AD was clearly associated with higher median number of secondary endpoints (18 endpoints) vs CD (12 endpoints) and substantially shorter median duration of trial (43 months) vs CD (60 months; p=.0129), with potential cost savings of up to 30%; iii) limited details on the AD methodology and decision-making process at the time of interim analysis.

Conclusions: The implementation of AD in oncology InMP development remains low as compared to CD. A degree of AD operational complexity vs CD could have been balanced by assumed stricter patient monitoring and compliance to the study protocol and collection of a larger set of scientific data. With a comparable number of enrolled patients, AD could substantially shorten overall study duration, which in turn leads to trial's cost savings of up to 30%.

Background: Early-phase clinical trials are a unique opportunity for patients with cancer to benefit from innovative treatments. These trials usually demand newly-collected tumor tissue for research purpose, requiring patients to undergo new biopsies. Some trials require a prescreening by next-generation sequencing (NGS), but the analysis can be challenged by both the quality and the quantity of the samples. Biopsies may have procedural complications with negative impact on patients.

Methods: We retrospectively reviewed the records of patients referred to the Early Drug Development (EDD) Unit of European Institute of Oncology, who performed fresh biopsies for research purpose. We aimed at assessing safety of the biopsies and the adequacy of the tumor tissue for NGS testing.

Results: A total of 731 patients were referred to the EDD Unit from January 2014 to December 2022. Median age was 56 years (range 20 — 83) and 79% of patients were female. The most common tumor type was breast cancer (40%), followed by lung adenocarcinoma (6.2%), cholangiocarcinoma (5.8%), and carcinoma of unknown primary (5.8%). Three hundred fifty-five patients (48.6%) underwent a new biopsy at trial entry. Liver (148, 41.7%), lymph nodes (64, 18%), skin (47, 13.2%) and breast (7.3%) were the most frequent sites for biopsy. The median time from trial's informed consent to biopsy was 3 days (range 0 — 83). The tumor tissue was commonly adequate for histological diagnosis (98%); NGS testing was successful in 122 (88.4%) of the 138 cases in which the trial required NGS testing. Nine out of the 16 unsuccessful NGS were performed on liver tissue. Eleven patients (3.1%) had procedural complications from the biopsy (5 pain, 3 minor bleeding, 2 pneumothoraxes, 1 bradycardia), but none required hospitalization nor led to sequelae. The only treatments administered were painkillers.

Conclusions: Approximately half of the patients referred to our EDD Unit performed a fresh biopsy. The procedure was generally safe, with only a minority of patients (3%) having non-serious complications. About 10% of NGS failed due to poor sample quality or quantity, highlighting the importance to implement specific information and Standard Operating Procedure for samples intended for NGS.

711TiP A phase I/II, first-in-human, open-label, dose-escalation study of TAK-186, an EGFR × CD3ε COBRA T cell engager, in adult patients with unresectable, locally advanced, or metastatic solid tumors

A.J. Weickhardt[1], S. Frentzas[2], C. Lemech[3], J. Srimani[4], J. Yin[5], W.L. Trepicchio[6], C. Gorgun[7], G. Kichenadasse[8]

Background: TAK-186 is a COnditional Bispecific Redirected Activation (COBRA) T-cell engager designed to bind to epidermal growth factor receptor (EGFR). Protease-mediated activation of the prodrug, primarily in the tumor microenviroment, generates an active dimer of EGFR-bound TAK-186 which engages CD3 T cells via the CD3ε binding domain. As the tumor microenvironment has increased protease activity vs healthy tissues, TAK-186 could potentially have an improved safety profile and therapeutic efficacy in solid tumors compared with other T-cell engagers that do not depend on conditional activation.

Trial design: This is a first-in-human, open-label, phase 1/2 study of TAK-186 (NCT04844073), with a planned enrollment of ∼123 patients (pts) with unresectable, locally advanced/metastatic *EGFR*-expressing solid tumors, including but not limited to non-small cell lung cancer (NSCLC), colorectal cancer (CRC), and head and neck squamous cell cancer (HNSCC). Eligibility criteria include age ≥18 yr, ECOG PS ≤1, and measurable disease per RECIST v1.1. Pts who received an immune checkpoint inhibitor (ICI) prior to enrollment must have ICI immune-related toxicity resolved to Grade ≤1 or baseline (prior to ICI). Key exclusion criteria include history of autoimmune disease, major surgery ≤8 wks or radiation therapy <2 wks before first dose of TAK-186, history of clinically significant cardiac or gastrointestinal disorders. The study will be conducted in two phases: a dose-escalation phase (sequential cohorts of escalating doses) followed by a cohort-expansion phase (advanced/metastatic *EGFR*-expressing NSCLC, CRC, HNSCC). Pts will be followed for survival after treatment discontinuation. The primary objective is characterization of safety, tolerability, and dose-limiting toxicities. Secondary objectives include characterization of pharmacokinetics, pharmacodynamics, immunogenicity, and preliminary anti-tumor activity. Tumor evaluation will be done using RECIST 1.1 and modified RECIST 1.1. Safety data will be summarized by CTCAE v5.0. Cytokine release syndrome will be reported by ASTCT consensus grading. Recruitment is ongoing.

Clinical trial identification: NCT04844073.

Background: CDK7, part of the CAK complex regulates cell cycle progression, making it a potential therapeutic target for malignancies with aberrant cell cycle regulation. Cell cycle arrest in cancer cells affects DNA damage repair and genomic instability, potentially triggering apoptosis and anti-tumor immune response. Q901, is a potent covalent CDK7 inhibitor, with demonstrated *in vivo* activity against resistant models, and has potential as a treatment for various cancers where standard care has failed.

Trial design: This phase 1/2 multicenter, open-label study (NCT05394103) evaluates the safety, pharmacodynamics, and pharmacokinetics of Q901 in adult patients with solid tumors in the USA and Korea. In phase 1 dose escalation, Q901 is administered intravenously once weekly for four weeks, then once every two weeks in patients with advanced or metastatic ovarian, CRPC, HR^+ $HER2^-$ breast, endometrial, colorectal, small-cell lung, or pancreatic cancers. The study will establish the MTD, DLT, and RP2D of Q901 monotherapy, using a modified Toxicity Probability Interval (mTPI) design targeting a DLT rate of ∼30%. Up to 6 dose levels/50 patients will be evaluated in phase 1. Upon determining the RP2D, the study advances to phase 2. Cohort 1 will recruit HR^+ $HER2^-$ breast cancer patients receiving Q901 combined with fulvestrant, who have received at prior endocrine and CDK4/6 targeted treatment, along with up to two additional prior lines of systemic anticancer therapy. Cohort 2 consists of extensive-stage SCLC patients treated with Q901 monotherapy after failing first-line standard of care. Each cohort will enroll up to 20 patients to assess safety and activity in selected cancer types.

Clinical trial identification: NCT05394103.

Background: Genes encoding subunits of the switch/sucrose non-fermentable (SWI/SNF) chromatin remodeling complex are often mutated in cancer, occurring in 20% of all human cancers (Shain *PLOS One* 2013 ; Fernando *Nat Commun* 2020). The SWI/SNF complex contains 1 of 2 mutually exclusive ATP catalytic enzymatic subunits, SMARCA2 (BRM) or SMARCA4 (BRG1). Cells with SMARCA4 loss rely on its paralog, SMARCA2, making it an attractive therapeutic target (Helming *Cancer Cell* 2014 ; Hoffman *PNAS* 2014 ; Oike *Cancer Res* 2013). Multiple tumor types have *SMARCA4* mutations, including thoracic sarcomas, lymphomas, and cancers of the lung, ovaries, and skin (Shain 2013 ; Fernando 2020). PRT3789 induces proteosome-dependent degradation of SMARCA2. Preclinical data indicate that PRT3789 is a potent and selective degrader of SMARCA2, which induces robust synthetic lethality in SMARCA4-deficient cancers.

Trial design: This phase 1 (NCT05639751), open label, multicenter, dose-finding study evaluates the safety, tolerability, preliminary efficacy, pharmacokinetics (PK), and pharmacodynamics (PD) of PRT3789. Adults with advanced or metastatic solid tumors with a SMARCA4 mutation, who have progressed on, or are intolerant to, standard therapy are eligible to enroll. Other key eligibility criteria include measurable disease by RECIST v1.1 or nonmeasurable (but evaluable) disease, ECOG PS 0—1, and resolved acute effects of prior therapy. Successive cohorts will receive escalating doses of intravenous PRT3789 once weekly for 3 weeks (1 cycle). PRT3789 treatment will continue until disease progression or unacceptable toxicity, whichever occurs first. A Bayesian optimal interval method will inform dose escalation, de-escalation, or maintenance based on the number of patients with dose-limiting toxicities (DLTs), until the maximum tolerated dose and recommended phase 2 dose (RP2D) are determined. The primary endpoints are safety, tolerability, DLTs, and RP2D. Secondary endpoints include objective response rate, progression-free survival, duration of response, disease control rate, and PK and PD profiles of PRT3789. The study began enrolling patients in January 2023.

Clinical trial identification: NCT05639751.

714TiP A phase Ia/Ib, first-in-human, dose-escalation study evaluating the safety, tolerability, and efficacy of IOS-1002, a LILRB1, LILRB2, and KIR3DL1 targeting HLA-derived fusion protein administered alone or in combination with a PD-1 antibody in patients with advanced solid tumors

S.J. Luen[1], E.S. Ahern[2], C. Berger[3], J. Desai[4], S. Frentzas[5], H. Gan[6], M. Gualandi[7], B. Markman[8], M. Millward[9], A. Rafiei[7], B. Tran[4], C. Renner[3]

[1]Cancer Medicine Department, Peter MacCallum Cancer Center, Melbourne, VIC, Australia; [2]Medical Oncology, Monash Health-Monash Medical Centre, Clayton, QLD, Australia; [3]Clinical Development, ImmunOs Therapeutics AG, Zurich, Switzerland; [4]Medical Oncology Dept., Peter MacCallum Cancer Centre, Melbourne, VIC, Australia; [5]Medical Oncology Department, Monash Health-Monash Cancer Centre, Bentleigh East, VIC, Australia; [6]Medical Oncology, Austin Health-Austin Hospital, Heidelberg, VIC, Australia; [7]Research&Development, ImmunOs Therapeutics AG, Zurich, Switzerland; [8]Medical Oncology, Alfred Hospital, Melbourne, VIC, Australia; [9]School of Medicine, University of Western Australia, Perth, WA, Australia

Background: IOS-1002 is a recombinant homodimer of the human leukocyte antigen B57 free heavy chain linked to a human IgG4 Fc backbone associated with human β2 microglobulin. The binding of IOS-1002 to LILRB1, LILRB2, and KIR3DL1 receptors blocks the interaction with tumor-expressed ligands such as HLA-G. Through this mechanism, IOS-1002 enhances the immune response of diverse sets of both innate and adaptive immune cells and leads to tumor cell killing. The anti-tumor effect is enhanced by combining IOS-1002 with a PD-1 check point blockade inhibitor in preclinical models The present study evaluates the safety, tolerability, pharmacokinetics, efficacy, immunogenicity, and pharmacodynamics of IOS-1002 as monotherapy and as combination therapy with a PD-1 monoclonal antibody in subjects with advanced solid tumors.

Trial design: The phase 1a/1b trial is being conducted at five sites in Australia and has started enrollment as of March 2023. The trial is separated in 2 parts: Dose Escalation (A): Subjects are enrolled into 10, 30, 100, 300, 800, and 1200 mg dose levels sequentially and treated with IOS-1002 Q2W IV. Guided by the dose-limiting toxicities (DLTs) observed, an accelerated dose titration design is used for the first 3 dose levels followed by a 3+3 dose escalation. The DLT period is defined as 4 weeks following cycle 1 day 1 infusion. Once monotherapy reaches the 800 mg dose level, the combination therapy with a 3 + 3 dose escalation starts at a dose of 300 mg Q2W for IOS-1002 in combination with a PD-1 mAb at approved dose and schedule. The IOS-1002 RP2D or MAD as identified for monotherapy and PD-1 combination will then be used in the dose expansion part. Dose Expansion (B): Following the toxicity and activity profile observed in part A, a tumor-specific cohort expansion study in up to 6 potential disease entities with 20 patients per cohort will be initiated, 3 as IOS-1002 monotherapy and 3 as IOS-1002 + PD-1 combination. Depending on the disease entity and line of treatment, the PD-1 cohort will include PD-1 naïve, pre-exposed and refractory patients, respectively.

Clinical trial identification: Clinical Trials Registry Number: NCT05763004.

715TiP ARTS-021-1001: Phase I/II study of ARTS-021, a potent, oral administrated, selective CDK2 inhibitor, in advanced or metastatic solid tumors

Y. Wang[1], Q. Sheng[1], T. Ji[1], J. Liang[2], N. Schomer[1], J. Fu[2], T. Zhang[2], W. Xiong[2], D. Cheng[2], Z. Liu[2], Q. Ding[2], F. Li[1], Y. Chen[1], G. Berk[1]

[1]Allorion Therapeutics, Inc., Natick, MA, USA; [2]Allorion Therapeutics, Inc., Guangzhou, China

Background: ARTS-021 is an investigational, reversible, orally administrated CDK2 selective inhibitor that inhibits CDK2 at nanomolar potency and with over 600-fold selectivity against CDK1. Results from pre-clinical research support ARTS-021 as a monotherapy in CCNE1-amplified cancers and in combination with CDK4/6 inhibitors in ER+ breast cancer.

Trial design: This is a first in human, open label, multicenter phase1/2 dose escalation and dose expansion study to evaluate the safety, tolerability, PK, PD, and anti-tumor activity of ARTS-021 1) as a single agent in advanced or metastatic CCNE-1 amplifed solid tumors; 2) in combination with Carboplatin to treat refractory/resistant CCNE-1 amplified ovarian cancer that has failed standard therapies; 3) in combination with endocrine therapy (fulvestrant/letrozole) and CDK4/6 inhibitor(palbociclib/ribociclib/abemaciclib) to treat HR+ HER2- breast cancer patients have failed standard therapies. The phase 1 (dose-escalation) portion will have an accelerated dose escalation followed by a BOIN design. After R2PD is identified, the combination arms will be initiated at one dose level below the monotherapy R2PD. Phase 1 primary endpoints are assessment of safety, tolerability, and pharmacokinetics (PK). The secondary endpoint is preliminary efficacy. Once the RP2D is defined for both monotherapy and in combination, the trial will be advanced into three phase 2 expansion cohorts: monotherapy cohort (basket cohort), combination with Carboplatin (ovarian cohort), and combination with endocrine therapy (fulvestrant/letrozole) + CDK4/6 inhibitor (palbociclib/ribociclib/abemaciclib) (HR+ HER- breast cancer cohort). In addition, a food effect cohort will be included in the monotherapy basket cohort. The phase 2 primary end point is to estimate the anti-tumor efficacy in CCNE1 amplified cancer patients or CDK4/6 inhibitor resistant breast cancer patients. Objective tumor response rate will be measured per RECIST v1.1. The secondary endpoint of phase 2 study will be safety/tolerability. Archival tumor and paired fresh tumor biopsy will be collected throughout the study for exploratory pharmacodynamics (PD) and biomarker evaluation.

Background: Precision medicine (PM) is transforming outcomes in cancer. Increasingly, through the nationwide uptake of genomic profiling, actionable alterations are identified in patients that could benefit from targeted therapies licensed in other indications. Rare cancers are under-represented in PM trials yet account for 22% of cancers overall and have limited treatment options. There is also a lack of translational research to understand differential outcomes in treatment response. Opportunity exists to fine-tune biomarker selection to repurpose existing therapies in rare cancer indications and identify novel therapeutic targets.

Trial design: DETERMINE (www.cruk.org/determine) is an innovative, multi-pharmaceutical open-label phase II 'umbrella-basket' platform trial developed with patient and public involvement. The study will evaluate the efficacy of licensed targeted medicines in unlicensed indications in rare adult, paediatric and teenage young adult cancers with actionable genomic alterations. All patients will undergo a mandatory baseline biopsy to facilitate a comprehensive translational research programme, evaluating the genomic, transcriptomic, and immune microenvironment of rare tumours. Main eligibility criteria include children and adults (age agnostic), diagnosed with an advanced cancer (tumour agnostic), actionable genomic alteration (identified through standard of care profiling), and good performance status. The co-primary outcome measures are objective response and durable clinical benefit (absence of disease progression for at least 24 weeks). Eligible patients will be matched to treatment arms by a national molecular tumour board. A Bayesian adaptive design accounting for tumour histology, age and translational context will enable signals of efficacy to be identified in small numbers of patients, enabling application of learned observations for refinement of patient selection. Promising cohorts will be submitted to the CDF, who together with the NHS Clinical Policy team, will decide if a period of data collection is necessary to consider the drug as a routine treatment on the NHS. The study (opened Nov 2022) will enrol up to 650 patients over a 5 year period across the Experimental Cancer Medicine Centre network.

Clinical trial identification: NCT05722886.

Legal entity responsible for the study: Cancer Research UK Centre for Drug Development.

Funding: Roche Products Ltd. (UK) are providing seven drugs as part of the clinical study and have financially supported the initial set up of the study. Novartis Pharmaceuticals UK Limited are providing funds to support a treatment arm for the study.

717TiP An open-label, multicentre, dose-escalation, first-in-human phase I study to evaluate safety, tolerability and antineoplastic activity of OATD-02 (dual arginase 1 and arginase 2 inhibitor) in patients with selected advanced and/or metastatic solid tumors

M.A. Dudek[1], Z. Zasłona[2], R. Błaszczyk[3], M.M. Grzybowski[2], T. Rejczak[4], A. Cabaj[5], P. Dera[5], K. Lisiecki[6], P. Iwanowski[1], T. Charitos[1], S. Fung[1]

[1]Clinical Department, Molecure SA, Warsaw, Poland; [2]Biology, Molecure SA, Warsaw, Poland; [3]Medicinal Chemistry, Molecure SA, Warsaw, Poland; [4]DMPK, Molecure SA, Warsaw, Poland; [5]Preclinical Safety, Molecure SA, Warsaw, Poland; [6]CMC, Molecure SA, Warsaw, Poland

Background: Despite recent therapeutic progress, patients with advanced/metastatic solid tumors have limited options after standard of care therapies and high unmet medical needs. The arginine metabolism pathway is hyperreactive in several cancers and overexpression of arginases, arginase 1 (ARG1) and arginase 2 (ARG2), is considered as a poor prognostic factor and major contributor to the immunosuppressive tumor microenvironment. OATD-02 is the only small molecule with dual activity against intracellular ARG1 and ARG2. Data from non-clinical studies showed dose-dependent tumor growth inhibition with an associated increase in arginine levels in monotherapy setting. Prediction of human pharmacokinetics (PK) of OATD-02 resulted in a moderate oral bioavailability of 35% and the half-life of approx. 33 h.

Trial design: This phase I, open-label First-In-Human clinical study aims to determine if OATD-02 administration as a monotherapy is safe and results in immune activation effects through increased arginine levels and/or intrinsic anti-tumor activity. OATD-02 will be administered in patients with advanced and/or metastatic colorectal cancer, ovarian cancer, pancreatic ductal adenocarcinoma, or renal cell carcinoma. Up to 40 patients will be enrolled to receive OATD-02 orally q.d. until disease progression. The study will follow Bayesian Optimal Interval (BOIN) dose escalation/de-escalation design with overdose control based on dose-limiting toxicities (DLTs) during the evaluation period (first cycle). Six pre-defined dose levels are planned to be explored ranging from 2.5 mg to 30 mg. Primary endpoints include nature, frequency and severity of adverse events (AEs), and occurrence of DLTs. Secondary endpoints: PK and arginine assessments, anti-tumor activity parameters. Exploratory endpoints for safety and biologic effects include pharmacodynamic biomarkers (e.g. arginase, ornithine, microRNA), orotic acid and metabolites characterisation. As of May 2023, two patients have been enrolled. The study is ongoing. Clinical trial information: NCT05759923.

Clinical trial identification: EudraCT 2022-000697-25. Study Protocol No: OATD-02-C-01. Protocol version and date: Final version 2.0, 13 December 2022. NCT05759923.

718TiP DEKA-1 a dose-finding phase I trial: Observing safety and biomarkers using DK210 (EGFR) for inoperable locally advanced and/or metastatic EGFR+ tumors with progressive disease failing systemic therapy

E. Moser[1], M. Salkeni[2], A. Marabelle[3], D. Kientop[1], J. Mumm[4]

[1]Clinical, Deka Biosciences, Germantown, MD, USA; [2]Medical Oncology, NEXT OncologyTM, Fairfax, VA, USA; [3]Drug Development Department, Institut Gustave Roussy, Villejuif, France; [4]Preclinical, DEKA Biosciences, Inc., Germantown, MD, USA

Background: Both interleukin-2 (IL-2) and interleukin-10 (IL-10) have been extensively studied for their stimulatory function on T cells and their potential to obtain sustainable tumor control in RCC, melanoma, lung, and pancreatic cancer as monotherapy, as well as combination with PD-1 blockers, radiation, and chemotherapy. While approved, IL-2 retains significant toxicity, preventing its widespread use. The significant efforts undertaken to uncouple IL-2 toxicity from its anti-tumor function have been unsuccessful and early phase clinical safety observed with PEGylated IL-10 was not met in a blinded phase 3 trial. Deka Biosciences has engineered a novel molecule coupling wild-type IL-2 to a high affinity variant of Epstein Barr Viral (EBV) IL-10 via a scaffold (scFv) that binds to epidermal growth factor receptors (EGFR). This patented molecule, termed $DK2^{10}$ (EGFR), is retained at high levels within the tumor microenvironment for days after dosing. In addition to overlapping and non-redundant anti-tumor function, IL-10 reduces IL-2 mediated cytokine release syndrome risks and inhibits IL-2 mediated T regulatory cell proliferation.

Trial design: $DK2^{10}$ (EGFR) is being evaluated in an open-label, dose-escalation (phase 1) study with 5 (0.025-0.3 mg/kg) monotherapy dose levels, and (expansion cohorts) in combination with PD-1 blockers, or radiation or chemotherapy in patients with advanced solid tumors overexpressing EGFR. Key eligibility criteria include: 1) confirmed progressive disease on at least one line of systemic treatment, 2) EGFR overexpression or amplification documented in histology reports, 3) at least a 4 week or 5 half-lives window since last treatment, and 4) excluding subjects with long QT syndrome, multiple myeloma, multiple sclerosis, myasthenia gravis or uncontrolled infectious, psychiatric, neurologic, or cancer disease. Plasma and tissue samples will be investigated for pharmacodynamic and predictive biomarkers and genetic signatures associated with IFN-gamma secretion, aiming to select subjects for treatment in phase 2.

Clinical trial identification: NCT05704985.

719TiP A phase I/Ib study of the Werner (WRN) helicase inhibitor HRO761 as single agent and in combination with irinotecan or tislelizumab in patients with microsatellite instability-high (MSIhi) or mismatch repair deficient (dMMR) advanced solid tumors

M. Moschetta[1], T. Doi[2], Y. Kuboki[2], R. Sundar[3], H. Möbitz[4], I. Jaco[4], M. Cortes Cros[4], S. Ferretti[4], D. Jankovic[1], M. Thérier[1], G. Clementi[1], Y. Li[5], R. De Kanter[4], C. Quadt[1]

[1]Translational Clinical Oncology, Novartis Institutes for Biomedical Research (NIBR), Basel, Switzerland; [2]Experimental Therapeutics Department, National Cancer Center Hospital East, Kashiwashi, Japan; [3]Haematology-Oncology, NUHS-National University Health System, Singapore; [4]Oncology, Novartis Institutes for Biomedical Research (NIBR), Basel, Switzerland; [5]Global Drug Development, Novartis Pharmaceuticals Corporation, East Hanover, NJ, USA

Background: HRO761 is a first-in-class selective WRN inhibitor that binds allosterically to the helicase domain of the WRN protein locking it in an inactive conformation. HRO761 has shown anti-tumor activity in MSIhi preclinical models.

Trial design: This is a phase I/Ib (NCT05838768), global, multicenter (approximately 27 sites to open across 14 countries) dose finding study that consists of a dose escalation part to allow the determination of a dose range for optimization (DRO) or a recommended dose (RD) for HRO761 single agent (s.a.), and an optional randomized dose optimization part (Arm A). HRO761 will be administered orally daily in a 28-day cycle. The dose escalation part will enroll MSIhi/dMMR advanced/metastatic (a/m) CRC and solid tumors (approximately 40 patients), and the randomized dose optimization part will enroll patients with a/m MSIhi /dMMR CRC (20 patients per dose) and solid tumors (up to 10 pts per dose). Based on an integrated analysis of the safety, tolerability, pharmacokinetic, pharmacodynamic, and preliminary anti-tumor activity data of HRO761, RD will be determined and subsequently tested in optional expansion arms of a/m MSIhi/dMMR CRC (20-40 patients), and solid tumor (20-40 patients). HRO761 at the RD will be investigated in a dose escalation in combination with either tislelizumab (Arm B) or irinotecan (Arm C) to determine the RD of the combinations. After the determination of the RDs, the combination treatments will be tested in expansion cohorts of a/m MSIhi or dMMR CRC and other solid tumors. AEs will be assessed according to CTCAE v5. Tumor response will be determined according to RECIST 1.1 criteria. Key eligibility criteria include: 1) Patients with advanced unresectable or metastatic MSIhi or dMMR solid tumors who have progressed after or are intolerant to prior standard therapy; 2) patients should have received at least one prior line of chemotherapy or targeted therapy, and prior immune checkpoint inhibitor therapy (Arm A and C). Checkpoint inhibitor therapy is permitted but not required and prior adjuvant therapy is allowed in Arm B.

Clinical trial identification: NCT05838768, First posted 3 May 2023.

720TiP Phase I, open-label, first-in-human (FIH) study of JZP815 in advanced or metastatic solid tumors harboring mitogen-activated protein kinase (MAPK) alterations

A-R. Naqash[1], J.S. Wang[2], C.A. Perez[3], J.T. Henry[4], B. Bashir[5], A. Panneerselvam[6], S. Markova[7], R.S. Cheung[8], D.R. Spigel[9]

[1]Department of Medical Oncology/Phase 1 program, Stephenson Cancer Center, University of Oklahoma, Oklahoma City, OK, USA; [2]Department of Drug Development, Florida Cancer Specialists & Research Institute-Lake Mary Cancer Center, Sarasota, FL, USA; [3]Department of Drug Development, Sarah Cannon Research Institute at Florida Cancer Specialists, Orlando, FL, USA; [4]Department of Research, Sarah Cannon Research Institute at HealthONE, Denver, CO, USA; [5]Department of Medical Oncology, Sidney Kimmel Cancer Center-Thomas Jefferson University Hospital, Philadelphia, PA, USA; [6]Department of Biostatistics, Jazz Pharmaceuticals, Palo Alto, CA, USA; [7]Department of Global Clinical Pharmacology and Pharmacometrics, Jazz Pharmaceuticals, Palo Alto, CA, USA; [8]Department of Clinical Development, Jazz Pharmaceuticals, Palo Alto, CA, USA; [9]Department of Oncology, Sarah Cannon Research Institute and Tennessee Oncology, Nashville, TN, USA

Background: MAPK activation by RAS and RAF mutations often drives human cancer. Targeting MAPK represents a promising route for drug development. JZP815 is a potent, selective pan-RAF kinase inhibitor that binds RAF proteins which inhibits MAPK signaling and tumor cell growth. Preclinically, JZP815 inhibited solid tumor growth in xenograft models harboring *RAS/BRAF* mutations, repressed a MAPK signaling marker, and generated synergy with other MAPK inhibitors.[1] JZP815 also inhibited BRAF-CRAF dimer activity, representing a known resistance mechanism to $BRAF^{V600E}$-specific inhibitors. The profile of JZP815 supports its progress into this FIH study.

Trial design: This phase I, open-label, multicenter study (NCT05557045) investigates the safety, dosing, and JZP815 antitumor activity in patients $\geq$18 years old with advanced or metastatic solid tumors harboring a documented, clinically significant alteration in MAPK. The study comprises a dose exploration phase (Part A) to characterize safety and tolerability, determine maximum tolerated dose (MTD) and/or recommended phase 2 dose (RP2D), and pharmacokinetic (PK) profile; Part B is an expansion phase to further assess RP2D and examine antitumor activities across patient subsets based on mutation and/or tumor type, including $NRAS^{Q61}$-mutated melanoma. The starting dose is 20 mg twice daily (oral capsules). In Part A, MTD will be based on dose-limiting toxicities (DLTs) using a Bayesian optimal interval design. Patients ($n \leq 6$) may then be enrolled in pre-expansion cohorts at doses at or below MTD to obtain further safety, PK, and pharmacodynamics data before identifying RP2D. Patients will be treated until disease progression, death, unacceptable toxicity, or withdrawal. Primary endpoints include incidence and nature of DLTs (Part A), objective response rate per RECIST 1.1 (Part B), duration of response (Part B), and adverse events, changes in laboratory values or vital signs, and dose interruptions and reductions (Parts A and B). The study is enrolling with planned enrollment up to 332 patients. 1 Hauptschein R, et al. *Cancer Res*. 2022;82:2677. https://doi.org/10.1158/1538-7445.AM2022-2677

722TiP CLAUDIO-01: A multicentric phase I/II trial to evaluate the safety and efficacy of SOT102 as monotherapy and in combination with standard of care (SoC) in patients with gastric, gastroesophageal junction(GEJ), and pancreatic adenocarcinoma

R. Obermannova[1], A. Hollebecque[2], T. Macarulla[3], R. Alvarez Gallego[4], E. Van Cutsem[5], R.S. Conde[6], A-R. Hanauske[7], V. Boura[8], J. Tabernero[9]

[1]Department of Comprehensive Cance Care, Masaryk Memorial Cancer Institute, Brno, Czech Republic; [2]DITEP, Institut Gustave Roussy, Villejuif, France; [3]Medical Oncology Dept., Vall d'Hebron Institute of Oncology (VHIO)-Cellex Center, Barcelona, Spain; [4]Integral Oncologico Clara Campal, Hospital Madrid Norte San Chinarro-Centro Integral Oncologico Clara Campal, Madrid, Spain; [5]Digestive Oncology Department, UZ Leuven-University Hospitals Leuven-Campus Gasthuisberg, Leuven, Belgium; [6]Medical Oncology Department, Institute Jules Bordet, Brussels, Belgium; [7]H-Consulting, Hamburg, Germany; [8]Clinical Development, SOTIO Biotech AG, Basel, Switzerland; [9]Medical Oncology Dept., Vall d'Hebron University Hospital, Barcelona, Spain

Background: SOT102 is an antibody-drug conjugate targeting CLDN18.2, based on a highly specific monoclonal antibody conjugated to PNU-159682, an anthracycline derivative, using site-specific conjugation technology. Preclinical data support the development of SOT102 in the clinical setting.

Trial design: CLAUDIO-01 is a multicenter, multimodular phase I/II trial in gastric/GEJ and pancreatic cancer patients in both advanced and first line. The trial consists of the following modules: • Part A: First-in-human, CLDN18.2 agnostic, single-agent dose escalation trial of SOT102 in advanced or metastatic gastric/GEJ or pancreatic cancer patients • Part B gastric, GEJ cohort/pancreatic cohort: CLDN18.2 agnostic dose escalation trial of SOT102 in combination with SoC for first-line treatment of patients with advanced or metastatic gastric/GEJ cancer (SoC: mFOLFOX with nivolumab) or pancreatic cancer (SoC: nab-paclitaxel/gemcitabine), which will start once monotherapy SOT102 dose level 3 in Part A is deemed safe The following expansion cohorts are planned upon identification of the recommended phase 2 dose (RP2D): • Part C gastric, GEJ/pancreatic cohort: Single-agent SOT102 in CLDN18.2 positive gastric/GEJ cancer patients after two or more prior systemic therapies and in pancreatic cancer after one or more prior systemic therapies. • Part D gastric, GEJ/pancreatic cohort: SOT102 in combination with SoC for first-line treatment in CLDN18.2 positive gastric/GEJ and pancreatic cancer patients Dose escalation follows an accelerated modified Fibonacci scheme with cohort sizes of 3+3 and includes safety observation periods. Monotherapy dose escalation is ongoing at the third dose level without dose-limiting toxicity. Enrollment to dose level 4 of Part A and to dose level 1 in both cohorts of Part B are planned to begin in June 2023. Primary objectives and endpoints: -To determine the MTD and RP2D of SOT102 as monotherapy and in combination with first-line SoC treatment (Parts A and B) - To assess the efficacy of SOT102 in monotherapy and in combination with first-line SoC treatment by ORR (Parts C and D).

Background: Angiogenesis plays a key role in development and progression of endocrine neoplasms and synergism has been observed when combined with immune-checkpoint inhibitors in other tumors. We aimed to demonstrate the activity and safety of cabozantinib (cabo) plus atezolizumab (atezo) in different endocrine neoplasms refractory to standard therapies.

Methods: This is a prospective, multi-center, open-label, phase II study including patients (pts) with advanced and refractory endocrine tumors in 6 independent cohorts (C): (1) well-differentiated neuroendocrine tumors of the lung (LungNET), (2) anaplastic thyroid cancer (ATC), (3) adrenocortical carcinoma (ACC), (4) pheochromocytoma/ paraganglioma (PPGL), (5) well-differentiated gastroenteropancreatic NET (GEPNET), (6) grade 3 extrapulmonary neuroendocrine neoplasms (G3 EP-NEN). All pts received atezo 1200 mg IV Q3W plus cabo 40 mg/day PO until progression or unacceptable toxicity. The primary endpoint was Overall Response Rate (ORR) by RECIST 1.1. With a Simon II stage design, 1 response of 9 pts/C were needed at 1st stage to continue accrual in 2nd stage. C1 and C6 did not pass 1st stage, and C2 and C4 were closed due to slow accrual.

Results: 93 pts were enrolled. Cabo and atezo were administered for a median of 5.8 m (95% CI: 3.4-7.5) and 6.3 m (95% CI: 3.5-7.7), respectively. Most frequent grade $\geq$3 toxicities were fatigue (7.5%), neutropenia (6.5%) and liver enzyme increase (6.5%). 2 pts died due to drug-related ischemic stroke and pancreatitis. Due to AE's, cabo and atezo treatment was interrupted in 67.7% and 35.5% of pts, and discontinued in 16.1% and 14% of pts, respectively. Cabo was reduced to 20 mg/day in 41.9% of pts. Survival was similar regardless of cabo reduction.

Table: 723O

	LungNET	ATC	ACC	PPGL	GEPNET	G3 EP-NEN
N	9	14	24	13	24	9
ORR (%)	0	21.4	8.3	7.7	16.7	0
median PFS (m [95% CI])	8.4 [7.7-NR]	4.1 [2.7-NR]	2.9 [2.8-5.7]	8.6 [5.7-NR]	13 [11.2-NR]	2.7 [2.6-NR]

Conclusions: Cabo plus atezo showed limited activity in progressive / refractory endocrine malignancies, surpassing the futility threshold in ATC. Atezo does not improve the outcomes of cabo as a single agent in NEN.

Clinical trial identification: EudraCT 2019-002279-32; NCT04400474.

Background: E expands memory T cells recognizing proteins from gut bacteria, which cross-react with tumor associated antigens. E contains 3 CD8 HLA-A2 epitopes with mimicry to IL13Rα2, BIRC5, and FOXM1, and the CD4 epitope UCP2.

Methods: Patients (pt) received E (300 µg/peptide, q2w x4 then q4w) with N (240 mg q2w x3 then 480 mg q4w) in cohorts: C1 (safety lead-in); ACC in C2a and C2b with 2nd/3rd and 1st -line systemic therapy metastatic disease, respectively; MPP in C3a after prior and in C3b as 1st -line systemic therapy. Based on C2a results, a randomized extension, RND-C2a, was initiated (65 pt, 4:1:1, E/N vs E vs N).

Results: Recruitment to C1, C2a and C2b is completed, MPP cohorts and RND-C2a are recruiting (Table). EN was well tolerated in C1 (3 pt) and thereafter, with E associated events limited to local skin events (50% of pt Gr 1/2, 4% Gr 3) and N-tox in expected range. Two main groups for C2a efficacy, one with no benefit (10 pt PD/death <week 8), one with better outcome (10 pt SD > week 8). No impact of TMB, MSI-status, PD-L1 expression, cytokines, chemokines, or hormones on efficacy. Post-hoc analyses identified predictors of lack of efficacy (no mitotane, ECOG > 1, ACC 1st diagnosis $\leq$9 months(mo), lesion size >125 mm, >3 organs involved, lymphopenia >grade 1); C2-post hoc group was created applying these factors.

EN induced specific T cell expansion in 91% of tested pt (67% of all treated pt); durations up to 19 mo. Strength of immune response correlated with progression-free survival.

Table: 724O

Cohort	Ongoing trt	DC = SD/PR/CR	Duration DC*˜	OR = PR/CR	Duration OR^	Progression-free survival*	Survival*	Alive	Follow-up survival*
ACC 2nd/3rd line

Background: DLL3 is highly expressed on small-cell lung cancer (SCLC) tumours and neuroendocrine carcinomas (NECs). BI 764532 is a DLL3/CD3 IgG-like T cell engager with potent preclinical activity. NCT04429087 is an ongoing phase I dose-escalation trial of BI 764532 in adults with locally advanced/metastatic DLL3+ (confirmed centrally) SCLC, extrapulmonary (ep) NEC or large cell neuroendocrine lung carcinoma. Here we focus on pts with epNEC.

Methods: BI 764532 was given intravenously in 4 regimens: Regimen A (RA; fixed dose q3w); RB1 (fixed dose qw); RB2 (step-in doses, then fixed dose); RB3 (step-in, followed by target dose). Treatment (Tx) continued until progressive disease, unacceptable toxicity, other withdrawal criteria or maximum Tx duration (36 months). Main objective: maximum tolerated dose (MTD) and/or recommended dose for expansion of BI 764532. Other objectives: safety, tolerability, pharmacokinetics, pharmacodynamics and preliminary efficacy based on investigator review (RECIST v1.1).

Results: As of 26 July 2023, 129 pts received ≥1 dose (≥ 0.03 µg/kg) of BI 764532 (RA: n=24; RB1: n=10; RB2: n=79; RB3: n=16). Male: 59%; median age: 60 (range 32−81); ECOG PS 0/1: 28/71%; prior PD1/PD-L1 Tx: 49%; ≥2 prior lines of Tx: 70%. Dose limiting toxicities: 1 pt on RA (Grade [G]3 confusion) and 6 pts on RB2 (G5 immune effector cell-associated neurotoxicity syndrome [ICANS]; G4 cytokine release syndrome [CRS]; G3 CRS; G3 ICANS; G3 nervous system disorder and G2 infusion-related reaction). MTD has not been reached; dose escalation is ongoing. 53 pts with epNEC have been treated (ongoing in 14). TRAEs (any/G≥3): 92/17%. The most common TRAEs (any/G≥3) were: CRS (72/4%); pyrexia (26/0%); dysgeusia (19/0%) and fatigue (17/0%); there were no Tx discontinuations due to TRAEs.
In the efficacy population, there were 46 pts with epNEC (gastrointestinal: n=23; genitourinary: n=16; unknown origin: n=7). ORR/DCR was 22/41%. In pts who received clinically active doses of BI 764532 (n=36), ORR/DCR was 28/47%.

Conclusions: BI 764532 showed clinically manageable tolerability; MTD has not been reached. Promising efficacy was observed in pts with epNEC. The study is ongoing.

Clinical trial identification: NCT04429087.

Endocrinology and Diabetes, UKW-University Hospital Würzburg, Würzburg, Germany; [5]Comprehensive Cancer Centre Mainfranken, University of Würzburg, Würzburg, Germany; [6]Endocrine Department, Queen Elizabeth Hospital-University Hospitals Birmingham NHS Foundation Trust, Birmingham, UK; [7]Institute for Pathology, University of Würzburg, Würzburg, Germany; [8]MRC LMS, MRC London Institute of Medical Science, London, UK; [9]Department of Internal Medicine I-Division of Endocrinology, University Hospital Würzburg, Würzburg, Germany

Background: Adrenocortical carcinoma (ACC) is a rare aggressive endocrine cancer with heterogeneous behaviour. Disease surveillance relies on frequent imaging, which comes with significant radiation exposure. We investigated the role of circulating cell-free DNA (ccfDNA)-related biomarkers (BM) for prognostication and monitoring of ACC.

Methods: We studied 33 patients with primary ACC and 23 healthy subjects (HS) as controls. ccfDNA was extracted by commercial kits from pre-surgical and serial EDTA plasma samples and quantified by fluorimeter (BM1). All ccfDNA samples passed the quality check showing a desired fragment length of 150-200 bp. Primary tumour DNA was isolated from paraffin-embedded tissue for 25/33 patients. Next-generation sequencing was performed using a customised panel of 30 ACC-specific genes (Cell3^{TM} Target Nonacus). Leucocyte DNA was sequenced to discriminate germline from somatic variants (BM2). BM1 and BM2 were merged into a combined ccfDNA-BM score to be correlated with clinical outcome.

Results: ccfDNA concentrations were higher in ACC than HS (median 0.40 *vs* 0.05 ng/µl, $P<0.001$) and correlated with tumour stage and ki67 index (R=0.48 and 0.55, respectively). 94% of ACC were positive for BM1 (cut off 0.146 ng/µl, median HS+2SD) and 45.5% for BM2 (at least one somatic mutation in ccfDNA, variant allele frequency 1.0-30.5%). Mutational status at ccfDNA matched with tumour DNA in 60% of cases (additional variants in 16% and missed variants in 12%). ccfDNA-BM score (0-1=negative, 2-3=positive) was strongly associated with progression-free and overall survival ($P=0.0004$, HR=8.68, 95%CI=2.88-26.5, and $P=0.003$, HR=3.35, 95% CI=1.34-8.37, respectively). Among 13 patients followed up for at least 3 months (range 1-6), 10 tumour-free at last imaging and 1/3 with early relapse had negative ccfDNA-BM score (100% *vs* 33%). In two recurrent cases, somatic mutations in ACC-specific genes remained detectable during monitoring.

Conclusions: ccfDNA-related BMs are frequently detected in patients with ACC, representing a promising non-invasive tool to predict early disease recurrence and complement imaging for monitoring. Our findings will be validated in a larger cohort of ACCs with long-term follow up.

727P Clinical outcome of anlotinib (A) and tislelizumab (T) in metastatic adrenocortical carcinoma(mACC): A one-arm single-center experience

H. Li[1], T. Su[2], J. Jiang[1], R. Ren[1]

[1]Department of Oncology, Ruijin Hospital, Shanghai Jiaotong University School of Medicine, Shanghai, China; [2]Department of Endocrinology, Ruijin Hospital, Shanghai Jiaotong University School of Medicine, Shanghai, China

Background: Adrenocortical carcinoma is a rare malignant disease with few treatment options. The combination of etoposide, doxorubicin and cisplatin with or without mitotane known as EDP/M, is recommended as first -line regimen based on FIRMACT study. It shows limited efficacy and intolerable toxicities. There is no standard second-line treatment, but antiangiogenesis therapy and PD-1 checkpoint inhibitors are widely applied in clinical practice. Here, we report the efficacy and safety of A, a multi-targeted tyrosine kinase inhibitor that inhibits VEGFR, FGFR, PDGFR, and c-Kit, combined with T, an immune checkpoint inhibitor, in the treatment of mACC.

Methods: Data was collected from electronic medical system at our center between 2019 and 2022. Patients who were diagnosed as mACC and treated with A+T regardless of prior therapy were included. Patients accepted A 12 mg once daily PO from day 1 to 14 and T 200mg IV on day 1 every 3 weeks. Baseline characteristics were recorded. Objective response rate(ORR) and disease control rate(DCR) were evaluated according to RECIST v1.1 and treatment related adverse events(TRAE) according to CTCAE v5.0. Progression free survival(PFS) and overall survival(OS) were analyzed using Kaplan Meier method.

Results: Overall, 37 patients were included. Median age was 50 years(19-76). 51.4%(19/37) were male. Median number of metastatic sites was 3. Median follow-up was 41 months. ORR was 35.1%(1 CR and 12 PR) and DCR was 78.4%(29/37). Median PFS was 8.2 months(95%CI 1.4-24.7) and median OS had not reached. Any grade TRAE rate was 89.2%(33/37) and grade 3/4 TRAE rate was 29.7%(11/37). No treatment related death was observed. Most common grade 3/4 TRAE included proteinuria(10.8%, 4/37), fatigue(8.1%, 3/37), adrenal crisis(5.4%, 2/37) and hepatic enzyme increase(5.4%, 2/37).

Conclusions: The combination of A and T showed promising clinical benefits with moderate toxicities in mACC patients. A+T might become a potential treatment option which need to be further confirmed in the randomized controlled clinical trial.

728P Brain metastases in advanced thyroid carcinoma: Clinical and molecular characteristics and outcomes

T. Megid[1], C.C. Barron[2], E.F. Saldanha[3], G.T. Moffat[4], R. Odwyer[5], A. Mesci[6], J. Lukovic[7], R. Tsang[6], O. Mete[8], M.K. Krzyzanowska[9], L. Ma[2]

[1]Oncology Department, Princess Margaret Cancer Centre, Toronto, ON, Canada; [2]Medical Oncology, UHN-University Health Network-Princess Margaret Cancer Center, Toronto, ON, Canada; [3]Clinical Oncology Department, A.C. Camargo Cancer Center-Unidade Antonio Prudente, São Paulo, Brazil; [4]Oncology Department, Queen's University-School of Medicine, Kingston, ON, Canada; [5]Gastrointestinal Malignancies, Princess Margaret Cancer Centre, Toronto, ON, Canada; [6]Radiation Oncology, UHN-University Health Network-Princess Margaret Cancer Center, Toronto, ON, Canada; [7]Radiation Oncology, Princess Margaret Cancer Centre, Toronto, ON, Canada; [8]Kaboratory Medicine and Pathobiology, UHN-University Health Network-Princess Margaret Cancer Center, Toronto, ON, Canada; [9]Department of Medical Oncology&-Hematology, UHN-University Health Network-Princess Margaret Cancer Center, Toronto, ON, Canada

Background: Brain metastases (BrM) from thyroid cancer are considered rare. Staging brain MRI is not routinely recommended by guidelines. Prognostication, management, and outcomes remain understudied in this population.

Methods: This is a single-center retrospective study of advanced (unresectable or metastatic) thyroid cancer treated at the Princess Margaret Cancer Centre from 2000

to 2020 who developed BrM. All patients (pts) had tumour next generation sequencing (NGS) by targeted gene panel. Clinical, molecular characteristics and treatment modalities were reviewed. Overall Survival (OS) was estimated from the date of BrM diagnosis using the Kaplan-Meier method.

Results: Of 166 consecutive pts with advanced thyroid cancer who had NGS, 36 pts had documented BrM (21,7%). Median age was 52,8yo. Most BrM pts (80,6%) were of follicular cell origin (papillary TCs beig the most frequent) and the remaining (19,4%) was of C-cell origin (Medullary TC) Most pts (72%) were asymptomatic and diagnosed with BrM incidentally from staging head/neck CT scan (16/26) or brain MRI/CT (9/26). 42% of pts were on systemic treatment before BrM diagnosis. The most frequent molecular alterations were: BRAFV600E (n=16), NRAS (n=8), TERT promoter (n=8), and RET (n=7). Median OS (mOS) from BrM to death was 20,1 months (m) (95% CI 1,87-39,1). Treatment for BrM included surgery (14%) and radiation (89%). Histological subtypes were not significantly associated with OS. Pts harboring *BRAF* or *NRAS* mutations had mOS of 38.4 m, while *RET* and other alterations had mOS of 18.5 m and 1.2m, respectively (p=0.01). Pts with 1-3 BrM had better OS than those with $\geq$ 4 BrM (p = 0,025); Pts who underwent BrM resection had a trend to improved OS compared to radiation alone (61.2 vs 18.1 m, p=0.38).

Conclusions: This study is the one of the largest analyses of BrM from advanced thyroid cancer with detailed clinical and genomic characterization including all histology subtypes. We found a higher incidence of BrM than previously reported. Most were diagnosed with BrM incidentally. Number of BrM (1-3), BrM treatment modality and Molecular subtype may be prognostic. Staging brain MRI may facilitate earlier BrM detection. Further studies are needed to confirm the impact of earlier BrM diagnosis on pts outcomes.

729P Prognostic significance of nodal micrometastases in patients with non-functioning pancreatic neuroendocrine tumors (NF-PanNETs): A survival analysis from a prospective observational study

V. Andreasi[1], S. Partelli[1], M. Schiavo Lena[2], F. Muffatti[1], A. Battistella[1], D. Tamburrino[1], N. Pecorelli[1], S. Crippa[1], G. Balzano[1], C. Doglioni[2], M. Falconi[1]

[1]Pancreatic Surgery Unit, IRCCS San Raffaele Scientific Institute, Milan, Italy; [2]Pathology Unit, IRCCS San Raffaele Scientific Institute, Milan, Italy

Background: Nodal metastases (N+) are one of the most powerful predictors of disease recurrence after surgery for non-functioning pancreatic neuroendocrine tumors (NF-PanNETs). However, the prognostic role of nodal metastases $<$ 5 mm, defined as micrometastases, has been poorly investigated so far. The aim of this study was to compare clinico-pathological features and survival outcomes between patients with NF-PanNETs without nodal involvement (N0), with nodal micrometastases (microN+) and with nodal macrometastases (macroN+).

Methods: Consecutive patients who underwent a formal pancreatic resection for NF-PanNETs at San Raffaele Hospital (Milan, Italy) between 2018 and 2021 and were enrolled in the DETECTYON trial were considered (NCT03918759). Nodal metastases were further classified as microN+ when their maximum diameter was $<$ 5 mm, or as macroN+ when their maximum diameter was $\geq$ 5 mm.

Results: Overall, 100 patients were included. Of these, 58 had N0 PanNETs, 15 had microN+ and 27 had macroN+. Patients with macroN+ had significantly larger tumors [median 35 mm (IQR 28-47)] as compared to patients with microN+ [25 mm (IQR 24-35), p=0.040] and N0 neoplasms (26 mm (IQR 18-34), p=0.003]. The rate of G2-G3 neoplasms was comparable between patients with N0 and microN+ PanNETs (45% versus 27%, p=0.203), whereas it was significantly higher among subjects with macroN+ tumors (n=21/27 - 78%). Median Ki67 was 2% in patients with N0 and microN+ neoplasms (p=0.429), whereas it increased to 6% in patients with macroN+ (p=0.006). After a median follow-up of 37 months, 16 patients (16%) experienced disease relapse. Patients with N0 PanNETs had a 4-year DFS rate of 97% as compared with 88% and 43% in patients with microN+ (p=0.152) and macroN+ (p<0.001), respectively. At multivariable analysis, distant metastases (HR 5.826, p=0.026) and macroN+ (HR 6.281, p=0.034) were identified as independent determinants of disease relapse.

Conclusions: NF-PanNETs with microN+ seem to be associated with a risk of recurrence similar to N0 neoplasms. MicroN+ may be regarded as a clinicopathological entity separate from macroN+, with a possible impact on postoperative surveillance protocols.

Clinical trial identification: These are the long-term outcomes of a prospective observational study: NCT03918759.

730P The outcome of combine radioligand and CAPTEM therapy in patients with advanced, unresectable, progressive GEP-NET

J. Cwikla[1], A.D. Kolasinska-Cwikla[2], A. Zrajkowska[1], M. Nowicki[1], J. Palucki[3]

[1]Diagnostic Imaging, Centrum Diagnostyczno Lecznicze Gammed, Warsaw, Poland; [2]Department Oncology and Radiotherapy, Maria Sklodowska-Curie Institute-Oncology Center, Warsaw, Poland; [3]Radiology, Maria Sklodowska-Curie National Research Institute of Oncology, Warsaw, Poland

Background: Prospective, single-arm, open-label, case series study evaluating efficacy and safety of combined radioligand therapy (RLT) and CAPTEM in advanced, unresectable progressive GEP-NET (NCT04194125). Primary endpoint: progression-free survival (PFS) secondary: ORR, DCR, clinical response, OS, safety.

Methods: Twenty-one patients in group of 23 screened subjects between February 2019 to May 2023 included into analysis. All patients with histopathological confirmation of GEP-NETs. Therapy consists of combine RLT (^{177}Lu DOTATOC) and CAPTEM. Disease status and treatment efficiency were evaluated by clinical assessment including PS, ORR, also biochemical response and safety profile of combine therapy.

Results: Clinical follow-up at least 48 months. Mean age 58.6 +12.6. Pancreatic (panNET) n=14, midgut n=7; NETG1=9, G2=10, G3=2. Cumulative activity ^{177}Lu (GBq) of whole therapy; median=25.1GBq (20.4-27.0), per therapy median=6.5 GBq (5.8-6.8). Median PFS for all (IQR) 31.5 months (16.0-n.r.), panNET PFS=28.0 m (14.0-n.r.), midgut PFS=31.5 m (24.5-n.r). After 6 weeks of follow-up 9 (42%) had partial response (PR) and 11 (52%) had stable disease (SD), after 3 m 9 had PR, 8 had SD, single had disease progression (DP). After 6 m 9 PR, 9 SD and 2 DP, after 12 m single 1 complete response, 10 PR, 5 SD and 2 DP. DCR after 6 weeks all patients, after 3 months 17 subjects (90%), 6 months 18 patients (85%) and after 12 months 16 subjects (89%). Clinical evaluation including 12 subjects with PS=1 improved to PS=0 in 6 subjects in 2 with PS=2 improve to PS=1, no change in 7 subjects. The most common AEs was a transient lymphopenia G2 (44%) and G3 (8%); others AEs and their significant intensity (at least G3) were observed sporadically, no G4, during and after therapy. Persistent lymphopenia noted in 16% of cases.

Conclusions: Combine therapy composed with RLT and CAPTEM is very effective therapy in advanced, GEP-NET in terms of improvement of PFS in those who had documented DP. Clinical response, DCR of combine therapy seen in most of subjects during follow-up. Significant benefit in terms of ORR reported in panNET but not in midgut. In panNET who had PR four of them had primary tumor removal, single with CR for 4 years.

Clinical trial identification: NCT04194125.

731P REWENEC: REal-World Evidence in NEC provides a reliable external control arm to avoid randomization for second-line clinical trials - A post hoc proof of concept analysis with the randomized phase II BEVANEC study

J. Hadoux[1], S. Ganame[2], A. Lievre[3], A. Durand[4], D. Tougeron[5], M. perrier[6], J-Y. Scoazec[7], E. Baudin[8], L. Gerard[9], C. Lepage[10], O. Boussari[2], T. Walter[11]

Background: Neuroendocrine carcinomas (NECs) are rare aggressive cancers. After first-line platinum—etoposide, there is no standard second-line treatment. The phase II randomized clinical trial BEVANEC evaluated a randomized treatment arm (RTA) FOLFIRI + bevacizumab (Fb) and a randomized control arm (RCA) FOLFIRI (F) with a long period of enrolment (5 years) and demonstrated no benefit of Fb. We hypothesized that a single-arm trial of Fb compared to an external control arm (ECA) of F could have led to the same results.

Methods: We compared the patient's characteristics and outcome in the RCA of BEVANEC versus a full or hybrid ECA generated with real world data of NEC patients from 2 retrospective French cohorts (CEPD and RBNEC) who received second-line F. We emulated a synthetic trial, REWENEC, incorporating an ECA of F and compared the results to that of BEVANEC. We assessed the potential impact of unmeasured

Table: 731P

		RCA	RTA		ECA
n		66	59		66
	Baseline characteristics				
		RCA vs RTA (rando)		**RTA vs ECA (IPW-PS)**	
sex	Male	63.6	67.8	61.6	65.2
	Female	36.4	32.2	38.4	34.8
Age		63.0	65.1	60.5	61.5
Ki67 index (%)	≤55	20.3	9.3	21.2	18.3
	>55	79.7	90.7	78.8	81.7
Cell size	SCNEC	52.7	53.1	47.6	48.3
	LCNEC	47.3	46.9	52.4	51.7
Metastatic sites	non liver	21.2	15.3	18.9	20.7
	liver	78.8	84.7	81.1	79.3
Primary tumour	colorectal	27.3	30.5	31.9	34.1
	other	72.7	69.5	68.1	65.9
	OS (%) [95%CI]				
		RCA	**RTA**		**ECA**
6m		60.5 [49.7;73.5]	56.6 [45.1;71.0]		54.7 [46.5;64.3]
12m		32.4 [22.6;46.5]	29.6 [19.5;44.9]		32.0 [24.6;41.6]
18m		15.9 [8.70;29.0]	20.0 [11.3;35.4]		19.9 [13.8;28.7]
median		6.6 [4.9;11.5]	8.9 [5.9;11.4]		6.9 [5.88;8.00]

confounders. An inverse probability weighting propensity score (IPW-PS) approach was used to balance measured confounders (MC) in the ECA.

Results: The ECA included 66 patients comparable to ETA and RCA. Measured confounders were more balanced between the RTA of BEVANEC and the ECA after IPW-PS than between the RTA and the RCA after randomization (Table). OS were similar in both ECA and RCA (Table). When substituting the RCA by the ECA and comparing it to the RTA, the synthetic REWENEC trial led to similar outcomes and conclusions as in the BEVANEC trial with no difference in median overall survival between Fb and F (Table). This suggest that randomization may not have been required in this setting.

Conclusions: Externally controlled trials might be an appropriate compromise between RCT and single-arm trials in NECs. Maintaining a platform of existing good quality data from prospective and retrospective studies would help to design these types of trials and accelerate clinical research in NECs.

GERM CELL (TESTICULAR) CANCER AND PENILE CANCER

732P Efficacy and safety of high-dose chemotherapy as second or subsequent salvage therapy in relapsed or refractory germ cell cancer patients: A multicentric analysis

C. Seidel[1], U.F.F. De Giorgi[2], N. Engel[1], M. Hentrich[3], S. Zschäbitz[4], E. Conolly[5], A.J. Weickhardt[6], P. Grimison[7], V. Wong[8], C. Oing[9], W. Alsdorf[1], C. Schaefers[1], C. Bokemeyer[1], B. Tran[10]

[1]Oncology, Hematology and Bone Marrow Transplantation, UKE Universitätsklinikum Hamburg-Eppendorf KMTZ, Hamburg, Germany; [2]Medical Oncology Department, IRST-Istituto Romagnolo per lo Studio dei Tumori Dino Amadori IRCCS S.r.l., Meldola, Italy; [3]Department of Hematology and Oncology, Rotkreuzklinikum München, Munich, Germany; [4]Medical Oncology Department, NCT-Nationales Zentrum für Tumorerkrankungen, Heidelberg, Germany; [5]Oncology, Chris O'Brien Lifehouse, Sydney, NSW, Australia; [6]Medical Oncology Dept., Olivia Newton-John Cancer Wellness&Research Centre, Heidelberg, VIC, Australia; [7]Medical Oncology Dept., Chris O'Brien Lifehouse, Camperdown, NSW, Australia; [8]Oncology, WEHI-Walter and Eliza Hall Institute of Medical Research, Parkville, VIC, Australia; [9]Sir Bobby Robson Clinical Trials Research Centre, Newcastle University, Newcastle upon Tyne, UK; [10]Medical Oncology Dept., Peter MacCallum Cancer Centre, Melbourne, VIC, Australia

Background: Recurrent metastatic germ cell cancer (GCC) is treated with salvage chemotherapy (CTX), either with high-dose (HD) CTX such as carboplatin and etoposide (HD-CE) or conventional-dose cisplatin-based chemotherapy (CD CTX). For relapse after first salvage CD CTX, HD-CTX is still a curative option, but data on efficacy and safety of HD-CTX in this setting is limited. This retrospective study aimed to explore the efficacy and safety of HD-CTX used as either first or subsequent salvage treatment.

Methods: Data on patients (pts.) characteristics, treatment outcome and safety were retrospectively collected from international expert centres to compare between Group A (HD-CTX as first salvage therapy) and Group B (HD-CTX at recurrence after or progression during salvage CD CTX). Analysis was conducted using *R* with Wilcoxon, χ^2 and log-rank test to compare characteristics and survival.

Results: A total of 275 GCC pts. from 18 centers were included in this analysis, 159 pts. (57.8%) in group A and 116 patients (42.2%) in group B. Treatment was conducted with HD-CE in 238 pts. (86%), with a median follow-up time from first salvage CTX of 27 months (SD 51.9) in group A and 35 months (SD 58.7) in group B. Patient characteristics including primary histology, IGCCCG risk, IPFSG score and locations of metastases were equally distributed in both groups. The median OS from first salvage treatment initiation was not reached (group A) versus 68.8 months (group B) (p=0.073), and from HD-CTX treatment not reached (group A) versus 31.2 months (group B) (p=0.002). The 2- and 5-year OS rates after HD-CTX were 76%/65% for group A and 56%/42% for group B, respectively. The objective response rate following HD-CTX was 79% (group A) versus 60% (group B) (p=0.013). Regarding toxicity, adverse events (other than hematologic) were reported in 59% in group A and 73% in group B (p=0.028). Treatment associated deaths were described in 8 patients (2.9%) with no difference between group A versus group B (p=0.221).

Conclusions: Salvage HD-CTX has curative potential in relapsed and refractory GCC patients leading to 65 % long-term survival when used as first salvage therapy and approximately 41% when used in the subsequent salvage setting.

733P Testicular cancer: Trends in incidence and demographics from 23,214 cases in California from 2000-2020

D.J. Benjamin[1], A. Shrestha[2], D. Fellman[2], A. Rezazadeh Kalebasty[3]

[1]Medical Oncology, Hoag Family Cancer Institute, Newport Beach, CA, USA; [2]Public Health Institute, Cancer Registry of Greater California, Sacramento, CA, USA; [3]Hematology/Oncology&Medicine Dept., UCI Health-University of California Irvine, Orange, CA, USA

Background: The incidence of testicular cancer (TC) has been rising over the past five decades for reasons currently unknown. As marijuana use is believed to increase the risk of TC, we sought to assess recent trends in incidence rates in California to see if further changes might be due to recent policy initiatives such as marijuana legalization.

Methods: Men diagnosed with TC between 2000 and 2020 were identified through the California Cancer Registry database (n = 23,214). Cancer occurrence by age and race/ethnicity were examined. Incidence rates by year of diagnosis and race/ethnicity were calculated, and age-adjusted to the 2000 US Standard Population.

Results: The incidence of TC among all racial/ethnic groups has been rising in California between 2000 and 2020. In particular, incidence has been rising at faster pace among Hispanic men and Asian/Pacific Islander men during this period. Among Hispanic men, the incidence rate was 4.2/100,000 in 2000 and rose to 6.7/100,000 in 2020. Similarly, the incidence rate for Asian/Pacific Islander men was 2.0/100,000 in 2000, decreased to 1.2/100,000 in 2002 and rose to 2.5/100,000 in 2020. This increasing trend for incidence rates is mainly observed among men below age 40.

Table: 733P Incidence rates for male malignant testicular cancer in California, 2000-2020

Year	All groups	Non-Hispanic white	Non-Hispanic black	Hispanic	Asian/Pacific Islander
2000	5.3	7.3	1.7	4.2	2
2001	5.2	7.4	2.1	3.7	1.6
2002	5	7.1	1.5	3.8	1.2
2003	5.3	7.7		4	1.4
2004	5.3	7.5	1.4	4.2	1.5
2005	5.5	7.8	1.3	4.3	2
2006	5.5	7.3	1.6	4.8	1.8
2007	5.5	7.5	1.9	4.6	2.1
2008	5.7	7.9	2.2	4.9	1.5
2009	5.6	7.3	1.9	5.1	2.2
2010	5.8	7.8	1.9	5.1	2.1
2011	5.5	7.3	1.3	5.3	2
2012	5.7	7.3	1.8	5.5	2.1
2013	6	8.3	1.8	5.3	2.4
2014	6.2	8	1.5	5.9	2.5
2015	6	7.2	1.3	6.3	2.2
2016	6.3	8.3	2	5.7	2.3
2017	6.4	7.7	1.7	6.6	2.6
2018	6.4	8	1.9	6.4	2.6
2019	6.3	7.3	1.6	6.8	2.4
2020	6.4	7.6	2	6.7	2.5

Rates are per 100,000 and age-adjusted to 2000 US Std Population (19 age groups — Census P25-1130) standard.

Conclusions: This is one of the largest epidemiological studies on TC. The incidence of TC has been rising in California since 2000, particularly among Hispanic and Asian/Pacific Islander men. The rise in TC rates started prior to the year of marijuana legalization (2015), thus suggesting other factors may be leading to rising incidence rates.

734P Primary retroperitoneal germ-cell tumours (pR-GCT): Evaluation of treatment outcomes of an international collaboration (PRIMERE study-IGG05)

P. Giannatempo[1], S. Nazzani[2], V. Bernasconi[2], M. Mego[3], I. Taglialatela[1], D. Bimbatti[4], S. Secondino[5], M. Claps[1], D. Biasoni[2], M. Catanzaro[2], M. Zimatore[1], T. Torelli[2], S. Stagni[2], A. Macchi[2], A. Tesone[2], P. Pedrazzoli[6], U. Basso[4], G. Procopio[1], F.G.M. De Braud[7], N. Nicolai[2]

[1]Medical Oncology Department, Fondazione IRCCS-Istituto Nazionale dei Tumori, Milan, Italy; [2]Department of Urology, Fondazione IRCCS-Istituto Nazionale dei Tumori, Milan, Italy; [3]Department of Oncology, Faculty of Medicine, Comenius University and National Cancer Institute of Slovakia, Bratislava, Slovak Republic; [4]Medical Oncology 1 Department, IOV-Istituto Oncologico Veneto IRCCS, Padua, Italy; [5]Medical Oncology Department, Fondazione IRCCS Policlinico San Matteo, Pavia, Italy; [6]Oncology Department, Fondazione IRCCS Policlinico San Matteo, Pavia, Italy; [7]Medical Oncology&Haemathology Department, Fondazione IRCCS-Istituto Nazionale dei Tumori, Milan, Italy

Background: pR-GCT corresponds to the clinical case of retroperitoneal ascertained GCT without radiological evidence of primary testicular tumor and accounts for up to 40 % of extragonadal GCTs. An occult primary testicular tumor is often missed at diagnosis. Treatment modalities and outcomes have not been specifically addressed, preventing robust recommendations. We performed an international call to assess prognosis of treatment outcomes of these patients.

Methods: Clinical, pathological and treatment data pts with pR-GCT between 04/1988 and 01/2022 were retrospectively collected across 4 referral centers. Kaplan Meier methods, univariable and multivariable Cox regression models (MCRMs) were used.

Results: Ninety-nine patients (median age 37 yrs - IQR: 29-45) were collected. Ninety-three (94%) had histological diagnosis by biopsy or primary retroperitoneal lymph-node dissection (RPLND): 60 (62.5%) had non-seminomatous pR-GCTs (pR-NSGCTs) and 33 (34.4%) had seminomatous pR-GCTs (pR-SGCTs). IGCCCG prognostic allocation was possible in 91 pts: 34 (35.8%) were good, 23 (24.2%) intermediate and 34 (35.8%) poor risk, respectively. All pts underwent cisplatin-based chemotherapy, usually BEP regimen (94.9%). After chemotherapy, 25 (25.3%) pts underwent orchiectomy: viable tumor was present in 8 (32%), burn-out lesions in 6 (24%) and no lesion in 11 (44%) cases. After a median follow-up of 45 mos (IQR:15-90), the 5-years OS was 58%, being 85% in case of pR-SGCT and 46% in case of pR-NSGCT. According to IGCCCG classification 5-years OS was 83.3% for good, 57% for intermediate and 42% for poor risk patients, respectively. No difference in term of OS (60% vs 56%, p-value 0.81) was observed between patient who had or not radical orchiectomy. At MCRMs only IGCCCG poor risk category (HR 3.2, CI: 1.18-8.84, p-value 0.02) was independent predictors of a worse OS.

Conclusions: Eventually, a significant proportion of pts with a pR-GCT had a misclassified primary testicular tumor. 5 yrs-OS according to IGCCCG classification is worse than expected. The role of a surgical exploration of the suspected primary tumor remains controversial and the existence of a real category of p-GCT cannot be excluded.

735P Causes of death in a complete cohort of testicular cancer patients diagnosed in Norway 1980-2009, with detailed treatment information

Ø. Kvammen[1], R. Hellesnes[2], H. Sagstuen Haugnes[2], A. Karlsdottir[3], H.F.S. Negaard[4], T. Tandstad[5]

[1]Department of Oncology, Helse Møre og Romsdal HF, Alesund, Norway; [2]Department of Oncology, University Hospital of North Norway, Tromso, Norway; [3]Department of Oncology, Haukeland University Hospital, Bergen, Norway; [4]Department of Oncology, Oslo University Hospital, Oslo, Norway; [5]Department of Oncology, St. Olavs Hospital-The Cancer Clinic, Trondheim, Norway

Background: Testicular germ cell tumors (TGCT) have an excellent prognosis. This study aimed to provide population-based clinical data on cause-specific deaths with detailed treatment information, as such data are scarce.

Methods: From the Cancer Registry of Norway we identified 6167 men with testicular cancer diagnosed 1980-2009, of whom 714 died before 2011. Excluding non-TGCT, clinical or post-mortem diagnoses, 588 were included. Information on Royal Marsden clinical stage (CS), comorbidity, treatment, follow-up and cause of death was obtained from patient journals.

Results: Of 588 deceased patients, 311, 191 and 86 were diagnosed in the 1980s, 90s and 00s, respectively. Most had seminoma (55%), and 48% were concurrent smokers. Median time to death (MTD) of TGCT, treatment complications or other causes was 1.5, 0.4 and 12.1 years, respectively. Of 315 deceased patients with initial CS1, 4% died of relapsed TGCT or treatment complications, while 35% died of non-TGCT cancer. Of 273 deceased patients with initial metastatic TGCT, 149 (55%) died of TCGT or treatment complications. Most had nonseminoma (77%). The primary treatment in these 149 patients was a combination of chemotherapy and surgery in 41%, chemotherapy alone in 33%, radiotherapy alone in 3%, trimodal treatment in 11%, radiotherapy and chemotherapy in 7%, while 4% received no treatment. Of the 149 patients, 95 (64 %) had CS4: pulmonary metastases, non-pulmonary visceral metastases or both were reported in 84, 42 and 34 patients, respectively. According to IGCCCG, 61%, 27% and 4% belonged to the poor, intermediate and good prognosis groups, respectively. Most (58%) died in primary treatment before entering follow-up. Of all 273 patients, 14 % died of non-TGCT cancer.

Conclusions: In this complete three-decade cohort, cause-specific death of TGCT was exceedingly rare in CS1 or good prognosis metastatic disease. TGCT death was rare if patients went into follow-up after primary treatment. Cause-specific mortality was most pronounced in patients receiving chemotherapy following post-chemotherapy surgery, in patients with nonseminoma or with visceral metastases.

Background: Only limited data exist on the management of residual masses in men who have received two lines of chemotherapy for advanced seminoma. Therefore, the role of FDG PET/CT scans, surgery and other additional treatments remains controversial in these men.

Methods: Data from men with pure seminoma and residual masses after salvage chemotherapy were retrospectively collected from 13 high-volume centers. We analyzed the clinical management of residual masses (imaging, surgery, pathological data, and additional treatment modalities) and long-term outcomes. Residual mass was defined as a lesion of $\geq$1 cm after two lines of platinum-based chemotherapy.

Results: Data from 92 patients (pts) with non-progressing residual masses after second-line chemotherapy have been collected and have been included in this analysis. A post-chemotherapy FDG PET/CT was performed in 54 (59%) pts. Viable seminoma was found in 3/12 pts who had a biopsy (bio+). Surgery was performed in 47 (51%) pts, irrespectively of FDG uptake (no=8, yes=16). Complete necrosis was found in 42 (89%), viable seminoma in 3 (6%), teratoma in 1, and leiomyoma in 1 pt, respectively. No viable tumor cells were found in 8 men with a negative PET (PET-) who underwent surgery (2bio+). 16/28 pts with a positive PET (PET+) underwent surgery: 12 complete necrosis, 2 viable seminoma, 1 teratoma, and 1 leiomyoma. Among those with a PET+, 5/28 pts (18%) experienced either viable seminoma in residual subsequent relapse. A second relapse occurred in 13/92 (14%). Only 4/47 (8%) pts who had residual masses resected post 1st salvage chemotherapy subsequently relapsed (3 had viable seminoma in the residuals). At a median follow-up of 4.35 years, 88 (92%) pts were alive. 4/92 patients died of cancer progression.

Conclusions: Most men with seminoma residual masses after 1st salvage chemotherapy may achieve a cure. Pending validation with more pts in this rare situation, FDG PET/CT may help guide the selection of post-chemotherapy resection candidates. PET/CT appears of high negative predictive value when negative (100% [95%CI 63-100]), while PET+ scans have a remarkable risk of being false positive (positive predictive value 16% [95%CI 3-40]).

737P Vascular fingerprint tool to identify testicular cancer patients at high-risk for early cardiovascular events after cisplatin-based chemotherapy

A.T. Meuleman[1], E. Volders[1], S. Lubberts[1], J.M. Kerst[2], M. Wymenga[3], M.J.B. Aarts[4], M. Brito Goncalves[5], J. Lefrandt[6], G. Steursma[1], C. Meijer[1], J. Nuver[7], J.A. Gietema[8]

[1]Medical Oncology, UMCG-University Medical Center Groningen, Groningen, Netherlands; [2]Medical Oncology, NKI-AVL-Netherlands Cancer Institute/Antoni van Leeuwenhoek Hospital, Amsterdam, Netherlands; [3]Internal Medicine, MST-Medisch Spectrum Twente, Enschede, Netherlands; [4]Medical Oncology, Maastricht University Medical Center (MUMC), Maastricht, Netherlands; [5]Medical Oncology, Instituto Português de Oncologia de Lisboa Francisco Gentil E.P.E. (IPO Lisboa), Lisbon, Portugal; [6]Internal Medicine, UMCG-University Medical Center Groningen, Groningen, Netherlands; [7]Medical Oncology, University Medical Center Groningen-UMCG, Groningen, Netherlands; [8]Medical Oncology, UMCG-University Medical Center Groningen, Groningen, Netherlands

Background: Testicular cancer (TC) patients treated with chemotherapy (CT) have an increased risk of early cardiovascular events. This study aims to validate a vascular fingerprint tool developed to identify TC patients at high-risk for such events (Lubberts, Eur J Cancer 63:180, 2016).

Methods: A multicenter prospective study (NCT02573584) was performed in metastatic TC patients (IGCCCG good or intermediate risk; retroperitoneal mass <5 cm). The vascular fingerprint was assessed before start of CT and consists of 5 risk factors: smoking, overweight (BMI>25 kg/m^2), hypertension (blood pressure >140/90 mmHg), dyslipidemia (fasting cholesterol >5.1 mmol/L or LDL >2.5 mmol/L) and diabetes mellitus (fasting glucose $\geq$ 7.0 mmol/L). Presence of $\geq$ 3 risk factors was defined as high-risk vascular fingerprint. A log-rank test was performed using a cardiovascular event within 1 year after start of CT as primary endpoint.

Results: 196 TC patients were included; 15 patients (7.7%) developed a cardiovascular event: [4 (2.0%) arterial events and 11 (5.6%) venous thrombotic events]. TC patients with a high-risk vascular fingerprint (n=62) had a higher risk of developing a cardiovascular event (HR: 3.27; 95% CI: 1.16 − 9.18; Log-rank: p=0.017). All patients with an arterial event had a high-risk vascular fingerprint compared to 5/11 patients with a venous event. Patients who developed a cardiovascular event were older (Table).

Table: 737P Risk factors before start of CT in TC patients with or without cardiovascular events

	Cardiovascular event (n = 15)	No cardiovascular event (n = 181)	
	Median (range) / n (%)	Median (range) / n (%)	*P**
Age at start of CT, years	40 (22-50)	31 (17-48)	**0.013**
Smoking	5 (33.3)	63 (34.8)	0.908
Overweight	13 (86.7)	107 (59.4)	**0.037**
Hypertension	7 (46.7)	47 (26.6)	0.132
Dyslipidemia	13 (86.7)	113 (70.2)	0.238
Diabetes mellitus	1 (6.7)	6 (3.5)	0.445
Total score vascular fingerprint	3 (0-4)	2 (0-4)	**0.035**
High-risk vascular fingerprint	9 (60.0)	53 (30.5)	**0.041**

*X^2-, Fisher's exact- or Mann-Whitney U test

Conclusions: The vascular fingerprint tool is effective in identifying TC patients at high-risk for early cardiovascular events and can be used to select TC patients for preventative strategies.

Clinical trial identification: NCT02573584, 12 October 2015.

Background: TMB is an established biomarker of efficacy with immune-checkpoint inhibitors (ICI) in a pan-cancer indication. TMB, however, has not been specifically considered for penile squamous cell carcinoma (PSCC).

Methods: We analyzed 397 PSCC cases to identify genomic alterations (GA) in >300 cancer-associated genes, genomic signatures, and TMB using a hybrid capture-based comprehensive genomic profiling (CGP) assay. TMB was categorized as low (<10 mutations [mut]/Mb), high (10-19), and very high (≥20). Tumor cell programmed cell-death ligand-1 (PD-L1) expression was determined by immunohistochemistry (IHC, Dako 22C3) and defined as tumor proportion score (TPS) ≥1%. Germline status of GA was predicted using a validated somatic-germline computational method. Separately, real-world clinical outcomes (RWCOS) data of patients with metastatic penile cancer receiving first-line ICI were obtained from the nationwide (US-based) de-identified Flatiron Health-Foundation Medicine clinico-genomic database (FH-FMI CGDB), which originated from approximately 280 US cancer clinics (∼800 sites of care).

Results: There were 339 (85.4%) TMB-low, 40 (10.1%) TMB-high and 18 (4.5%) TMB-very high PSCC. TMB ≥10 vs TMB-low PSCC revealed an enrichment of GA of PIK3CA (48.3% vs 18.3%; p<0.001) and KMT2D (29.3% vs 7.7%; p<0.001), and less frequent GA of CDKN2A (25.9% vs 45.7%, p=0.050). Most of these GA did not co-occur. PD-L1 expression was not impacted by TMB status. HPV identification was more frequent as TMB increased: 28.3% for the TMB-low, 50% for the TMB-high and 58.8% for the TMB-very high groups. In total, 95/1,377 (6.9%) GA were predicted to be of germline nature. In the FH-FMI CGDB cohort, 10 patients receiving ICI, 4 (40%) had a real-world overall survival (rwOS) >12 months with sustained benefit in 3/3 patients with TMB ≥10 mut/Mb.

Conclusions: Evaluation of advanced/metastatic PSCC by CGP based on TMB level revealed significant differences in biomarkers for the near 15% of cases that have high and very high TMB ≥10 mut/Mb. These PSCC cases represented a distinct tumor subgroup deserving further clinical investigation.

739P Penile squamous cell carcinoma tissue associated macrophages captured by multiplex immunfluorence are associated with clinical outcomes

J. Chahoud[1], F. Ionescu[2], M. Paravathaneni[3], L. Zemp[2], A. Yu[2], S. Eschrich[4], Y. Kim[4], D. Grass[5], J. Dhillon[6], B. Manley[2], P. Spiess[1]

[1]GU Oncology, H. Lee Moffitt Cancer Center&Research Institute-Magnolia Campus, Tampa, FL, USA; [2]GU, Moffitt Cancer Center, Tampa, FL, USA; [3]Medical Oncology, Moffitt Cancer Center, Tampa, FL, USA; [4]Biostat, Moffitt Cancer Center, Tampa, FL, USA; [5]Radiation Oncology, Moffitt Cancer Center, Tampa, FL, USA; [6]Pathology, Moffitt Cancer Center, Tampa, FL, USA

Background: Penile squamous cell carcinoma (PSCC) is rare and the immune enviroment of PSCC remains poorly characterized. In this study, we characterize the immune microenvironment using multiplex immunofluorescence (mIF) and image analysis approaches in 57 patients with PSCC.

Methods: Representative tissue microarrays blocks of 57 patients with primary PSCC treated at H. Lee Moffitt Cancer Center (Tampa, FL) were stained for 10 immune markers: CD20, CD3, CD4, CD8, CD45RO, CD68, CD206, CD163, NKp46, FOXP3. Two experienced pathologists using an image analysis system divided each tissue core into tumor and stroma compartments and assessed the densities of cell phenotypes.For analyses focusing on overall survival (OS) we used Cox regression and Log-rank test for Kaplan-Meier plots. The maximally selected rank statistics test was used to identify cut-points of continuous variables with maximal discriminatory value for clinical outcomes.

Results: 57 PSCC patients were included with median age 60 [IQR, 53-73]). 25 (44%) were pathologic stages 1-2, 25 (44%) were stage 3, and 7 (12%) were stage 4. 34 (60%) were HPV-negative. We did not observe significant differences in cell densities as defined by mIF in HPV(+) compared to HPV(−) PSCC. In univariable analysis, higher density of CD8+ cells in the tumor and stroma were associated with inferior median OS (36.6 months [95% CI, 19.0-84.1] vs 161.7 months [95% CI, 16.2-161.7]). Similarly, greater infiltration by tumor-associated (M2) macrophages in the tumor and stroma (CD68+CD163+CD206+) were associated with inferior median OS (13.3 months [95% CI, 1.0-not estimable) vs 80.1 months [95% CI, 27.1-161.2]. In Cox regression controlling for pathologic stage and M2 density as a continuous variable, the latter remained significantly associated with OS.

Conclusions: Multiplex image analysis of primary PSCC found no difference in the immune contexture of HPV(+) and HPV(-) patients. High levels of tumor-associated macrophages M2 was associated with inferior survival outcomes. Further characterization of T-cell subsets to gauge the exhausted status of T-cells is underway to explain the paradoxical effect noted, similar to that in kidney cancer immune environment.

Background: In the phase 3 RUBY trial (NCT03981796) dostarlimab (D) + carboplatin-paclitaxel (CP) significantly improved PFS vs CP alone in the mismatch repair deficient/microsatellite instability-high (dMMR/MSI-H; HR, 0.28) and overall population (HR, 0.64) with a favorable OS trend (HR, 0.64). Four molecular EC subgroups were identified for prognostic and potential predictive value. Validated surrogate methods more readily available include POLε mutation (mut), dMMR, TP53 abnormal, and no specific molecular profile (NSMP). Here, we present exploratory efficacy outcomes by molecular classification.

Methods: Patients (pts) with pA/rEC were randomised 1:1 to receive dostarlimab, or placebo (PBO), plus CP, followed by dostarlimab or PBO monotherapy for up to 3 years. POLε and TP53 status were determined by DNAseq; MMR/MSI status was determined by testing used for study enrollment (immunohistochemistry, polymerase chain reaction, or next generation sequencing). Order of classification was POLεmut → dMMR/MSI-H → TP53mut → NSMP. PFS and OS were assessed for each subgroup.

Results: Of 494 pts enrolled and randomised, mutational data were available for 400 pts (81.0%), classified as: 5 (1.3%) POLεmut, 91 (22.8%) dMMR/MSI-H, 88 (22.0%) TP53mut, and 216 (54.0%) NSMP. PFS and OS results favored the D+CP arm in the dMMR/MSI-H, TP53mut, and NSMP subgroups, with the largest benefit observed in the dMMR and TP53mut groups. No pts with POLεmut progressed in either arm as of data cut (Table). Safety was reported previously.

Conclusions: Dostarlimab+CP is associated with improved PFS and OS in the dMMR/MSI-H, NSMP, and TP53 subgroups and adds prognostic value in pA/rEC. Patients with POLεmut had the best prognosis, as expected. Further research may help to validate these exploratory findings.

Table: 740MO

	D+CP	PBO+CP
Overall, n	245	249
PFS by INV, HR (95% CI)	0.64 (0.507—0.800)	
OS, HR (95% CI)	0.64 (0.464—0.870)	
Patients with both MMR/MSI status and mutational data, n	191	209
POLεmut, n	2	3
PFS by INV, HR (95% CI)	NA[a]	
OS, HR (95% CI)	NA[a]	
dMMR/MSI-H, n	39	52
PFS by INV, HR (95% CI)	0.31 (0.17—0.56)	
OS, HR (95% CI)	0.4 (0.17—0.95)	
TP53mut, n	47	41
PFS by INV, HR (95% CI)	0.55 (0.3—0.99)	
OS, HR (95% CI)	0.41 (0.2—0.82)	
NSMP, n	103	113
PFS by INV, HR (95% CI)	0.77 (0.55—1.07)	
OS, HR (95% CI)	0.87 (0.56—1.36)	

[a]No PFS or OS events were observed for patients classified as POLεmut in either arm
INV, investigator assessment; NA, not applicable

Clinical trial identification: NCT01847274.

Background: Luveltamab tazevibulin (luvelta) is a novel FolRα-targeting ADC with a stable cleavable linker and a 3-aminophenyl hemiasterlin warhead (DAR 4) that induces cytotoxic and immunogenic cell death. Using site-specific conjugation technology and proprietary cell-free protein synthesis platform, luvelta is designed to target a broad range of FolRα expressing cancers, including EEC.

Methods: Following completion of the STRO-002-GM1 phase 1 study, a dose expansion cohort was enrolled consisting of metastatic EEC with progression after ≥ 1 platinum or immunotherapy-based regimen ($\leq$ 3 total lines) with $\geq$ 1% FolRα expression (any intensity using Ventana FolR1 IHC assay). Luvelta dose was 5.2 mg/kg q3w. In patients (pts) with prior pelvic irradiation, a dose of 4.3 mg/kg q3w was administered. The primary endpoint is objective response rate (RECIST v1.1) with secondary endpoints of safety and PK.

Results: 17 pts were enrolled (8 pts at 5.2 mg/kg and 9 pts at 4.3 mg/kg). Prior therapy: median lines=2; prior platinum=17 pts; and prior PD-1=4 pts. Median exposure was 12 weeks (range 3-38). Initial efficacy data is presented in the table.

Table: 741MO Best response (RECIST v1.1)

	Response evaluable patients (n=16)	Response evaluable patients with FolRα ≥ 25% (n=8)
Response (PR+PRu)	6 (37.5%)	4 (50%)
PR	4 (25%)	2 (25%)
PRu (unconfirmed PR)	2 (12.5%)	2 (25%)
SD	5 (31.3%)	3 (37.5%)
PD	5 (31.3%)	1 (12.5%)
Disease control rate (PR+PRu+SD)	11 (68.8%)	7 (87.5%)

The safety profile was consistent with prior reported data in ovarian cancer pts treated with luvelta. The most common Grade 3 or higher (G3+) adverse events (AEs) were neutropenia (53%), anemia (24%), and arthralgia(18%). There were no G3 eye disorder AEs, 1 G3+ pulmonary AE (G3 COVID pneumonia) and no G5 AEs. A single pt had an AE leading to discontinuation (G3 arthralgia).

Conclusions: Advanced EEC remains an area of high unmet need with a poor prognosis and limited treatment options. Preliminary data indicate that luvelta has a predictable and manageable safety profile with encouraging clinical activity in pts with recurrent/progressive FolRα expressing EEC. Luvelta warrants further development as a targeted agent for EEC.

Clinical trial identification: NCT03748186.

742MO Neoadjuvant immune checkpoint blockade in mismatch repair deficient endometrial cancer

M. de Bruyn[1], A.L. Eerkens[1], K. Brummel[1], A. Vledder[1], S.T. Paijens[2], M. Requesens[1], D. Loiero[3], N. van Rooij[1], A. Plat[1], P. Klok[1], F-J. Haan[1], D.N. Church[4], R. Wardenaar[5], F. Foijer[5], V.H. Koelzer[3], T. Bosse[6], J. Bart[7], M. Jalving[8], A.K.L. Reyners[8], H.W. Nijman[1]

[1]Gynaecology&Obstetrics, UMCG-University Medical Center Groningen, Groningen, Netherlands; [2]Radiotherapy, Erasmus MC, Rotterdam, Netherlands; [3]Institut für Pathologie und Molekularpathologie, USZ-Universitätsspital Zürich, Zurich, Switzerland; [4]Oncology Department, University of Oxford, Oxford, UK; [5]European Research Institute for the Biology of Ageing (ERIBA), UMCG-University Medical Center Groningen, Groningen, Netherlands; [6]Pathology, Leiden University Medical Center, Leiden, Netherlands; [7]Pathology, UMCG-University Medical Center Groningen, Groningen, Netherlands; [8]Medical Oncology, UMCG-University Medical Center Groningen, Groningen, Netherlands

Background: Recent studies suggest neoadjuvant immune checkpoint blockade (ICB) may be more efficacious than adjuvant treatment in mismatch repair deficient (MMRd) cancers. However, this has not been explored for endometrial cancer (EC). Here, we report results from a phase I feasibility study of neoadjuvant pembrolizumab in 10 MMRd EC patients.

Methods: MMRd EC patients of any stage or grade at intent-to-treat with primary surgery (at least a hysterectomy) were eligible for participation, and 10/10 patients have been recruited. Patients were treated with 2 three-weekly cycles of pembrolizumab monotherapy (200mg iv) prior to standard-of-care resection and adjuvant treatment if indicated. Radiologic and pathologic response rates, treatment-related adverse events (trAEs) and immune correlates of treatment were assessed.

Results: Patients had stage I-II (n=4) or stage III (n=6) disease at diagnosis, remained on-protocol and underwent definitive surgery. In patients with measurable disease on MRI (n=8), a partial radiologic response was observed in 3/8 patients. A pathological response (<90% viable cancer cells) was observed in 5/10 patients, with 2 major pathologic responses (<10% viable cancer cells). To date, no recurrences have been observed, with a median and longest disease-free survival of 17 and 26 months, respectively. Subclonal MMRp was observed in 2 patients after neoadjuvant treatment. 9/10 patients experienced grade 1/2 trAEs. A treatment-induced immunological response was detected in 9/10 patients with increased lymphoid infiltrates, clonal T cell expansion and diverse T cell phenotypes in post-treatment samples. In tumour-draining (sentinel) lymph nodes, significant clonal overlap with treatment-induced intratumoural T cell expansion was demonstrated.

Conclusions: Neoadjuvant ICB is safe and feasible in MMRd EC. Two cycles of pembrolizumab induced pathologic, radiologic and immunologic responses. Investigation of extended neoadjuvant treatment is warranted and currently being evaluated.

743MO Efficacy and safety of QL1706 plus paclitaxel and cisplatin/carboplatin +/- bevacizumab (Bev) as 1L treatment in recurrent or metastatic cervical cancer (r/mCC): A single-arm, multicenter phase II study

N. Liu[1], Z. Yang[2], D. Tang[3], H. Lou[4], K. Zhang[5], H. Cao[6], D. Zou[7], X. Zhang[8], S. Xue[8], X. Kang[8], D. Wang[2]

[1]Department of Gynecologic Tumor, Shandong Cancer Hospital Affiliated to Shandong University, Jinan, China; [2]Department of Gynecology, Cancer Hospital of China Medical University, Liaoning Cancer Hospital&Institute, Shenyang, China; [3]Department of Gynecological Oncology, The Affiliated Tumor Hospital of Xiangya Medical School of Central South University, Changsha, China; [4]Gynecological Surgery, Cancer Hospital of the University of Chinese Academy of Sciences/Zhejiang Cancer Hospital, Hangzhou, China; [5]Department of Obstetrics and Gynecology, The Affiliated Tumor Hospital of Xiangya Medical School of Central South University, Changsha, China; [6]Department of Oncology, Guizhou Provincial People's Hospital, Medical College of Guizhou University, Guiyang, China; [7]Department of Gynecology Oncology, Chongqing University Cancer Hospital, Chongqing, China; [8]Medicine, Qilu Pharmaceutical Co., Ltd., Jinan, China

Background: Pembrolizumab plus chemotherapy +/- Bev has been approved as the 1L treatment for r/mCC patients (pts) with PD-L1 CPS $\geq$1. QL1706, a bifunctional Mabpair product of anti-PD-1 and anti-CTLA-4 antibodies, has shown good safety and promising efficacy in previously treated r/mCC pts in a phase Ib study. Here we report the latest efficacy and safety results from a Ph 2 study of QL1706 plus paclitaxel and cisplatin/carboplatin +/- Bev as 1L treatment of r/mCC.

Methods: In this open-label, single arm, non-randomized, phase II study, eligible pts were pathologically confirmed r/mCC and had no prior systemic treatment. Pts were treated with QL1706 (5 mg/kg, IV, D1) plus paclitaxel (175 mg/m^2 or 135 mg/m^2, D1) and cisplatin (50 mg/m^2, D1/D2)/carboplatin (AUC = 5, D1) (cohort 1) or with Bev (15 mg/kg, D1/D2) (cohort 2) once every 3 weeks for 6 cycles. Thereafter, treatment maintained with QL1706 +/- Bev, until disease progression, intolerable toxicity, or other discontinuation events. The primary and secondary endpoints were safety and efficacy, respectively.

Results: A total of 60 pts were enrolled. As of data cutoff (Apr 24, 2023), the median follow-up time was 14.0 months. Overall 58 pts had $\geq$1 post baseline tumor assessment and analyzed for efficacy. The ORR was 81% (95% CI, 68.6—90.1) (8 CRs and 39 PRs). The DCR was 98.3% (95% CI, 90.8—100.0). The mPFS was 14.3 months (95% CI, 9.2-NE). The mPFS was numerically longer in cohort 2 vs cohort 1 (16.4 vs 12.5 months). The mOS was not reached. TRAEs occurred in 60 (100%) pts. The most common TRAEs ($\geq$30% in total population) were WBC count decreased (73.3%), neutrophil count decreased (58.3%), anemia (43.3%), platelet count decreased (38.3%), and alopecia (33.3%), Grade $\geq$3 TRAEs occurred in 43 (71.7%) pts. Treatment-related SAEs occurred in 20 (33.3%) pts. TRAEs leading to treatment discontinuation occurred in 16 (26.7%) pts. irAEs occurred in 36 (60%) pts (Grade $\geq$3, 13.3%).

Conclusions: QL1706 plus platinum-based chemotherapy +/- Bev was well tolerated and showed promising antitumor activity as 1L treatment of r/mCC. Ph 3 study of QL1706 plus platinum-based chemotherapy +/- Bev as 1L treatment of r/mCC is ongoing.

Ltd., Beijing, China; [16]BeiGene (Shanghai) Co. Ltd., Shanghai, China; [17]Volyn Regional Medical Center of Oncology, Lutsk, Ukraine

Background: Pts with R/M CC have poor prognoses with high unmet clinical needs and few treatment (tx) options. Dual targeting of solid tumors with anti-T-cell immunoreceptor with immunoglobulin and immunoreceptor tyrosine-based inhibitory motif domains (TIGIT) and anti-PD-1 mAbs enhances antitumor activity in preclinical studies and clinical studies of other tumors. AdvanTIG-202 (NCT04693234) is investigating the efficacy and safety of TIS (anti-PD-1 mAb) $\pm$ OCI (humanized Fc-intact IgG1 anti-TIGIT mAb) in pts with R/M CC. Primary analysis results are reported here.

Methods: Eligible pts with R/M CC had received $\geq$1 line of chemotherapy and were not amenable to curative tx. In Stage 1, 80 pts were randomized (1:1) to receive 200 mg TIS IV Q3W + 900 mg OCI IV Q3W (Cohort [C]1) or TIS monotherapy (C2) until disease progression, unacceptable toxicity, or withdrawal of consent. In Stage 2, C1 enrolled 98 additional pts. Primary endpoint: ORR per RECIST v1.1 by IRC for C1. Secondary endpoints: DoR, PFS, OS, and safety.

Results: As of June 16, 2022, 138 pts were enrolled and treated in C1 (median age 53.0 y); median study follow-up: 7.4 mo. In the safety analysis set (SS), the ORR was 22.5%, with 13 complete responses (CR; Table); 76.8% had a durable response of $\geq$6 mo. ORR was 26.2% in pts with PD-L1+ tumors (PD-L1 score $\geq$5%), with 10 CRs. Both analysis sets showed significant improvement in ORR vs historical control ORR of 15% in pts treated with anti-PD-1 therapy ($P<0.05$). Around 67% of pts experienced $\geq$1 tx-related adverse event (TRAE). Only 13% of pts experienced $\geq$grade 3 TRAEs; the most frequently reported were anemia (2%) and rash (1%). With limited enrollment in C2 (n=40), the ORR was 32.5%.

Table: 744MO

Cohort 1	Safety analysis set[a] (n=138)	PD-L1 + (n=84)
ORR, % (95% CI)	22.5 (15.8, 30.3)	26.2 (17.2, 36.9)
	n (%)	
Complete response	13 (9.4)	10 (11.9)
Partial response	18 (13.0)	12 (14.3)
Stable disease	56 (40.6)	34 (40.5)
Progressive disease	39 (28.3)	20 (23.8)
Not determined	12 (8.7)	8 (9.5)
mDoR, mo	NE	NE
95% CI	(5.6, NE)	(5.6, NE)
mPFS, mo	3.5	4.2
95% CI	(2.6, 4.9)	(2.7, 6.9)
mOS, mo	9.0	10.4
95% CI	(8.1, 10.4)	(8.1, NE)

Data cutoff: June 16, 2022.
Efficacy assessed by IRC.
[a]Pts who received $\geq$1 dose of any study drug. DoR, duration of response; IRC, independent review committee; m, median; mo, months; NE, not estimable; ORR, objective response rate; OS, overall survival; PFS, progression-free survival.

.

Conclusions: OCI + TIS showed promising antitumor activity and durable responses, regardless of PD-L1 expression, and was well tolerated in pts with previously treated R/M CC.

Clinical trial identification: NCT04693234.

Background: R-DXd is an antibody—drug conjugate comprised of a humanised IgG1 antibody against cadherin 6 (CDH6), a stable linker selectively cleaved within tumour cells, and a membrane permeable topoisomerase I inhibitor. Overexpression of CDH6, a cell adhesion protein, occurs in the majority of OVC cases and is associated with poor prognosis. In an ongoing phase 1 trial (NCT04707248), R-DXd demonstrated an acceptable safety profile and an early efficacy signal.

Methods: All patients received prior taxane and platinum therapies and were unselected for CDH6 tumour expression. Part A (dose escalation) assessed the tolerability of R-DXd at 1.6 to 9.6 mg/kg, and 8.0 mg/kg was determined to be the maximum tolerated dose. Doses of 4.8 to 8.0 mg/kg were expanded in Part B. A subgroup analysis of patients with OVC who received R-DXd at 4.8 to 8.0 mg/kg is reported here.

Results: As of 03 March 2023, 42 patients with OVC had received R-DXd at 4.8 ($n = 7$), 6.4 ($n = 20$), and 8.0 ($n = 15$) mg/kg: 40 (95%) had platinum-resistant disease, 29 (69%) had received prior bevacizumab, and 26 (62%) had received prior PARP inhibitors. The median prior lines of therapy was 4.0 (range 1 − 13). Twenty-one patients (50%) were still receiving study treatment. The median treatment duration was 18.1 wks (range, 3.0—93.9). Any-grade treatment-emergent adverse events (TEAEs) were experienced by 37 patients (88%), and grade ≥ 3 TEAEs were observed in 21 (50%). The most common all-grade TEAEs were nausea (55%), fatigue (40%), vomiting (38%), and diarrhoea (33%). AEs led to R-DXd discontinuation in 14% of patients. The confirmed overall response rate (RECIST v1.1) in patients with measurable disease was 38% (13 of 34): 67% (95% CI, 22.3 − 95.7; 4/6, including 1 CR) at 4.8 mg/kg, 33% (95% CI, 11.8 − 61.6; 5/15) at 6.4 mg/kg, and 31% (95% CI, 9.1 − 6.4; 4/13) at 8.0 mg/kg. Two patients with unconfirmed partial responses were still on treatment. Eleven of 21 GCIG-evaluable patients (52%) had a CA-125 response.

Conclusions: In heavily pretreated OVC patients without CDH6 preselection, R-DXd demonstrated acceptable safety and encouraging preliminary efficacy, which supports further clinical development in OVC.

Clinical trial identification: NCT04707248.

Background: In platinum-resistant ovarian cancer, non-platinum chemotherapy is the standard of care after progression on combination bevacizumab and chemotherapy. We assessed the activity of DOC, DC or OC compared to SOC in bevacizumab pre-exposed population.

Methods: NRG-GY023 is an open-label, randomized, phase II trial conducted in the United States with a targeted sample size of 164 patients (pts). Eligibility included high-grade serous/endometrioid, or clear cell platinum-resistant ovarian cancer with 2-5 prior systemic therapies. Prior use of bevacizumab is required. Treatments were randomly assigned 1:2:2:2 to SOC (weekly paclitaxel, topotecan or liposomal doxorubicin), DOC, DC or OC. The primary end point was progression-free survival (PFS). Secondary end points included overall survival and overall response rate. Interim futility analysis was planned when 28 PFS events (60% information) were available in any pair of one experimental arm with the SOC; arms with a hazard ratio (HR) estimate (ref: SOC) $>$ 0.87 would be discontinued.

Results: By the data cutoff (10/31/2022), 120 pts were enrolled with a median age 65 yo [IQR: 58-69] and 10% were with germline or somatic BRCA mutation. All received prior bevacizumab in either the upfront or recurrent setting. Other prior therapies included PARP inhibitor (49%) and immunotherapy (11%). 103 pts were treated (15 SOC, 30 DOC, 28 DC, and 30 OC, respectively). At the data cutoff, median follow-up time was 4.3 months (IQR: 2.0-7.9). Median PFS was 4.2 (95% CI, 1.9-5.0), 2.6 (95% CI, 2-4.2), 2.3 (95% CI, 2-4.6), and 2.3 (95% CI, 2.1-3.9) months with SOC, DOC, DC and OC, respectively. The HR estimates (ref: SOC) were 1.01 (95% CI, 0.44-2.31), 1.21 (95% CI, 0.52-2.84), and 1.34 (95%CI, 0.58-3.08) for DOC, DC and OC, respectively. Hematologic adverse events were more common with SOC. Safety signals were consistent with past experience.

Conclusions: None of the experimental arms improved PFS compared with SOC. SOC was active in this heavily pretreated population.

Clinical trial identification: NCT04739800.

Background: BOUQUET (NCT04931342) is an ongoing platform study evaluating multiple treatments in biomarker-selected patients (pts) with rare eOC that tends to respond less well to standard therapies. We report interim results from the cobi (MEK1 inhibitor) and atezo (anti-PD-L1) + bev (anti-VEGF) arms.

Methods: Eligible pts had measurable persistent/recurrent platinum-resistant (not primary-refractory) non-high-grade serous/non-high-grade endometrioid eOC by central pathological assessment and had received 1–4 prior lines of non-hormonal systemic therapy. Tumour samples were tested centrally using the FoundationOne CDx NGS assay. Pts with *BRAF/KRAS/NRAS* or *NF1* alterations were treated with oral cobi 60 mg/d, d1–21 q28d. Pts ineligible for any open biomarker-selected arm received IV atezo 1200 mg + bev 15 mg/kg both on d1 q21d. The primary efficacy endpoint is investigator-assessed confirmed objective response rate (cORR) per RECIST v1.1.

Results: As of the clinical cut-off date, 20 pts have received cobi (8 low-grade serous ovarian cancer [LGSOC], 5 mucinous carcinoma [MUC], 5 clear-cell carcinoma [CCC], 1 carcinosarcoma [CS], 1 mesonephric-like adenocarcinoma [MLA]) and 21 atezo + bev (15 LGSOC, 3 CCC, 2 MUC, 1 CS). Pts were heavily pretreated ($\geq$3 prior lines: 65% of cobi pts, 48% of atezo + bev pts). cORRs were 16% with cobi and 14% with atezo + bev (Table). For cobi-treated LGSOC + MLA, cORR was 33% (3/9) and disease control rate (complete/partial response [CR/PR] or stable disease $\geq$16 wks) was 89% (8/9). At data cut-off, treatment was ongoing in 9 pts in the cobi arm and 15 in the atezo + bev arm; all CR/PR in both arms were ongoing.

Table: 747MO

Parameter	Cobi (n=20)[a]	Atezo + bev (n=21)
Clinical cut-off date	8 Sep 2022	13 Oct 2022
Median follow-up, mo (range)	6.9 (0–10)	7.4 (2–10)
cORR, n/N (%) [95% CI]	3/19 (16) [3–40]	3/21 (14) [3–36]
CR, n (%)	1 (5)	0
PR, n (%)	2 (11)	3 (14)
Disease control rate, n (%) [95% CI]	8 (42) [20–67]	15 (71) [48–89]
6-month progression-free survival rate, % (95% CI)	41 (18–63)	75 (56–94)
Median treatment duration, mo (range)	3.6 (0–10)	Atezo/bev: 6.3/6.9 (1–10)
Adverse events, n (%)		
Grade 3/4	7 (35)	9 (43)
Grade 5	1 (5)[b]	0
Leading to any treatment discontinuation	0	2 (10)

[a]n=19 for efficacy (no measurable disease at baseline in 1 pt).
[b]Cardiac arrest, not considered treatment related.

Conclusions: The 33% cORR with cobi in heavily pretreated LGSOC/MLA is promising; additional pts will be enrolled. Tolerability was consistent with prior experience. BOUQUET continues to evaluate biomarker-driven therapies for rare eOC.

Clinical trial identification: NCT04931342.

Background: The primary analysis of Study 309/Keynote-775 demonstrated clinically and statistically significant progression-free survival (PFS), overall survival (OS), and objective response rate (ORR) improvements in pts with aEC randomized to LEN + pembro vs chemotherapy (all-comers and pts with mismatch repair-proficient [pMMR] tumors). Pts received pembro for up to 2 yrs and continued LEN until progression or toxicity. This exploratory analysis reports outcomes in pts who completed 2 yrs of pembro and continued LEN at the final prespecified OS analysis (cutoff: 1 Mar 22).

Methods: Pts with aEC and 1 prior platinum-based chemotherapy (up to 2 if 1 given in [neo]adjuvant setting) were randomized to LEN 20 mg PO QD + pembro 200 mg IV Q3W (up to 35 cycles) or chemotherapy (doxorubicin 60 mg/m^2 IV Q3W or paclitaxel 80 mg/m^2 IV QW [3 wks on; 1 wk off]), and stratified by MMR status (pMMR pts were further stratified by ECOG PS, geographic region, and pelvic irradiation history). We report PFS, OS, ORR, duration of response (DOR), and safety in all-comer and pMMR pts who completed 35 cycles (≈2 yrs) of pembro and continued LEN.

Results: Of 411 pts randomized to LEN + pembro (pMMR n=346), 41 (pMMR n=30) completed 35 pembro cycles, continued LEN, and are included in the analysis. Median PFS (95% CI) was 34.1 mos (20.1-not evaluable [NE]) in pMMR pts and 34.1 mos (27.7-NE) in all-comers. Median OS (95% CI) was not reached (NR [NE]) in pMMR pts and all-comers. ORR (95% CI) was 63.3% (43.9-80.1) in pMMR pts and 63.4% (46.9-77.9) in all-comers; 7 pMMR pts and 8 all-comers had a complete response. Median DOR was NR (range, 3.5-39.5+) in pMMR pts and all-comers. Grade ≥3 treatment-related adverse events occurred in 80.5% of all-comers (Table).

Table: 748P

	pMMR pembro completers (n=30)	All-comer pembro completers (n=41)
Median PFS[a,b] (95% CI), mos	34.1 (20.1-NE)	34.1 (27.7-NE)
Median OS[b] (95% CI), mos	NR (NE-NE)	NR (NE-NE)
OS rate at 36 mos[b] (95% CI), %	84.3 (63.2-93.8)	89.0 (73.1-95.7)
ORR[a] (95% CI), %	63.3 (43.9-80.1)	63.4 (46.9-77.9)
CR[a] (95% CI), %	23.3 (9.9-42.3)	19.5 (8.8-34.9)
Median DOR[a,b] (range), mos	NR (3.5-39.5+)	NR (3.5-39.5+)
Probability of pts with extended DOR[a], %[b]		
≥24 mos	78.3	83.8
≥36 mos	69.6	70.9
Drug-related AEs[c], n (%)		
Any grade		41 (100)
Grade ≥3		33 (80.5)

[a]Blinded Independent Central Review, RECIST v1.1
[b]Product-limit (Kaplan-Meier) method for censored date.
[c]Reported in all-comers only.
AE, adverse event; CR, complete response.

Conclusions: Ongoing clinical benefit in pembro completers who continued LEN supports LEN + pembro as standard of care in pts with aEC who received prior platinum therapy.

Clinical trial identification: NCT03517449.

Background: In the RUBY (NCT03981796) trial, dostarlimab (D)+carboplatin/paclitaxel (CP) demonstrated significant PFS improvement compared to placebo (PBO)+CP in pts with pA/rEC. PROs are reported here for the dMMR/MSI-H population.

Methods: Pts with pA/rEC were randomized 1:1 to D+CP or PBO+CP Q3W (6 cycles) followed by D or PBO monotherapy Q6W $\leq$3 years or disease progression. EORTC QLQ-C30 and EORTC QLQ-EN24 were secondary endpoints. PROs were administered at baseline (BL), day 1 of each cycle (C), end of treatment (EOT), and all follow-ups. Change (chg) from BL to EOT was calculated for assessed scales. Mixed models for repeated measures were used to generate least-squares means (LSM), adjusting for within-pt correlations across time points within a pt and controlling for BL values. Improvement is indicated by higher scores for QoL and functional scales and lower scores for symptom scales.

Results: Of 494 pts enrolled, 118 were dMMR/MSI-H. Mean BL scores and mean chg from BL to EOT for global QoL, functional scales, and select symptom are shown in the

Table: 749P

	D+CP		PBO+CP	
	BL Mean (SD)	BL to EOT Mean chg (SD)	BL Mean (SD)	BL to EOT Mean chg (SD)
EORTC QLQ-C30				
Global QoL	66.7 (25.9)	3.0 (19.4)	67.3 (23.9)	-11.1 (29.1)
Physical F	74.9 (21.8)	-5.0 (17.1)	69.1 (23.3)	-6.1 (26.9)
Role F	66.6 (32.2)	0.9 (29.7)	72.9 (32.2)	-7.8 (36.6)
Emotional F	75.9 (18.1)	9.2 (17.5)	75.9 (20.1)	-6.7 (30.4)
Cognitive F	86.3 (20.7)	-1.5 (17.8)	88.0 (19.3)	-9.3 (31.5)
Social F	74.5 (30.3)	6.1 (34.7)	80.2 (27.2)	-12.0 (33.8)
Pain[a]	32.3 (27.3)	-3.0 (29.7)	32.3 (32.1)	8.2 (32.8)
Fatigue[a]	33.9 (25.2)	-5.1 (26.9)	35.1 (27.7)	7.2 (36.0)
EORTC QLQ-EN24				
Back and pelvis pain[a]	35.3 (31.0)	-10.8 (24.0)	36.5 (32.7)	-3.1 (38.3)

[a]Lower scores indicate reduced symptom severity F, function

table. Mean chg from BL to EOT showed improvement in global QoL, emotional and social function, pain, and back/pelvis pain for D+CP. Only back/pelvis pain showed improvement for PBO+CP. Significant differences (LSM [standard error]) between arms were reported for chg from BL to EOT for QoL (14.7 [5.45]; P=0.008), role (12.7 [5.92]; P=0.032), emotional (14.3 [4.92]; P=0.004) and social function (13.5 [5.43]; P=0.014), and fatigue (-13.3 [5.84]; P=0.025).

Conclusions: Pts receiving D+CP demonstrated improvements in several QoL domains relative to BL at EOT, with significant improvements over PBO+CP, in global QoL, role, emotional, and social function, and fatigue. Dostarlimab+CP significantly improved PFS while maintaining QoL, further supporting its use as a standard of care in pts with dMMR/MSI-H pA/rEC.

Clinical trial identification: NCT01847274.

Background: The RUBY trial (NCT03981796) evaluated the efficacy and safety of dostarlimab (D)+carboplatin-paclitaxel (CP) vs CP alone in pA/rEC. D+CP significantly improved progression-free survival (PFS) in the mismatch repair deficient/microsatellite instability-high (dMMR/MSI-H; HR, 0.28) and overall population (HR, 0.64) with a favorable OS trend (HR, 0.64). Here, PFS2 and OS adjusted for subsequent anticancer therapy are reported.

Methods: Pts were randomised 1:1 to receive D+CP or placebo (PBO)+CP Q3W for 6 cycles, followed by D or PBO monotherapy Q6W for up to 3 years. PFS2 was a secondary endpoint for the dMMR/MSI-H and overall populations. Post hoc treatment switching-adjustment (for subsequent use of dostarlimab, pembrolizumab, durvalumab, nivolumab, or pembrolizumab with lenvatinib) was implemented using 2 methods: inverse probability of censoring weighting (IPCW) and rank-preserving structural failure time (RPSFT).

Results: Of 494 pts randomised (D+CP, n=245; PBO+CP, n=249), 118 were dMMR/MSI-H (D+CP, n=53; PBO+CP, n=65). Overall, 15.5% of pts in the D+CP arm and 34.5% of pts in the PBO+CP arm received subsequent immunotherapy. PFS2 benefit was observed with D+CP for all populations (Table). When adjusted for subsequent therapy, the HRs for OS for D+CP vs PBO+CP for both IPCW and RPSFT were similar to the unadjusted HR for OS in all populations, with increased survival with D+CP (Table). Safety was reported previously.

Conclusions: Consistent with results of the primary efficacy analysis, dostarlimab+CP demonstrates PFS2 and OS benefits vs PBO+CP in pts with pA/rEC despite the use of subsequent therapies. These results provide additional support for the use of dostarlimab+CP as standard of care in pts with pA/rEC..

Background: With the introduction of molecular classification of endometrial cancer (EC), the importance of Lynch syndrome and hereditary EC has been emphasized. For a successful conduct of EC-therapy, the patient's expectations, preferences, and needs should be considered. The aim of this survey was to evaluate the status quo and the patients' understanding of their own condition, including genetic counseling.

Methods: We developed an international online and paper survey with 80 questions for endometrial cancer patients. It included questions on demographics, medical history, tumor classification, therapy, preferences and expectations concerning treatment modalities.

Results: To date, 656 endometrial cancer patients (mean age: 65.0 [20.0; 92.0] years) completed the survey from a total of seven countries, mainly from Germany (56.1%) and Switzerland (40.5%). The majority of patients (77.4 %) were in follow-up and not receiving current cancer therapy, while 16.1 % were still receiving treatment, of which 6.4 % were due to cancer recurrence. Overall, 14.3% of the patients suffered from a recurrent disease. One third of patients (35.1%) reported that their tumor had been tested for molecular classification, and more than half (56.9%) did not know if this had occurred. Genetic counseling was only given to 21.7% of patients, 63.1% did not receive any form of it. From the patients understanding, 19.6% believe that a family history or genetic alteration could be responsible for tumorigenesis – 30.6% do not know. On the contrary, 68.1% of the patients answered that there were cases of cancer in their blood relatives – 19.1% had one or more cases of colorectal cancer in the family history, 13.9% endometrial, 10.9% gastric and 3.9% ovarian cancer. 16.4% of all patients had a second malignancy in their medical history. In general, 32.4 % of patients would like doctors to spend more time on explanations.

Conclusions: This survey underlines the great need for better access to molecular profiling and genetic counseling in women with endometrial cancer. Programs should be developed to empower patients and to educate medical staff.

Background: Adding pembrolizumab (P) to standard first-line chemotherapy +/- bevacizumab in cervical cancer significantly improved survival. However, more than half of patients (pts) will present a relapse before 12 months. Virtually all cases of cervical cancer are attributable to HPV infection. Preclinical evidence suggests that histone deacetylase inhibitor vorinostat (V), might be active in both HPV 16 and HPV 18 related infections and might improve immunotherapy efficacy giving the rationale for combining P + V in cervical cancer.

Methods: PEVOsq is an open-label, non-randomized, multi-center, basket phase II trial, evaluating the efficacy of P+V in pts with recurrent and/or metastatic squamous carcinomas. Pts had to be PD1/PD-L1 antagonist-naïve with no restriction in terms of prior lines of treatments. P dose was 200 mg Q3W IV, and V 400 mg QD PO. Sample size was determined using an A'Hern design. Primary endpoint was objective response rate (ORR) according to RECIST 1.1. Secondary endpoints included safety, progression-free survival (PFS), overall survival (OS), and duration of response (DOR).

Results: Among 112 included pts, 25 were included in the cervix cohort. Median age was 52 years [range(r): 31-75]. The median number of prior lines of therapies was 1 [r: 0-3]. Among 23 pts evaluable for activity criteria, ORR was 39.1% [95%CI: 19.7-61.5]. Median PFS was 4.2 months [95%CI: 2.3-8.2] and OS was 10.3 months [95%CI: 5.7-NR]. DOR was 15.2 months [95%CI 1.4-NR]. Grade 3/4 Treatment related AE were frequent (44%). Seventeen pts (68%) had at least one treatment interruption and/or dose reduction due to toxicity for V including hematotoxicity, gastrointestinal disorders, asthenia, and creatinine increase. Six pts (24%) had at least one administration delayed due to toxicity for P. Median dose intensity for V was 271.4 mg/j [r: 108.7 — 400]. Dose intensity for V was 271.1mg/d [r: 108.7-400.0] and 260.5mg/d [r: 199.4-400.0] in pts with ORR and others (SD/PD), respectively. Results according to PDL1, MSI, TMB and HPV will be presented at the meeting.

Conclusions: Combining P and V in cervical cancer was effective even though dose adaptations for V were frequent.

Clinical trial identification: NCT04357873, EudraCT 2019-003839-33.

753P IN10018 in combination with pegylated liposomal doxorubicin (PLD) in platinum-resistant ovarian cancer (PROC): A single-arm, phase Ib clinical trial

L. Wu[1], J. Wang[2], L. Wang[3], W. Lu[4], K. Wang[5], A. Lin[6], N. Li[1], L. Li[2], N. Su[3], S. Xie[7], J. Jiang[7]

[1]Gynecologic Oncology, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China; [2]Gynecologic Oncology, Hunan Cancer Hospital, Changsha, China; [3]Gynecologic Oncology, The Affiliated Cancer Hospital of Zhengzhou University&Henan Cancer Hospital, Zhengzhou, China; [4]Gynecologic Oncology, Women's Hospital School of Medicine Zhejiang University, Hangzhou, China; [5]Gynecologic Oncology, Tianjin Medical University Cancer Institute and Hospital, Tianjin, China; [6]Gynecologic Oncology, Fujian Provincial Cancer Hospital, Fuzhou, China; [7]Clinical Research, InxMed (Nanjing) Co., Ltd., Nanjing, China

Background: IN10018 is a highly potent and selective oral inhibitor of focal adhesion kinase (FAK). Our previous work showed promising objective response rate (ORR) and progression-free survival (PFS) of IN10018 in combination with PLD in PROC patients (Wu et al, ASCO2022). Here we present the fully enrolled study data, especially the overall survival (OS).

Methods: In this single-arm, open-label, phase Ib trial, PROC pts (high-grade serous only) received IN10018 in combination with PLD treatment until intolerable toxicity or disease progression. The primary endpoint was ORR, the second endpoints including disease control rate (DCR), duration of response (DOR), PFS, OS, and safety.

Results: As of April 28, 2023, a total of 61 PROC pts (median age 55 years) were enrolled with median follow-up duration of 14.0 months (range: 0.9 - 32.8 months). 90.2% (55/61) pts had 1-3 prior lines of therapy, 34.4% (21/61) had prior bevacizumab treatment and 27.9% (17/61) had prior PARPi treatment. The safety profile of the combination is comparable to these single agents alone without additive toxicities. No IN10018 related death was observed, and 9.8% (6/61) pts reported IN10018 related SAEs which were also PLD related. The most frequently reported IN10018 related AEs assessed by investigators were proteinuria, decreased appetite, fatigue and AEs of gastrointestinal origin such as nausea, diarrhea, vomiting. Majority of these IN10018 related AEs were grade 1 and 2. No IN10018 related grade 4 or 5 AEs were reported. Efficacy (as assessed by investigator) was evaluable in 54 pts. 25 responders (including 1 confirmed CR, 21 confirmed PRs and 3 unconfirmed PRs) and 20 SDs were reported. The ORR was 46.3% (95% CI: 32.6%, 60.4%), the DCR was 83.3% (95% CI: 70.7%, 92.1%). The mDOR was 6.9 months (95% CI: 4.2 — 9.1 months). The mPFS was 7.3 months (95% CI: 5.2 — 9.0 months). The mOS was 20.9 months (26/61 OS events, 95% CI: 14.4 — NA) in all treated population and maturing.

Conclusions: The combination of IN10018 with PLD showed manageable safety profile and prolonged survival in PROC pts. A placebo-controlled, randomized, double-blind phase II trial is ongoing to confirm the observed efficacy and safety.

Clinical trial identification: NCT05551507.

754P Ubamatamab (MUC16xCD3 bispecific antibody) with cemiplimab (anti-PD-1 antibody) in recurrent ovarian cancer: Phase I dose-escalation study

R.E. O'Cearbhaill[1], K.N. Moore[2], O. Yeku[3], J.F. Liu[4], S. Bouberhan[3], E.P. Hamilton[5], J.Y. Hou[6], E. Van Nieuwenhuysen[7], K. Papadimitriou[8], S-Y. Yoo[9], S. Govindraj[9], J. Brouwer-Visser[9], M. Peterman[9], T. Schmidt[9], B. Barnes[9], P. Madia[9], M. Zhu[9], T.S. Uldrick[9], E.A. Miller[9], D. O'Malley[10]

[1]Department of Medicine, Memorial Sloan Kettering Cancer Center and Weill Cornell Medical College, New York, NY, USA; [2]Stephenson Cancer Center, University of Oklahoma Health Sciences Center/Sarah Cannon Research Institute, Oklahoma City, OK, USA; [3]Cancer Center, Massachusetts General Hospital, Boston, MA, USA; [4]Medical Oncology, Dana-Farber Cancer Institute, Boston, MA, USA; [5]Sarah Cannon Research Institute, Tennessee Oncology, Nashville, TN, USA; [6]Division of Gynecologic Oncology, Columbia University Medical Center, New York, NY, USA; [7]Department of Oncology, Leuven Cancer Institute, Leuven, Belgium; [8]Multidisciplinary Oncologic Centre Antwerp (MOCA), Antwerp University Hospital, Antwerp, Belgium; [9]Global Development, Regeneron Pharmaceuticals, Inc., Tarrytown, NY, USA; [10]Division of Gynecologic Oncology, The Ohio State University and The James Cancer Center, Columbus, OH, USA

Background: Ubamatamab (REGN4018) is a mucin16 (MUC16) x CD3 bispecific antibody. Cemiplimab, an anti-PD-1 antibody, enhanced its activity in preclinical studies. In phase 1 (NCT03564340), ubamatamab monotherapy resulted in an acceptable safety profile and durable responses. We now present ubamatamab combined with cemiplimab dose escalation results.

Methods: Patients (pts) with recurrent platinum-experienced ovarian cancer (OC) received weekly intravenous (IV) ubamatamab at a dose range of 1—450 mg after initial step-up dosing. Cemiplimab 350 mg IV every 3 weeks was added beginning Day 29—36. Dose escalation initially followed a modified 3+3 design, then Bayesian optimal interval design. Primary endpoints were safety and PK. Secondary endpoints included confirmed objective response rate (ORR), Kaplan-Meier estimated duration of response (DoR) and progression-free survival (PFS) (RECIST 1.1), and CA125 response (GCIG).

Results: 35 pts were enrolled, 29 (82.9%) received ≥1 dose of cemiplimab. Median number of prior therapies was 5 (range 1—10). Median duration of ubamatamab and cemiplimab exposure was 11 (range 2—75) and 12 (3—69) weeks, respectively. The most common treatment-emergent adverse events (TEAE) were pain (82.9%) and cytokine release syndrome (68.6%, all Grade [G] 1/2). The most common G≥3 TEAE were anaemia (25.7%), pain (20.0%) and neutropaenia (11.4%, 1 dose-limiting toxicity [DLT], 60 mg). Ubamatamab 1—250 mg weekly with cemiplimab was tolerable. In the highest dose cohort (450 mg), haemophagocytic lymphohistiocytosis (G4, DLT) was observed. Objective responses were observed at ubamatamab doses 10—250 mg (n=25). In 22 of these pts receiving ≥1 dose of cemiplimab, ORR was 18.2% (95% CI: 5.2—40.3), median DoR 8.3 months (4.2—not estimable), CA125 response rate 22.7% (7.8—45.4) and 6-month PFS 47.6% (25.7—66.7). Two pts with target lesion growth (+17%, +31%) before adding cemiplimab to ubamatamab had subsequent partial responses. Ubamatamab PK was not impacted by cemiplimab.

Conclusions: In pts with heavily pretreated OC, an acceptable safety profile and durable responses were observed with ubamatamab + cemiplimab. A randomised phase 2 expansion of ubamatamab +/- cemiplimab is ongoing.

Clinical trial identification: NCT03564340.

Background: Retifanlimab (Zynyz™) is a programmed death receptor-1 (PD-1)—blocking antibody recently approved in the United States for the treatment of adult patients with metastatic or recurrent locally advanced Merkel cell carcinoma. POD1UM-101 (NCT03059823) is an ongoing first-in-human dose finding and cohort expansion study in patients with advanced solid tumours. We have previously reported significant clinical activity with safety for retifanlimab representative of the class in the MSI-H or dMMR endometrial cancer expansion cohort (Berton D, SITC 2021). We present final study results.

Methods: Eligible patients had histologically proven, unresectable recurrent/metastatic MSI-H or dMMR endometrial cancer, Eastern Cooperative Oncology Group performance status (ECOG PS) $\leq$1, disease progression during or following 1 to $\leq$5 prior systemic treatments, measurable disease (per RECIST v1.1), and were naïve to prior immune checkpoint inhibitors. MSI-H and dMMR status were centrally confirmed. Patients received retifanlimab 500 mg every 4 weeks for up to 2 years. The primary study endpoint was safety. Confirmed best overall response and duration of response were evaluated by independent central reviewer (ICR).

Results: A total of 76 patients with centrally confirmed MSI-H (65 [85.5%]) or dMMR (11 [14.5%]) disease were enrolled, with the last patient initiating treatment on 29 December 2020. Median age was 67 (range 49—88) years, 70 (92%) had endometrioid histology, 67 (88%) had metastatic disease, and 61 (80%) had visceral metastases. Most patients had received prior radiotherapy (54 [71%]) or surgery (68 [90%]). All patients except for one, had received prior chemotherapy for advanced disease with 33 (43.4%) patients receiving $\geq$2 prior systemic therapies. The overall response rate by ICR was 43% (95% CI: 32—55). Final results for this cohort including safety and secondary efficacy endpoints will be presented.

Conclusions: Retifanlimab has shown notable clinical activity in previously treated MSI-H or dMMR endometrial cancer, which is consistent with other checkpoint immunotherapies.

Clinical trial identification: NCT03059823, EudraCT 2017-000865-63.

Background: CLDN6 is expressed at high levels in multiple cancers with little to no expression in normal tissues and has been implicated in the initiation, progression, and metastasis of some cancers. CLDN6 is an ideal target for development of new therapeutics. TORL-1-23 is first-in-class ADC targeting the tumor-specific antigen CLDN6.

Methods: This ongoing first in human study (TORL123-001, NCT05103683) characterizes the safety, tolerability, dose-limiting toxicities (DLTs), maximum tolerated dose (MTD), and recommended phase 2 dose (RP2D) of TORL-1-23 in participants with advanced solid tumors. Pharmacokinetics (PK), immunogenicity and clinical efficacy are also assessed. TORL-1-23 is administered IV every 3 weeks. In Dose Escalation, cohorts up to 6 participants are evaluated at each dose level according to an accelerated titration design. In Dose Expansion, patients with CLDN6-expressing cancers will be evaluated to confirm the RP2D in ovarian cancer, NSCLC, and other CLDN6+ cancers using an IHC companion diagnostic. Doses above the historic MTD for MMAE containing ADCs are being evaluated given the favorable safety/tolerability at doses $<$2.4 mg/kg.

Results: 30 patients with ovarian (n=22), testicular (n=5), and endometrial (n=3) cancers were enrolled across 9 dose levels ranging from 0.2 to 3 mg/kg IV every 3 weeks (as of 01MAY2023). 93% of pts had received $\geq$ 3 prior lines of treatment in the metastatic setting. The most common treatment-related adverse events were Gr1/2 fatigue (n=6), anemia (n=5), and peripheral neuropathy (n=4). No DLTs were observed at doses $\leq$2.4 mg/kg. Sustained PK exposure of TORL-1-23 over the dosing interval and low levels of circulating MMAE are noted. Partial responses (PR) were observed in 7/22 (32%) efficacy evaluable participants with CLDN6+ disease (6 ovarian, 1 testicular) across dose levels. 3/3 (100%) participants with CLDN6+ ovarian cancer responded at the 2.4 mg/kg dose level. Data from 3 mg/kg are pending.

Conclusions: In participants with heavily-pretreated CLDN6-expressing ovarian cancer, the novel TORL-1-23 ADC has a favorable safety/tolerability profile and encouraging antitumor activity in a phase 1 dose finding study. Further evaluation in ovarian cancer and other CLDN6+ cancers is warranted.

Clinical trial identification: NCT05103683.

757P The efficacy and safety of recombinant human adenovirus type 5 (H101) intra-tumor therapy in patients with recurrent or metastatic cervical cancer: A prospective, open-label, single-arm study

Q. Zhang, Z. Liu, J. Zhang, J. Wang, T. Wang, J. Su, F. Shi, F. Wang

Department of Radiation Oncology, The First Affiliated Hospital of Xi'an Jiao Tong University, Xi'an, China

Background: H101 has promising efficacy and favorable safety in patients with persistent /recurrence/metastasis (P/R/M) gynecological cancer, but the evidence regarding the effect of H101 on cervical cancer remains rare. Thus, the purpose of this study is to evaluate the efficacy and safety of H101 intra-tumor injection in P/R/M cervical cancer.

Methods: This is a prospective, open-label, single-arm study, with an expected sample size of 60. P/R/M cervical cancer patients who had received at least one line of systemic therapy or could not tolerate chemotherapy were eligible. Patients were given H101 intro-tumor injection ($0.5\text{-}1.5\times10^{12}$) viral particles from day 1 to day 5 combined with or without radiotherapy in sequential, 3 weeks for a cycle (1-4 cycles totally). The primary endpoint is local control (LC) and the secondary endpoints include objective response rate (ORR), progression-free survival (PFS), overall survival (OS) and adverse events (AEs). This trial was registered at www.clinicaltrials.gov with identifier number NCT 05051696.

Results: Between September 2021 to April 2023, 53 patients were enrolled, in which 49 patients (92.45%) completed at least 1 tumor assessment with a median follow-up time of 8 months (95%CI: 7-11months). The LC rate at 3 months was 73.5% (95%CI: 60.7%-86.3%), and the median PFS and OS were currently not reached. The ORR was 69.4% (95%CI: 56%-82.8%), and the disease control rate (DCR) was 81.6% (95%CI: 70.4%-92.9%) by RECIST1.1. The most frequently reported AEs were fever (62.8%), fatigue (32.65%), vomiting (20.41%), bleeding (16.3%), pain (16.3%) and bird-flue like symptoms (16.3%). All frequently occurring AEs were grade 1 or 2. High grade AE was only observed in 3 patients with rectovaginal fistula grade 3. Neither unexpected safety signals nor treatment related death occurred.

Conclusions: We present here for the first time that H101 is a strong candidate for virotherapy in P/R/M cervical cancer. These results demonstrate that H101 combined with or without radiotherapy could improve clinical outcomes significantly in patients with P/R/M cervical cancers with acceptable toxicity.

Clinical trial identification: NCT05051696.

Background: Vulvar and vaginal squamous cell carcinoma (VVSCC) are rare, representing 4% of gynecologic cancers. At recurrent/metastatic stage systemic treatments are limited without gold-standard, chemotherapy response rate is poor. Immunotherapy has been approved for some metastatic SCC. Translational analyzes suggest that SCC share common molecular features as epigenetic. Modulating the epigenome might improve the efficacy of immunotherapy. Combining pembrolizumab (P) to an epidrug vorinostat (V) has been proposed in the PEVO basket trial. We described here the VVSCC cohort.

Methods: PEVOsq is an open-label, non-randomized, multi-center, basket phase II trial, evaluating the efficacy of P combined to V in patients with recurrent/metastatic SCC of the cervix, head and neck, anus, vulva/vagina, penis, and lung. Patients had to be PD1/PD-L1 antagonist-naïve. There was no selection based on PD-L1 expression, HPV status, or number of prior lines of treatments. P dose was 200 mg Q3W IV, and V 400 mg QD PO. Sample size was determined using an A'Hern design with the following hypotheses (alpha=5%, power=90%, p0=5%, p1=30%). The primary endpoint was objective response rate (ORR) according to RECIST 1.1. Secondary endpoints included safety, progression-free survival (PFS), overall survival (OS).

Results: Among 112 included patients, 17 had a VVSCC metastatic/recurrent cancer. Median age was 63 years old [range: 40-85], 14 (82.4%) had a metastatic disease and 3 (17.6%) a locally advanced relapse. Lung 50.0%) and lymph nodes (78.6%) were the major metastatic sites. Inclusion in PEVOsq was the first-line treatment for most of patients, with a median number of prior treatment lines of 0 [range: 0-1]. Three patients out of 16 evaluable patients (18.8%) had an OR: 1 (6.3%) CR and 2 (12.5%) PR. Median PFS was 1.3 months [95%CI: 1.1-4.3]. Median OS was 17.5 months [95% CI: 2.3-NR]. Four patients (23.5%) had a G3/4 treatment related AE. Results according to PDL1, MSI, TMB and HPV will be presented at the meeting.

Conclusions: P combined with V is safe and produce encouraging efficacy in VVSCC patients.

Clinical trial identification: NCT04357873, EudraCT 2019-003839-33.

Background: Concurrent chemo-radiotherapy (CCRT) with platinum-based regimen is the standard treatment for locally advanced cervical cancer (LACC), however, 30% of patients developed recurrence and metastasis. Epidermal growth factor receptor (EGFR) is highly expressed in most cervical squamous cell carcinomas with poor survival prognosis. Nimotuzumab combined with CCRT had good antitumor activity and safety in LACC. In order to evaluate the efficacy and safety of nimotuzumab combined with CCRT in locally advanced cervical squamous cell carcinoma patients, we conducted a randomized, controlled, open-label, multicenter study (NCT04678791).

Methods: All patients with locally advanced cervical squamous cell carcinoma were randomized (1:1) to receive nimotuzumab (400mg, iv, weekly, for 6 weeks) combined with CCRT (cisplatin: 40 mg/m^2, weekly, for 6 weeks; IMRT/VMAT: 45-50.4 Gy/25-28f; high-dose rate brachytherapy: 30-40 Gy, in 8 weeks) or CCRT alone. The primary endpoint was 3-year progression free survival (PFS) per RECIST v1.1. The secondary endpoints were 3-year overall survival (OS), objective response rate (ORR), complete response (CR) rate per RECIST v1.1, and safety per CTCAE v5.0.

Results: Totally 291 patients were enrolled. 147 patients in the Nimo group (nimotuzumab combined with CCRT) and 144 in the CCRT group (CCRT alone). The median follow-up time was 1.8 months, and follow-up is ongoing. The baseline characteristics were balanced between the two groups. The median PFS of the Nimo group was longer than that of CCRT group (9.5 vs. 7.0 months, P=0.129), the 3-year PFS and 3-

year OS were not reached. A total of 28 (19.05%) patients achieved partial response (PR) and 99 (67.35%) achieved CR in the Nimo group, 17 (11.81%) and 93 (64.58%) in the CCRT group, respectively. The ORR was 86.39% vs. 76.39% (P=0.028). The incidence of grade 3 or higher adverse reactions had no significant difference between the two groups (P > 0.05).

Conclusions: Nimotuzumab combined with concurrent chemo-radiotherapy showed longer survival trend and significantly improved the ORR in patients of locally advanced cervical squamous cell carcinoma with a good tolerance.

Clinical trial identification: NCT04678791.

Background: Although concurrent chemoradiotherapy is the standard treatment for locally advanced cervical cancer, elderly patients are often intolerable to chemotherapy. It's urgent to explore a suitable regimen for these population. Cervical squamous cell carcinoma (CSCC) is characterized by the high expression of epidermal growth factor receptor (EGFR). Nimotuzumab is a recombinant humanized anti-EGFR monoclonal antibody with good safety. This study aimed to investigate the efficacy and safety of nimotuzumab plus radiotherapy in the treatment of elderly patients with locally advanced cervical squamous cell carcinoma (LACSCC).

Methods: It's a prospective, multicenter, and single-arm trial. Key inclusion criteria included aged $\geq$ 65 years, histologically diagnosed CSCC with clinical stage IB3-IVA, ECOG 0-2, and refusing chemotherapy. Patients received nimotuzumab with 200mg/w for 6 weeks, underwent radiotherapy, including intensity-modulated radiotherapy (IMRT), volumetric intensity modulated arc therapy (VMAT) (45-50.4Gy, 1.8-2.0Gy/f, 25-28f), and brachytherapy (HR-CTV D90, 80-85Gy). Brachytherapy combined with external beam radiotherapy was completed within 8 weeks. The current endpoints include objective response rate (ORR), complete response rate (CRR), disease control rate (DCR), and safety.

Results: This trial enrolled 122 elderly LACSCC patients from Nov 2021 to Jan 2023. The median age was 72.5 years old (range from 65 to 92) with clinical stage IB3-IVA. The addition of nimotuzumab to radiotherapy exhibited a significant improvement in short-term efficacy with ORR of 87.70% (107/122), CRR of 42.62% (52/122), and DCR of 92.62% (113/122). The partial response was 45.08% (55/122), progressive disease was 2.50% (3/122), and stable disease was 4.92% (6/122). So far, no drug-related adverse events have occurred.

Conclusions: Nimotuzumab plus radiotherapy provided significant improvements in ORR, CRR, and DCR in elderly patients with LACSCC. No drug-related adverse events were observed. Our results demonstrate that nimotuzumab combined with radiotherapy may provide a choice for this population with better efficacy and tolerance.

Background: The Cancer Genome Atlas (TCGA) classified endometrial cancer (EC) into molecular subgroups with different prognosis and predictive value of response to immunotherapy or chemotherapy. Testing for surrogate biomarkers (BM) of TCGA groups may be clinically cost-effective. According to these BM groups, we evaluated differences in efficacy of avelumab (A) and pegylated liposomal doxorubicin (PLD) in recurrent EC pts.

Methods: Open-label, single-arm, multicenter, phase II study in recurrent/metastatic EC. Pts were treated with intravenous A 10 mg/kg (q2W) and PLD 40 mg/m^2 (q4W). Primary endpoint was 6 months (m) progression free survival (PFS). Archival tumor tissue was collected for molecular classification according to BM of the TGCA groups. POLE mutations, mismatch repair markers (MMR) and p53 abnormalities were analysed to classify EC tumors. EC groups were as follows: POLE (POLE mutant); P53-ABN (POLE wt, p53 abnormal): MSI (microsatellite instability) (POLE wt, p53 wt, abnormal MMR); MSS (microsatellite stable) (POLE wt, p53 wt, normal MMR). Differences in PFS and overall survival (OS) were evaluated among BM groups.

Results: BM analysis was performed in 41 pts: 26 (63.4%) were p53-ABN, 7 (17.1%) MSI, 7 (17.1%) non-specific molecular profile (NSMP), and 1 (2.4%) POLE. MSI/MSS classification showed 33 (80.5%) MSS tumors, 7 (17.1%) MSI, and 1 (2.4%) POLE. 6-m PFS was 45% [95% CI 31.9%-63.4%] with a median PFS of 5.68m [95% CI 3.58-7.98]. NSMP group showed the best PFS results: 6-m PFS, 66.7% and median, 9.2m (95% CI 1.7 — NR). 6-m PFS of MSI and P53-ABN groups was 28.6% and 42.3%, respectively. 6-m PFS was numerically better in MSS (46.9%) than in MSI (28.6%). Median OS time was 11.6m [95%CI; 7.4-NR] and 12-m OS was 47.5% [34.3%-65.8%]. Median OS in the NSMP, p53-ABN and MSI groups was 26.0m, 12.6m and 5.3m, respectively. OS was better in p53-ABN group than in MSI (HR: 3.44 [1.36; 8.69], p=0.01). OS was also better in MSS group than in MSI (HR: 3.78 [1.52; 9.43], p<0.01).

Conclusions: A and PLD has activity in pre-treated recurrent EC. Pts with MSS and p53-ABN had better outcomes than those with MSI. Interestingly pre-treated NSMP pts show a median OS >2 y.

762P Pamiparib combined with surufatinib as a neoadjuvant therapy for advanced ovarian cancer patients in the entire population: Preliminary results of a prospective, exploratory, single-arm phase II clinical study

B. Xia[1], W. Jiang[2], J. Chen[1], Y. Chen[3], W. Shan[1], W. Shen[1], Y. Tian[2], Y. Chen[2], X. Chen[2], W. Wu[2], Y. Ma[2], J. Wang[2], W. Qi[2], Z. Wang[3], X. Li[1], X. Huang[1], H. Lin[3], B. Hong[2], H. Zhou[2]

[1]Gynaecology, The First Affiliated Hospital of USTC, Division of Life Sciences and Medicine, University of Science and Technology of China, Hefei, China; [2]Gynaecology, The First Affiliated Hospital of USTC/Anhui Provincial Hospital, Hefei, China; [3]Gynaecology, The First Affiliated Hospital of Bengbu Medical College, Bengbu, China,

Background: Optimal tumor reduction surgery is crucial for for advanced ovarian cancer (OC) prognosis. Neoadjuvant chemotherapy can increase surgery chances for OC, but the benefit to patients (pts) is limited. PARP inhibitors combined with anti-angiogenic drugs have significant benefits in the first-line maintenance and recurrence treatment of OC. This study aims to evaluate the efficacy and safety of Pamiparib combined with Surufatinib neoadjuvant therapy (NAT) for advanced unresectable OC in the entire population.

Methods: This is a single-center, single-arm, phase II study following Simon's two-stage design. 20 pts with newly diagnosed unresectable (Fagotti score $\geq$ 8 or upper abdominal CT score $\geq$ 3) FIGO III-IV OC were recruited. Enrolled pts will receive NAT with Pamiparib (40 mg bid q3w for 3 cycles) combined with Surufatinib (250mg bid q3w for 2 cycles), followed by interval debulking surgery (IDS) and4 cycles of platinum-containing chemotherapy. The primary endpoint is complete resection rate (R0), and secondary endpoints include objective response rate (ORR), pathologic complete response(pCR) rate, progression-free survival, overall survival, and safety.

Results: As of Aug 30, 2023, of the 20 enrolled pts, 16 had completed genetic testing, and 14 were homologous recombination deficiency (HRD) positive, with 9 cases of BRCA1/2 mutations. By Aug 30, 2023, 17 pts completed NAT and IDS with an ORR of 100%. 15 pts achieved R0 surgery (88.24%), and 2 pts achieved R1. All 20 pts were evaluable by GCIG CA125 criteria, and CA125 response was all observed (100%). Grade 3 or 4 treatment-related adverse events that occurred are neutropenia, thrombocytopenia, anemia, and hepatic dysfunction.

Conclusions: Pamiparib combined with Surufatinib as a new neoadjuvant "chemotherapy-free" regimen showed extremely high R0 and ORR rates with manageable toxicity profiles. Currently, the experiment is still ongoing and further analysis and reporting of more data will be conducted.

Clinical trial identification: NCT05652283, Release date: 6 December 2022.

763P Penpulimab + anlotinib plus chemo-less therapy in first-line treatment for persistent, recurrent, or metastatic cervical cancer: A single-arm, phase II study (ALTN-AK105-II-06)

Q. Xu, J. Liu, L. Li, Y. Lin, Y. Chen, Y. Song, L. Luo

Gynecologic Radiotherapy, Fujian Provincial Cancer Hospital, Fuzhou, China

Background: Anlotinib is a novel multi-target tyrosine kinase inhibitor, inhibiting tumour angiogenesis and proliferative signalling. Penpulimab is a novel human immunoglobulin G1 (IgG1) anti-programmed cell death-1 (PD-1) antibody. ALTN-AK105-II-06 (ChiCTR2200062897) aimed to assess the effiacy and safety of penpulimab + anlotinib plus chemo-less therapy as fist-line therapy for persistent, recurrent, or metastatic cervical cancer.

Methods: Eligible adults with persistent, recurrent, or metastatic cervical cancer not previously treated with systemic chemotherapy and not amenable curative treatment, with CPS more than 1% PD-L1 expression, and ECOG 0-1 were considered eligible for enrolment. Patients received 2 cycles of chemotherapy (paclitaxel 175 mg/m2 + cisplatin 50 mg/m2 or carboplatin AUC 5) + penpulimab 200mg Q3W + anlotinib 10mg, following with penpulimab and anlotinib for maintenance therapy. Patients were treated on continuous 3 weeks of penpulimab for up to 2 years, until disease progression, or unacceptable toxicities. The primary endpoint was objective response rate (ORR). Secondary endpoints included progression-free survival (PFS), disease control rate (DCR), duration of response (DoR), overall survival (OS), 6-month PFS, safety and quality of life.

Results: From Sep 2022 to May 2023, 15 patients were recruited with a median age of 47 years (range: 44-66), FIGO histopathological stage IIB (26.7%), III (46.7%) and IV (26.7%) were enrolled. 46.7% patients had ECOG PS 1. At data cutoff date (May 08, 2023), 14 patients had at least one post treatment anti-tumor assessment. 1 (7.1%) patient achieved CR, 11 (78.6 %) patients achieved PR, 1 (7.1%) SD and 1 (7.1%) patient NE. The ORR was 85.7%. Median PFS and OS were not reached. Grade $\geq$3 TRAEs incidence was 42.86% (hypertension: 21.43%, neutropenia: 21.43% leukopenia: 14.29%, and hypertriglyceridemia: 7.14%).

Conclusions: This chemo-less therapy of only 2 cycles of chemotherapy + penpulimab + anlotinib in first-line treatment, maintaining with penpulimab and anlotinib showed promising efficacy with a favourable toxicity profile for patients with persistent, recurrent, or metastatic cervical cancer.

Clinical trial identification: ChiCTR2200062897 (China Clinical Trial Registry).

764P Tislelizumab (Anti-PD-1) combined with definitive chemoradiotherapy in recurrent and/or metastatic cervical cancer (PILOT-2020-511): A single-arm, phase II trial

J. Zhu, G. Ke

Gynecologic Oncology, Fudan University Shanghai Cancer Center, Shanghai, China

Background: Tislelizumab is an investigational, humanized, IgG4 monoclonal antibody with high affinity and binding specificity for programmed cell death-1 (PD-1) emerging as promising investigational agents for the treatment of advanced cervical cancer. This phase II trial evaluated the combination of Tislelizumab plus definitive chemoradiotherapy in patients with recurrent and/or metastatic cervical cancer who relapsed after prior platinum-based therapy.

Methods: PILOT-2020-511 was a single-arm, phase 2 trial done at Fudan University Shanghai Cancer Center (Shanghai, China). Patients aged 18-70 years with recurrent and/or metastatic cervical cancer, with an ECOG performance status of 0-2, and adequate organ and bone marrow function were eligible for inclusion. Patients received concurrent radiotherapy (58-60 Gy in 28 fractions), chemotherapy (4-6 cycles of intravenous paclitaxel [135 mg/m2] and carboplatin [AUC=5]), and tislelizumab (200 mg intravenously every 3 weeks for up to 1 year, or until disease progression or unacceptable toxicity). The primary endpoint was the complete response rate at 3 months after radiotherapy by investigator assessment. Secondary endpoints were overall survival, progression-free survival, duration of response, quality of life (not reported here), and safety. The trial is registered with Chictr.org.cn, ChiCTR2000034748 and follow-up is ongoing.

Results: Between September 1, 2020, and December 25, 2022, 41 patients were enrolled. The median age was 58 years (IQR 52-67), 30 (73.2%) of 42 patients had lymphatic metastasis, and 11 (26.8%) patients were organic metastasis. 40 (97.6%) of 41 patients completed the planned chemoradiotherapy and 32 (78%) of 41 had a complete response. The 1-year overall survival was 66.8% and 1-year progression-free survival was 61.8%. The most common grade 3 or worse adverse event was lymphopenia. The most common immune-related adverse event was thyroid dysfunction.

Conclusions: Combining Tislelizumab with definitive chemoradiotherapy provided encouraging activity and acceptable toxicity in patients with recurrent and/or metastatic cervical cancer, and this regimen warrants further investigation.

Background: Senaparib (IMP4297) is a novel, high potency PARP inhibitor and showed promising antitumor activity for advanced ovarian cancer in phase I studies. This open label, multicenter, single arm, phase II study aimed to evaluate the efficacy and safety of senaparib in pts with BRCA mutated recurrent PSOC.

Methods: Pts with germline and/or somatic BRCA mutated recurrent PSOC who had previously received $\geq$ 2 lines of platinum-based chemotherapy were enrolled. Senaparib 100 mg was administered orally once daily. The primary endpoint was independent review committee (IRC)-assessed objective response rate (ORR) and secondary endpoints included investigator (INV)-assessed ORR, progressive free survival (PFS), duration of response (DOR), overall survival (OS) and safety.

Results: As of 30 Jan 2023, 93 pts were enrolled. Treatment was still ongoing in 26 pts. Median age was 55 y (range 31—77), and 59%/41% pts were partially/fully platinum sensitive, with a median 2 prior systemic therapies (range 2-7). After a median follow up of 15.7 months, efficacy was assessed in 91 pts who received treatment of senaparib and $\geq$ 1 tumor evaluated and met the criteria for the response evaluable set. The INV-assessed confirmed ORR was 59.3% (95% CI, 48.4-69.2) and disease control rate (DCR) was 93.4% (95% CI, 86.2-97.5). Median DOR was 10.3 mo (95% CI, 8.2-12.0). Median PFS was 11.1 mo (95% CI, 8.3-13.8). Median OS was 31.6 mo (95% CI, 25.2-not reached) with 90% and 69% of 1 year and 2 years survival rate. IRC had not finished the assessment. 4% of pts discontinued treatment. The most common ($\geq$ 20%) TEAEs were anemia (71%), decreased white blood cell count (55%), decreased platelet count (54%), decreased neutrophil count (50%), and nausea (28%). Grade $\geq$3 TEAEs in $\geq$5% of pts were anemia (42%), decreased neutrophil count (17%), decreased white blood cell count (16%), and decreased platelet count (16%). 2 pts reported fatal TEAEs, both of which were judged not related to treatment.

Conclusions: Senaparib demonstrated clinically meaningful antitumor activity and manageable safety profile in BRCA1/2 mutated recurrent PSOC. The OS was immature but seemed to be improved.

Clinical trial identification: NCT04089189.

766P A comparative study of sequential and interdigitated brachytherapy with chemoradiation in patients of locally advanced carcinoma cervix

S. Singh[1], H. Mishra[1], R. Mishra[1], I. Jaiswal[1], M. Shah[1], A. Pandey[2], K. Chowdhury[3]

[1]Radiotherapy, Institute of Medical Sciences, Banaras Hindu University, IMS-BHU, Varanasi, India; [2]Radiotherapy, PGIMER-Post Graduate Institute of Medical Education and Research, Chandigarh, India; [3]Faculty of Medicine, Institute of Medical Sciences, Banaras Hindu University, IMS-BHU, Varanasi, India

Background: Prolongation of overall treatment time (OTT) in carcinoma cervix is well known to adversely affect local control and survival. The OTT would be unduly prolonged if brachytherapy (BT) was started only after completion of external beam radiation (EBRT) as multiple insertions are required for high-dose-rate BT. This study was carried out to compare treatment outcomes of shortening the OTT by interdigitated BT as opposed to conventional sequential BT in terms of late toxicities, disease free survival (DFS) and overall survival (OS).

Methods: The study included 70 patients of cancer cervix who met the inclusion criteria. Patients were randomized into study and control arms. All the patients received EBRT (45Gy/20 fractions over 4 weeks) with concurrent Cisplatin and 3 fractions of BT (7 Gy/fraction). Patients in the control arm received weekly BT after one week following EBRT to complete the entire treatment in 7 weeks. In the study arm, BT was interdigitated with EBRT after 15 fractions. Subsequent BT fractions were given on days 27 and 34 to complete the treatment in 5 weeks. The two groups were compared in terms of late toxicities, DFS and OS at a follow up of two years.

Results: A total of 63 patients completed the planned treatment. The OTT and mean biologically equivalent dose (BED_{10Gy}) after reduction for accelerated repopulation was significantly better in the study arm (p=0.001). At two years of follow up, 80% of patients in the study arm and 72.72% in the control arm had no local or distant failure. Also, death occurred in 13.33% patients and 18.18% patients in the study and control arm, respectively. No statistically significant difference was reached in terms of OS and DFS despite a trend towards better DFS in the interdigitated BT arm. The incidence of late lower gastro-intestinal toxicities was found to be higher in the study arm but this difference was not significant.

Conclusions: Interdigitated BT with chemoradiation appears to be an acceptable option for shortening OTT with similar survival outcomes and acceptable toxicities in comparison to sequential brachytherapy. Owing to a shorter OTT, this approach is radiobiologically superior with a more efficient utilization of machines at centers with heavy patient load.

767P Phase I/II study of toripalimab with cisplatin-based concurrent IMRT for local advanced cervical cancer

P. Jiang[1], S. Wei[1], C. Li[1], A. Qu[1], R. Liu[2], M. Wang[3], H. Guo[4], J. Wang[1]

[1]Radiation Oncology Department, Peking University Third Hospital, Beijing, China; [2]Rheumatology Immunology Department, Peking University Third Hospital, Beijing, China; [3]Medical Oncology Department, Peking University Third Hospital, Beijing, China; [4]Obstetrics and Gynecology Department, Peking University Third Hospital, Beijing, China

Background: Cisplatin-based concurrent chemoradiation therapy (CCRT) has been increasingly used for local advanced cervical cancer (LACC). However, recurrence is common after cisplatin-based CCRT. Several treatment strategies have been explored to further improve the outcome. We aimed to evaluate the safety and efficacy of anti-PD-1 (Toripalimab, a humanized immunoglobulin G monoclonal antibody against programmed death 1) combined with cisplatin-based concurrent IMRT for locally advanced cervical cancer.

Methods: This is an open-label, nonrandomized, prospective phase I/II study in a single arm. Patients with untreated LACC (2018 FIGO stage IB3, IIA —IVA) were enrolled. All patients were treated with CCRT for 56 days including cisplatin (40 mg/m2, Q1W) combined with image-guidance volume modulated Arc therapy (IG-VMAT) to pelvis (50.4Gy in 28 fractions, pelvic and paraortic nodes with simultaneous nodal boost to 59.4 Gy, 28 fractions), and followed by HDR intracavitary (30-36 Gy in 5-6 fractions) brachytherapy. Toripalimab was administered intravenously at 240 mg every 2 week for 4 cycles. The primary endpoint was incidence and severity of acute adverse events up to 3 months of completing treatment. The secondary endpoints were ORR and PFS.

Results: From Sep 2020 to Sep 2022, a total of 30 patients were enrolled. Median age was 58 years [range: 23—71]. The median follow-up duration was 8.5 months [range: 3.2—27.3]. 29 patients (29/30, 96.7%) completed the treatment, 1 patient (1/30, 3.3%) terminated the treatment because of hemophagic syndrome, who with a history of liver fluke disease. ORR was 100.0% (30/30) at 3 months after treatment. Treatment-related grade 3 or 4 adverse events occurred in 80% (24/30) of patients, primarily leukopenia (63.3%), lymphopenia (36.7%), anemia (26.7%), neutropenia (16.7%). The grade 1-2 potentially immune-related adverse events were chromatosis 5 (16.7%), rash 2 (6.7%), pruritus 2 (6.7%), hypothyroidism 2 (6.7%), adrenal insufficiency 2 (6.7%), No treatment-related deaths occurred.

Conclusions: Toripalimab combined with cisplatin-based concurrent IMRT was tolerable and showed promising antitumor activity in patients with LACC, while immunotherapy-related toxicities should be carefully managed.

Clinical trial identification: NCT04368273.

768P Preliminary results of an open-label, multicentric, phase Ib/II study to assess the safety and efficacy of AsiDNA, a DNA repair inhibitor, in addition to PARP inhibitor in patients with relapsed platinum sensitive ovarian cancer already treated with PARPi for at least 6 months (RevoCAN)

P. Pautier[1], J-S. Fresnel[2], B. You[3], F. Bazan[4], C. Lebreton[5], A. Leary[6], D. Chaltiel[7]

[1]Medicine Dept., Gustave Roussy Cancer Campus, Villejuif, France; [2]Medicine Dept., Institut de Cancérologie de l'Ouest, Angers, France; [3]Oncology Department, Lyon Sud Hospital Center-HCL, Pierre-Bénite, France; [4]Oncology Department, CHRU Besancon-Hopital Jean Minjoz, Besancon, France; [5]Medicine Dept., Institute Bergonié-Centre Régional de Lutte Contre le Cancer (CLCC), Bordeaux, France; [6]Medicine Dept., Institut Gustave Roussy, Villejuif, France; [7]Bio Statistics, Institut Gustave Roussy, Villejuif, France

Background: The duration of progression-free survival (PFS) in patients with platinum-sensitive recurrent ovarian cancer after response to platinum-based therapy is significantly longer with poly (ADP-ribose) polymerase inhibitors (PARPi). Unfortunately, after initial disease control, resistance to PARPi always occurs at some point. AsiDNA™ is a first-in-class DNA damage repair (DDR) inhibitor designed to prevent the repair of DNA damage in tumor cells. It is an oligonucleotide that mimics DNA double strand breaks, producing a false signal noise which acts as a decoy to disrupt the DDR at the "real" sites of DNA damage. The objective was to reverse acquired resistance to PARPi.

Methods: Patients (pts) who received a PARPi (niraparib, olaparib or rucaparib) in maintenance after platinum-based therapy for at least 6 months and who had an isolated increase of CA125 according to Rustin criteria without RECIST progression were includable. Part A: to assess the feasibility of the association of AsiDNA™ 600 mg in a IV weekly perfusion (higher active dose) + PARPi (last dose taken by the patient before entering the study) Part B: to assess the preliminary efficacy on CA-125 (decrease of 50%). Evaluation was to be done at 10, 15, 20 and 25 pts.

Results: 6 patients were included in the dose de-escalation part. No DLT was observed (no related gr 3-4 AE). No more gr 3-4 AE was observed during the treatment of the 10 patients. Among the 10 patients evaluable for efficacy, none had a CA125 response. However, according to RECIST criteria, there were 6 pts with a stable disease, 1 with complete response and 3 with progressive disease. Study was stopped after 12 pts (the company stopped the fabrication of AsiDNA™ for new pts).

Conclusions: AsiDNA in addition to PARPi in pts with biological progression under PARPi is safe, and stabilization (> 6 months) has been observed in 3 pts.

Clinical trial identification: EudraCT 2020-000825-18.

769P Pharmacokinetic boosting of olaparib: An open-label, prospective, cross-over study

J. Overbeek[1], N. Guchelaar[2], M.I. Mohmaed Ali[3], P.B. Ottevanger[4], H. Bloemendal[4], S. Koolen[2], R. Mathijssen[2], I. Boere[5], P. Hamberg[6], A. Huitema[3], G. Sonke[7], F. Opdam[7], R. Ter Heine[1], N. Van Erp[1]

[1]Pharmacy, Radboud University Medical Center, Nijmegen, Nijmegen, Netherlands; [2]Department of Medical Oncology, Erasmus MC Cancer Institute, Rotterdam, Netherlands; [3]Department of Pharmacy&Pharmacology, Netherlands Cancer Institute/Antoni van Leeuwenhoek, Amsterdam, Netherlands; [4]Medical Oncology Department, Radboud University Medical Center, Nijmegen, Nijmegen, Netherlands; [5]Medical Oncology Department, Erasmus University Medical Center, Rotterdam, Netherlands; [6]Medical Oncology, Franciscus Gasthuis&Vlietland, Schiedam, Netherlands; [7]Department of Medical Oncology, NKI-Netherlands Cancer Institute/AVL-Antoni van Leeuwenhoek Hospital, Amsterdam, Netherlands

Background: Pharmacokinetic (PK) boosting is the intentional use of a drug-drug interaction to enhance systemic drug exposure. PK boosting of olaparib, a CYP3A-substrate, has the potential to reduce PK variability and financial expenses. The aim of this study was to investigate equivalence of a boosted, reduced dose of olaparib compared to the non-boosted standard dose.

Methods: This randomized, cross-over, multicenter trial compared the PK of olaparib 300 mg twice daily (BID) followed by olaparib 100 mg BID boosted with the non-therapeutic CYP3A-inhibitor cobicistat 150 mg BID for 7 days, or *vice versa,* in patients treated with olaparib. Equivalence was defined as a geometric mean ratio (GMR) of area-under-the-curve over one dosing interval ($AUC_{0\text{-}12h}$) and 90% Confidence Interval (CI) within the no-effect boundaries of 0.57-1.25.

Results: Of 15 included patients, 12 were eligible for PK analysis. The $AUC_{0\text{-}12h}$ increased with the boosted reduced dose with a GMR of 1.45 (90% CI 1.27-1.65). The maximum plasma concentration was comparable (GMR 0.97; 90%CI 0.84-1.12), and the trough plasma concentration increased (GMR 4.14; 90%CI 3.25-5.27). PK parameters of both therapies are shown in the table. No grade ≥3 adverse events were reported during the study.

Table: 769P Pharmacokinetic parameters of the standard monotherapy and boosted therapy of olaparib. Data are represented as geometric mean (CV%) [Confidence interval]

	Monotherapy [95%CI]	Boosted therapy [95%CI]	Geometric mean ratio [90%CI]
$AUC_{0\text{-}12h}$ (mg*h/L)	29.4 (46%) [22.2 — 38.9]	42.7 (41%) [33.2 — 55.1]	1.45 [1.27 — 1.65]
C_{max} (mg/L)	6.37 (37%) [5.07 — 8.00]	6.19 (28%) [5.19 — 7.39]	0.97 [0.84 — 1.12]
T_{max} (h)	1.25 (66%) [0.85 - 1.83]	1.67 (42%) [1.30 — 2.16]	1.34 [1.03 — 1.75]
C_{trough} (mg/L)	0.39 (107%) [0.21 — 0.73]	1.56 (77%) [0.99 — 2.46)	4.14 [3.25 — 5.27]

Conclusions: Boosting a 100 mg olaparib dose with the strong CYP3A-inhibitor cobicistat increases olaparib exposure with 45%, compared to the standard dose of 300 mg. Boosting of olaparib is therefore a promising strategy to reduce the olaparib dose. These results encourage a prospective study of boosted olaparib with toxicity-guided dose reductions. If adequate tolerability is established, boosting can lead to a substantial reduction in olaparib therapy costs. Drs. N.A.D. Guchelaar and M.I. Mohmaed Ali have equally contributed to the study.

Clinical trial identification: NCT05078671.

770P Tolerability and efficacy of trabectedin plus pegylated liposomal doxorubicin (PLD) in elderly patients with ovarian cancer (OC): GEICO 105-O study

M.J. Rubio Perez[1], A. Manzano Fernández[2], L.M. De Sande González[3], P. Estevez Garcia[4], M.D.M. Gordon Santiago[5], D. Soto de Prado[6], B.A. Hernando Fernandez[7], E.M. Guerra Alia[8], A. Carbo Bague[9], I. Romero[10], M. Corbellas Aparicio[11], A. Gonzalez-Haba Martinez[12], C.E. Robles Barraza[4], J. Martinez-Garcia[13], A. Gonzalez Martin[14]

[1]Medical Oncology, Hospital Universitario Reina Sofía, Cordoba, Spain; [2]Medical Oncology, Hospital Clinico San Carlos, Madrid, Spain; [3]Medical Oncology, Complejo Asistencial Universitario de León-Hospital de León, León, Spain; [4]Medical Oncology, Hospital Universitario Virgen del Rocio, Seville, Spain; [5]Medical Oncology, Hospital de Jerez, Jerez de la Frontera, Spain; [6]Medical Oncology, Hospital Clinico Universitario de Valladolid, Valladolid, Spain; [7]Medical Oncology, Complejo Hospitalario de Burgos-Hospital General Yagüe, Burgos, Spain; [8]Medical Oncology, Hospital Universitario Ramon y Cajal, Madrid, Spain; [9]Medical Oncology, ICO Girona-Institut Català d'Oncologia Girona, Girona, Spain; [10]Medical Oncology, IVO-Fundación Instituto Valenciano de Oncología, Valencia, Spain; [11]Medical Oncology, Hospital Universitario Doctor Peset, Valencia, Spain; [12]Medical Oncology, Hospital Infanta Cristina, Badajoz, Spain; [13]Medical Oncology, Hospital Clínico Universitario Virgen de la Arrixaca, El Palmar, Spain; [14]Medical Oncology, Clinica Universidad de Navarra, Madrid, Spain

Background: Scarce data have been published for elderly patients (pts) (≥70 years) with OC, who are often underrepresented in clinical trials. Trabectedin (T) plus PLD is approved for relapsed platinum-sensitive OC, and there is a need to gain insights into the safety and efficacy of this scheme in the elderly.

Methods: GEICO conducted a retrospective study with 15 Spanish hospitals, including pts ≥70 years at the start of T+PLD, with relapsed platinum-sensitive high-grade OC (platinum-free interval [PFI] ≥6 months). Pts received at least one cycle of T+PLD according to Summary of Product Characteristics between January 2015 and December 2019. Toxicity, efficacy, dosing, and patient characteristics data were extracted from medical charts.

Results: Forty-three pts with a median of 74 years (70-86) were recruited. The most common FIGO stage at diagnosis was IIIC (51.2%). At baseline, the median PFI was 9 months (81.4% 6-12, 18.6% >12), ECOG 0/1/2 (32.6%, 39.5%, 9.3%), 81.4% of pts had measurable disease, and 76.7% had relevant comorbidities (21.4% hypertension). The median of previous lines was 2 (1-5). The initial dose of T was 1.1 mg/m2 in 81.4% of pts and 79.1% received PLD 30 mg/m2 (reduced initial doses were given due to pts fragility). The median number of T+PLD cycles was 5 (1-21) (46.5% received ≥6 cycles) and 51.2% of pts had delayed infusions. Treatment ended due to personal decision (7.0%), medical decision (23.3%), progression (39.5%), toxicity (23.3%), and other (7.0%). There were no toxic deaths. The main G3-4 adverse reactions were neutropenia (18.6%), asthenia (11.6%), thrombocytopenia (7.0%), mucositis (4.7%), transaminitis (4.7%), and anemia (2.3%). The mPFS was 7.7 months (95% CI 4.4-9.4) with a favorable disease control rate of 72.1% (CR 9.3%, PR 32.6%, SD 30.2% RECIST 1.1). Median OS was 19.5 months (95% CI 12.8-27.2). Seven pts had s/gBRCA1/2 (16.2%) and 13 (30.2%) BRCA unknown. For BRCAmut, T+PLD response was CR 28.6%, PR 42.9%, SD 14.3%, PD 14.3%.

Conclusions: T+PLD is well tolerated by OC pts with 70 years or older. The adverse reactions are comparable to those published for younger pts and efficacy remains beneficial. Albeit in a small sample, a high overall response rate was observed for BRCAmut pts.

771P Genomic characterization of advanced endometrial carcinosarcoma: Identification of potentially actionable targets

U.F.F. De Giorgi[1], Z. Kuang[2], N.A. Danziger[3], J.A. Moore[4], D.I. Lin[4], G. Mangili[5], S. Pignata[6], E.S. Sokol[7], S. Sivakumar[2]

[1]Medical Oncology Department, IRCCS Istituto Romagnolo per lo Studio dei Tumori (IRST) "Dino Amadori", Meldola, Italy; [2]Oncology, Foundation Medicine, Inc., Morrisville, NC, USA; [3]Pathology Department, Foundation Medicine, Inc., Cambridge, CA, USA; [4]Oncology, Foundation Medicine, Inc., Cambridge, CA, USA; [5]Oncology, IRCCS Ospedale San Raffaele, Milan, Italy; [6]Urology and Gynecology Dept., Istituto Nazionale Tumori IRCCS-Fondazione G. Pascale, Naples, Italy; [7]Cancer Genomics Research Department, Foundation Medicine, Inc., Cambridge, CA, USA

Background: Endometrial carcinosarcoma is an aggressive variant of high-grade endometrial carcinoma, whose genomic landscape is poorly studied due to the low disease prevalence and the lack of known druggable molecular drivers. In this study, we explored the genomic profiles of this tumor to assess new targeted therapy and immunotherapy options for this uncommon and challenging disease.

Methods: We retrospectively analyzed 2,177 cases of endometrial carcinosarcoma from the Foundation Medicine database containing results from comprehensive genomic profiling (CGP) performed by next generation sequencing, to detect genomic alterations (GA), microsatellite instability (MSI), tumor mutational burden (TMB), and genomic loss of heterozygosity (gLOH,) as a surrogate for homologous recombination deficiency (HRD). PD-L1 was evaluated using DAKO 22C3.

Results: The median age in the cohort was 67y (interquartile range: 61-72y). *TP53* was the most common GA, found in 83.7% of cases. Additionally, samples harbored GAs in *PIK3CA* (34.2%), *PTEN* (23.5%), *KRAS* (16.0%), *ARID1A* (14.8%) *ERBB2* (8.5%), *BRCA2* (2.7%) and *BRCA1* (2.0%). Immune checkpoint biomarkers were also prevalent; 171/2177 (7.9%) of assessable samples were TMB-high (≥10 mutations/megabase), 141/2170 (6.5%) were MSI-high, 795/1382 (30.7%) had PD-L1 positivity (TPS≥1%). HRD (gLOH≥16%) was observed in 351/1727 (20.3%) cases. A co-occurrence analysis revealed unique molecular subsets. *TP53* was mutually exclusive with GAs in *PTEN* and *ARID1A* (OR = 0.2, p<1E-4). *PTEN* and *ARID1A* were highly co-occurrent (OR = 9.2, p<1E-4) and strongly overlapped the MSI-High subset (OR>40, p<1E-4). *ERBB2* GAs, while co-occurrent with *TP53* (OR = 2.2, p = 0.01), showed mutually exclusivity with *PTEN* (OR 0.4, p<1E-4) and TMB-high status (OR 0.3, p = 0.02).

Conclusions: To our knowledge, this is the largest reported series of endometrial carcinosarcoma, which could open new avenues for personalized approaches based on the identified targets including *PIK3CA*, HRD/gLOH, MSI, TMB, *ERBB2* and *ARID1A*.

Background: Homologous Recombination Deficiency (HRD) is assessed by detection of mutations in *BRCA1/2* genes (*BRCAm*) and/or genomic instability score (GIS+). In ovarian cancer, HRD has become an important biomarker to stratify patients for appropriate clinical management and treatment. Myriad myChoice CDX Plus is currently the gold standard for assessing HRD on tumor samples. There is an increasing interest in transitioning into inhouse HRD assays that fulfill analytical concordance and, also, demonstrate clinical validation. Sophia DDM Dx HRD solution is one of the alternatives, which has reached an overall percent agreement of 93% with Myriad, demonstrating also clinical validation in PAOLA-1 trial. In this study, we present the real-world results of HRD testing in Spain.

Methods: Phase 1 (Apr2021-Jun22), consisted in the analysis of 1322 cases from 90 centers, using Myriad myChoice. Phase 2 (Jul2022-Dec22) included 1333 cases from 135 centers, analyzed with Sophia HRD solution in 4 academic centers, after an internal validation.

Results: Phase 1 reported 47% BRCAwt/GIS-, 24% BRCAwt/GIS$^+$, 14% BRCAm (BRCAm/GIS- y BRCAm/GIS+), and 15% inconclusive cases using myChoice. In phase 2, Sophia HRD identified 47% BRCAwt GIS-, 25% BRCAwt/GIS+, 15% BRCAm, and 13% inconclusive cases. The distribution of HRP (range 42.4-50%) and HRD (range 35.7-40.7%) cases was similar among the reference centers. In addition to GIS and *BRCA1/2*, Sophia reported *CCNE1* amplification (5.3%), as well as mutations in *BRIP1* (2.4%), *RAD51C* (1.1%), *RAD51D* (1.2%) and *PALB2* (1.9%). As expected, *CCNE1* amplification was more frequent in HRP (86.5%) than HRD (13.5%).

Conclusions: The results obtained from a cohort of 2655 ovarian cancer samples by two different methods, Myriad myChoice and Sophia HRD, confirm the analytical concordance between HRD assays. Percentages of BRCAwt/GIS-, BRCAwt/GIS+, BRCAm, and invalid cases were almost identical. In conclusion, Sophia DDM^{TM} Dx HRD solution shows a high interlaboratory agreement, providing clinically relevant molecular information, and improving the interaction between referral and reference centers.

774P CCNE1 amplification defines a good prognostic subgroup among BRCAwt/HRDneg advanced high-grade ovarian cancer (HGOC)

F. Blanc-Durand[1], N.Y.L. Ngoi[1], E. Rouleau[2], S.Y.R. Ang[3], P. Pautier[4], J. Michels[5], K. Ouali[6], C. Genestie[7], S. Cotteret[8], Y.W. Lim[9], S.E. Lim[1], D. Lim[10], S.T. Wijaya[11], A.C. Seong[1], A. Leary[5], D.S. Tan[12]

[1]Department of Haematology-Oncology, National University Cancer Institute Singapore, Singapore; [2]Tumor Genetics, Gustave Roussy-Cancer Campus, Villejuif, France; [3]Hematology-Oncology, NCIS-National University Cancer Institute Singapore, Singapore; [4]Département de Médecine, GINECO and Institut Gustave-Roussy, Villejuif, France; [5]Department of Medical Oncology, Institut Gustave Roussy, Villejuif, France; [6]Medical Oncology Dept., Gustave Roussy-Cancer Campus, Villejuif, France; [7]Pathology Department, Institut Gustave Roussy, Villejuif, France; [8]Genetics, Institut Gustave Roussy, Villejuif, France; [9]NCIS-National University Cancer Institute Singapore, Singapore; [10]Pathology, Cancer Science Institute (CSI)-National University of Singapore (NUS), Singapore; [11]Medical Oncology, NCIS-National University Cancer Institute Singapore, Singapore; [12]Medical Oncology department, NUHS-National University Health System, Singapore

Background: Around 50% of HGOC is characterized as negative for homologous recombination deficiency (HRDneg) based on lack of *BRCA* mutation and low genomic instability score (GIS). ∼15% of HGOC patients harbor *CCNE1* amplification (*CCNE1amp*) which has been presumed to be associated with chemoresistance, HRDneg and poor prognosis. We aimed to determine the genomic profiles and outcome of *CCNE1*amp HGOC in comparison to non-*CCNE1amp* HRDneg HGOC.

Methods: We conducted a retrospective analysis of patients (pts) with advanced HGOC (excluding clear-cell and mucinous histology) with available genomic data from Institut Gustave Roussy, France and National University Cancer Institute, Singapore. *CCNE1amp BRCA1/2 and RAD51C/D* mutations were detected by next-generation sequencing on tumor samples. GIS was evaluated by Myriad MyChoice or Foundation Medicine LOH. Progression free survival (PFS) (date of diagnosis to first progression) and pathological response to neoadjuvant chemotherapy by chemotherapy response score (CRS) were collected.

Results: We identified 55 *CCNE1amp* and 104 HRDneg non-*CCNE1*amp tumors. Pts with *CCNE1amp* tumor were significantly older (64 versus 61.5 years, $p<0.01$). Overall, 81% were high-grade serous, 8% carcinosarcomas, and 62% benefited from complete cytoreductive surgery. As expected, no *BRCA1/2* or *RAD51C/D* mutations were detected in the *CCNE1amp* cohort. 19% of *CCNE1amp* tumors were classified HRD positive and 81% HRDneg. Among *CCNE1amp*, 31% of patients experienced a good pathological response (CRS3) versus 18% in the HRDneg cohort ($p=0.26$). Median PFS was 21.1 months in the *CCNE1amp* cohort versus 14.2 months in the HRDneg cohort ($p=0.008$) and median overall survival was 55.3 months versus 42.9 months ($p=0.044$). In multivariate analysis including completeness of surgery, *CCNE1amp* was statistically associated with better PFS, HR=1.6 (95%CI 1.06-2.5).

Conclusions: We report clinical and molecular features associated with *CCNE1* amplification in advanced HGOC. As expected *CCNE1* amplifications are mutually exclusive from *BRCA* mutations, however 20% were HRD according to GIS. We observed unexpected high rates of CRS3, and significantly improved outcomes compared to non-*CCNE1amp* HRDneg tumors.

Background: The phase 3 iPocc trial reported improved progression-free survival (PFS) in OC patients receiving IP over intravenous (IV) carboplatin with IV dose-dense paclitaxel. We sought to identify biomarkers that can predict sensitivity to IP therapy.

Methods: 117 pre-treatment frozen samples were subjected to mRNA profiling (Affymetrix HTA 2.0) and ACT Genomics ACTOnco®+ next generation sequencing. Cox regression analyses were performed to identify genes significantly correlated with PFS following IP treatment ($p < 0.05$). Homologous recombination repair deficiency (HRD) is defined by loss-of-heterozygosity (LOH) score ≥ 0.48.

Results: Patients receiving IP (n=61) or IV (n=56) had similar clinico-pathological distributions. We identified a 72-gene signature that was significantly correlated with PFS in IP but not in IV patients. Tumors harboring a signature with reduced VEGFA/VEGFR2 and PI3K signaling had low IP resistant score (IPRS) and were associated with improved outcomes for IP therapy. There was no difference in IPRS between BRCA1/2 wildtype and mutant tumors ($p = 0.55$). HRD tumors had a significantly higher IPRS than non-HRD tumors ($p = 0.03$). A high IPRS was significantly correlated with poorer PFS after IP therapy (median: ~18 months vs not reached/NR, $p < 0.0001$), with no correlation seen after IV therapy (median: 25 vs 24 months, $p = 0.9$). Low IPRS IP patients had improved PFS compared with low IPRS IV patients (median: NR vs 25 months, $p = 0.0261$). Paradoxically, when IPRS is high, IP patients have worse PFS than IV patients (median: ~18 vs 24 months, $p = 0.004$). Low IPRS was also able to predict improved outcomes in appendiceal cancer patients receiving hyperthermic IP therapy with the DNA cross-linking agent mitomycin-c (median PFS: 4.4 vs 1.5 years, $p = 0.01$).

Conclusions: The IPRS shows promise in identifying a subset of OC patients likely to benefit from IP platinum treatment. Validation in a larger cohort is warranted.

Clinical trial identification: NCT01506856.

776P Multi-omics analysis of chemo-refractory high-grade serous carcinoma patients: Insights from the DECIDER study

D. Afenteva[1], T.A. Muranen[1], A. Rajavuori[2], S. Jamalzadeh[1], K. Zhang[1], V. Ariotta[1], V-M. Isoviita[1], A. Lahtinen[1], K.A. Lavikka[1], O. Lehtonen[1], Y. Li[1], G. Marchi[1], J. Oikkonen[1], S. Salloum[1], K. Huhtinen[3], S. Hietanen[2], A. Virtanen[4], J. Hynninen[2], S. Hautaniemi[1]

[1]Research Program in Systems Oncology, University of Helsinki-Faculty of medicine, Helsinki, Finland; [2]Department of Obstetrics and Gynecology, University of Turku-Faculty of Medicine, Turku, Finland; [3]Cancer Research Unit, Institute of Biomedicine and FICAN West Cancer Centre, University of Turku, Turku, Finland; [4]Department of Pathology, Helsinki University Hospital, Helsinki, Finland

Background: Neoadjuvant chemotherapy (NACT) followed by interval debulking surgery (IDS) is a treatment strategy recommended for patients with high-grade serous carcinoma (HGSC), who are ineligible for primary debulking surgery (PDS). The presence of the inherently resistant cancer phenotype in the primary tumor is a key factor determining disease progression in such cases.

Methods: We collected the data from 159 NACT-treated patients enrolled in the prospective, longitudinal, multi-region DECIDER study which aims to develop effective means to overcome drug resistance in HGSC. 60 patients with platinum-free interval (PFI) above 6 months and partial/complete response as primary therapy outcome according to the RECIST1.1 criteria were considered as responsive, and 31 patients with PFI below 45 days and progressive/stable disease — as refractory. We integrated multiple types of patient data focusing on the pre-NACT samples, explored potential links between genomic features and patient survival, and specifically employed bulk-RNA sequencing data for hypothesis-generating.

Results: In terms of many different clinical or genomic features, samples derived from chemo-refractory patients resembled chemo-responsive. Homologous recombination (HR)-related mutation signatures and loss of the core HR genes were less frequent in the chemo-refractory patients than in the NACT-patients with at least partial response to the primary therapy. Using PRISM to retrieve the epithelial ovarian carcinoma (EOC)-specific expression profiles and PROGENy to infer pathways activity scores, we found a significantly lower activity (p value = 0.022) of JAK-STAT pathway in the refractory, as compared to the reference group. Further analysis using GSEA supported this conclusion, revealing lower expression levels of transcriptional target genes affected by the Interferon alpha/beta and gamma pathways. Kassandra deconvolution algorithm detected a significantly lower infiltration (p value = 0.026) of CD4 T-cells in the refractory group.

Conclusions: Altogether, these results highlight the importance of the immune component in HGSC primary tumors in the context of intrinsic resistance to NACT.

777P Targeting cadherin-6 in epithelial ovarian cancer: Clinical significance of its expression and efficacy of raludotatug deruxtecan (R-DXd) in patient-derived cell models

D. Shintani[1], M. Hanaoka[2], Y. Kaneda[3], A. Ogasawara[2], M. Yano[4], T. Katoh[5], M. Yasuda[5], M. Nagata[3], K. Hasegawa[1]

[1]Gynecologic Oncology, Saitama Medical University International Medical Center, Saitama, Japan; [2]Gynecologic Oncology, Saitama Medical University International Medical Center, Hidaka, Japan; [3]Translational Science, Daiichi Sankyo Co., Ltd.-Shinagawa R&D Center, Shinagawa-ku, Japan; [4]Obstetrics and Gynecology Dept., Oita University Faculty of Medicine, Yufu, Japan; [5]Department of Pathology, Saitama Medical University International Medical Center, Saitama, Japan

Background: Cadherin-6 (CDH6) is a transmembrane glycoprotein, whose aberrant expression has been reported in several human carcinomas. Raludotatug deruxtecan (R-DXd) is an antibody-drug conjugate (ADC) targeting CDH6 with a topoisomerase I inhibitor (DXd) as a payload which is being developed for several malignancies, including epithelial ovarian cancer (EOC). Our aim was to understand the clinical

significance of CDH6 expression in EOC and investigate the efficacy and specificity of R-DXd in EOC using patient-derived cell (PDC) models.

Methods: We performed immunohistochemical staining (IHC) for CDH6 in 232 EOC surgical samples and 23 ascites cell blocks. CDH6 IHC was scored for intensity and percent tumor cell staining. A score greater than or equal to 1+ intensity in $\geq$10% of tumor cells was defined as positive. The in vitro cytotoxicity and specificity of DS-6000a were evaluated in PDC models of EOC in 3-dimensinal (3D) cell culture using a luminescence-based 3D cell viability assay.

Results: A total of 117 (64.6%) of 181 patients tested positive for CDH6 expression in archival specimens from primary surgery. CDH6 expression was more frequently observed in high-grade serous carcinomas (89.0%, $p < 0.0001$). CDH6-positive patients showed shorter overall survival than CDH6-negative patients ($p = 0.0006$). 38 of the 51 (74.5%) tumors and 15 of the 23 (65.2%) ascites cells specimens from patients with recurrent disease tested positive for CDH6, respectively. Recurrent tumors had higher CDH6 scores than tumors at primary surgery, using 24 paired samples ($p = 0.0039$). R-DXd, DXd (free payload), control ADC and anti-CDH6 naked antibody were tested for their cytotoxicity in two CDH6-positive and two CDH6-negative PDC models. R-DXd showed significant cell growth inhibitory effect against both CDH6-positive but not in either CDH6-negative PDC models. DXd demonstrated cytotoxicity in all PDC models, regardless of CDH6 expression, whereas control ADC and anti-CDH6 naked antibody showed no growth inhibitory effects.

Conclusions: CDH6 is an attractive target for EOC and R-DXd is a promising agent for the treatment of CDH6-expressing EOC.

Background: Advanced ovarian clear cell carcinoma (OCCC) has extremely poor prognosis. AT-rich interactive domain 1A *(ARID1A)* mutation-related chromatin remodeling errors are key molecular features of OCCC. Dysregulated of receptor tyrosine kinases-related signaling pathways are common in OCCC.

Methods: We employed combination of poly (ADP-ribose) polymerase (PARP) inhibitors (nirapaib) and lenvatinib targeting key kinases in OCCC to reinforce single-inhibitor initiated pathway rewiring in cell lines, OCCC xenografts, patient-derived xenograft (PDX) model, and ex vivo tumor studies. The potential mechanisms were explored by RNA sequencing before and after combination treatment and related pathways of differentially expressed genes analyzed.

Results: The combination of niraparib and lenvatinib exhibited significant synergistic effects against platinum-resistant OCCC cell lines, in OCCC xenografts, and ex vivo tumor studies. Moreover, the combination of the niraparib and lenvatinib enhanced induction of apoptosis and prolonged survival in PDX model ($p = 0.0032$). RNA sequencing analyses revealed significant enrichment in structural constituent of ribosome ($p = 0.00078$). Four ribosomal protein expressions (RPS2, RPS5, RPL3 and RPL9) were validated by real-time quantitative PCR. Nucleophosmin (NPM1) expression, which has been implicated in ribosome biogenesis, was found inhibited by niraparib and lenvatinib. Using Kaplan-Meier plotter database (https://kmplot.com/analysis/) of 1435 ovarian cancer patients, increased NPM1 mRNA expression portended a poor overall survival ($p = 0.0025$). Our findings taken together imply that combination of niraparib and lenvatinib reduces OCCC progression via attenuation Src phosphorylation, NPM1 expression, and ribosomal biogenesis in OCCC.

Conclusions: Our study supports exploring combination of niraparib and lenvatinib in the treatment of platinum-resistant OCCC.

Background: HRD is used to identify HGOC patients most likely to benefit from PARPi. Unlike commercially available genomic scar HRD tests (CT), functional testing by RAD51, have potential to provide a real-time readout of actual HR status and may be more reliable to detect HRD.

Methods: This single-institution study assesses the immunofluorescence-based RAD51 foci test and correlates it to CT and treatment outcomes in newly diagnosed advanced HGOC pts between 2020-2023. Tumors with <10% RAD51+ tumor cells in S/G2-phase were classified as HRD positive (HRD+). HRD status agreement rate between CT and RAD51 was calculated. Median progression-free survival (mPFS) was estimated in each subgroup.

Results: Overall, 53 pts had CT and RAD51 tests performed on archival tumour samples. Both tests were contributive for 38 pts. As 1st line therapy, all pts received platinum chemotherapy. As maintenance, 47% received PARPi and 18% Bevacizumab alone. % of HRD+ according CT and RAD51 was 55.3% (21/38) and 42.1% (16/38), respectively. Concordance rate between both tests was 50% (95%CI 34.8-65.2), with 12 and 7 pts identified as HRD+ only by CT and RAD51.

Table: 779P

HRD test	HRD RAD51	HRP RAD51
HRD CT	9	12
HRP CT	7	10

Based on CT, mPFS of HRD+ and HRP pts was 19.4m and 16.1m, respectively (HR 0.69; 95%CI, 0.26-1.85). Based on RAD51, mPFS for HRD and HRP pts was 19.4m and 14.3m (HR 0.70; 95%CI, 0.25-1.93), respectively. Among pts with consistent HRD test results, mPFS was 19.4 m and 11 m for HRD and HRP pts, respectively. Among disparate results, mPFS was 17.4m and 16.1m for pts defined as HRD only by CT and RAD51, respectively.

Conclusions: Our preliminary data showed both tests identified HRD and HRP subpopulations with similar outcomes despite low correlation between them. Among pts with HRP by CT, RAD51 identified a subset of HRD+ with better mPFS. Combination of genomic and functional HRD tests could improve molecular diagnostic accuracy of HGOC.

780P Role of BRCA1 promotor methylation in homologous recombination deficiency (HRD) in high-grade ovarian cancer

H. Fiegl[1], D. Reimer[1], S. Schnaiter[2], K. Leitner[1], K. Wimmer[2], E. Schamschula[2], K. Steger[1], C. Marth[1], A.G. Zeimet[1]

[1]Department Gynecology&Obstetrics, Innsbruck Medical University, Innsbruck, Austria; [2]Insitute of Human Genetics, Innsbruck Medical University, Innsbruck, Austria

Background: In high-grade ovarian cancer (OC) TCGA found *BRCA1*meth inferior to *BRCA*mut regarding prognosis probably due to lower sensitivity to platinum (Pt^{++})-based chemotherapy.

Methods: In 143 high-grade OCs tested for *BRCA* mutations, additionally *BRCA* DNA methylation was determined using MethyLight PCR and genome-wide LOH and Aneuploidy Normalized Telemetric imbalance (ANTI) by means of SNP-Array analysis (GSA-24 v 3.0/Illumina) as surrogates of genome-wide DNA-scarring. For LOH and ANTI a "clinical-threshold" was calculated by Pt^{++}-response, determined at the first recurrence. Both were integrated in a common HRD-Score (cut-off: $\geq$1.912 for HRD positivity).

Results: In the present cohort, *BRCA1* DNA methylation (me*BRCA1*) was detected in 15 (10%) and mostly *BRCA*wt OCs (n=14, 17%). Only one *BRCA1*mut OC had concomitant me*BRCA1. BRCA2* DNA methylation was not observed. In terms of genomic scars, me*BRCA*wt and *BRCA*mut OCs had similar HRD scores, which were higher than those in unmethylated *BRCA*wt OCs ($p<0.003$). In *BRCA*wt OCs, *BRCA1* methylation levels *(PMR-values)* were higher in HRD pos. than in HRD negative OCs ($p<0.001$). Progression free survival (PFS) of patients with me*BRCA1* OCs was non-inferior to that of *BRCA*mut OC patients. Worst PFS and OS was found in the subgroup of unmethylated *BRCA*wt OCs compared to patients with *BRCA*mut and me*BRCA1* OCs in univariate (p=0.003; p=0.022) and multivariate survival analysis (p=0.006, p=0.018). All but one of the cancers classified as Pt^{++}-refractory or -resistant at first relapse (92%) were unmethylated *BRCA*wt OCs. None of the me*BRCA1* cancers were rated Pt^{++}-refractory or -resistant, and only one *BRCA*mut OCs was associated with a Pt^{++}-resistant first relapse. 98.6% of the recurrences originating from OCs with genetically or epigenetically altered *BRCA* genes were Pt^{++}-sensitive, of which 77% were considered highly sensitive.

Conclusions: High-grade OCs without genetic or epigenetic *BRCA* alterations exhibit worst PFS. Based on genome-wide scarring, *BRCA1* promotor methylation seems to exert an equivalent detrimental effect on the DNA repair by homologous recombination as pathogenic BRCA mutations.

781P Chemotherapy sensitivity score based on ex vivo 3D tumour testing to predict clinical response for ovarian cancer patients

J. Walraven[1], C.D. de Kroon[2], A. van Altena[3], D. van der Meer[4], L. Ceton[4], J. van der Valk[4], T. Sijsenaar[4], F. Grillet[4], M. Garcia Montero[4], W. Vader[4], P.B. Ottevanger[1], J.R. Kroep[5]

[1]Medical Oncology, Radboud University Medical Center, Nijmegen, Netherlands; [2]Gynaecology, Leiden University Medical Center, Leiden, Netherlands; [3]Gynaecology, Radboud University Medical Center, Nijmegen, Netherlands; [4]R&D, VitroScan B.V, Leiden, Netherlands; [5]Medical Oncology, Leiden University Medical Center, Leiden, Netherlands

Background: Precision medicine for cancer patients has brought effective novel therapy options over the past decades. However, treatment for high-risk ovarian cancer is still based on platinum containing chemotherapy. Around 30% of primary disease patients do not respond, and 40% of complete responders relapse within a year. Strong predictive markers are lacking. This study reports a predictive chemotherapy sensitivity score to support patient-centred and better informed treatment decisions.

Methods: 89 ovarian cancer patients eligible for chemotherapy were included in the trial between 2019 and 2022 in the Netherlands (IRB P18.032). Tumour clusters were isolated from ascites and solid tumour, seeded into a 384-well plate, and exposed to carboplatin, paclitaxel, three second-line chemotherapies, PARPi, and six immunotherapies. Next, ex vivo drug sensitivity was quantified using high-throughput 3D imaging and extraction of morphological features. The chemotherapy sensitivity score was generated by correlation of the assay results with the patients' response to carboplatin-paclitaxel. In parallel, patients' relative sensitivity to other chemo-, targeted- and immunotherapies was assessed.

Results: The platform enabled accurate prediction of carboplatin-paclitaxel with a classification accuracy of 80%. Differential ex vivo patient response profiles were observed across second-line therapies, and 11% of the samples demonstrated a strong response to at least one of the immune compounds, indicating that our test method could provide alternative treatment options. For doxorubicin, the ex vivo results match clinical response (n=3), providing further evidence for the predictivity of the assay. Importantly, the assay has a success rate of 89%.

Conclusions: The prediction of clinical response to first-line therapy and identification of patient-specific sensitivity to ten second-line therapies in parallel, allows the support of informed treatment decisions for multiple treatment classes. Its two-week timeline makes the assay applicable in a clinical environment. A prospective trial for patients with suboptimal response and recurrent disease is ongoing.

Clinical trial identification: CME LUMC-P18.032.

782P Correlation between chemotherapy response score (CRS) and germline BRCA1/2 (gBRCA) status in women diagnosed with FIGO stage IIIC/IV high-grade serous ovarian cancer (HGSOC)

D. Netto[1], X. Wang[2], B. Barnes[3], A.R. Clamp[1], J. Hasan[1], C.L. Mitchell[1], Z. Salih[1], B. Winter-Roach[4], R. Edmondson[3], J. Shaw[5], S. Desai[6], H. Schlecht[7], G.J. Burghel[8], S. Taylor[9], G. Evans[10], G.C. Jayson[11], R.D. Morgan[1]

[1]Medical Oncology Department, The Christie NHS Foundation Trust, Manchester, UK; [2]Statistics, The Christie NHS Foundation Trust, Manchester, UK; [3]Division of Cancer Sciences, The University of Manchester, Manchester, UK; [4]Surgical Oncology, The Christie NHS Foundation Trust, Manchester, UK; [5]Histopathology, Manchester University NHS Foundation Trust, Manchester, UK; [6]Pathology, The Christie NHS Foundation Trust, Manchester, UK; [7]Genomics, Wythenshawe Hospital-Manchester University NHS Foundation Trust, Manchester, UK; [8]North West Genomic Laboratory Hyb, GLH-The North West Genomic Laboratory Hub, Manchester, UK; [9]Manchester Cancer Research Centre, Manchester University, Manchester, UK; [10]Clinical Genetics, Manchester University NHS Foundation Trust, Manchester, UK; [11]Medical Oncology, The University of Manchester, Manchester, UK

Background: CRS after neoadjuvant chemotherapy (NACT) and g*BRCA* status predict survival outcomes of women diagnosed with advanced HGSOC. We investigated the correlation between CRS and g*BRCA* to understand the potential of CRS as an inexpensive biomarker for PARPi therapy.

Methods: Analysis of the OC g*BRCA* testing database from a tertiary referral centre. Eligible criteria included women with FIGO stage IIIC/IV HGSOC who received NACT and had g*BRCA* tested between 01/09/2017 and 31/12/2022. Univariable and Multivariable (MV) Cox Proportional-Hazards Models were applied to assess the association between PFS, OS and clinical factors. Two-Proportions Z Test was applied to assess the proportions of CRS1+2 or CRS3 between g*BRCA*.

Results: 536 women were eligible. Mean age 66 years (range 36—89). 139 had FIGO stage IVB HGSOC. 71% received 3-weekly carboplatin with paclitaxel. Median PFS was 14.4 months (95%CI 13.6—15.4) and OS 38.0 months (95%CI 34.8—42.6) in the overall population. Performance status (0—1 vs. 2—4), cytoreductive surgery (Yes vs. No) and g*BRCA* status (mutant[MT] vs. wild type[WT]) were predictive (PFS) and prognostic (OS) in the overall population (all $P<0.05$). 363 women underwent delayed primary surgery (DPS) and had a CRS. Of these, 90% received 3—4 cycles of NACT and 96% had optimal ($\leq$1 cm) cytoreduction. In the NACT-DPS group, MV analysis showed that residual disease ($\leq$1 vs. >1 cm), CRS (3 vs. 1+2) and g*BRCA* status (MT vs. WT) were predictive (PFS) (all $P\leq0.02$). Proportion testing showed women with g*BRCA2* were more likely to have CRS3 vs. CRS1+2 than those with g*BRCA1* (P=0.008). Women with g*BRCA1* (P=0.075) and g*BRCA2* (P=0.078) were not more likely to have CRS3 vs. CRS1+2 then those with WT.

Conclusions: We found a correlation between CRS3 and g*BRCA2*, but not g*BRCA1*, in women with FIGO stage IIIC/IV HGSOC treated with NACT-DPS. CRS should be evaluated in a prospective study as a predictor of PARPi efficacy.

Table: 782P

CRS	g*BRCA1*	g*BRCA2*	WT	PFS, months (95%CI)
1	7	1	60	12.1 (11.5—15.7)
2	19	9	146	15.4 (14.4—16.7)
1+2	26 (84%)	10 (45%)	206 (66%)	14.9 (14.0—16.0)
3	5 (16%)	12 (55%)	104 (34%)	22.8 (20.7—27.9)

783P The role of JARID1B in ovarian cancer

K. Leitner, K. Steger, D. Reimer, H. Fiegl, C. Marth, A.G. Zeimet

Department of Obstetrics and Gynecology, Innsbruck Medical University, Innsbruck, Austria

Background: JARID1B (jumonji A/T rich interactive domain) is a lysine specific demethylase which is able to remove tri- and di-methyl marks from H3K4 (histone 3 — H3, lysine 4 — K4). It is overexpressed in many tumors. In ovarian cancer (OC) high *JARID1B* mRNA-expression is associated with poor outcome and chemoresistance. The aim of this study was to explore the role of *JARID1B* mRNA-expression in OC.

Methods: *JARID1B* mRNA-expression was investigated in 238 epithelial OCs and put in relation to clinicopathological characteristics, *BRCA1/2*-mutational status, homologous recombination deficiency (HRD) status and *BRCA1/2* mRNA-expression levels. Additionally, nineteen non-neoplastic fallopian tubal and sixteen non-neoplastic ovarian samples were used as a control group.

Results: *JARID1B* mRNA-expression in OCs was significantly higher compared to non-neoplastic tubal and ovarian tissue ($P<0.001$ and $P=0.003$, respectively). High *JARID1B* mRNA-expression was associated with worse PFS and OS in univariate analysis, which could be confirmed in multivariate Cox-regression analysis (PFS: HR=1.577, P=0.035 and OS: HR=1.710, P=0.009). A strong correlation between *JARID1B* and *BRCA1/2* mRNA-expression was found ($r^2=0.233$, P=0.001 and $r^2$0.196, P=0.011; respectively). *JARID1B* expression was significantly lower in *BRCA1*-mutated OCs compared to BRCA1 wild-type cancers (P=0.021). Regarding *BRCA2* mutational status, no significant differences in *JARID1B* expression between wildtype and mutated cancers were revealed. In tumors with HRD levels of *JARID1B* were significantly lower compared to HR proficient tumors (P=0.006).

Conclusions: High *JARID1B* mRNA-expression is associated with worse PFS and OS. As *JARID1B* is known to inhibit the expression of the anti-angiogenic and anti-metastatic epithelial chemokine CCL14 it is conceivable that the low *JARID1B* expression observed in *BRCA1*-mutated cancers may contribute to the better prognosis generally seen in these cancers. This could also be underlined by the significant lower levels of *JARID1B* expression in cancers with high HRD scores. In order to further investigate the role of JARID1B in OC analyses on its interplay with CCL14 are ongoing.

784P HPV integration promotes HPV carcinogenesis via remodeling chromatin interactions between universal stripe factors and super-enhancer in HPV-related carcinoma

C. Cao[1], Z. Zhu[2], P. Wu[1]

[1]Department of Gynecologic Oncology, Tongji Hospital affiliated to Tongji Medical College of Huazhong University of Science and Technology, Chibi, China; [2]College of Informatics, Huazhong Agricultural University, Wuhan, China

Background: The incidence of HPV integration is increased during the disease progression from precancerous lesions to carcinoma, and HPV integration is reputed as a key effect to escape eliminations from the host cells. Although HPV integration is identified in HPV-related carcinoma, the mechanisms underlying HPV carcinogenesis remain unclear.

Methods: Here, 6768 HPV integration sites from cervical carcinoma (CESC) and 470 from head & neck carcinoma (HNSC), high-through chromosome conformation capture (Hi-C), ChIP-seq, ChIP-PCR and RNA-seq were analyzed to identify the HPV integration characteristics in HPV-host interactions. Manual HPV-integration cells, an HPV integration mouse model (K14-HPV, FVB/N), and CRISPR-Cas9 knock-out cells were performed to demonstrate the chromatin remolding between universal stripe factors (USFs) and super-enhancers.

Results: In CESC and HNSC, USF motifs were enriched in HPV integration sites and integrated HPV-host interaction regions. In addition, HPV integration sites and integrated HPV-host interaction regions marked increased chromatin accessibility (ATAC-seq) and super-enhancer elements (H3K27ac, H3K4me1, and H3K4me3), with USF motifs enrichment in these regions. By dividing the tumor samples according to HPV status, USF genes were found to be upregulated in CESC and HNSC, which could be validated by tumor samples, manual HPV-integration cells, and the K14-HPV integration mouse model. Furthermore, three-dimensional chromatin analyses reveal the chromatin interactions between USF genes and super enhancers in tumor cells. The expression patterns of USF genes and chromatin interactions between USF genes and the super-enhancer were reversed via super-enhancer CRISPR-Cas9 knock-out, thus reversing malignant phenotypes of tumor cells in vitro and in vivo.

Conclusions: Overall, we identify that HPV integration remodels chromatin interactions between USFs and super enhancers to promote malignant phenotypes in HPV-related carcinoma, which provides insight into the three-dimensional mechanism in HPV-related carcinogenesis.

785P The predictive role of circulating exosomal PD-L1 in cervical cancer immunotherapy

W. Tang[1], Q. Wu[2], Q. Guo[2], J. Chen[2], T. Zhang[2], Q. Wang[2], F. Gao[2], N. Liu[1], P. Xie[3]

[1]The Second Ward of Uterine Tumor, Shandong Cancer Hospital Affiliated to Shandong University, Jinan, China; [2]The Second Ward of Uterine Tumor, Shandong Cancer Hospital and Institute, Jinan, China; [3]Oncology Department, Shandong Cancer Hospital Affiliated to Shandong University, Jinan, China

Background: The purpose of this study is to investigate the effect of radiotherapy on programmed death ligand 1 (PD-L1) expression and explore the predictive role of exosomal PD-L1 (ExoPD-L1) in immunotherapy for cervical cancer.

Methods: The consecutive tumor sample of 40 primarily diagnosed CC patients who accepted radical radiotherapy (RT) were collected before and during RT. Blood samples of 37 advanced CC patients who accepted ICIs combination therapy were collected from each participant before and during treatment. Exosomes were identified by Western blot (CD9/TSG101/Calnexin), transmission electron microscope and nanoparticle tracking analysis. ExoPD-L1 detection was conducted by ELISA. The knockout of PD-L1 was conducted via CRISPR/Cas9 assay and the overexpress of PD-L1 was conducted by lentiviral transfection. Lymphocyte were detected by multicolor flow cytometry.

Results: The consecutive detection of PD-L1 showed a dynamic change during RT. Compared with the level before RT, PD-L1 expression elevated in most patients (87.5%) after RT. And the responders (n=18) had elevated ExoPD-L1 level at the first two circles in the ICIs combination therapy ($P<0.001$). The median follow-up time was 14.13m. The mPFS in increased vs. decreased group: NR vs.11.02m ($P=0.025$). Continuous blood sampling of mice models also found that effective therapeutic intervention could increase ExoPD-L1 in the early stage. The combination of exosome inhibitor GW4869 and anti-PD-1 further inhibited tumor growth. Mice were injected with external ExoPD-L1^{OE}and ExoPD-L1^{KO}. The results showed that ExoPD-L1^{OE} suppressed body immunity and promoted tumor growth. The results of flow cytometry showed that ExoPD-L1^{OE} inhibited CD8$^+$T cells from releasing interferon-γand granzyme B. And ExoPD-L1^{OE} also suppressed the CD8$^+$T cells proliferation in spleen. The coculture of CD8$^+$T cells and exosomes in vitro also confirmed the above conclusion.

Conclusions: Compared with unstable tumoral PD-L1, ExoPD-L1 can better predict the efficacy of immunotherapy in CC, which was with easy accessibility and continuation. Exosome PD-L1 played an immunosuppressive role by inhibiting the proliferation and functional factor release of CD8$^+$T cell.

Background: Endometrial cancer (EC) is the most common gynecological malignancy, and treatments based on its molecular subtypes have recently been proposed. Patient-derived xenografts (PDX) are models that preserve the heterogeneity and histology of tumors, and may mimic the effects of drugs in patients. Here, we report a preclinical study of farletuzumab ecteribulin (MORAb-202, FZEC), a novel antibody-drug conjugate (ADC) targeting folate receptor alpha (FRα), using a panel of EC-PDX models with different molecular subtypes.

Methods: We developed a panel of 36 EC-PDX models with four molecular subtypes. We investigated FRα expression based on the H-scores. The antitumor activity of FZEC was evaluated in 24 EC-PDX models, including three POLE-mutated, two MSI-H hypermutated, 11 copy number (CN)-high, and eight CN-low tumors, with various levels of FRα expression in the four treatment groups (control saline, FZEC 5 mg/kg, 12.5 mg/kg, and eribulin 3.2 mg/kg, n=6 in each group). Each drug was administered intravenously, and tumor size was measured twice a week for a 21-day observation period. The intratumoral distribution of eribulin was periodically visualized using an anti-eribulin antibody with the Opal multi-fluorescent staining system.

Results: The median H-scores of FRα expression in the 36 PDX and original tumors were 9.5 (0−184) and 74 (11-184), respectively, indicating a trend toward decreased FRA expression on the PDX. There was no relationship between FRA expression and molecular subtypes. The efficacy of FZEC was evaluated using 24 EC-PDX models. Antitumour activity was observed across all four molecular subtypes. Tumor shrinkage was associated with FRα expression in FZEC 5 mg/kg group, whereas an overall FRA-independent tumor shrinkage was observed in FZEC 12.5 mg/kg and eribulin 3.2 mg/kg groups. Intratumoral imaging analysis using tumors on day 21st showed an association between the antitumor effect and intratumoral accumulation of eribulin.

Conclusions: These results suggest that FZEC may be a promising treatment for FRα-expressing EC of all four molecular subtypes.

787P A NGS panel for molecular classification of endometrial carcinoma

H. Wen[1], Q. Guo[1], S. Tang[2], X. Wu[1], X. Zhou[2], D. Peng[3], B. Li[3], X. Zhu[3], S. Ma[3], H. Lu[3], J. Zhang[3], Z. Zhang[3]

[1]Gynecologic Oncology, Fudan University Shanghai Cancer Center, Shanghai, China; [2]Pathology, Fudan University Shanghai Cancer Center, Shanghai, China; [3]Medical Science, Burning Rock Biotech, Guangzhou, China

Background: The conventional classification tools for endometrial carcinoma (EC) is tiresome, including DNA sequencing, IHC or PCR-CE. Large NGS panels are used to simplify test but costly. Here, we propose a concise NGS panel for economically classifying EC.

Methods: Retrospectively enrolled EC cases of hysterectomy with bilateral salpingo-oophorectomy from Fudan University Shanghai Cancer Center from 2020 to 2022 were assessed. A 46-gene NGS Panel was used to identify POLE exonuclease domain mutations, microsatellite instability-high (MSI-H), TP53 mutations, and other clinically valuable targets.

Results: Tumor tissue samples of 331 EC patients were evaluated. The median age of patients was 55 years (range, 49-62), and 284 (85.8%) cases were endometrioid endometrial carcinoma. Patients in stage IA and IB EC were 204 (61.6%) and 52 (15.7%), respectively. The median follow-up time was 18.5 months (n=303). According to WHO classification criteria, patients were stratified into POLE mut (n=47; 14.2%), MMRd (n=79; 23.9%), NSMP (n=148; 44.7%) and p53 abn (n=57; 17.2%), whose prognosis was consistent with previous studies, POLE mut with most favorable prognosis and p53 abn with the worst. NGS reached 91.8% (n=269) concordance with IHC when detecting MMRd. The 24 inconsistent samples were validated by PCR, of which 17 (70.8%) were consistent between PCR and NGS. The concordance of NGS and IHC in detecting p53 was 65.0% (n=201), but patients detected by NGS alone had significantly worse prognosis than those detected by IHC alone, implying higher accuracy of the panel. Given NGS panel performance, particularly in detecting MMRd and p53 abn, our panel provided a reliable EC classification approach. In addition, the most frequent genetic alterations detected in at least 20% of patients were PTEN (83.4%), PIK3CA (59.2%), ARID1A (58.6%), TP53 (29.3%), CTNNB1 (27.8%), and KRAS (23.6%), which might guide the following treatment.

Conclusions: Our study demonstrates that the concise NGS panel is an effective "one-stop" strategy to precisely classify EC with high clinical availability. Further follow-up data are needed to testify to the effect of the classification on the prognosis of different adjuvant therapies or rare pathological subtypes.

Background: Endometrial cancer (EC) can be classified into four molecular subgroups: *POLE* mutant, MSI/dMMR, non-specific profiles and *P53* mutant (P53mut). P53mut EC comprise ∼20% of cases and have the worst prognosis. There is an urgent medical need to better understand P53mut EC in order to propose effective new therapeutic strategies.

Methods: We conducted a retrospective analysis of P53abn EC patients from PORTEC3 (NCT00411138) with available DNA for a large-scale panel sequencing (Discovery Cohort). Results were confirmed on an independent cohort of EC patients (Gustave Roussy, France and National University Cancer Institute, Singapore) identified by their molecular profile using FoundationOneCDX or FoundationOne Liquid CDX panel (Validation Cohort). Molecular findings were correlated with clinicopathologic features from medical record review.

Results: 39 P53abn cases were included in the discovery cohort. Molecular profiling was able to distinguish 4 mutually exclusive subgroups: *CCNE1* amplified (15%), *ERBB2* amplified (21%), *PTEN* alteration (21%) and a non-specific group. In the Validation Cohort, 71 P53mut EC patients were included. 40 patients were molecularly characterized on tumor tissue and 31 on circulating tumor DNA. Median age was 66 years, 38% presented with primary metastatic diseases, 40% were serous, 30% endometrioid and 20% carcinosarcoma. We detected the same four molecular subgroups defined by *CCNE1amp (13%)*, *ERBB2amp* (16%), and *PTEN* mutation or loss (34%). These subgroups were also almost exclusive to one another. Only two patients (3%) harbored co-alterations. In terms of outcomes, we did not observe any overall survival difference between these subgroups.

Conclusions: Among *P53mut* EC, we detected 3 nearly mutually-exclusive molecular subgroups: *CCNE1* amplified, *ERBB2* amplified and *PTEN* loss, accounting together for 60% of cases. Whether these subgroups might benefit from personalized therapeutic strategies is currently being explored.

789P Real-world (RW) duration of treatment in first-line maintenance (1Lm) niraparib monotherapy in epithelial ovarian cancer (EOC): CHAR1ZMA study

F. Backes[1], T. Boyle[2], J. Perhanidis[3], J. Lim[4], J. Hartman[5], J.M. Schilder[6], J. Hurteau[7], A. Golembesky[8], R. Salani[9]

[1]Obstetrics and Gynecology, Ohio State University Wexner Medical Center and James Hospital Comprehensive Cancer Center, Columbus, OH, USA; [2]Oncology Epidemiology, GSK, Upper Providence, PA, USA; [3]Real-World Analytics, Value Evidence and Outcomes Oncology, GSK, Waltham, MA, USA; [4]Global Value Evidence and Outcomes Oncology, GSK, Upper Providence, PA, USA; [5]Value Evidence and Outcomes, GSK, Philadelphia, PA, USA; [6]Synthetic Lethality, GSK, Philadelphia, PA, USA; [7]Synthetic Lethality&Immuno-Oncology, GSK, Waltham, MA, USA; [8]Oncology, GSK, Durham, NC, USA; [9]Department of Obstetrics and Gynecology, David Geffen School of Medicine at UCLA, Los Angeles, CA, USA

Background: RW data on 1Lm niraparib use in patients (pts) with EOC are sparse. The CHAR1ZMA study described treatment (tx) discontinuation for pts with EOC prescribed 1Lm niraparib monotherapy using a US RW database.

Methods: Eligibility criteria were previously described [1]. Pts were selected from the nationwide electronic health record-derived de-identified Flatiron Health database. Time to tx discontinuation (TTD; index [start of 1Lm niraparib] to 1Lm niraparib end date) was estimated via Kaplan-Meier methods. Results were stratified by early discontinuers (pts discontinued ≤90 days) and persisters (pts discontinued >90 days post-initiation/censored), and by breast cancer gene (*BRCA*)/homologous recombination deficiency (HRD) status.

Results: Among 414 EOC pts, 83% had stage III/IV disease, 26% were HR-deficient (HRd), and median age at index was 67 yrs. Median follow-up was 12.4 mo. Median TTD was 7.5 mo (95% confidence interval [CI] 5.9, 9.0) overall and increased by 4.9 mo to 12.4 mo (95% CI 10.3, 17.3) for persisters (n=296). Drug toxicity was cited as a reason for tx discontinuation in 67% of early discontinuers (n=118) and 22% of persisters (n=133) (Table). Disease progression was cited as a reason for tx discontinuation in 32% of early discontinuers and 74% of persisters. Dose modifications varied by discontinuation status (no dose modification was reported in 28% of persisters and 59% of early discontinuers). In the HRd subgroup, median TTD was 13.1 mo (95% CI 9.2, 22.2) overall (n=106), and increased by 9.1 mo to 22.2 mo (95% CI 13.5, not reached) for persisters (n=83).

Conclusions: This RW study demonstrates pts with EOC on 1Lm niraparib for >90 days have a much longer TTD than all pts. Effective clinical management of drug toxicity among 1Lm niraparib pts in the first 90 days of tx may help pts stay on tx and experience full therapeutic benefit.

Table: 789P

n (%)	Overall (n=414)	Early discontinuers (n=118)	Persisters (n=296)
BRCA*/HRD status			
HR-deficient	106 (25.6)	23 (19.5)	83 (28.0)
HR-proficient	71 (17.1)	15 (12.7)	56 (18.9)
BRCA wild-type	346 (83.6)	98 (83.1)	248 (83.8)
BRCA mutant	48 (11.6)	9 (7.6)	39 (13.2)
Discontinued	251 (60.6)	118 (100.0)	133 (44.9)
Reasons for tx discontinuation†			
Toxicity	108 (43.0)	79 (66.9)	29 (21.8)
Disease progression	137 (54.6)	38 (32.2)	99 (74.4)

Background: Endometrial carcinoma (EC) guidelines (NCCN, ESGO) suggest molecular analysis (MA) for incorporation into risk criteria. Prognostic value of TCGA-based classification has been validated, but adoption into adjuvant treatment decisions is still under evaluation. Examples of real-world upfront MA analysis in EC are scarce. We aim to evaluate our routine implementation of Next Generation Sequencing (NGS) of EC patients.

Methods: In November 2020, we implemented routine immunohistochemistry (IHC) (p53, MMR) & NGS for TCGA-based prognostication of all EC primary resections at a single institution. NGS was a 69 gene panel including *POLE*, *TP53*, *PTEN*, *CTNNB1*, *KRAS*, *ERBB2*, & *PIK3CA*. A questionnaire directed to treating oncologists evaluating impact of MA on adjuvant management decisions and counselling was utilized.

Results: 189 patients amongst 7 treating gynecologic oncologists were evaluated over the initial 13 months. Primary stage of disease was; I: 139 (73.5%), II: 11(5.8%), III: 27 (14.3%), IV: 12 (6.4%). Prognostic classifiers were: POLE: 10 (5.3%); MMRd 52 (27.5%); NSMP: 86 (45.5%); and p53: 41 (21.7%), including multiple-classifiers: 10 (5.3%) MMRd-p53 and 4 (2.1%) POLE-p53. The classifiers with the most impact for providers were MMRd: 27 (14.3%) and p53: 22 (11.6%). Prognostic classification impacted patient counselling in 72 (38.1%) of patients (POLE 66.7%; MMRd 59.5%; p53 52.5%; NSMP 12.6%; $p<0.001$), with NSMP having the least impact. MA impacted treatment recommendations in 19 (10%) of patients. MA altered treatment recommendations compared to recommendations by histological properties in 8 (4.2%) patients. MA significantly impacted treatment recommendations with increasing stage (I: 5.8%, II: 9.1%, III: 22.2%, IV: 33.3%, $p=0.002$). MA significantly altered treatment recommendations deviating from histological recommendations with increasing stage (I: 1.4%, II: n/a, III: 14.8%, IV: 16.7%, $p=0.002$).

Conclusions: Comprehensive uniform molecular analysis of endometrial carcinoma via combined IHC and NGS upon primary resection is feasible and contributes to patient counseling and treatment recommendations.

791P Development and validation of nomograms to predict survival in patients with high-grade serous ovarian cancer

X. Peng[1], J. Liu[2]

[1]Department of Obstetrics and Gynecology, Linxiang City People's Hospital of Hunan Province, Linxiang, China; [2]Department of Vascular and Endovascular Surgery, Chinese PLA General Hospital, Beijing, China

Background: The current American Joint Committee on Cancer TNM and FIGO systems are without sufficient details encompassing the variety of ovarian cancer. To develop and validate nomograms for overall survival (OS) and cancer-specific survival (CSS) in patients with high-grade serous ovarian cancer (HGSOC).

Methods: The collection of data from California, Connecticut, Detroit, Georgia, Hawaii Iowa was formed as the development cohort. A cohort of data from Kentucky, Louisiana, New Jersey, New Mexico, Seattle, and Utah formed the external validation cohorts. We developed the nomograms using the Cox prediction model. We applied five-method comparisons to screen the best model for both nomograms, and the nomogram models underwent successful independent external validations to support their reliability. We assessed nomogram model performance by examining overall accuracy (Brier score), calibration (calibration plots and Hosmer—Lemeshow calibration test), and discrimination (Harrell C index).

Results: The development cohorts included 2465 patients which were split into two parts (7:3) for the development (n=1726) and internal validation (n=739) for the model, and the 5-year overall survival was 18·6% (458/2465). The OS nomogram showed that Scope Reg LN Sur (0-100), AJCC_N (0-89.37), Systemic Sur Seq (0-74.25), the year of diagnosis (0-69.15), and Surg Prim Site(0-51.52) shared the larger contribution to prognosis. Followed by AJCC_ M (0—48.42) and age (0—45.31). The C index of 5-year OS and CSS nomograms was 0.715 (95% CI 0.688—0.741) and 0.719 (0.693—0.745) in the development cohort, 0.695 (0.646—0.744) and 0.702 (0.653—0.750) in the internal validation cohorts. The external validation cohorts included 961 patients, were 0.684 (0.644—0.724) and 0.687 (0.648—0.727). The nomograms performed well according to overall accuracy, discrimination, and calibration when they were applied to the validation cohorts.

Conclusions: Our nomograms are credible methods that can be used to predict OS and CSS in patients with HGSOC. They should be offered to clinicians to assess patient prognosis, make prognosis-based decisions and be conducive to stratifying patients in clinical trials or population-based analyses, and inform patients clinically.

Editorial acknowledgement: We gratefully thank the SEER database for providing data support. we also express sincere gratitude to Steve for guiding us on how to handle the data of alive or dead of other causes to perform Cause-specific survival analysis. At the same time, we thank the Free Statistics team for providing technical guidance and valuable tools for data analysis and visualization.

Background: The curative role of surgery in early stage I & II OC is well established. Nevertheless, a significant number of them relapse. The modeled CA-125 KELIM score estimated during 1st-line chemotherapy is a prognostic factor, thought to be a pragmatic indicator of the tumor intrinsic chemosensitivity. We assessed the prognostic value of KELIM in patients with optimally debulked FIGO stage I & II diseases regarding PFS and OS in the GCIG meta-analysis dataset (MAOV), where different adjuvant chemotherapy regimens were assessed.

Methods: Individual patient KELIM values were previously estimated in 5,884 patients included in MAOV (Corbaux, 2021). Patients with optimally resected FIGO I & II diseases were selected. The prognostic value of KELIM was assessed using univariate & multivariate analyses, according to histological subtype, and disease stage I or II.

Results: 628 and 515 patients had optimally resected stages I & II OC, respectively, including clear cell (CCC) (46.7%); serous (23.7%); endometrioid (12.4%); and mucinous carcinomas (3.9%). 52% had CA-125 $\geq$ 35 UI/L after surgery. The respective median standardized KELIM values were 1.32, 1.18, 1.16, and 1.08 ($P < 0.0001$). In univariate & multivariate analyses, a favorable KELIM score $\geq$1.0 (vs unfavorable KELIM score $<$1.0) was associated with longer PFS and OS (5-year PFS, 68.3% vs 55.9%, $P<0.0001$, HR 0.61 [0.48-0.77]; 5-year OS, 80.7% vs 72.8 %, $P<0.0001$, HR 0.50 [0.36-0.68]), as was the histological subtype. CCC was associated with worse OS, HR 1.84 [1.17 — 2.90], and endometroid with better OS, HR 0.33 [0.17 — 0.66]). When assessed within histological subtypes, KELIM was a significant prognostic factor in CCC (PFS, HR 0.41 [0.30-0.56]; OS, HR 0.33 [0.23-0.47]) and in serous carcinomas (PFS, HR 0.54 [0.39-0.75]; OS, HR 0.59 [0.37-0.94]), but not in endometrioid and mucinous carcinomas.

Conclusions: KELIM during adjuvant chemotherapy plays an important prognostic role in optimally resected stage I-II ovarian cancers, especially in CCC and serous carcinomas, suggesting the potential role of chemosensitivity beyond surgery. KELIM may help identify pts at higher risk of relapse/death, requiring closer follow-up.

Background: The modeled CA-125 longitudinal kinetic parameter KELIM^{TM} during 1st-line chemotherapy is as a pragmatic indicator of the tumor primary chemosensivitiy. However, the links between KELIM^{TM} and the beneath chemotherapy-induced tumor biological effects had to be explored. We studied the links between KELIM^{TM} values and pathological response, and changes in TILs, in ovarian cancer patients treated with neo-adjuvant chemotherapy (NACT) +/- interval debulking surgery (IDS).

Methods: In the randomized phase II trial CHIVA (NCT01583322), 188 patients were treated with NACT carboplatin-paclitaxel +/- nintedanib, +/- IDS. Patient KELIMs were previously calculated. The pathological response was assessed with the Chemotherapy Response Score on the omentum (CRS 1-3), and with an enriched pathological response pR score based on the available tumor tissue block when omentum was lacking (pRS 1-3), obtained after NACT. Changes in stromal TILs (sTILs, % of the stromal surface on lymphocytes) and intra-epithelial TILs (ieTILs, qualitative appreciation, 0-2) in baseline tissue and after NACT were analyzed.

Results: A strong association was found between patient KELIM^{TM} value and the omentum CRS after NACT (n=67; median KELIM^{TM}, 0.71 for CRS-1; 1.26 for CRS-2; 1.66 for CRS-3; P<0.01). Consistent, a correlation was observed between KELIM and tumor pRS (n=103; median KELIM^{TM}, 0.73 for pRS-1; 1.25 for pRS-2; 1.61 for pRS-3; P <0.01). At baseline before NACT, no relationships between KELIM^{TM} and TILs were found. After NACT, a significant association was observed between higher patient KELIM^{TM} values and higher intra-epithelial TILs infiltrate after NACT (n=99; median KELIM, 0.88 for ieTILs score 0-1; vs 1.26 for ieTILs score 2; P = 0.03).

Conclusions: High consistency was found between patients KELIM^{TM} and the pathological response after neo-adjuvant chemotherapy, assessed with the omentum CRS score, or the larger tumor pRS score. Omentum may not necessarily needed to assess the pathological response. Intra-epithelial TILs change after NACT was strongly associated with KELIM^{TM}-assessed chemosensitivity, thereby opening hypotheses about mechanisms of platinum-sensitivity.

Clinical trial identification: NCT01583322.

Ltd., Singapore; [5]Pathology, Cancer Science Institute (CSI)-National University of Singapore (NUS), Singapore; [6]Hematology-Oncology, NCIS-National University Cancer Institute Singapore, Singapore; [7]Obstetrics and Gynaecology, NUS-National University of Singapore-National University Health System (NUHS), Singapore; [8]Obstetrics and Gynaecology, NUHS-National University Health System, Singapore; [9]Clinical Research, Cancer Science Institute (CSI)-National University of Singapore (NUS), Singapore; [10]Radiology, NUH-National University Hospital (S) Pte. Ltd., Singapore; [11]Obstetrics and Gynaecology, National University Hospital, Singapore; [12]Medical Oncology Department, NUHS-National University Health System, Singapore

Background: OCCC, compared to other histologies, are less responsive to platinum based chemotherapy and suffer a worse prognosis. *ARID1A* mutations (mt) are the most common mt in OCCC. *ARID1A* loss has been described to increase replication stress in various tumor models. Anti-metabolites like gem are effective in *ARID1A*-mt in-vitro.

Methods: We performed a retrospective analysis of the molecular features and treatment outcomes of advanced or relapsed OCCC pts treated at our institution between January 2000 to May 2022. Treatment response was assessed per RECIST1.1. Next-generation sequencing (NGS) was performed where sufficient archival tissue was available (n=60). We hypothesize that gem is more effective than non-gem therapies, especially in *ARID1A*-mt.

Results: Of 90 advanced or relapsed OCCC patients (pts), median age was 53 years, with median 1 prior line of treatment received. 67 (74.4%) received 2 or more lines, of whom 35 (52.2%) included gem based therapy, mostly in 2nd line (19/35). 12 pts received platinum-gem with bevacizumab (bev), 18 pts received platinum-gem, 5 received gem monotherapy. 30/60 (50%) were *ARID1A*-mt. Across all treatment lines, the disease control rate (DCR) to gem was 61.1%. In 2nd line, DCR was significantly better for gem over non gem (Odds Ratio (OR) OR 6.5, p=0.004), seemingly more for *ARID1A*-mt (OR of mt VS wild-type (wt) 28 VS 4.2). Early use of gem (2nd against later lines) and incorporation of bev significantly improved DCR on multivariate analysis (Early use OR 4.1, p: 0.04; Bev OR 7.2, p: 0.02). There was a trend to improved median

progression-free survival (mPFS) of 2L gem against non-gem based therapy (7.2 versus 3.2 months(m); Hazard Ratio (HR): 3.48, p = 0.06). This was significant in ARID1A mts (gem VS non-gem: 295 VS 70 days; HR: 4.3, p=0.04) but not in ARID1A-wt (p=0.14). Overall survival was not statistically significant in this study.

Conclusions: This is the largest study of OCCC pts receiving gem based therapy. We show that gemcitabine improved DCR for all OCCC patients, and mPFS in *ARID1A*-mt especially when used earlier. To maximise gem efficacy, earlier treatment combined with bevacizumab should be considered in OCCC.

Background: The GEICO-88R study assessed the real-world use of niraparib as maintenance treatment in patients (pts) with platinum-sensitive recurrent high-grade ovarian cancer (OC) within the Spanish expanded access program. A preplanned sub-analysis of long-term responders (LTR) is presented.

Methods: In this retrospective study across 57 Spanish sites pts received niraparib at a fixed starting dose (FSD) of 300 mg/day or individualized starting dose (ISD) according to weight and platelet count. A specific assessment of LTR to niraparib maintenance treatment (exposure ≥1 year) was performed, describing patient characteristics, niraparib dosing, tolerability, and effectiveness.

Results: This sub-analysis included 107 pts (33.8% of 316 from general study), with median age 64 years (43-88) and a median of 2 previous lines (53.3% 1-2, 46.7% ≥3). Main initial FIGO stages were III (58.8%) and IV (18.6%). Forty-five (42%) pts received prior bevacizumab and 81.3% were gBRCAwt. 99 pts had surgery at primary diagnosis (72.7% primary and 27.3% interval debulking), R0 in 69.9%. 31 (29%) pts had surgery at relapse, R0 in 64.5%. At baseline, ECOG was 0 (56.1%) or 1 (43.9%). Relevant comorbidities were reported in 46.7% of pts. Niraparib was initiated at FSD in 24 pts and at ISD in 83 (80.7% at 200 mg/day; 19.3% at 300 mg/day). Overall median dose was 200 mg. Median treatment duration was 26.2 months (12-60.7). 68.2% of pts required at least one dose interruption or reduction. 39 (36.4%) pts remained on treatment upon analysis (91.1% discontinued due to progression, 2.9% toxicity, and 4.4% physician/patient decision). The most frequent all-grade adverse events were thrombocytopenia (42.1%), anemia (36.4%), and asthenia (29.9%), with no significant differences between FSD vs ISD pts. Of 85 pts with pre-niraparib measurable disease, PR+CR was 63.5%. With median follow-up of 29.95 months, median PFS, PFS2 an OS were 27.2 (95% CI 23.6- 29.6), 42.3 (95% CI 34.2-NA) and not reached (85.4% of pts alive).

Conclusions: A durable response was achieved in a substantial proportion of pts, even despite the high risk of this population (majority BRCAwt, pre-treated, significant comorbidities) with a good tolerability profile in a real-world setting.

Clinical trial identification: NCT04546373.

Background: LGSOC is a rare disease. Few data of large size have been published.

Methods: We conducted a multicenter retrospective analysis of LGSC patients selected from the French Epidemiological Strategy and Medical Economics Ovarian Cancer database between 2000 and 2019. This database includes all ovarian cancer pts treated in 18 French Comprehensive Cancer Centers. The main objective was to describe the management of these patients. Secondary objectives were to analyse progression-free survival (PFS) and overall survival (OS) and prognostic factors in the stage III/IV population.

Results: Out of the 13032 pts, 230 (1.8%) with a confirmed diagnosis of stage III (n=171)/IV (n=59) LGSOC were identified. Median age at diagnosis was 55.5y (19.8-88.2). 128 (55.6%) pts had primary debulking surgery (PDS) and 35 (15.2%) neoadjuvant chemotherapy (NACT) and interval debulking surgery (IDS). 49 (21.3%) pts did not have debulking surgery and 18 (7.9%) patients had surgery after 6 courses of NACT. 223 pts (97.0%) received platinum-based chemotherapy (PBC) including bevacizumab (Bev) for 79 pts (34.3%). Endocrine therapy maintenance was given in 27 pts. After a median follow up of 73.6m [69.9-80.0], median OS was 93.4m (95%CI [71.2-176.9]) in the whole population. Median OS according to timing of surgery was 146.0m (95%CI [110.4-NR]) with PDS vs. 75.5m (95%CI [48.7-Not Reached]) with NACT-IDS vs. 61.8m (95%CI [42.4-NR]) with 6 courses of NACT and closing surgery. Patients not candidate for surgery received PBC (n=49) +/-Bev (14/49) +/- maintenance endocrine therapy (13/49). With a median follow-up of 64.6m (38.6-93.6), median PFS and OS were 15.9m (95%CI [13.4-20.6]) and 38.0 m (95%CI [33.0-65.0]) respectively. OS multivariable analyses are shown in the table.

Table: 796P

	HR	95%CI	p value
Initial FIGO stage			
III			
IV	2.40	1.48,3.91	**<0.001**
Timing of surgery			
Primary debulking surgery			
Interval debulking surgery or closing surgery	1.93	1.13, 3.34	**0.018**
No surgery	2.65	1.50;4.68	**<0.001**
Age (continuous variable)	1.01	1.00, 1.03	**0.038**
Bevacizumab first line			
No			
Yes	0.82	0.51, 1.30	0.393

Conclusions: In this large size population of advanced LGSOC, FIGO IV stage, absence of PDS and age are associated with poorer OS.

797P Impact of consolidation cycles in predicting recurrence in patients treated with EMA-CO for high-risk gestational trophoblastic neoplasia

A. Deleuze[1], T. Hajri[2], P.A. Bolze[3], T. De La Motte Rouge[1]

[1]Medical Oncology Department, Centre Eugene-Marquis, Rennes, France; [2]Oncology, Hospices Civiles de Lyon-HCL-Lyon University Hospital Center, Lyon, France; [3]Gynecology and Surgical Oncology Department, Lyon Sud Hospital Center, Pierre Bénite, France

Background: EMA-CO is the most used combined chemotherapy regimen for treating high-risk gestational trophoblastic neoplasia (GTN) patients. It is administered weekly until normalization of hCG levels, followed by two consolidation cycles. Premature discontinuation of EMA-CO chemotherapy due to dose-limiting toxicities may occur before achieving the target hCG threshold. Despite its widespread use, the effectiveness of consolidation cycles in preventing recurrence in GTN patients remains unclear. In this study, we aimed to evaluate the impact of EMA-CO consolidation cycles on recurrence.

Methods: We conducted a non-interventional, retrospective study in patients selected from the French Center for Trophoblastic Diseases in Lyon and identified 276 patients with a GTN diagnosis and treated with EMA-CO regimen between November 1999 and November 2020 from our database. Exclusion criteria for this study included resistance to EMA-CO chemotherapy (n=31). We assessed the impact of two cycles of EMA-CO consolidation on the 2-year recurrence-free survival (RFS).

Results: A total of 245 patients met the eligibility criteria for this study, of whom 88.6% (217/245) received consolidation cycles of EMA-CO. Choriocarcinomas were diagnosed in 42% (102/245) of the patients, while invasive mole was observed in 58% (143/245) of cases. The median FIGO score was 8 (range 1 − 19). After a median follow-up of 23 months, the 2-year RFS was 93% (95%CI 0.90 to 0.96) in the consolidation group and 90% (95% CI 0.79 to 1.0) in the group of patients who didn't receive consolidation cycles (HR 0.79; 95% CI 0.23 to 2.72, p=0.71). Grade $\geq$ 2 adverse events occurred in 43% of patients, with neutropenia being the most frequent (31%).

Conclusions: In this study, the 2-year RFS was not significantly different between the groups. These findings suggest that consolidation cycles may not influence recurrence in patients with gestational trophoblastic neoplasia. Considering the non-negligible toxicity of EMA-CO, our results raise the question of optimizing therapy through de-escalation and/or shortening of chemotherapy after hCG normalization.

798P Survival analysis of non-metastatic gestational choriocarcinoma (NMGCC) patients treated with chemotherapy

S.A. Alshwayyat[1], T.A. Alshwayyat[2], H. Kamal[3], M. Alshwayyat[2]

[1]Medicine School, JUST-Jordan University of Science and Technology, Irbid, Jordan; [2]Faculty of Medicine, JUST-Jordan University of Science and Technology, Irbid, Jordan; [3]Medicine, JUST-Jordan University of Science and Technology, Irbid, Jordan

Background: To date, there is no consensus on the FIGO recommendations for NMGCC in which chemotherapy (CTX) should be initiated after diagnosis in these patients. Therefore, we conducted the first study involving a large sample of patients with NMGCC to evaluate the effect of chemotherapy on overall survival (OS) and cancer-specific survival (CSS) in patients with NMGCC.

Methods: Data were obtained from the National Cancer Institute Surveillance, Epidemiology, and End Results (SEER) database between 2000 and 2019. Patients who met any of the following criteria were excluded: diagnosis not confirmed by histology; not the first tumor or other malignancies in the body; not arising from the placenta; unknown data; or metastatic status. Chi-square tests were used to compare clinicopathological features, while survival rates and prognostic factors were identified using the Kaplan-Meier estimator, log-rank tests, and Cox proportional hazard regression.

Results: The study population comprised 526 patients. Among them 128 patients with "Surgery," 127 patients with "CTX" and 261 patients with "Surgery + CTX". Most patients (55.3%) were aged 30 years or older, with a median age of 32 years. The largest racial group was white (63.5%; n=334). A total of 54.4% of the patients had a tumor size greater than 4 cm, with a median tumor size of 4.2 cm. Most cases were localized (71.5%, n=376). "Surgery + CTX" had the most favorable survival outcome with a 5-year OS of 96.6%, followed by "Surgery" (95.9%) and then "CTX" (93%). No significant differences were found in OS or CSS between the groups ($P<0.33$ and $P<0.57$, respectively). Older age was a poor prognostic factor for the OS and CSS. Multivariable analysis confirmed that there was no statistically significant difference between the effect of all therapeutic groups on OS and CSS, "Surgery + CTX" (HR=0.7, 95%CI:0.28-1.8 and HR=0.65, 95%CI:0.2-2, respectively).

Conclusions: The results of this study showed that CTX did not affect OS or CSS in patients with NMGCC. Multicenter prospective studies are needed to validate and build upon these findings; however, our results provide a starting point for a better understanding of these rare cancers.

799P Clinicopathological characteristics and oncological outcomes of three subtypes of neuroendocrine carcinoma of the cervix: A multicenter retrospective study of 288 patients

Y. Gu, Y. Xiang

Gynecology&Obstetric Dept., PUMCH-Peking Union Medical College Hospital/Beijing Xiehe Hospital-Dongdan Campus, Beijing, China

Background: Neuroendocrine carcinoma of the cervix (NECC) is a rare type of cervical cancer, and is divided into small cell neuroendocrine carcinoma (SCNEC), large cell neuroendocrine carcinoma (LCNEC) and mixed neuroendocrine-non-neuroendocrine neoplasm (MiNEN). Present studies on NECC mainly focus on SCNEC, and the clinical features of LCNEC, especially MiNEN, are not well understood.

Methods: The multicenter, retrospective study enrolled 288 patients. The primary outcomes were progression-free survival (PFS) and overall survival (OS). The Kaplan-Meier method and Cox proportional hazard analysis were performed.

Results: With a median follow up of 25 months, the 5-year PFS of NECC, SCNEC, LCNEC and MiNEN was 40.2%, 40.4%, 30.3%, and 41.6%; and the 5-year OS was

45.4%, 44.0%, 32.3%, and 50.3%. In the whole cohort, it showed that LVSI (HR=1.996, 95%CI:1.275～3.126, p=0.003) and >2/3 stromal invasion (HR=2.009, 95% CI:1.222～3.303, p=0.006) were independent risk factors of PFS; age>45 (HR=1.956, 95%CI: 1.170～3.272, p=0.011), LVSI (HR=1.722, 95%CI: 1.016～2.918, p=0.043) and >2/3 stromal invasion (HR=1.778, 95%CI: 1.024～3.087, p=0.041) were independent risk factors for OS. In patients undertaking surgery, it revealed that LVSI (HR=1.996, 95%CI:1.275～3.126, p=0.003) and NACT (HR=1.691, 95%CI: 1.040～2.748, p=0.034) were independent risk factors, and that adjuvant chemoradiotherapy was an independent protective factor of PFS (HR=0.201, 95%CI: 0.103～0.428, p<0.001); age>42 (HR=2.377, 95%CI: 1.417～3.986, p=0.001) and LVSI (HR=2.450, 95%CI: 1.388～4.324, p=0.002) were independent risk factors of OS, and that adjuvant chemoradiotherapy was an independent protective factor of OS (HR=0.175, 95%CI: 0.079～0.388, p<0.001).

Conclusions: This multicenter retrospective study first focused on three pathological subtypes of NECC. SCNEC has a worse biological behavior than the other two types. Patients with MiNEN did not show better prognosis than the other two. LVSI and >2/3 stromal invasion and adjuvant chemoradiotherapy are prognostic factors for PFS; age, LVSI, and >2/3 stromal invasion and adjuvant chemoradiotherapy are prognostic factors for OS in patients with NECC.

800P Response to chemotherapy following PARP inhibition in UK ovarian cancer (OC) patients

S. Howlett[1], A.M. Berner[2], K. Connolly[3], A. Orosco Ttamina[4], A. D'Angelo[5], G. Gullick[5], H. Abdallah[6], J. Wood[6], U. Mukherjee[7], M. Azhar[8], D. Lee[9], P. Mahalingam[10], L. Tookman[10], L.H. Cossar[11], R. Miller[12], M. Hall[13], S. Khalique[14]

[1]Medical Oncology Department, Wexham Park Hospital, Slough, UK; [2]Barts Cancer Institute, London, Private Address-Dr. Alison Berner, London, UK; [3]Oncology, ECC-Edinburgh Cancer Centre-SCAN, Edinburgh, UK; [4]Oncology, St. Bartholomew's Hospital-Barts Health NHS Trust, London, UK; [5]Oncology, Royal United Hospitals Bath-NHS Foundation trust, Bath, UK; [6]Oncology, University Hospitals of Leicester NHS Trust, Leicester, UK; [7]Oncology, UCLH-University College London Hospitals NHS Foundation Trust, London, UK; [8]Oncology, Leeds Cancer Centre, Leeds, UK; [9]Medical Oncology Department, Leeds Cancer Centre, Leeds, UK; [10]Medical Oncology Department, Imperial College London-Hammersmith Campus, London, UK; [11]Medical Oncology, The Clatterbridge Cancer Centre-Liverpool, Liverpool, Merseyside, UK; [12]Medical Oncology Department, UCLH-University College London Hospitals NHS Foundation Trust, London, UK; [13]Medical Oncology Dept., Mount Vernon Cancer Centre, Northwood, Middlesex, UK; [14]Oncology, Mount Vernon Cancer Centre, London, UK

Background: *BRCA* mutated recurrent platinum sensitive OC patients (pts) who received a maintenance poly-adenosine ribose phosphatase inhibitor (PARPi) show a lower-than-expected response to subsequent chemotherapy in retrospective trial analysis. What are real world outcomes for UK pts, including *BRCA* wild-type (WT)?.

Methods: Retrospective data analysis of OC pts who received subsequent chemotherapy following a PARPi (minimum 14 days) between 01/01/18-31/12/21 across 10 UK sites. Responses were evaluated by imaging/CA125 or clinical status, with DCR (defined as CR/PR or SD at first post-chemotherapy assessment, excluding pts with progression). Statistical tests used: Kaplan-Meier (OS and PFS) and Fisher's Exact Test (DCR and ORR).

Results: 311 OC patients: stage III (n = 180, 58%) and IV (n = 106, 34%). 21% were *BRCA* mutant (MT) (n = 64). PARPis included olaparib (n = 47, 15%), niraparib (n = 220, 71%) and rucaparib (n = 44, 14%), with median duration of use of 189 days (range 14-1351). First post-PARPi chemotherapy was platinum-based (PBC) in 72% (n = 223); 2nd line in 37% (n = 116), 3rd line 47% (n = 147), later line in 15% (n = 48). 234 pts had evaluable responses: ORR to first post-PARPi treatment was 28% for PBC, 27% for non-platinum chemotherapy (NPC) (non-significant, ns); DCR was 44% to PBC, 33% to NPC (ns), median PFS was 5.8 months (m) for PBC, 5.4 m for NPC (ns). Across the 311 pts, median OS was 17.4 m for PBC and 13.6m for NPC (HR 0.56, p = 0.001). Preliminary analysis shows no significant difference in duration of PARPi use, ORR, DCR, according to *BRCA* status. PFS/OS data will be presented with respect to number of lines and *BRCA* status. Limitations include retrospective non-trial based follow up..

Conclusions: UK OC patients show similar PFS, OS, ORR and DCR to subsequent treatment following maintenance PARPi irrespective of *BRCA* status.

Background: Maintenance treatment with olaparib has demonstrated significant improvements in median progression-free survival (PFS) compared with placebo in patients with platinum-sensitive relapsed ovarian cancer (PSROC) who are in response to platinum-based chemotherapy (PBC). Olaparib was the first-in-class poly (ADP-ribose) polymerase inhibitor (PARPi) approved as monotherapy in the EU in 12/2014 (hard capsules, HC, 400 mg twice daily) in *BRCA*-mutated (*BRCA*m) PSROC. In addition, film-coated tablets (FT, 300 mg, twice daily) were approved in 05/2018 in PSROC regardless of BRCA status. After entering routine clinical practice, real-world data on olaparib were limited and this non-interventional study (NIS) was initiated. Here, final survival results are reported.

Methods: The prospective NIS C-PATROL (NCT02503436) was performed at 68 sites (50 hospitals, 18 office-based) in Germany. Routine clinical data were collected of *BRCA*m PSROC patients treated with olaparib according to label.

Results: Between 28 Oct 2015 and 30 Sep 2019, 282 patients were enrolled. Of these, 269 patients were included in the analysis (median age: 60 yrs; ECOG ≤1: 93%; ≥2 relapses: 32%; ≥3 prior PBC: 34%). 46 patients started with FT and 223 patients with HC; 70 patients switched from HC to FT. Median follow-up was 23.5 months (range 0.00 − 80.5) and median olaparib treatment duration was 13.6 months (0.1−80.9). 10% of patients received olaparib for ≥5 years. Median PFS was 14.3 months (95% CI 12.2−18.0). Median overall survival was 35.4 months (95% CI 29.2−47.1). 132

Table: 800P Response to first post PARPi treatment in 227 pts with known *BRCA* status

Endpoint	First post PARPi treatment					
	Platinum based			Non-platinum based		
	BRCA MT	*BRCA* WT		*BRCA* MT	*BRCA* WT	
ORR (%)	28	28	*OR = 0.99, p = 1*	17	28	*OR = 0.53, p = 1*
DCR (%)	38	47	*OR = 0.70, p = 0.3*	17	33	*OR = 0.41, p = 0.6*
PFS (m)	5.3	6.1	*HR = 0.84, p = 0.3*	9.4	5.4	*HR = 1.0, p = 1*
OS (m)	18.0	17.2	*HR = 0.93, p = 0.7*	15.6	13.1	*HR = 0.71, p = 0.4*

patients received at least one subsequent medication. Adverse events (AEs) were consistent with known tolerability profile of olaparib. 31 patients (11.3%, safety set: total n=274) discontinued olaparib treatment and 60 patients (21.9%) received reduced olaparib dose due to AEs.

Conclusions: This real-word study supports efficacy and tolerability of olaparib maintenance therapy after PBC in patients with *BRCA*m PSROC. Long-term exposure to olaparib was observed with no new safety signals.

Clinical trial identification: NCT02503436.

803P Pre-treatment systemic inflammatory markers predict survival in endometrial cancer cases: A Japanese gynaecologic oncology group 2043 exploratory data analysis

S. Nishio[1], K. Murotani[2], W. Yamagami[3], S. Suzuki[4], H. Nakai[5], K. Kato[6], H. Tokunaga[7], H. Nomura[8], Y. Yokoyama[9], K. Takehara[10]

[1]Obstetrics and Gynecology, Kurume University, Kurume, Japan; [2]Biostatistics Center, Kurume University Hospital, Kurume, Japan; [3]Obstetrics and Gynecology, Keio University School of Medicine, Shinjuku-ku, Japan; [4]Gynecology, Aichi Cancer Center Hospital, Nagoya, Japan; [5]Obstetrics and Gynecology, Kindai University-Faculty of Medicine, Osaka, Japan; [6]Obstetrics and Gynecology, Kitasato University School of Medicine, Sagamihara, Japan; [7]Obstetrics and Gynecology, Tohoku University School of Medicine, Sendai, Japan; [8]Obstetrics and Gynecology, Fujita Health University, Toyoake, Japan; [9]Obstetrics and Gynecology, Hirosaki University Graduate School of Medicine, Hirosaki, Japan; [10]Gynecologic Oncology, Shikoku Cancer Center, Matsuyama, Japan

Background: Japanese Gynecologic Oncology Group (JGOG) 2043 was a trial to assess the efficacy of three different chemotherapeutic regimens as adjuvant therapy in endometrial cancer (EC) patients with post-operative recurrent risk. Inflammation predisposes patients to tumorigenesis by damaging DNA, stimulating angiogenesis, and potentiating pro-proliferative and anti-apoptotic processes. This study investigated whether pre-treatment systemic inflammatory markers (PTSIMs) are associated with survival outcomes in EC.

Methods: Women with EC were recruited to the JGOG 2043 study, excluding patients who did not receive chemotherapy and those lost to follow-up. PTSIMs, including neutrophil-to-lymphocyte ratio (NLR), platelet-to-lymphocyte ratio (PLR), and hemoglobin, albumin, lymphocyte, and platelet (HALP) score were analysed in terms of clinicopathological factors, progression-free survival (PFS), and overall survival (OS). Optimal cut-off values for NLR, PLR, and HALP score were determined using the web application Cutoff Finder for PFS and OS. Survival estimates were calculated using the Kaplan—Meier method. Differences in survival between groups were assessed using a log-rank test.

Results: In total, 712 patients were enrolled in the JGOG 2043 study, with a median age of 59 years (interquartile range (IQR), 52—64) and body mass index (BMI) of 22.4 kg/m^2 (IQR 19—25). The optimal cut-off values for PFS were 1.478 for NLR, 0.01695 for PLR, and 35.52 for HALP score. Similarly, the optimal cut-off values for OS were 1.88 for NLR, 0.02623 for PLR, and 19.87 for HALP score. Regarding the optimal cut-off values for PFS, NLR was associated with BMI; PLR with age, BMI, and surgical stage; and HALP score with BMI, surgical stage, and lymph node metastasis. For the optimal cut-offs for OS, NLR was associated with BMI, PLR, and BMI; and HALP score was associated with age and BMI. In PFS, HALP score was the prognostic factor (NLR: p=0.068; PLR: p=0.086; HALP score: p=0.025). In OS, PLR and HALP score were prognostic factors (NLR: p=0.1; PLR: p=0.028; HALP score: p=0.028).

Conclusions: PTSIMs are associated with survival outcomes in EC. In particular, HALP score was a prognostic factor for both PFS and OS.

805P Tumor-informed ctDNA detection as a predictive marker for postoperative residual disease in epithelial ovarian cancer: A feasibility study

C. Grimm[1], V. Paspalj[2], M. Postl[2], L. Saal[3], C. Brueffer[3], N. Segui Gracia[3], M. Alcaide[3], S. Polteraueer[2], L. Oton[3], Y. Chen[3], G. Hofstetter[4], L. Müllauer[4]

[1]Gynecology and Gynecologic Oncology, MedUni Wien-Medical University of Vienna, Vienna, Austria; [2]General Gynecology and Gynecologic Oncology, MedUni Wien-Medical University of Vienna, Vienna, Austria; [3]SAGA Diagnostics AB, SAGA Diagnostics AB, Lund, Sweden; [4]Department of Pathology, MedUni Wien-Medical University of Vienna, Vienna, Austria

Background: Complete tumor resection is the most relevant prognostic factor for overall survival in high grade serous ovarian cancer (HGSOC) patients. The current standard for classification of postoperative residual disease (RD) is surgeon's subjective evaluation at the end of surgery. Thus, a reliable objective predictive marker is currently missing.

Methods: In this prospective single-center feasibility study, patients with HGSOC, who underwent surgery between July 2021 to December 2022, were included. Tumor tissue was assessed intraoperatively and blood samples were performed preoperatively, at day 2 and 10 postoperatively and subsequently at cycle 1, 3 and 6 of chemotherapy. Low-coverage whole genome sequencing (WGS) was used to identify structural variants (SV), single nucleotide variants (SNVs) and indels in tumor tissue in order to develop personalized digital PCR (dPCR) fingerprint assays.

Results: So far, 33 patients are included in the present analysis, with a median follow up time of 7 (IQR 2-10) months. In all tumor samples, dPCR assays were successfully developed and validated, with a median of 5 biomarkers (SVs and SNVs) per patient. For each patient, an individual SV profile could be established, which remained largely constant throughout multiple tumor localizations of each patient. 32/33 (97%) patients had circulating tumor DNA (ctDNA) detected at baseline at levels ranging from 0.0005 - 31% VAF. Three (10%) patients have been lost to follow without postoperative ctDNA samples. ctDNA was persistently detected in all patients with macroscopic tumor residuals. A significant decrease in ctDNA was observed in all patients with stage I-IIIB disease who had macroscopic complete resection (8 patients). In 8/22 (36%) patients with complete resection, ctDNA decreased below the detection limit. Clinical follow up is ongoing, and analysis of longitudinal samples will be presented at the congress.

Conclusions: In this feasibility study, tumor-informed ctDNA was preoperatively detectable in 97% participants. In patients with multiple tumor biopsies, the fingerprint could be used for monitoring of each location. A decrease in ctDNA detection correlated with complete tumor resection.

Background: MBO is a severe complication of advanced cancer. An interprofessional ambulatory outpatient MBO program with nurse-led proactive call management was established to support patients (pts) with gynecologic cancers at Princess Margaret Cancer Centre, showing reduction of hospitalization needs and improved outcomes.

Methods: "My Bowels on Track" is a pilot ambulatory electronic monitoring program for pts with gynecologic cancers with or at risk of MBO. Educational materials, secure messaging systems and $\leq$13 questions (Q) are offered weekly/biweekly. Based on Q answers, an alerting system flags pts with symptoms (yellow and red alerts indicate moderate and high concern, respectively) and no response to Q. Pts are contacted by nurses following clinical or compliance alerts. The primary objective is to assess the adherence ($\geq$70% Q completion considered adherent) on the first two months on the program. A secondary objective is to assess the sensitivity of the alerts to trigger recommendations. Adherence was calculated as a rate. Alert sensitivity was assessed with a generalized estimation equation.

Results: 40 pts enrolled between 08/21 and 09/22. Median age was 64.5 years (range 29-79). Primary diagnosis was ovarian (75%), uterine (17.5%) or cervical (7.5%) cancer, and 92.5% of pts were on systemic therapy. Clinical/radiological active MBO was present in 30% and 12.5% of pts prior to and at enrollment, respectively. Median duration of the program was 55 days (range 8-121). The two-month adherence was 65% (95% CI 50-80%), and the overall adherence was 60% (95% CI 43-75%). 65 symptom related alerts (75% yellow; 25% red) were reported in 60% (24/40) of pts. There were 59 recommendations triggered by alerts (29% dietary, 22% laxatives, 20% clinic assessment, 16% other medication, 8% emergency department referral, 5% other). The sensitivity of the alerts to trigger actions was 72% (95% CI 58-82%).

Conclusions: This pilot electronic MBO monitoring program with real-time patient reported outcome assessment was feasible, with 65% adherence at two months. Based on questionnaire answers an alerting system flagged symptoms of concern in 60% of participants, with a high sensitivity to provide actions or recommendations as a response to alerts.

807P Predicting surgical outcomes in patients with advanced ovarian cancer through MRI based preoperative evaluation

S. Liu[1], Z. Xu[1], X. Lv[1], Y. Tang[2], Y. Liu[1], X. Wang[1], G. Cao[1], Y. Fu[1], Z. Li[1], M. Wang[1], L. Li[1], Q. Guo[1]

[1]Department of Obstetrics and Gynecology, Xijing Hospital, Air Force Medical University, Xi'an, China; [2]Department of Radiology, Xijing Hospital, Air Force Medical University, Xi'an, China

Background: Ovarian cancer (OC) is the most lethal gynecologic tumor and is characterized by a widespread metastasis in abdominal cavity. Accurate preoperative evaluation is important for the specification of surgical procedures and prediction of surgical outcomes.Currently, a variety of imaging techniques can be used for preoperative evaluation of ovarian cancer such as the Computed Tomography (CT) Suidan score. However, the Magnetic resonance imaging (MRI) based preoperative evaluation was not fully explored. Here, our study explores the feasibility of MRI as a preoperative assessment in OC patients.

Methods: This is a prospective, non-randomized, single-center trial of 134 epithelial ovarian cancer (EOC) patients treated with surgical cytoreduction between 2018 and 2022. All patients underwent preoperative MRI scan. The imaging score consists of lesion size scores in 33 areas of the abdominal cavity.

Results: Complete cytoreduction (CC) was achieved in 81 (60.4%) of 134 patients. CC patients with a median MRI score of 10(4 - 44) and the median MRI score of patients who were incompletely cytoreduced (IC) was 15(5 - 48). By comparing imaging scores with those seen in surgery, we found that MRI evaluation is in good agreement with intraoperative observation. However, for areas such as the small bowel mesentery, the MRI score is lower than the intraoperative score, while for lymph node metastases the MRI score is higher than the intraoperative score. Through multi-factor analysis, we have screened clinical and imaging criteria related to IC including CA125 level, prognostic nutritional index (PNI), diaphragmatic surface of spleen lesion, gallbladder fossa lesion and small bowel mesentery lesion. Based on these criteria, we have constructed preoperative imaging scores and the 'predictive score' was assigned to each criterion based on its multivariate OR.

Conclusions: Our research explores the feasibility of incorporating tumor load into MRI based preoperative assessment for OC patients. Also, we identified 5 criteria associated with IC, and developed a predictive model which may be helpful in treatment planning.

808P Cell-free human papillomavirus (HPV) DNA is a sensitive biomarker for monitoring treatment response and for detecting relapse in locally advanced cervical cancer

L. Sivars[1], E. Tham[1], K. Hellman[2]

[1]Department of Molecular Medicine and Surgery, Karolinska Institutet, Huddinge, Sweden; [2]Department of Gynecologic Cancer, Karolinska University Hospital, Stockholm, Sweden

Background: Human papillomavirus (HPV) is the cause of the majority of cervical cancer cases and has been suggested to be released as cell-free DNA (ctHPV DNA) into the circulation. We here analyse if ctHPV DNA could be detected in plasma from patients with locally advanced cervical cancer (LACC) and if ctHPV DNA could be used as a prognostic biomarker and/or to detect relapses earlier than by traditional methods.

Methods: 74 patients with LACC were included, 66/74 had biopsies positive for one of 13 high-risk HPV-types using a bead-based assay. Droplet digital PCR (ddPCR) assays were developed for the HPV-types found. 418 longitudinal plasma samples from these 66 patients were then analysed using ddPCR assays for the corresponding HPV-type found in the biopsies. Results were correlated to tumor- and clinical characteristics.

Results: 92.4% of pre-treatment plasmas were positive for ctHPV DNA. ctHPV DNA levels were correlated to tumor stage. Persistent ctHPV DNA in end-of-treatment or early follow-up (1-4 months after finished treatment) plasma were correlated with worse progression-free survival (log rank test, $p < 0.001$) compared to if ctHPV DNA was not found. The positive predictive value (PPV) of ctHPV-status at early follow-up for predicting disease progression was 87.5% and the negative predictive value (NPV) was 89.3%. ctHPV DNA was found in plasma before relapse was diagnosed on radiology (median 315 days, mean 280 days) in all patients (n=10) who experienced relapsed after complete clinical response to treatment.

Conclusions: ctHPV DNA in follow-up plasma is a promising prognostic biomarker in patients with locally advanced cervical cancer, useful for analysis of response to therapy and for early detection of relapses. Drs. E. Tham and K. Hellman have equally contributed to the study.

809P Mental and socioeconomic burden in endometrial and cervical cancer patients: A Swedish population-based study of survivorship

J. Wang[1], A.L. Feldman[2], G. Bencina[3], M. Andersson[4], S. Salomonsson[4], F. Fang[5], K. Sundström[1]

[1]Clintec, Karolinska Institutet, Stockholm, Sweden; [2]Department of Neurobiology, Care Sciences and Society, Karolinska Institutet, Stockholm, Sweden; [3]MSD, Zagreb, Croatia; [4]MSD-Merck Sharp & Dohme (Sweden) AB, Stockholm, Sweden; [5]IMM, Karolinska Institutet, Stockholm, Sweden

Background: Gynecological cancer may have severe implications in women, as these diagnoses are likely to have negative consequences on mental health and socioeconomic status. We used the Swedish national population and healthcare registries to assess the association between diagnosis of endometrial or cervical cancer and risk for mental disorders, as well as for socioeconomic consequences.

Methods: We performed a population-based nested case-control study based on more than 5 million women in Sweden, identifying 6,060 cases of cervical cancer and 17,932 cases of endometrial cancer diagnosed during 2006-2018. Each cancer case was matched with five healthy controls randomly selected from the population born in the same year. Data on comprehensive set of mental disorders, loss of employment, early retirement or need for sickness benefit, family receipt of financial assistance, decrease of individual income and family income before versus after cancer diagnosis were retrieved from population registries. Conditional logistic regression and stratified Cox regression models with confounder adjustment were conducted to estimate odds ratios (OR) and 95% confidence intervals (CI).

Results: Mental disorders were prevalent to a moderate degree before diagnosis among cervical cancer patients, but less prevalent in endometrial cancer patients. After cancer diagnosis, incident (i.e. new) mental disorders started emerging within the first 2-5 years and then persisted. The risk was higher following cervical cancer (OR=3.7, 95% CI=3.5-4.1) as compared to endometrial cancer (OR=2.1, 95% CI=2.0-2.2). Before cancer diagnosis, economic status was comparable between cancer patients and control women. Financial assistance and income decrease rose early after diagnosis, with 1.2-2.1 times increased risk among cancer patients. Unemployment, early retirement and need for sickness benefit doubled from two years after cancer diagnosis and onwards. Impact was more pronounced among cervical cancer patients.

Conclusions: Women with cervical cancer and endometrial cancer are affected mentally and financially after the cancer diagnosis. The impact is more pronounced among cervical cancer patients.

810P The influence of preoperative conization (pc) to patient's (pts) outcome and tumor biology of cervical cancer (CC)

D.S. Trantaki[1], B. Wolf[1], L-C. Horn[2], N. Dornhöfer[1], B. Aktas[3]

[1]Gynecology, UKL-Universitätsklinikum Leipzig, Leipzig, Germany; [2]Pathology, UKL-Universitätsklinikum Leipzig, Leipzig, Germany; [3]Gynaecology Department, Universitätsklinikum Leipzig-Klinik und Poliklinik für Frauenheilkunde, Leipzig, Germany

Background: Recent studies suggested that tumor size reduction by means of pc prior to radical surgery might improve survival outcomes (SO) in CC pts. Whether pc has a beneficial effect in CC pts undergoing radical surgery in the form of total mesometrial resection (TMMR) is unclear. Because of the prevention of intraoperative tumor spillage by performing a closed colpotomy is essential to all TMMR, we hypothesized that pc would not affect SO in TMMR pts.

Methods: We performed a retrospective analysis of data which was collected in the Leipzig Mesometrial Resection trial. All pts had been treated for primary CC staged IB1 – IVA (2018-FIGO) by open abdominal hysterectomy performed as total or extended mesometrial resection (TMMR/EMMR). Recurrence-free (RFS) and overall survival (OAS) were analyzed. Cox proportional hazards regression models (Cox-R) were built to define the effect of pc. RFS and OAS within the conization group were analyzed to determine whether there is a difference between R0 (tumor removed completely) and R1 (tumor removed incompletely) conization.

Results: 542 pts were included, of which 202 had received pc. After 1:1 propensity score matching including 163 pts with conization and 163 controls, pc was associated with significantly increased RFS (95.6% vs. 82.3%, HR 3.2, $p<0.001$) and OAS (99.2% vs. 85.6%, HR 6.4, $p<0.001$). In multivariable Cox-R pc was the only independent factor affecting RFS (HR 0.3, $p<0.01$). Analysis of the martingale residuals in a Cox regression null-model only including tumor-size revealed a continuous increase of recurrence risk with each increment in maximum tumor diameter for pts without pc, reaching a recurrence risk of 45% at a tumor size of 70 mm. In contrast, the recurrence risk for pts who had undergone pc plateaued at 12% at a tumor size of 37 mm. The sub analysis between R0 and R1 conization pts showed no difference in RFS and OAS.

Conclusions: In this study, pc was independently associated with improved survival in CC pts treated with TMMR/EMMR. Since intraoperative tumor spillage was avoided by closed colpotomy, factors other than the prevention of local tumor cell dissemination might play a role in improving survival. There is a need of further research to understand the concrete effect of pc to tumor biology.

Sánchez Pérez de Tavares, Santo Domingo, Dominican Republic; [7]Oncology, CELAN, Guatemala City, Guatemala; [8]Medical Oncology, Latin American Cooperative Oncology Group (LACOG), Porto Alegre, Brazil; [9]Clinical Research, CRIO-Centro Regional Integrado de Oncologia, Fortaleza, Brazil; [10]Oncology, Hospital de Amor (Hospital De Cancer De Barretos)-Fundacao Pio XII, Barretos, Brazil; [11]Clinical Research, ICESP-Instituto do Cancer do Estado de Sao Paulo, São Paulo, Brazil; [12]Clinical Research, CPO-Hospital São Lucas da PUCRS, Porto Alegre, Brazil; [13]Oncology, Sanatorio De La Mujer, Rosario, Argentina; [14]Oncology, Hospital Pérola Byington, São Paulo, Brazil; [15]Statistics, Latin American Cooperative Oncology Group, Porto Alegre, Brazil; [16]Medical Oncology Department, ICESP-Instituto do Cancer do Estado de Sao Paulo, São Paulo, Brazil

Background: Cervical cancer disproportionately affects patients (pts) in developing countries and is one of the leading causes of death in Latin America (LatAm). Understanding the epidemiological landscape of cervical cancer is warranted to plan prevention and treatment strategies for the continent.

Methods: The **EVITA LATAM (LACOG 0820)** study is a multicenter retrospective and prospective cohort of pts with cervical cancer FIGO Stage IB2 to IVA diagnosed after January 2018. Its primary objective is to describe the histologic subtypes and stages of cervical cancer in Latin America. We hereby describe demographic, clinical, and pathologic characteristics, and explore factors associated with diagnosis in earlier stages.

Results: From Nov/2021 to Jan/2023, 516 pts were included in 12 centers across Brazil, Argentina, Peru, and the Dominican Republic. Median age was 45.0 (range: 21.8 – 90.5) years, 213 (41.3%) were white and 244 (47.3%) were of mixed race. Current or former smoking was reported by 133 (25.7%) pts; 265 (51.3%) pts did not complete secondary education, and 441 (85.5%) were treated in public institutions. Four (0.8%) pts had received HPV vaccination and 73 (14.1%) never used contraception. PAP smear had never been performed by 62 (12.0%) patients and 126 (24.4%) received PAP smear regularly. Regarding histology, 420 (81.4%) pts presented with squamous cell carcinoma, and 66 (12.8%) with adenocarcinoma. Stages are described in the table. ECOG PS was 2 or worse in presentation for 58 (11.2%). Performing PAP smears regularly was associated with diagnosis at earlier stages (OR 1.69, 95%CI 1.15 - 2.49, P-value 0.0072).

Table: 811P FIGO stages and screening program adherence

	Overall	Regular PAP smear	Not regular PAP smear
	N = 508	N = 122	N = 386
Stage (N, %)[a]			
I	32 (6.3%)	12 (9.8%)	20 (5.2%)
II	170 (33.5%)	48 (39.3%)	122 (31.6%)
III	247 (48.6%)	52 (42.6%)	195 (50.5%)
IV	59 (11.6%)	10 (8.20%)	49 (12.7%)

Ordinal regression, OR 1.69, 95%CI 1.15 - 2.49, P-value 0.0072.
[a]Eight patients did not have stage information so they were excluded from this table.

Conclusions: This large study in LatAm findings showed that low rates of HPV vaccination and PAP smear coverage remain alarming, and less than half of pts received PAP smear regularly. More efficient HPV vaccination strategies synchronized with well-conducted Pap smear-based screening should be prioritized in LatAm countries.

Clinical trial identification: NCT04947605.

812P Mental and socioeconomic burden in co-parents and children of patients with endometrial and cervical cancer: A Swedish population-based study

K. Sundström[1], G. Bencina[2], M. Andersson[3], S. Salomonsson[4], F. Fang[5], J. Wang[6]

[1]CLINTEC, Karolinska Institutet, Huddinge, Sweden; [2]MSD, Zagreb, Croatia; [3]MSD-Merck Sharp & Dohme (Sweden) AB, Stockholm, Sweden; [4]MSD-Merck Sharp & Dohme (Sweden) A B, Sollentuna, Sweden; [5]IMM, Karolinska Institutet, Stockholm, Sweden; [6]CLINTEC, Karolinska Institutet, Stockholm, Sweden

Background: Gynecological cancer in women may have negative mental and societal consequences impacting not only patients, but also their family members. The impact may differ between families afflicted by cervical and endometrial cancer, as the two cancers develop at different ages (median age at diagnosis 49 vs. 60 years, respectively), and is not well understood. We assessed the health and education status of family members to a woman with cervical or endometrial cancer, to elucidate potential mental and socioeconomic consequences in these.

Methods: We performed a population-based nested case-control study in Sweden, identifying 11,602 cases of cervical cancer and 34,007 cases of endometrial cancer diagnosed during 1991-2016. Each cancer case was matched with five healthy controls randomly selected from the population with same birth year. Their children and respective co-parents were identified through the Swedish multi-generation register and mental health and educational outcomes traced through the Swedish Patient Register and Statistics Sweden. A comprehensive set of mental disorders of co-parents and children and attained highest level of education of the children after mother's diagnosis, were assessed.

Results: Co-parents and children of cervical cancer patients had 30-40% increased risk of mental disorders after women's cancer diagnosis compared to relatives of healthy controls. The increase among children emerged right after cancer diagnosis (OR=1.32, 95%CI=1.05-1.65), whereas among the co-parents emerged from 2 years after (OR=1.42, 95%CI=1.02-1.98). For endometrial cancer, the association was present but weaker. Children aged 0-18 at mothers' cervical cancer diagnosis were less likely to reach a higher level of education as compared to children to women without cervical cancer (OR 0.87, 95%CI 0.83-0.91). The corresponding educational impact on children of women with endometrial cancer was inconclusive.

Conclusions: Children and co-parents of women with cervical or endometrial cancer are affected adversely mentally after the cancer diagnosis, and children to mothers with cervical cancer display a generational impact in terms of lower education attainment.

814P Clinical significance of isolated pulmonary recurrence in patients with endometrioid endometrial cancer who achieved complete remission after primary treatment

J. Yoo[1], S. Lee[2], S.I. Kim[3], I.S. Hwang[4], J. Choi[5], K.H. Lee[6]

[1]Obstetrics and Gynecology, The Catholic University of Korea-Daejeon St. Mary's Hospital, Daejeon, Republic of Korea; [2]Obstetrics and Gynecology, The Catholic University of Korea-Seoul St. Mary's Hospital-Catholic Medical Center, Seoul, Republic of Korea; [3]Obstetrics and Gynecology, The Catholic University of Korea-St. Vincent's Hospital, Suwon, Republic of Korea; [4]Obstetrics and Gynecology, The Catholic University of Korea-Seoul St. Mary Hospital, Seoul, Republic of Korea; [5]Obstetrics and Gynecology, The Catholic University of Korea-College of Medicine, Seoul, Republic of Korea; [6]The Catholic University of Korea-College of Medicine, Seoul, Republic of Korea

Background: This study was to evaluate the clinical significance of pulmonary recurrence for patients who achieved complete remission after primary treatment of endometrioid endometrial cancer.

Methods: This multicenter retrospective study included patients who had undergone primary treatment for endometrial cancer at six different hospitals between 2009 and 2019. Inclusion criteria were patients with endometrioid histology and no evidence of residual disease after primary treatment including standard surgical procedure. Patients who developed pulmonary metastasis during follow-up were identified. Time to second objective disease progression (PFS2) was defined as time from the start of second-line therapy to second recurrence, and second-line overall survival (OS2) was defined as time from the start of second-line therapy to death.

Results: Of the 1074 patients who met the inclusion criteria, 90 experienced recurrences. Pulmonary recurrence was the most frequent site of first recurrence, accounting for 34.4% (31/90) of all recurrences. Isolated pulmonary recurrence accounted for 64.5% (20/31) of all pulmonary recurrences, whereas 35.5% (11/31) of patients had concurrent recurrences at other sites. The median PFS2 and OS2 of patients with isolated pulmonary recurrence were significantly longer than those with concurrent recurrences at other sites (PFS2, 17.0 vs. 9.0 months, log-rank $P = 0.004$; OS2, not reached vs. 28.0 months, log-rank $P = 0.001$). During the median follow-up period of 88.0 months, 73.7% of patients with isolated pulmonary recurrence had recurrence or progression after second-line treatment, but only 15.8% of the patients died. On the other hand, during the median follow-up period of 33.0 months, 88.9% of patients with concurrent recurrence at other sites had recurrence or progression after second-line treatment and 66.7% died. Multivariable analysis identified isolated pulmonary recurrence as an independent factor for longer OS2 (HR, 0.18; 95% CI, 0.03-0.59; $P = 0.009$).

Conclusions: Our study showed that isolated pulmonary recurrence is associated with prolonged OS2 in patients with recurrent endometrioid endometrial cancer.

Background: Incidence of metastatic endometrial carcinoma (EC) is increasing worldwide. Recent therapeutic innovations reinforce the need to better understand patients (pts) characteristics, treatment patterns and clinical outcome in the real-world setting.

Methods: Patients beginning 1st or 2nd line chemotherapy (chemo) during the year 2019 were included in this multicenter, retrospective cohort study and were followed until December 31, 2021 or death. Up to 9 pts were included in each of the 30 centers across France. Two hundred pts, 127 in 1st line (cohort 1) and 73 in 2nd line (cohort 2), were enrolled. Median age was 71 years (min: 39 max: 93) and 31 % were > 75 years old. Significant comorbidities included overweight (BMI > 25 kg/m^2) in 49 % of pts, medically treated hypertension, diabetes mellitus and deep venous thrombosis in 28.5%, 14.5% and 11%, respectively. ECOG performance status was 2 or 3 in 12% of pts. Endometrioïd carcinoma was the most common histological subtype (62%), followed by serous carcinoma (22%) and carcinosarcoma (5%). One third of pts had a FIGO IVB disease. MMR status was available only in 34% of pts and 21% of them was deficient.

Results: In 1st line, most pts received carboplatin and paclitaxel association (79%) or other platinum-based combinations (17%). Median PFS and OS were 8.5 months (mos) (CI 95%: 6.3-10.5) and 13.2 mos (CI95%: 10.9-16.6), respectively. The presence of liver metastases was the main prognostic factor for PFS and OS. In 2nd line, data from pts in cohorts 1 (49% received 2nd line chemo during the follow-up period) and 2 were pooled (n=135). Anthracycline and weekly paclitaxel as a single agent were used in 52% and 10%, respectively while platinum-based protocol was used in 23% of patients. Median PFS and OS were 4.0 mos (CI95%: 3.5-5.3) and 9.6 mos (CI95%: 8.3-11.8), respectively. A 3rd line of chemo was administered to 78 pts (39%): 31% received gemcitabine and 17% a platinum-based combination. Median PFS was 2.6 mos (CI95%: 2.1-4.1).

Conclusions: In this real-life cohort, metastatic EC affected older and frail women and was associated with poor overall survival despite chemo. There is an urgent need of new therapeutics.

816P Laparoscopic versus open-surgery in FIGO stage II endometrioid endometrium cancers: Is there a prognostic effect?

A.G. Zeimet[1], T.P. Bargujar[1], K. Leitner[1], K. Steger[1], T. Bartl[2], C. Marth[1], D. Reimer[1]

[1]Department of Obstetrics and Gynecology, Innsbruck Medical University, Innsbruck, Austria; [2]Department of Obstetrics and Gynecology, Universitätskliniken der MedUni Wien-AKH Wien, Vienna, Austria

Background: Based on two randomized trials (LACE and LAP2) minimal invasive surgery has turned into surgical standard in early stage endometrial cancer (EC) including "high-risk" patients. These recommendations are predominately based on "low-risk" cancers, which were mainly represented in both trial collectives. We herein provide a retrospective study focusing on potential differences in clinical outcome in early stage endometrioid ECs treated by laparoscopy or open surgery.

Methods: 420 early stage ECs were retrospectively dichotomized according to the surgical approach and correlated to recurrence rate and clinical outcome. In addition, subgroup analyses were performed according relevant clinical risk parameters, namely FIGO stage, grading and LVSI.

Results: The analyzed collective consisted of 73.8% stage IA, 19.5% stage IB, and 6.7% stage II cases. 23% of patients exhibit G3 tumors and LVSI was detected in 12.4%. Minimal invasive surgery was performed in 54.5% of study patients. During a median follow-up of 5.0 years, recurrence or death were observed in 8.3% and 6.7%, respectively. Recurrences were located in the vaginal cuff (60.0%), in locoregional lymph nodes (31.4%), and in 8.6% in both sides. No distant metastases were observed. Under consideration of the mentioned clinicopathologic parameters, surgical approach in FIGO stage I did not influence recurrence rate and survival. However, in stage II disease, a laparoscopic approach was clearly associated with a higher recurrence rate (85.7% vs. 14.3%; $p = 0.013$). All recurrences were located in the vaginal cuff, and in one case, additional relapse was found in loco-regional lymph nodes. Moreover, laparoscopy in stage II disease was associated with impaired progression-free and overall survival (HR 8.86 (1.01 – 20.85) and HR 6.36 (1.10 – 28.61)).

Conclusions: We herein demonstrate that a laparoscopic approach in stage II endometrial cancer is associated with higher recurrence rates and impaired clinical outcome. These data could be interpreted in line with results of the LACC trial in cervical cancer. Although, grounded on a retrospective analysis, these hypothesis-generating results warrants a confirmatory trial, which is ongoing.

817P A systematic review of recruitment of ethnic minorities to RCTs of systemic anti-cancer therapies in gynaecological cancers

L. Steventon[1], K. Man[2], P. Chambers[1], S. Nicum[3], L. Wei[2]

[1]Cancer Services, UCLH-University College London Hospitals NHS Foundation Trust, London, UK; [2]Research Department of Practice and Policy, UCL-University College London, London, UK; [3]Medical Oncology, UCL-University College London, London, UK

Background: Emerging evidence suggests pharmacogenomic differences between ethnic groups contributes to disparate treatment effects in cancer patients treated with systemic anti-cancer therapies (SACT). It is important to understand the representation of ethnic minority groups in research, and how this relates to patient outcomes. This systematic review compared participation of ethnic minority groups in contemporary gynae-oncology RCTs of SACT, and described the global distribution of research sites.

Methods: Medline, Embase and ClinicalTrials.gov databases were systematically searched. Phase II & III RCTs of SACT for ovarian, cervical, endometrial, vaginal and vulvar cancers of any stage, published 01/11/2012-01/11/2022 and reporting ethnicity were included. SACT licensed at time of search were eligible. Studies of non-systemic agents, vaccines, radiotherapy or surgery alone were excluded. Outcomes were recruitment by ethnicity and location of research sites. Recruitment by ethnicity was extracted, participation calculated for each group and compared by indication, trial phase and publication period, as well as to incidence in real-world populations. PRISMA guidance was used to report results.

Results: 26 RCTs met inclusion criteria. 17,041 patients participated; 79.8% (13,595) were "Caucasian", 9,1% (1552) "Asian", 3.7% (630) "Black/African American", and 6.1% (1,031) "Other/Unknown". The remaining 1.3% (233) comprised other groups. "Caucasian" patients were over-represented in RCTs for each disease indication, and recruited at a higher rate to phase II than phase III RCTs. "Black/African American" patients recruited at a lower rate to phase III than phase II RCTs.Of 26 studies, 20 were conducted in multiple countries, 5 only in the US, and 1 only in Italy. Of 5478 sites, 4,390 (80.1%) were located in North America or Europe, 187 (3.4%) in East Asia, and 901 (16.5%) in other regions. Notably, no sites were located in Africa or South Asia.

Conclusions: Ethnic minorities are under-represented in contemporary gynae-oncology RCTs. Efforts must be made to include ethnic minority patients to ensure findings are generalisable to real-world populations.

Background: Folate receptor alpha (FolRα) is a validated target in the treatment of platinum resistant ovarian cancer (PROC) with high FolRα expression. There continues to be a high unmet need to treat PROC with low to moderate expression levels of FolRα. Luveltamab tazevibulin (luvelta) is a novel FolRα targeting ADC, with a stable cleavable linker and a 3-aminophenyl hemiasterlin warhead (DAR4) that induces cytotoxic and immunogenic cell death. Luvelta is generated using cell free antibody production and site-specific conjugation technology and is designed to target a broad range of FolRα expressing cancers. Luvelta demonstrated preliminary efficacy data (ORR of 37.5%; mDOR of 5.5 months; mPFS of 6.1 months) in 32 patients with advanced relapsed EOC who had FolRα expression of >25% of any intensity in a

phase 1 study STRO-002-GM1 (NCT03748186). Sub-analysis demonstrated a higher ORR at 5.2 mg/kg (43.8% versus 31.3%, n=32) compared to 4.3 mg/kg. The safety profile was shown to be manageable, with the most common grade 3 and higher adverse events consisting of neutropenia, arthralgia, and anemia. This data forms the basis for a pivotal study of luvelta in patients with PROC whose tumors express a broad level of FolRα expression.

Trial design: REFRaME-O1 is a multicenter, international, open-label, 2-part seamless phase 2/3 study of luvelta in subjects with relapsed PROC expressing FolRα. Part 1 consists of a dose-optimization stage and will randomize ∼50 subjects 1:1 to the treatment of luvelta at 4.3 mg/kg Q3W or luvelta 5.2 mg/kg Q3W + prophylactic pegfilgrastim for 2 cycles followed by 4.3 mg/kg Q3W. Part 2 will commence with the selected optimized dose and will include a control arm consisting of investigator's choice chemotherapy, with a 2:1 randomization schedule. Key inclusion criteria are progressive PROC, up to 3 prior regimens, TPS of ≥25% for FolRα expression, and measurable disease. Key exclusion criteria are primary platinum refractory disease and prior treatment with a FolRα ADC or ADC containing a tubulin inhibitor.

Background: Folate receptor α (FRα), a cell-surface protein encoded by the folate receptor 1 gene, is upregulated in epithelial ovarian cancers and lung adenocarcinomas. AZD5335 is an antibody-drug conjugate comprising an antibody portion that binds with high affinity to FRα conjugated to a topoisomerase 1 inhibitor (TOP1i) payload. Upon binding, AZD5335 releases TOP1i within the cell. The TOP1i payload then traps TOP1 on the replicating DNA and induces DNA double-strand breaks, ultimately resulting in cell death. AZD5335 is active in preclinical models of high-grade ovarian cancer (Gymnopoulos et al. Presented at AACR 2023; abstract LB025).

Trial design: FONTANA (NCT05797168) is a modular, first-in-human, open-label, multicentre study of AZD5335 in patients with advanced solid tumours. The study will evaluate AZD5335 as monotherapy in patients with ovarian cancer or lung adenocarcinoma (Module 1), or AZD5335 in combination with AZD5305, a selective poly(-ADP-ribose) polymerase 1 inhibitor, in patients with ovarian cancer (Module 2). Each module consists of a dose-escalation and dose-optimisation cohort. Key features of this study include the use of randomised dose-optimisation cohorts and a Bayesian-logistic regression model-based dose escalation in Module 2. Eligible patients are aged ≥18 years, ECOG performance status 0−1, must have received prior therapy, and have adequate organ and marrow function. Asymptomatic and stable brain metastases are allowed. The primary objectives are to assess the safety and tolerability, and to establish the dose limiting toxicity. Secondary objectives include assessment of objective response rate, duration of response, disease control rate, and progression-free survival by RECIST v1.1, and overall survival; characterising the pharmacokinetics of AZD5335 when given as monotherapy or in combination; and assessing immunogenicity. The study will be open to recruitment by 25 May 2023.

Clinical trial identification: NCT05797168.

Background: Although recent two phase 3 randomized controlled trials showed survival benefit of secondary cytoreductive surgery (CRS) in first relapsed ovarian cancer, the patients who received PARP inhibitor (PARPi) as first-line maintenance were not included in these trials. In addition, the treatment consensus for recurrence after PARPi has not been established because subsequent platinum-based chemotherapy is not sensitive in relapsed patients after PARPi maintenance. Therefore, there is a significant need for optimal strategy including secondary CRS in patients

whose cancer progresses while using a PARPi. The aim of SOCCER-P is to find out whether secondary CRS is beneficial in patients who have progressed on PARPi maintenance.

Trial design: It is a multicenter, randomized phase II trial of secondary CRS in patients with relapsed ovarian cancer who have progressed on PARPi. This trial included patients with the first recurrence of platinum-sensitive ovarian cancer who had a progression-free interval of at least 6 months after the end of the last platinum-containing therapy and progressed on PARPi maintenance. Patients who are considered likely to be completely resected according to the international model (AGO or iMODEL) or based on a consensus between the surgeon and designated radiologist are eligible for this study. 124 subjects are randomly assigned to undergo secondary CRS and subsequent chemotherapy (carboplatin [AUC 5, day 1] plus pegylated liposomal doxorubicin [30 mg/m2, day 1] every 4 weeks) plus or minus bevacizumab (six cycles of bevacizumab [10 mg/kg, days 1 and 15] followed by maintenance bevacizumab [15 mg/kg every 3 weeks]), or to receive chemotherapy plus or minus bevacizumab alone. The primary endpoints were progression-free survival (PFS). And we also assess overall survival and PFS2 defined as the time from randomization to tumor progression on a next-line tretment or death. A one-sided log-rank test with an overall sample size of 124 subjects (62 in the control group and 62 in the treatment group) achieves 80.1% power at a 0.100 significance level to detect a hazard ratio of 0.6500 when the hazard rate of control group is 1.05.

Clinical trial identification: NCT05704621.

Background: Combined inhibition of ATR and PARP has been shown to overcome resistance to PARPis in PARPi-resistant cell lines and pt-derived xenograft (PDX) models. Cerala, a selective and potent ATR inhibitor, in combination with olaparib, has demonstrated activity in pts with homologous recombination deficiency-positive, PARPi-resistant OC (CAPRI; NCT03462342). However, in combination with olaparib, the dose and duration of cerala treatment is limited by haematological toxicity. Compared to approved PARPis which target both PARP1 and PARP2, AZD5305 is a highly selective and potent PARP1i which may improve upon the current safety profile of the olaparib and cerala combination. AZD5305 monotherapy was well tolerated in an ongoing phase 1 study of pts with *BRCA1/2-*, *PALB2-* or *RAD51C/D*-mutant advanced breast, prostate, pancreatic or OC (PETRA; NCT04644068); AZD5305 in combination with cerala demonstrated durable tumour regression in *BRCA1/2*-mutant, PARPi-resistant, breast and OC PDX models. Thus, combining cerala and AZD5305 may provide a better therapeutic index compared with olaparib and cerala.

Trial design: D5330C00004 (NCT02264678) is a modular, phase 1, open-label trial assessing cerala in combination with anti-cancer agents in pts with advanced solid malignancies. Module 5 investigates cerala in combination with AZD5305 in pts with recurrent platinum-sensitive, high-grade, epithelial ovarian, fallopian tube or primary peritoneal cancer (including serous or endometrioid histology), in dose escalation (Part A) and expansion (Part B) cohorts. Key inclusion criteria are age $\geq$18 years and prior PARPi treatment. Pts in Part B must have a known or suspected *BRCA*, *RAD51C/D* or *PALB2* mutation. Primary objectives are safety and tolerability of cerala in combination with AZD5305 including the number of adverse events (AEs) and serious AEs, in order to select a recommended phase 2 dose (Part A). Secondary objectives include assessment of antitumour activity, pharmacokinetics and pharmacodynamic biomarkers. Recruitment started in April 2023 and sites across North America, Europe and Asia Pacific will enrol up to 150 pts in total.

Clinical trial identification: NCT02264678; 15 October 2014.

Background: ICT01, an anti-BTN3A targeted mAb that selectively activates γ9δ2 T cells, is being studied in the ongoing phase 1/2a EVICTION Trial in advanced solid and hematologic cancers (NCT04243499). ICT01-activated γ9δ2 T cells are known to kill acute myeloid leukemia blasts and lymphoma cell lines both *in vitro* and *in vivo*, making γ9δ2 T cells of interest as a novel immunotherapeutic strategy against hematologic cancers. Here we present data from the EVICTION phase 1 in relapsed/refractory hematological cancers.

Methods: Patients with hematologic cancers who failed available standard of care received IV ICT01 alone (200 µg to 75 mg) every 21 days. Antitumor assessment by imaging or bone marrow analysis was done every 8 weeks after using the Response Evaluation Criteria in Lymphoma (RECIL) and IWG Criteria for AML. Safety reviews were conducted prior to dose escalation. Disease Control Rate (DCR) was the primary efficacy endpoint and defined as the sum of complete response (CR), CR with incomplete recovery (CRi), partial response (PR) and stable disease (SD). Blood samples were collected for pharmacokinetic and pharmacodynamic analyses.

Results: Dose escalation was completed with 26 patients (1 Diffuse Large B-cell Lymphoma, 1 Follicular Lymphoma, 24 AML), with no dose-limiting toxicities and a good safety profile similar to that in solid tumors. First-dose infusion-related reaction, nausea, fever and vomiting (Grade 1/2) were the most common treatment-related AEs. Only 2 Grade 3 events of neutropenia were reported and resolved with continued treatment. Target occupancy on circulating T cells $\geq$ 30% was observed 30 min post doses $\geq$ 700 µg, with activation and migration of >95% γ9δ2 T cells from the blood within 24hrs of dosing. Ten of 26 patients were evaluable at week 8 with an observed DCR of 30%. One DLBCL patient still receiving ICT01 at 7 mg has had a PR from Wk 40 to Wk 94/C32. In the 20 mg dose group, two AML patients achieved stable disease at week 8 with one still on study at Wk 53/C19.

Conclusions: The good safety profile and encouraging clinical activity data in these last-line patients support further testing of ICT01 in a first-line AML phase 2a expansion cohort in combination with VEN/AZA in EVICTION that will start mid-2023.

Clinical trial identification: EudraCT 2019-003847-31; NCT04243499.

Background: SAR'579, a trifunctional anti-CD123 NKp46×CD16 NKCE, enabling a cytolytic synapse between natural killer (NK) cells and CD123+ tumor cells leading to NK cell activation and tumor cell killing. We report preliminary PK/PD of SAR'579 from a phase 1/2 trial in pts with R/R AML, B-ALL or HR-MDS (EudraCT 2021-004287-98 Apr 26, 2023/NCT05086315).

Methods: SAR'579 was administered IV twice weekly or once weekly (QW) per dose level (DL) in first 2 weeks of cycle 1 and QW for rest of induction cycles. Peripheral blood (to measure plasma concentrations and immunogenicity assessment) and bone marrow samples were collected for PK/PD analysis during each induction cycle. Analysis of cytokines, as potential safety and PD markers, including IL-6, TNFα and IFNγ, was performed using Meso Scale Discovery®.

Results: From Dec 14, 2021, to Oct 17, 2022, 19 pts were treated across 5 DLs (3 in DL1 and 4 each in DL2 to DL5) between 10-3000 µg/kg/dose. No dose limiting toxicities were observed. At 1000 µg/kg QW, 3/8 pts achieved complete remission (CR) (2 CR/1 incomplete hematologic recovery). Early immunogenicity was 26% with no impact on safety/efficacy. Post first administration of SAR'579, circulating maximum (max) concentration increased with dose increase with a supra-dose proportionality between DL1 and DL5. PK linearity was achieved at 3000 µg/kg QW (DL5) at the end of cycle 1.

Table: 823O Median (max) peak cytokine concentrations (pg/mL) observed during DL1-5

	DL1	DL2	DL3	DL4	DL5
IL-6	63.6 (1355.4)	118.3 (264.3)	62.7 (450.1)	29.7 (126.7)	52.3 (445.3)
TNFα	12.6 (14.7)	19.2 (88.0)	9.7 (12.1)	7.2 (11.9)	17.9 (27.4)
IFNγ	21.4 (50.7)	88.7 (233.4)	81.8 (152.8)	123.8 (420.4)	58.1 (256.6)

Cytokine release syndrome levels of IL-6 (>500/1000 pg/mL) were measured in a single DL1 pt.

Conclusions: SAR'579 was well tolerated till 3000 µg/kg QW with clinical benefit in pts with R/R AML. Observed peak cytokine levels did not show significant dose-related increase and no association between elevated peak cytokine levels and clinical

responses. The results are consistent with the improved safety profile compared to CD123-targeted T-cell engagers.

824O Treatment and survival in patients with localized primary ocular adnexal MALT lymphoma: A large bicentric cohort study

L-R. Gao[1], X. Li[2], X. Wang[1], Y. Wu[1], L. Wang[2], S. Qi[1], Y. Li[1]

[1]Department of Radiation Oncology, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China; [2]Department of Hematology, Beijing TongRen Hospital, Capital Medical University, Beijing, China

Background: Despite the generally favorable prognosis of POAML, There is limited understanding of the extent to which primary ocular adnexal mucosa-associated lymphoid tissue lymphoma (POAML) impacts a patient's risk of death and how different treatment managements affect prognosis and toxicities in this specific MALT site.

Methods: This study analyzed major long-term outcomes of patients with POAML lymphoma and the prognostic significance of baseline clinical features. We reviewed the clinical features, treatments, disease course and long-term outcome of 262 patients with Ann-Arbor stage IE POAML diagnosed between 2000 to 2012. Outcomes were analyzed using crude overall survival (OS) and relative survival (RS) by standardized mortality ratio (SMR). A cross-sectional study was conducted using OSDI questionnaires to evaluate the long-term ocular adverse effects.

Results: The median age was 55 years. With a median follow-up of 66 month, the 5-year OS, lymphoma-specific mortality and competing non-lymphoma mortality were 96.8%, 0.4% and 2.3%, respectively, and the estimated 10-year corresponding rates were 90.0%, 0.4% and 4.2%; the overall SMR was 1.02 (95% confidence interval [CI]: 0.60-1.61, P = 0.963). The OS and RS rates were similar across the treatment groups; however, RT associated with significantly decreased risks of failure (11.0%, n = 82, p = 0.006), compared to observation (33.3%, n = 81), surgery (28.6%, n = 70), and CT/IT groups (24.1%, n = 29). The cross-sectional study indicated that RT wasn't obviously increased the intermediate-severe grades of dry eye diseases for a relative long-time after treatment.

Conclusions: Overall, a diagnosis of stage IE POAML lymphoma had similar long-term survival to the general population. RT associated with lower failure rates and minor ocular adverse effects.

825O Genomic traits of therapeutic response to anti-PD-1 therapy in peripheral T cell lymphoma

N. Lou[1], M. Yang[2], X. Han[3]

[1]Clinical Laboratory, Chinese Academy of Medical Sciences and Peking Union Medical College-National Cancer Center, Cancer Hospital, Beijing, China; [2]Department of Medical Oncology, Chinese Academy of Medical Sciences and Peking Union Medical College-National Cancer Center, Cancer Hospital, Beijing, China; [3]Clinical Pharmacology Research Center, CAMS-PUMC-Chinese Academy of Medical Sciences and Peking Union Medical College-Dongdan Campus, Dongcheng-qu, China

Background: The use of immune checkpoint inhibitors has revolutionized the treatment of solid tumors and hematologic malignancies, clinical evidence has demonstrated anti-PD-1 therapy to be effective tools in PTCL. However, factors that may influence primary sensitivity or resistance to anti-PD-1 therapy in PTCL, such as TMB and genomic alterations, have not yet been clarified.

Methods: We enrolled 89 peripheral T cell lymphoma (PTCL) patients in phase II clinical trial of geptanolimab and performed targeted next-generation sequencing for 440 cancer-associated genes. Clinical data were collected and correlated with genetic mutations. In vitro, studies were conducted to evaluate the effect of *JAK3* mutations on PD-L1 expression.

Results: PD-L1 expression was significantly elevated in complete response (CR)/partial response (PR) patients compared to progressive disease (PD) patients, while tumor mutation burden (TMB) didn't exhibit significant prognostic value which may be confounded by the variation across PTCL subtypes. The most frequent mutations occurred in *TP53*, *KMT2C*, *KMT2D*, *JA3*, *LRP1B,* and *SETD2*. Shorter time to death was related to mutations in *SETD2* (HR=5.73, P=0.0135) or *KME2D* (HR=3.17, P=0.0533). Shorter PFS was correlated with *JAK3* mutations (HR=5.97, P=0.0144). The subset PTCL patients (86.4%) with enrichment of non-APOBEC-related mutation signature had higher TMB level (P=0.076) and superior PFS (P=0.031) to non-APOBEC-enriched samples. In vitro experiments revealed *JAK3* A573V, M511I, and E958K mutations led to lower PD-L1 expression through downregulated of the expression of PI3K and MAPK.

Conclusions: In this study we comprehensively depicted the pre-treatment mutation profiles of PTCL and identified genetic alterations with prognostic value for anti-PD-1 therapy. Notably, we found *JAK3* mutations which are vital and prevalent in PTCL reduced PD-L1 levels in vivo and in vitro, which are of great clinical and biological sense.

826O A single-arm, multicenter clinical study of radiotherapy combined with toripalimab in stage I/II extranodal NK/T cell lymphoma

M. Jiang, L. Liang

Department of Medical Oncology, Cancer Center, West China School of Medicine/West China Hospital of Sichuan University, Chengdu, China

Background: The current standard of care for extranodal NK/T cell lymphoma (ENKTL) is L-asparaginase or pegaspargase-based multiagent chemotherapy combined with radiotherapy. However, overall survival was significantly lower in those patients with inadequate response to L-asparaginase-based multiagent chemotherapy.

Methods: In this prospective, single-arm, multicenter, phase II clinical study, patients with stage I/II ENKTL who did not achieve CR after 2-3 cycles of multiagent chemotherapy containing L-asparaginase or pegaspargase were enrolled. Patients received toripalimab (240 mg, d1, Q3w) plus radiotherapy (95% PTV 56 Gy/28f, d1-d5/w), sequentially with or without 2 to 4 cycles chemotherapy. Then patients received toripalimab for 1 year or until disease progression or intolerable toxicity. The primary endpoint was CR rate.

Results: From February 2019 to present, 22 patients were enrolled who have received the response assessment at least once after radiotherapy. All were originated from the upper aerodigestive tract with a median age of 45 years (range 26-64). 14 were male. 17 (77.3%) and 5 (22.7%) patients were Lugano stage I and II, respectively; 81% were primary tumor invasion (PTI). 8/22 patients (36.4%) had PR, 8/22 had (36.4%) SD, 6/22 (27.2) had PD after previous 2-3 cycles chemotherapy. All patients completed the radiotherapy. The ORR was 90.9%, including 17 CR (77.3%), 3 PR (13.6%), 2 PD (9.1%). 8 patients who responded to previous chemotherapy continued 2 cycles of chemotherapy after completion of radiotherapy. Others received toripalimab alone (median dose: 11; range 3-17). Up to date, the median follow-up time was 23 months (range 3-78), the 2-year PFS rate was 81.6%, and all patients survived. The main adverse events during and after radiotherapy were oral mucositis and hypothyroidism. No grade 3 or higher toxicity occurred.

Conclusions: Toripalimab combined with radiotherapy is safe and have promising efficacy for stage I/II ENKTL who have poor response after previous standard chemotherapy.

Clinical trial identification: ChiCTR2100045147.

827P Mutational spectra of the Korean patients with germline predisposition in hematologic malignancies: Five years of experience at a tertiary university hospital

I-S. Kim

Labortory Medicine, Pusan National University Yangsan Hospital, Yangsan, Republic of Korea

Background: An expanding number of genes predisposing to hematologic malignancies are being discovered by next-generation sequencing (NGS) technology. The 5th edition of the World Health Organization and International Consensus Classification revised their classification of hematologic neoplasms with germline predisposition acknowledging this development. We aimed to identify the mutational spectrum of germline predisposition in hematologic malignancies from Korean patients.

Methods: The study included 444 patients tested for hematologic malignancy panel testing at Pusan National University Yangsan Hospital from January 2019 to December 2022. The assay consisted of 200 genes related to hematologic malignancies and was performed with NGS on genomic DNA extracted from bone marrow specimens or peripheral blood. We identified potential germline variants by retrospective analysis of NGS results. Variant allele frequency $>$ 0.3 of pathogenic or likely pathogenic variants in a known germline predisposition gene was considered potential germline variants. We could not confirm each variant's germline status due to the absence of cultured skin fibroblast specimens.

Results: Thirty-seven (8.33%) patients harbored 38 potential germline variants. *DDX41* (21.62%, 8 patients), *RUNX1* (10.81%, 4 patients), *GATA2* (10.81%, 4 patients), and *PAX5* (10.81%, 4 patients) were the most common genes. One patient had 2 variants in the *SBDS* gene, a compound heterozygote. Frameshift (18 variants, 47.37%) and missense (10 variants, 26.32%) were the main proportion of the 38 potential germline variants.

Conclusions: We found that *DDX41*, *RUNX1*, *GATA2*, and *PAX5* are the most common genes in potential germline variants in hematologic malignancies in Korea. This study provides insight into the pathophysiology of germline predisposition in hematologic malignancies.

828P Clinical features and outcomes of neurologic paraneoplastic syndromes in Hodgkin lymphoma

B.J. McCormick[1], A.S. Lopez Chiriboga[2], H. Tun[3], M. Alhaj Moustafa[3]

[1]Internal Medicine, Mayo Clinic-Florida, Jacksonville, FL, USA; [2]Neurology, Mayo Clinic-Florida, Jacksonville, FL, USA; [3]Hematology/Oncology, Mayo Clinic-Florida, Jacksonville, FL, USA

Background: Neurologic paraneoplastic syndromes (NPS) due to Hodgkin lymphoma (HL) affect both the central nervous system (CNS) and peripheral nervous system (PNS) with wide-ranging manifestations, such as limbic encephalitis, cerebellar degeneration, and neuropathies. We summarize the clinical findings and outcomes of 23 patients with HL associated with NPS.

Methods: Medical charts of adult patients at Mayo Clinic were retrospectively analyzed based on common endpoints and clinical features. Clinical diagnosis of NPS was made utilizing established criteria by Graus et al (*Neurol Neuroimmunol Neuroinflamm*, 2021). Survival analysis was performed using Kaplan-Meier estimates.

Results: We analyzed 23 patients with HL with NPS seen at Mayo Clinic from 1995 to 2022. Baseline disease included 17 patients with classical HL and 6 patients with nodular lymphocyte-predominant HL. Median follow-up was 97.1 months (95% CI 66.3-150.3). Baseline demographics included mean age 40 years with 61% males and 87% Caucasian patients. CNS PS was seen in 17 patients. Death had occurred in 5 patients at the time of review, including 4 without PS resolution, although no patients died from PS. NPS was the presenting sign of HL relapse in 39% patients. Following HL treatment, PS relapse was observed in 2 of 5 patients with prior complete PS resolution, temporally linked to HL relapse. Median overall survival (mOS) in patients with no PS improvement was 38.4 months, whereas mOS could not be reached in patients with complete/partial PS resolution (p=0.043). All 6 patients without PS improvement had CNS syndromes, whereas 3 of 5 patients with complete PS resolution had PNS disease. Paraneoplastic antibodies (anti-Tr most common) were detected in 7 of 21 tested patients without mortality or relapse associations. All 5 patients who experienced complete resolution of PS exhibited HL remission.

Conclusions: In our series of 23 patients with HL and NPS, survival was significant higher in patients with complete PS resolution. Despite HL treatment, NPS may be irreversible due to cytoxic neuronal loss; thus, timely recognition of PS is essential in providing effective therapy, requiring oncologic treatment as shown in our series of patients who only achieved complete resolution of NPS with HL remission.

829P Age and sex related genomic profiles of follicular lymphoma

R. Imperial[1], E. Kimbrough[1], M. Alhaj Moustafa[1], A. Novak[2], M. Albitar[3], H. Tun[1]

[1]Hematology and Oncology, Mayo Clinic-Florida, Jacksonville, FL, USA; [2]Division of Hematology, Department of Internal Medicine, Mayo Clinic-Rochester, Rochester, MN, USA; [3]Hematology and Oncology, Genomic Testing Cooperative, Irvine, CA, USA

Background: Follicular lymphoma (FL) is the second most common B-cell non-Hodgkin lymphoma that is defined by unique somatic mutation and gene expression profile. Differences in the genomic profile of FL by age and by sex have not been well characterized.

Methods: We analyzed data from 155 patients with FL who underwent next generation sequencing and RNA expression analysis using the Genomic Testing Cooperative Hematology Plus platform. The DNA and RNA panels assessed 179 genes and 1408 genes, respectively. Our analysis was based on sex (male n=75, female n=80) and age ($<$50 years, n=20; 50-74 years, n=109; $>$75 years, n=26). Data and statistics were analyzed with Bioconductor R package Maftools and Broad Institute Gene Set Enrichment Analysis.

Results: At least one somatic mutation in epigenetic genes: *KMT2D* (n=106), *CREBBP* (n=98), *EZH2* (n=41) and *EP300* (n=27) were present in 95% of all patients (n=155). Mutations in *B2M* were significantly enriched in females (10% vs 1.3%, p=0.035), while mutations in *MEF2B* were significantly enriched in males (24% vs 10%, p=0.030). Mutations in *EP300* were enriched in the young cohort ($<$50; 35% vs 14%, p=0.047). Mutations in genes: *BCR* (Breakpoint Chain Region; 23% vs 3.9%, p=0.0033), *CREBBP* (81% vs 60%, p=0.047), *STAT6* (23% vs 8.5%, p=0.042) and *TET2* (19% vs 6.2%, p=0.045) were enriched in the elderly cohort ($>$75). All *BCR* mutations (missense and truncations), occurred within the N-terminus kinase domain of the gene. These mutations have not been well characterized in FL and are predicted to be deleterious; involving a coiled-coil domain essential for oligomerization and gene function. These mutations may compromise its function as a regulator of RAC1 and RHOA proteins. Correlation with limited available clinical data also suggests that these mutations are seen with aggressive FL or FL undergoing transformation. RNA expression did not show any significant differences based on age or sex.

Conclusions: Our study suggests that there are age and gender specific genomic alterations in FL. We plan to follow up with validation studies in a larger cohort.

830P Isolation of cell-free DNA of patients with mucosa-associated lymphoid tissue (MALT) lymphoma

J.M. Berger[1], A. Kienzle[1], T. Hatziioannou[1], E. Tomasich[1], M. Mayerhoefer[2], B. Kiesewetter-Wiederkehr[1], A.S. Berghoff[1], M. Preusser[1], M. Raderer[1]

[1]Division of Oncology, Department of Medicine I, Medical University of Vienna, Vienna, Austria; [2]Radiology, Memorial Sloan Kettering Cancer Center, New York, NY, USA

Background: To evaluate treatment efficacy for gastric extranodal marginal zone B-cell lymphoma of mucosa-associated lymphoid tissue (MALT-lymphoma), histologic assessment via multiple gastric biopsies every 3 months constitutes the current gold standard. Currently, non-invasive diagnostic measures including PET-MRI to monitor therapy response in MALT lymphoma patients remain experimental for the time-being. While liquid biopsies isolating cell-free DNA (cfDNA) are used in other tumor entities for diagnostic and treatment monitoring measures, no data for gastric MALT-lymphoma have been published so far. Thus, we performed a pilot series to assess cfDNA in therapy-naïve gastric MALT-lymphoma patients.

Methods: For the isolation of cfDNA, blood from patients with MALT lymphoma was collected using PAXgene Blood ccfDNA tubes (Qiagen). cfDNA was isolated using the QIAamp Circulating Nucleic Acid Kit (Qiagen). DNA concentration was measured using fluorescence quantification (Qubit, Thermo Fisher). Quantitative data were compared to 68-Ga-Pentixafor-PET/MRI performed within 4 weeks assessing active lymphoma volumes. Clinical parameters were obtained by chart review.

Results: A total of 15 patients (4 males, 11 females) with MALT lymphoma at a median age of 64 years (range: 44-79) were included in this study. cfDNA could be isolated in all patients with a median concentration of 5.4ng/ml plasma (range: 3.6-12.4ng/ml). Compared to a healthy control cohort (n=5), cfDNA levels were significantly increased in MALT lymphoma patients (3.8ng/ml vs. 5.9ng/ml, $p=0.025$). In 12/15 patients, a follow-up blood draw could be obtained after a median 3.3 months (range 0.9-7.0 months). cfDNA levels remained stable during that time period with a mean concentration of 5.7ng/ml at baseline and 6.3ng/ml at follow-up ($p>0.05$). Correlation between metabolically active tumor volume and cfDNA concentration will be reported as soon as radiologic reclassification is completed.

Conclusions: cfDNA may be used as a non-invasive biomarker for disease monitoring in patients with MALT lymphoma.

831P Decitabine sensitized TP53-mutated diffuse large B cell lymphoma to R-CHOP treatment via activation of endogenous retrovirus

L. Wang, Y. Fang, M-C. Zhang, W. Zhao

Hematology, Shanghai Institute of Hematology, Shanghai, China

Background: *TP53* mutations (*TP53*^{mut}) occur in 10-20% of diffuse large B-cell lymphoma (DLBCL) and is an unfavorable biomarker of DLBCL progression, conferring resistance to immunochemotherapy, high-dose chemotherapy, autologous stem cell transplantation, and anti-CD19 chimeric antigen receptor T-cell therapy. How to target *TP53*^{mut} remains a great challenge in treating DLBCL.

Methods: Survival of 667 newly diagnosed DLBCL patients were assessed, including 576 patients with R-CHOP and 91 patients with decitabine plus R-CHOP (DR-CHOP, NCT02951728 and NCT04025593). RNA sequencing data from *TP53*^{mut} and *TP53*^{wt} DLBCL tumors were analyzed. To further elucidate the underlying mechanisms of decitabine sensitizing *TP53*^{mut} DLBCL to R-CHOP treatment, *TP53*^{mut} DLBCL cell lines (*TP53*^{mut} p.R248Q, p.R273C and p.R175H) and patient-derived xenograft models (PDX, p.R248Q, p.R273C and p.R175H) were established and treated with decitabine, or doxorubicin ± decitabine.

Results: *TP53*^{mut} independently predicted inferior prognosis in R-CHOP-treated DLBCL, which could be counteracted by DR-CHOP treatment. In *TP53*^{mut} patients, multiple viral regulation pathways were repressed, accompanied by inhibition of immune modulation. *TP53*^{mut} DLBCL possessed increased methyltransferase *SUV39H1* expression and H3K9 trimethylation (H3K9me3), contributing to repression of endogenous retroviruses (ERVs) and immunosuppressive tumor microenvironment. In *TP53*^{mut} DLBCL cell lines, decitabine downregulated *SUV39H1*, inhibited H3K9me3 occupancy on ERVs, triggered ERV expression, thereby unleashed interferons program, and CD4^{+}T/CD8^{+}T cell activation. In *TP53*^{mut} PDX models and *TP53*^{mut} patients, improved anti-tumor effect was observed upon combined treatment of decitabine and doxorubicin via SUV39H1-H3K9me3-ERVs axis.

Conclusions: The present study demonstrated decitabine induced a viral mimicry pathway with peripheral blood CD4^{+}T/CD8^{+}T cell activation in *TP53*^{mut} DLBCL and sensitized *TP53*^{mut} DLBCL to R-CHOP treatment. Our findings highlighted an ERV regulatory circuitry in *TP53*^{mut} DLBCL and assigned essential roles of ERVs for epigenetic reprogramming tumor microenvironment in *TP53*^{mut}-driven cancers.

Clinical trial identification: NCT02951728, NCT04025593.

832P Characterisation of EXS73565: A potent and selective MALT1 inhibitor with low drug-drug interaction risk and potential in lymphoma

M. Gooyit[1], A. Payne[2], C. Carvalheda[3], D. Evans[3], C. Radoux[3], S. Richards[3], J. Besnard[3], S. Varzandeh[4], A. Gavard[4], S. Robinson[4], F. Breitgoff[4], A. Cooke[5], A. Bradley[3], M. Dominguez[6], P. Ray[7]

[1]Early Development, Exscientia, Boston, MA, USA; [2]Project Biology, Exscientia Ltd., Oxford, UK; [3]Computational Deisgn, Exscientia Ltd., Oxford, UK; [4]Biology, Exscientia Ltd., Oxford, UK; [5]Medicinal Chemistry, Exscientia, Boston, MA, USA; [6]Early Development, Exscientia Ltd., Oxford, UK; [7]Medicinal Chemistry, Exscientia Ltd., Oxford, UK

Background: MALT1 plays a key role in antigen receptor signalling and preclinical data indicate that MALT1 protease inhibition may have benefit in tumours with dysregulated NF-κB signalling, including activated B-cell-diffuse large B-cell lymphoma (ABC-DLBCL). MALT1 inhibitors are in clinical development as monotherapies and in combination with other agnets for the treatment of oncology and haematology indications, including lymphoma.

Methods: EXS73565 ('565) was designed using generative design, machine learning and molecular dynamics approaches. The compound was characterised in MALT1 protease assays and DLBCL functional studies. *In vivo* efficacy of '565 was assessed in mouse xenograft models, alone and in combination with the BTK inhibitor ibrutinib. Profiling of '565 was undertaken in a range of selectivity and preclinical studies.

Results: '565 is a potent and selective allosteric inhibitor of the MALT1 protease and inhibits the production of IL-10 and proliferation of DLBCL cells. In ABC-DLBCL xenograft studies, '565 demonstrated significant tumour growth inhibition. Tumour target engagement was demonstrated through measurement of the MALT1 protease target, RelB, and effects on NF-κB target genes. In an ABC-DLBCL xenograft model with low sensitivity to single-agent MALT1 and BTK inhibition *in vivo*, combining '565 and ibrutinib provided significant synergistic efficacy. Evaluation of '565 showed limited activity against CYP450 enzymes, hepatic and renal transporters. Notably, '565 avoids inhibition of UGT1A1 (an enzyme involved in metabolising bilirubin and certain small molecule drugs) in comparison to some clinical stage MALT1 inhibitors which carry a high UGT1A1 inhibition risk.

Conclusions: We describe the characterisation of EXS73565, an allosteric inhibitor of MALT1 which is currently in IND/CTA-enabling studies. Importantly, we show that '565 exhibits a low drug-drug interaction and hyperbilirubinemia risk, offering the prospect of fully exploring the potential of MALT1 inhibition as a monotherapy and/or in combination with other targeted agents.

833P New targets for adult T cell leukemia/lymphoma (ATLL): A map for ATLL immunotherapy

Z. Rezaei Borojerdi[1], S.A. Rezaee[2]

[1]Hematology Oncology, Shariati Hospital-Tehran University of Medical Sciences (TUMS), Tehran, Iran; [2]Inflammation and Inflammatory Diseases, Mashhad University of Medical Sciences, Mashhad, Iran

Background: In this study, we summarize the chemokines that are involved in malignant HTLV-1 associated disease, adult T cell leukemia/lymphoma (ATLL) progression. The interaction of virus and host were evaluated in chemokine level.

Methods: The expression of CCR6, CXCR-3, the HTLV-1 proviral load (PVL), HTLV-1-Tax, and HBZ were assessed in 12 asymptomatic HTLV-1carriers (ACs), 12 healthy controls (HCs) and 12 ATLL patients. We applied quantitative real-time PCR (qRT-PCR) and TaqMan method.

Results: As per results, the level of CXCR3 gene expression in ATLL patients compared to HTLV-1 virus carriers and healthy people showed a significant difference (P=0.00 and P=0.008). Also, the mean expression of CCR6 genes in ATLL patients compared to HTLV-1 virus carriers had a significant difference of P=0.04, but in the ATLL group there was no significant difference compare to the healthy group.

Conclusions: Our study results illustrate that the expression of chemokine receptors is directly related to the course and stages of the disease as well as the prognosis of the disease. In carriers, compared to healthy individuals, we still have a higher level of expression of chemokine. In addition with the progression of the conflict and the progression to malignancy and involvement of T lymphocytes (the producer of these chemokines) as shown in our study, we can conclude that with decreased levels of these chemokine receptors can lead to malignancy with a poor prognosis. Our findings confirms previous studies that Tax protein may not be expressed in ATLL patients. Additionally an oncoprotein may involve in inducing malignancy, but in the absence of Tax, HTLV-1-HBZ protein implicated in the maintenance of mechanism of the virus to escape from the host cell immune system. We also found an increase in virus load as HTLV-1 carriers move toward. So these chemokines could be suggested as influential targets for the prognosis and proper therapy of ATLL.

834P Phase II clinical study of VR-CAP regimen for first-line treatment of marginal zone lymphoma

J. Chu, H. Wang, S. Yao, Z. Yan, Z. Yao, S. Zhao, Y. Liu

Internal Medicine, Henan Cancer Hospital/Affiliated Cancer Hospital of Zhengzhou University, Zhengzhou, China

Background: Marginal zone lymphoma (MZL) is a relatively common group of inert B-cell non-Hodgkin's lymphoma (B-NHL) originating from peripheral memory lymphocytes. Some patients cannot achieve complete remission or relapse quickly after standard first-line treatment. Studies have shown that the NF-KB signal pathway in MZL is in an abnormally activated state, while bortezomib is a proteasome inhibitor targeting the NF-KB pathway. This multicenter phase II clinical study evaluated the efficacy and safety of VR-CAP regimen in the first-line treatment of MZL, and explored the best beneficiaries of VR-CAP regimen (rituximab, cyclophosphamide, epirubicin, bortezomib and prednisone).

Methods: The patient received 6 cycles of VR-CAP first-line treatment. Each cycle lasts for 3 weeks, and rituximab (375 mg/m2) is given intravenously on the 0th day, cyclophosphamide (750 mg/m2) and epirubicin (70 mg/m2) are given intravenously on the 1st day, bortezomib (1.3 mg/m2) is given subcutaneously on the 1st and 4th days, and prednisone (100 mg) is given orally on the 1st to 5th days. The primary end point was 2-year progression-free survival (PFS), and the secondary end point was objective response rate (ORR), including complete response (CR) and partial response (PR); Total survival (OS) and security.

Results: At present, 23 patients were enrolled, the median age was 55 years (25-74 years). By February 2023, 15 patients had completed all six courses of treatment; 6 patients completed 4 courses of treatment; Two patients stopped treatment by themselves, and 22 patients could evaluate the curative effect. Sixteen patients (72.7%) and five patients (22.7%) achieved CR/CRu and PR respectively. PFS and OS were 82.2% and 82.0% respectively in two years. Among the 13 patients who have completed all the treatment, the common therapeutic adverse events are anemia (73.9%), gastrointestinal reaction (52.2%), thrombocytopenia (30.4%), pulmonary infection (21.7%), neurotoxicity (8.7%), rituximab-related rash (8.7%).

Conclusions: VR-CAP first-line treatment of lymphoma in the marginal region has a good effect, the objective response rate (ORR) is 95.5%, and the patient is well tolerated. All adverse events are mainly 1-2 grades.

Clinical trial identification: NCT04433156.

835P A safe and effective immunochemotherapy with oral sobuzoxane and etoposide for untreated diffuse large B cell lymphoma patients aged 80 and over

K. Miyashita[1], W. Utsunomiya[1], K. Hirata[2], M. Higuchi[1], Y. Tachikawa[1], I. Choi[1], Y. Suehiro[1]

[1]Department of Hematology, National Hospital Organization Kyushu Cancer Center, Fukuoka, Japan; [2]Department of Cell Therapy, National Hospital Organization Kyushu Cancer Center, Fukuoka, Japan

Background: Very old patients usually have various comorbidities, poor performance status and poor frailty. Therefore, as patients get aged, they generally tend to be intolerable to intensive chemotherapy. In Japan, sobuzoxane, which is an oral anti-cancer drug that inhibits DNA topoisomerase II, was approved in 1994 and has been used for patients with lymphoma. Thus far, we have treated lymphoma patients with an attenuated chemotherapy, oral sobuzoxane and etoposide plus rituximab (R-PVP).

Methods: We retrospectively analysed 30 patients aged 80 and over who were newly diagnosed with diffuse large B-cell lymphoma (DLBCL) and initially treated with R-PVP therapy from 2008 to 2022.

Results: The median age of the patients was 84 years (range, 80-93). The median number of Charlson Comorbidity Index (CCI) was 4 (range, 2-11). Median four doses of both sobuzoxane 400 mg and etoposide 25 mg were orally administered every other day per cycle, and rituximab 375 mg/m^2 intravenously once. Patients received a median of six cycles of R-PVP at a four-week interval. With a median follow-up of 26.4 months (range, 5.4-72.9), median progression 'free survival (PFS) and overall survival (OS) time was 13.9 and 32.0 months, with a 5-year PFS and OS rate of 24% (95% CI, 8-46%) and 28% (95% CI, 10-49%), respectively. The most frequent grade 3 or 4 adverse event was neutropaenia (53%). No deaths were documented due to the toxicities of the treatment. A multivariate logistic regression analysis revealed that serum LDH value of >=1.5x upper limit of normal was the only unfavourable variable for both PFS and OS in R-PVP therapy (PFS: hazard ratio (HR), 5.60; 95% CI, 1.64-19.11; $p = 0.006$; OS: HR, 4.83; 95% CI, 1.22-19.17; $p = 0.025$). In a cohort of 20 patients who underwent R-PVP and 25 R-miniCHOP over the past decade, using the Kaplan-Meier method, there were no statistical differences between the groups regarding PFS and OS (median PFS: R-PVP 9.3 months vs. R-miniCHOP 26.4 months, $p = 0.307$; median OS: R-PVP not reached (NR) vs. R-miniCHOP NR, $p = 0.375$).

Conclusions: Our findings may suggest that R-PVP therapy is one of safe and effective treatments for a subgroup of patients, *i.e.* those who have high CCI or low tumour burden, among untreated DLBCL patients aged over 80.

836P EX103, a re-designed CD20xCD3 bispecific antibody, showed a favorable safety and potent single-agent antitumor activity in heavily pretreated relapsed/refractory patients with B cell non-Hodgkin lymphoma

M. Sun[1], K. Zhou[2], C. Ji[3], F. Lu[3], C. Chang[4], W. Zhang[5], D. Yang[5], J. Lu[5], J. Li[5], Y. Cheng[5], Y. Li[5], J. Qi[1]

[1]GCP Center Stage I Ward, Institute of Hematology and Blood Disease Hospital, Chinese Academy of Medical Sciences, Tianjin, China; [2]Hematology Dept., Henan Cancer Hospital, Zhengzhou, China; [3]Hematology Dept., Qilu Hospital of Shandong University, Jinan, China; [4]Hematology Dept., Shanghai Sixth People's Hospital, Jiaotong University, Shanghai, China; [5]Clinical Dept., Guangzhou Excelmab Inc., Guangzhou, China

Background: In recent years, T cell engaging bispecific antibody emerged as a promising therapy in relapsed or refractory (R/R) B-cell non-Hodgkin lymphoma (B-NHL). However, severe cytokine release syndrome (CRS) remains to be a significant challenge in TCB treatment. To overcome this issue, we re-designed a new CD20xCD3 bispecific antibody (EX103) with a much lower affinity to CD3. The new molecule induced significantly lower IL-6 release in preclinical tox study. Preliminary EX103

phase I dose escalation data demonstrates a favorable safety and a promising single-agent antitumor activity, in heavily pretreated R/R B-NHL patients.

Methods: The dose-escalation part (8 cohorts ranging from 1.2 to 36 mg) of this phase I, multicenter, single-arm, open-label clinical trial has enrolled at 4 study sites in China. Objectives include safety, dose finding (RP2D), and antitumor activity. Eligible patients received intravenous(iv) step-up doses of EX103 (with 1 priming dose and 2 intermediate doses followed by 1 target dose) in a 28-day dose limiting toxicity (DLT) period, and then a target dose every 2 weeks for up to 24 cycles or until disease progression or unacceptable toxicity. As of July 2023, 5 cohorts were completed.13 patients were evaluable. The median number of prior lines of treatment was 5 (2−8).

Results: Maximum tolerated dose was not reached. The most common adverse events were CRS and pyrexia, all were grade (Gr) 1-2, no Gr 3 or higher. Most CRS occurred in 1st or 2nd cycle, and resolved within 48 hours. No neurologic AE occurred. In DLBCL patients received EX103 ≥6mg (n=4), the overall response rate (ORR) was 75.0%, including 3 Complete Response (CR) (1 each in 6 or 12 or 18 mg) . In FL/MZL patients ≥6mg (n=4), ORR was 100.0%, 3 FL (1 each in 6 or 12 or 18 mg) and 1 MZL (12 mg) achieving Partial response (PR). 1 MCL patient (3mg) achieved CR. 1 CLL patient (3mg) achieved SD.For 2 patients who failed prior CAR-T therapy, one achieved PR (12mg) and another achieved SD (18mg). The preliminary Disease Control Rate (DCR) is 84.6% (11/13).

Conclusions: The preliminary data show favorable safety and remarkable antitumor activity, even at low doses, in heavily pretreated patients with R/R B-NHL, including those who failed prior CAR-T therapy.

Background: Anbalcabtagene autoleucel is a novel anti-CD-19 CAR-T therapy that has shown promising clinical results, with a complete response (CR) rate of 73.7% in relapsed or refractory LBCL patients at interim analysis. This biomarker analysis aims to understand the mechanism associated with the treatment outcome.

Methods: Patients with relapsed or refractory LBCL were enrolled to receive Anbal-cel at a dose of $2x10^6$ cells/kg. Tumor biopsies were performed at baseline to assess the expression levels of CD19, PD-L1, and CD112/CD155. Peripheral blood mononuclear cell (PBMC) samples for immune phenotyping and serum sampled for ctDNA analysis were collected at day 0, 14, 28, and 3-month intervals thereafter until progression.

Results: PD-1 and TIGIT were highly expressed on baseline PBMC. PD-1 was expressed more on $CD8^+$ CAR^+ T-cells whereas TIGIT on $CD4^+$ CAR^+ T-cells. PD-1, LAG-3 and TIM-3 expressions were significantly increased from D14 at non-CR group. TIGIT expression was significantly increased at D28 at non-CR group. The non-CR group demonstrated the significantly increased level of IL-4^+/ IL-5^+ Th2 type CAR^+ T-cells whereas $GATA^+$ Th2/Tc2 type CAR^+ T-cells were significantly lower in non-CR group. Additionally, $CD57^+CD27^-CAR^+$ T-cells, a marker of terminal differentiation/ functional senescence, were significantly increased in the non-CR group from D14. CD226+ CAR+ T-cells were also significantly lower in the non-CR group. $CD45RA^+$ CAR+ $T_{EFF/EMRA}$ cells post-infusion were significantly lower in the non-CR group and $CD38^+HLA\text{-}DR^+$ CAR^+ T-cells, a marker of susceptibility of cell death, were significantly higher in the non-CR group. The activation of CAR+ T-cells measured by ICOS, 4-1BB, CD226 and CD94 was not different between the two groups. The most frequently detected mutations were related to cell cycling, epigenetic regulation, immune escape, apoptosis etc. Changes in ctDNA concentration were reversely correlated with treatment outcome.

Conclusions: Anbal-cel's unique immunologic and genetic changes demonstrated potential to correlate with treatment outcomes and warrant to confirm with more data.

Clinical trial identification: CRC01-01 (NCT04836507).

Lee Moffitt Cancer Center University of South Florida, Tampa, FL, USA

Background: Axi-cel, a chimeric antigen receptor T-cell (CAR T) therapy evaluated in ZUMA-1, and epcor, a bispecific antibody evaluated in EPCORE NHL-1, are treatments for R/R LBCL. In the absence of a head-to-head trial, we conducted an unanchored MAIC to estimate relative treatment effects of axi-cel versus epcor in 3L+ R/R LBCL.

Methods: ZUMA-1 patient-level data were matched (using a logistic propensity score model) to baseline characteristics representing pre-specified clinically relevant prognostic factors in EPCORE NHL-1 (N=157): International Prognostic Index score, ECOG performance status, disease stage, response to last therapy, number of prior lines, primary refractoriness, LBCL subtype, and prior autologous stem cell transplant. Outcomes were objective response rate (ORR), duration of response (DOR), progression-free survival (PFS), overall survival (OS), and grade ≥3 cytokine release syndrome (G3+ CRS). Neurotoxicity was not analysed as definitions differed. Relative effects were hazard/odds ratios (HR/OR). Base case analyses included ZUMA-1 pivotal Cohorts 1+2 (C12; N=101). Scenario analyses of OS and CRS added ZUMA-1 safety Cohorts 4+6 (C1246; N=182).

Results: The effective sample size (ESS) for axi-cel was 30 in the base-case (Table). Axi-cel improved PFS (median 12.5 months) versus epcor (median 4.4 months). ORR, DOR and OS results were comparable with point estimates favoring axi-cel. A higher rate of G3+ CRS was associated with axi-cel but the difference was reduced in the scenario analysis.

Table: 838P MAIC results

Outcome	Weighted axi-cel versus epcoritamab (95% confidence interval)	
	Base case (C12) ESS=30	Scenario (C1246) ESS=43
ORR OR	1.55 (0.65−3.69)	N/A
PFS HR	0.51 (0.31−0.85)	N/A
DOR HR	0.84 (0.46−1.52)	N/A
OS HR	0.77 (0.45−1.30)	0.67 (0.41−1.10)
G3+ CRS OR	5.31 (1.21−23.32)	4.43 (1.10−17.92)

Conclusions: Our MAIC suggests axi-cel may be more efficacious in terms of PFS versus epcor but with a higher risk of CRS G3+. Of note, median follow-up was short in EPCORE NHL-1 (10.7 months) compared to ZUMA-1 (60 months [C12] and 24 months [C46]) and differences in prior CAR T exposure could not be adjusted for (39% in EPCORE NHL-1 vs 0% in ZUMA-1).

Background: Axi-cel is a chimeric antigen receptor T-cell (CAR T) therapy evaluated in ZUMA-1 while glofit is a bispecific antibody evaluated in NP30179. Without direct evidence, we estimated relative treatment effects of axi-cel versus glofit in 3L+ R/R LBCL using an unanchored MAIC.

Methods: A logistic propensity score model was used to weigh ZUMA-1 patient-level data to match the baseline characteristics of NP30179 (N=155) on pre-specified clinically relevant prognostic factors: ECOG performance status, disease stage, response to last therapy, prior lines of therapy, lactate dehydrogenase, primary refractoriness, LBCL subtype, and prior autologous stem cell transplant. Outcomes were objective response rate (ORR), duration of response (DOR), progression-free survival (PFS), overall survival (OS), and grade ≥3 (G3+) cytokine release syndrome (CRS) and neurological events (NE). Relative effects were hazard/odds ratios (HR/OR). Base case analyses included ZUMA-1 pivotal Cohorts 1+2 (C12; N=101) while scenario analyses of OS, CRS, and NE included ZUMA-1 safety Cohorts 4+6 (C1246; N=182).

Results: Axi-cel improved ORR and PFS versus glofit (Table; effective sample size [ESS] = 32). Median PFS for axi-cel versus glofit were 15 and 11.4 months, respectively. DOR and OS were comparable with point estimates favoring axi-cel. In the scenario analysis, OS was also improved with axi-cel (ESS = 63). Axi-cel was associated with higher rates of G3+ CRS and NEs but the former was comparable in the scenario analysis.

Table: 839P MAIC results

Outcome	Weighted axi-cel versus glofitamab (95% confidence interval)	
	Base case (C12) ESS=32	Scenario (C1246) ESS=63
ORR OR	2.32 (1.01−5.33)	N/A
PFS HR	0.62 (0.40−0.96)	N/A
DOR HR	0.72 (0.35−1.48)	N/A
OS HR	0.70 (0.42−1.18)	0.63 (0.42−0.95)
G3+ CRS OR	4.93 (1.42−17.08)	2.83 (0.89−8.97)
G3+ NE OR	22.59 (7.25−70.36)	15.54 (5.53−43.63)

Conclusions: Findings suggests axi-cel may be more efficacious in terms of ORR and PFS compared to glofit but with a higher risk of certain adverse events. Of note, median follow-up was shorter in NP30179 (12.6 months) than ZUMA-1 (60 months [C12] and 24 months [C46]) and differences in prior CAR T use could not be accounted for (34% in NP30179 versus 0% in ZUMA-1).

840P Genomic landscape, immune characteristics and prognostic mutation signature of extranodal NK/T cell lymphoma, nasal type in China

Y. Chai[1], Y-C. Wei[2], D. Zhang[1], F. Qi[3], M. Dong[4]

[1]*Medical Oncology Dept., Chinese Academy of Medical Sciences and Peking Union Medical College-National Cancer Center, Cancer Hospital, Beijing, China;* [2]*Medical Oncology Dept., Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China;* [3]*Medical Oncology Dept., Chinese Academy of Medical Sciences-National Cancer Center, Cancer Hospital, Beijing, China;* [4]*Medical Dept., Chinese Academy of Medical Sciences and Peking Union Medical College-National Cancer Center, Cancer Hospital, Beijing, China*

Background: This study aimed to obtain a deeper understanding of the molecular mechanisms underlying extranodal NK/T-cell lymphoma, nasal type (ENKTCL) by conducting Next-Generation Sequencing (NGS) of patients with ENKTCL.

Methods: This study included patients with ENKTCL who had complete tissue NGS results from two prior prospective studies. Group 1 comprised early-stage patients, while advanced-stage or relapsed patients were classified into Group 2. R language was used to visualize the mutation data.

Results: 40 out of 98 patients with ENKTCL from two prospective clinical trials were included. Group 1 comprised 67.5% (n=27) of the patients, while group 2 accounted for 32.5% (n=13). Mutations in KLRC2 (29.6%), CIITA (25.9%), KLRC1 (25.9%), ITK (18.5%) were exclusively observed in group 1, with KLRC2 mutations occurring significantly more frequently in group 1 than group 2 (P = 0.037). KMT2D and TP53 exhibited the highest mutation rates and displayed different amino acid alterations in the two groups. The top KEGG pathway enriched by mutated genes was non-small cell lung cancer in group 1, and hepatitis B pathway in group 2. Patients with JAK3 wild-type exhibited remarkably improved PFS and OS rates than those with JAK3 mutations (P = 0.003, P = 0.033). Improved OS was also observed in patients with BCOR wild-type, although no significantly difference was found in PFS (P = 0.049, P = 0.172). Patients with PD-L1-positive expression had a significantly longer OS compared to those with PD-L1-negative expression ($P = 0.037$). Patients with PD-L1 expression < 50% were more likely to have BCOR mutations (41.7% vs. 0%, P = 0.012) and JAK3 gene mutations (33.3% vs. 0%, P = 0.033) than those with PD-L1 expression ≥ 50%.

Conclusions: The present study has, for the first time, explored disparities in mutation rates, mutation sites, and associated pathways among patients with early-stage versus advanced-stage/relapsed ENKTCL. JAK3 mutations, BCOR mutations, and PD-L1-negative expression were associated with poor prognosis of ENKTCL. Patients with PD-L1 expression < 50% were more likely to have BCOR mutations and JAK3 mutations than those with PD-L1 expression ≥50%.

841P Ki67-revised risk index to risk-stratify patients with extra-nodal natural killer/T cell lymphoma

S. Li[1], L-M. Gao[2], Y. Zhong[1], J-P. Yun[1], Y-H. Huang[1]

[1]*Department of Pathology, State Key Laboratory of Oncology in South China, Collaborative Innovation Center for Cancer Medicine, Sun Yat-sen University Cancer Center, Guangzhou, China;* [2]*Department of Pathology, West China School of Medicine/West China Hospital of Sichuan University, Chengdu, China*

Background: Although several clinical parameters-based prediction indexes of extra-nodal natural killer/T-cell lymphoma (ENKTL) are proposed, these indexes include none of pathological index and had insufficient accuracy. A superior clinically feasible prediction index for ENKTL in the modern chemotherapy era is warranted.

Methods: 600 ENKTL patients receiving non-anthracycline based therapy from Sun Yat-sen University Cancer Center were subdivided into training and internal validation datasets. An external validation dataset included 191 patients from West China Hospital was enrolled. Ki67 proliferative index and 14 pretreatment clinical parameters were tested against overall survival (OS) and progression-free survival (PFS). A prediction model was constructed and validated.

Results: Factors independently associated with inferior OS were as follows: Ki67 ≥ 70%; age > 60 years; ECOG PS ≥ 2; B symptoms; stage-III/-IV disease and detectable EBV-DNA copy number. Each of these six factors contributed one point to a prediction model that stratified patients into four risk groups: 0-1 point, low-risk; 2 points, intermediate-risk;3 points, intermediate high-risk; 4-6 points, high-risk. In the training dataset, the 5-year OS rates were 91%, 75%, 65% and 26% for the low-, intermediate-, intermediate high- and high-risk group, respectively ($P < 0.001$). The 5-year PFS rates were 79%, 62%, 48% and 15%, respectively ($P < 0001$). The time-dependent area under the receiver-operator characteristic (AUROC) curve and Harrell's C-statistic of Ki67-revised Risk Index (KRI) for OS and PFS prediction demonstrated a better performance than that of the international prognostic index (IPI), Korean prognostic index (KPI), prognostic index of natural killer lymphoma (PINK) and nomogram-revised

risk index (NRI). Concordant results were successfully validated in both internal and external validation datasets.

Conclusions: KRI is a new promising prediction index to risk-stratify patients with ENKTL receiving non-anthracycline based therapy.

842P Multicenter real-world study of newly diagnosed advanced-stage extranodal natural killer/T cell lymphoma (ENKTL): Proposal for intensive therapy

Y-C. Wei[1], F. Qi[2], B-M. Zheng[3], C-G. Zhang[1], Y. Xie[2], C. Bo[4], W-X. Liu[3], W. Liu[2], H. Fang[4], S. Qi[4], D. Zhang[1], Y. Chai[1], Y. Li[4], W. Wang[3], Y. Song[2], J. Zhu[2], M. Dong[1]

[1]Department of Medical Oncology, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China; [2]Department of Lymphoma, Key Laboratory of Carcinogenesis and Translational Research (Ministry of Education/Beijing), Peking University Cancer Hospital&Institute, Beijing, China; [3]Department of Radiation Oncology, Key Laboratory of Carcinogenesis and Translational Research (Ministry of Education/Beijing), Peking University Cancer Hospital&Institute, Beijing, China; [4]Department of Radiation Oncology, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China

Background: Advanced-stage ENKTL is characterized by its low prevalence, poor prognosis, and inconclusive optimal therapy. This study investigated the treatment of newly diagnosed advanced-stage ENKTLs.

Methods: Newly diagnosed stage III/IV ENKTL patients from two large Chinese cancer centers in the last 10-15 years were retrospectively analyzed.

Results: With a median follow-up of 75.03 (range, 0.33-292.13) months, the median overall survival (OS) for the 195 newly diagnosed stage III/IV ENKTL patients was 19.43 (range, 0.33-292.13) months, and estimated 1-, 2-, 3-, and 5-year OS were 59.5%, 46.3%, 41.8%, and 35.1%, respectively. First-line multi-modality therapy prolonged OS compared to single-modality therapy ($P<0.001$). Chemotherapy (CT)+radiotherapy (RT) compared to CT alone ($P=0.007$), and hematopoietic stem cell transplantation (HSCT) compared to non-HSCT ($P<0.001$) both significantly improved OS. For patients $\leq$60 years yet ineligible for HSCT, other therapies with complete remission led to comparable OS ($P=0.141$) with no significant differences in baseline features. Patients treated with chidamide maintenance therapy (MT) achieved a median progression-free survival (PFS) of 55.83 (range, 53.27-92.33) months and a median OS of 60.65 (range, 53.70-95.70) months. Non-anthracycline (ANT)- compared to ANT-, asparaginase (ASP)- compared to non-ASP-, and gemcitabine (GEM)- compared to non-GEM-based CT regimens, led to prolonged PFS ($P=0.031$; $P=0.005$; $P=0.009$) and OS ($P=0.010$; $P=0.086$; $P=0.003$), respectively. GEM+ASP combinations slightly improved PFS and OS compared to regimens containing GEM or ASP alone ($P>0.05$). GEM+ASP combinations led to significantly superior PFS ($P=0.058$ [log-rank], $P=0.036$[Breslow]) and OS ($P=0.008$) compared to ANT+ASP regimens. First-line intensive therapy, including CT, RT, HSCT, and chidamide MT, was therefore proposed and could improve long-term survival for advanced-stage ENKTLs.

Conclusions: We propose the first-line intensive therapy for newly diagnosed advanced-stage ENKTLs, including CT, RT, HSCT, and chidamide MT. GEM+ASP combinations appear to yield the optimal efficacy and survival. RT, consolidative HSCT, or chidamide MT are recommended.

844P Progression -free survival prediction of multiple myeloma patients in five European countries using machine learning models

M.L. Pleguezuelo Witte[1], M. Muller[2], J. Hartmann[2], C. Ricarte[3], T. Moehler[4], M. Lopez[5], K. Jindal[1]

[1]Global Oncology, IQVIA, London, UK; [2]Advanced Analytics, IQVIA, Frankfurt am Main, Germany; [3]Global Oncology, IQVIA, Courbevoie, France; [4]TSSU-Medical Sciences, IQVIA, Neu-Isenburg, Germany; [5]Global Oncology, IQVIA, Madrid, Spain

Background: The objective of this study is to apply machine learning (ML) models to multiple myeloma(MM) patient-level data to evaluate if ML models can identify high-risk features linked to faster disease progression.

Methods: Data for 15,931 MM patients in France, Spain, UK, Germany, and Italy were extracted from Oncology Dynamics (OD), a large cross-sectional survey that collects drug-treated patient-level data through a panel of cancer specialists. The analyses include 6 years (2017-2022) of records. Progression-free survival (PFS) was measured as the time from start of therapy to date of progression. The underlying data included treatment regime, line of therapy (LOT), ECOG status, stem cell transplant (SCT) eligibility, Durie-Salmon stage, cytogenetic risk, and age and gender. Machine Learning-based survival models (Gradient Boosted Survival Trees, Random Survival Forest) were applied to predict outcomes. Additionally, Shapley values were calculated to assess the model's decision making and identify key risk drivers.

Results: Data was split into Training (80%) and Test Data (20%). The output of the model was the ML derived risk score: higher risk score was associated with shorter PFS. Model performance was good (Harrell's C-Index = 0.741). Data shows that higher LOTs and not being eligible for SCT are associated with increased risk of disease progression. Inversely, being in the 1st LOT, ECOG asymptomatic and certain drug regimens (e.g., Lenalidomide or Dexamethasone/Lenalidomide) are associated with longer PFS.

Conclusions: This is a first successful step in leveraging OD data for the development of a prognostic score for MM patients using machine learning algorithms. ML models applied to secondary market research can support optimal disease management and planning of clinical trials. Also, given the heterogeneity of treatment plans across Europe, further investigation into country-specific differences in PFS may be studied.

845P A machine learning based clinical platform for cancer subtyping and data integration in hematological malignancies

M. Tang[1], Z. Antic[2], P. Fardzadeh[1], C. Schröder[2], S. Pietzsch[2], J. Lentes[2], W. Hofmann[2], L. von Wolffersdorff[1], M. Zimmermann[3], M. Horstmann[4], W. Nejdl[1], G. Cario[5], M. Stanulla[3], A.K. Bergmann[2]

[1]L3S Institute, Leibniz University of Hannover, Hannover, Germany; [2]Department of Human Genetics, MHH-Medizinische Hochschule Hannover, Hannover, Germany; [3]Department of Pediatric Hematology and Oncology, MHH-Medizinische Hochschule Hannover, Hannover, Germany; [4]Department of Pediatric Hematology and Oncology, University Medical Center Hamburg-Eppendorf, Hamburg, Germany; [5]Department of Pediatrics, UKSH-Universitätsklinikum Schleswig-Holstein-Campus Kiel, Kiel, Germany

Background: Next Generation sequencing (NGS) has greatly advanced precision oncology. The growing amount and complexity of NGS data, along with other clinical data such as drug responses and measurable residual disease (MRD), present a big challenge for data integration and interpretation. Machine learning, especially deep neural networks, offer a promising approach for efficiently analyzing intricate relationships within large datasets, with the potential of improving clinical outcomes.

Methods: We performed targeted RNA sequencing in routine diagnostics and sequenced 1849 cases with hematological neoplasms, primarily pediatric B-cell precursor acute lymphoblastic leukemia (BCP-ALL). We used featureCounts in megSAP pipeline and Uniform Manifold Approximation and Projection (UMAP) to analyze the gene expression data, and Bokeh to create the web interface for data integration and visualization. Scikit-learn and PyTorch were used to develop shallow machine learning models and deep learning neural networks (NN), respectively.

Results: Our platform integrates various genetic and clinical data based on UMAP analysis of gene expression patterns. It improves the point-of-care decision making and facilitates the discovery of new patterns such as subpopulations with different genetic and clinical features. The platform is supported by machine learning algorithms for cancer subtyping. Six basic machine learning algorithms were coupled with feature selection methods and the best F1 score achieves 98%. We also built a biologically informed deep NN that can accurately predict BCP-ALL subtypes (F1=97%) with a good interpretability, which helps to identify crucial genetic aberrations associated with disease subtypes.

Conclusions: Our machine learning based platform can not only provide support for clinical decision-making but also bring novel translational insights for hematological malignancies.

846P Artificial intelligence-driven identification of onco-hematology patients who may develop severe COVID-19

S. Assaad[1], J-Y. Blay[1], H. Crochet[2], P-E. Heudel[3], S. Bouam[4], M-P. Revel[4], G. Chassagnon[4], C. Bigenwald[5], L. Albiges[6], F. André[7], E. Battistella[8], O. Teboul[9], D. Pescia[9], B. Bertrand[9], E. D'Amico-Gandia[9], W. Kandeil[10], M. Guillet[11], A. Remorino[12], D. Dellamonica[13], N. Paragios[14]

[1]Medicine Department, Centre Léon Bérard, Lyon, France; [2]DSI, Center Leon Berard, Lyon, France; [3]Oncologie, Centre Léon Bérard, Lyon, France; [4]Radiology, Hopital Cochin AP-HP, Paris, France; [5]Cancer Medicine, Institut Gustave Roussy, Villejuif, France; [6]Medical Oncology, Institut Gustave Roussy, Villejuif, France; [7]Breast Cancer Unit, Medical Oncology Department, Gustave Roussy-Cancer Campus, Villejuif, France; [8]Machine Learning, Broad Institute, Cambridge, CA, USA; [9]Engineering, Therapanacea, Paris, France; [10]Vaccines and Immune Therapies, AstraZeneca, Zug, Switzerland; [11]Global Commercial, AstraZeneca, Phoenix, AZ, USA; [12]AstraZeneca SAS, Courbevoie, France; [13]Digital Healthcare Delivery, AstraZeneca AG, Zug, Switzerland; [14]Direction, Therapanacea, Paris, France

Background: The widespread implementation of COVID-19 vaccines achieved a great success in the general population. However, an unmet medical need exists for onco-hematological and other immunocompromised patients for whom vaccines may not provide optimal protection. Identifying these patients to consider additional layers of protection, including passive immunization with monoclonal antibodies, has been a challenge. Herein, we propose an artificial Intelligence (AI) driven methodology to aid the identification of patients at risk of severe COVID-19 via a minimal number of variables.

Methods: A multi-centric training (340 patients) and an external testing (103 patients) retrospective cohort with homogeneous population characteristics were built. Inclusion referred to hematological or lung cancer patients with COVID-19 infection and absence — except vaccination — of any COVID-19 preventive treatments. The E-CRF included 70+ clinical and demographic variables. Patients were classified into two different COVID-19 severity populations, mild and moderate/severe, based on oxygen support. We sought to identify (i) the minimal set of independent variables (signatures) characterizing these populations, and (ii) the best AI solution acting on these signatures to predict the severity of infection via an end-to-end integration of statistical importance and AI methods.

Results: Using the training cohort we identified 7 variables (age and cancer stage ranked as most important) enabling the prediction of moderate/severe cases with a balanced accuracy of 72% (AUC 0,76) on the internal cohort. The model performed equally well on the external testing cohort yielding a similar balanced accuracy of 73% (AUC 0,77). Most importantly the model reached a 85% performance on the severe cases.

Conclusions: The conducted analysis leads to promising insights towards identifying onco-hematological patients who are most vulnerable to develop severe COVID-19. This may help to offer additional prevention strategies to protect them from COVID-19 and can potentially be further extended to other immunocompromised populations.

847P Fatal infections among leukemia patients

H. Zhou[1], Q. Liu[2], L. Zou[2]

[1]Department of Oncology, West China Medical Center of Sichuan University, Chengdu, China; [2]Division of Medical Oncology, West China Medical Center of Sichuan University, Chengdu, China

Background: Infection is an important cause of death in patients with leukemia, while no studies have reported its incidence. We conducted a population-based analysis of fatal infections in patients with leukemia to analyze trends and address the current lack of evidence.

Methods: Data were collected from the National Cancer Institute's Surveillance, Epidemiology, and End Results (SEER) Program registries. SMR was estimated as the ratio of the number of leukemia patients with fatal infections to the number of fatal infections in the general population with similar age, sex, race and calendar year distribution.

Results: Of 137820 leukemia patients, 2863 had a fatal infection. The fatal infection rate per 100,000 person-years was 389.32 and the SMR was 3.38 (95% CI 3.67-3.99, $p < 0.05$). Patients with acute monocytic leukemia had the highest SMR (SMR=89.01;95% CI 50.87-144.54). SMR for fatal infections decreases gradually with age, with the highest being in patients aged 0-19 years SMR=222.47; 95% CI 183.18-267.69). Notably, the risk of fatal infections continues to rise in patients with leukemia compared to the general population, with the highest risk in patients diagnosed in 2011-2018 (SMR= 9.87; 95% CI 8.58-11.30).

Conclusions: The risk of fatal infections has increased in recent years with the introduction of novel drugs. Prevention and treatment of fatal infections remains an important aspect of improving the overall survival. Close monitoring of patients with acute monocytic leukemia, as well as younger patients, should be considered for the timely administration of antibiotics and modification of chemotherapy regimens.

848P Mortality after rasburicase vs allopurinol anti-hyperuricemia monotherapy in patients with liquid tumors

M.S. Cairo[1], J.R. Gallagher[2], E.J. Drea[3], Y.J. Barnes[3], C. Clark[3], S. Carroll[2]

[1]Departments of Pediatrics, Medicine, Pathology, Microbiology, and Immunology, and Cell Biology and Anatomy, Maria Fareri Children's Hospital at Westchester Medical Center, New York Medical College, Valhalla, NY, USA; [2]Clarity Pharma Research, LLC, Spartanburg, SC, USA; [3]Oncology, Sanofi, Cambridge, MA, USA

Background: This observational real-world study used propensity score matching (PSM) to compare tumor lysis syndrome (TLS) associated mortality in patients (pts) with hematological malignancies who received either rasburicase or allopurinol monotherapy. Goldman/Cairo previously published that rasburicase significantly, more rapidly reduces uric acid exposure (AUC) compared to allopurinol in pts with/at risk of TLS.

Methods: In 2021, 266 oncologists provided anonymized data for 715 liquid tumor pts treated in past year for hyperuricemia (HU) risk and TLS potential. Out of 715, 282 rasburicase and allopurinol pts without spontaneous TLS or TLS before HU treatment (Tx) were matched using 11 pre-HU Tx covariates: acute renal failure, age, anti-cancer Tx, creatinine, gender, LDH, perceived risk, renal disease, tumor type, uric acid, and white blood cells. Matched pts met 1:1, nearest neighbor, caliper matching requirements (width=0.2) of standard deviation of logit of the PSM (d score) on covariates, regardless of whether pts later developed TLS post-HU Tx. Assessments include mean uric acid (UA) levels, anti-cancer Tx, and, as feasible, timing of death relative to HU Tx.

Results: The PSM was almost 0.6 before and near 0 after matching; no covariate had a large imbalance ($|d| > 0.25$) before and after. Of 141 pts in each pt group, TLS-associated mortality was significantly less likely among rasburicase pts (2.1% [$n = 3$] vs. 7.1% [$n = 10$], $P = 0.047$) (71% reduction). Of 63 pt subset who developed TLS after HU Tx, TLS-associated fatalities were even less likely among rasburicase vs. allopurinol pts (8.3% [$n = 3$] vs. 37% [$n = 10$], $P = 0.005$). Comparing 13 who died vs. 269 who lived, no significant difference in mean UA was found (13.5 mg/dL vs. 11.4, respectively). Rituximab, cyclophosphamide, doxorubicin, vincristine, and prednisone regimen (R-CHOP) was the predominant Tx among those who did not die (15%, $n = 41$). Only 1/13 pts died of R-CHOP. Seven pts died within 2 weeks of allopurinol ($n = 6$) or rasburicase ($n = 1$) monotherapy (timing not established for other 6).

Conclusions: PSM corrects before and after overall covariate and individual baseline covariate imbalances and rasburicase compared with allopurinol significantly reducing TLS-associated mortality.

Background: Many disease processes are thought to be impacted by altered long non-coding RNAs (lncRNAs) expression. lncRNAs are typically expressed differently throughout healthy and cancerous hematopoiesis. In the domains of haematology and oncology, they represent a class of biomarkers that is receiving increasing attention. According to recent studies, the expression levels of particular lncRNAs are correlated with the prognosis of paediatric patients with acute lymphoblastic leukaemia. To determine the potential roles of lncRNAs involved in pathogenesis of T-ALL, we analyzed the expression profile of lncRNAs in pediatric T-ALL.

Methods: Twenty five pediatric T-All patients were enrolled and subjected to whole transcriptome analysis in comparison with healthy controls. The results from NGS were validated ex vivo, using real time PCR in the same cases and in a different cohort of 25 T-ALL cases and healthy controls. The results were also comapred with public databases in silico. Potential functions of subtype-specific lncRNAs were determined by using coexpression-based analysis on distally (trans-pattern) located protein-coding genes.

Results: A total of 672 differentially expressed lncRNAs were identified. Moreover, the top 10 upregulated lncRNAs were selected and further assessed by RT-qPCR in vitro in the same samples and a different cohort. We found that lncRNAs LINC01221, LINC00977, RP11-472G21.2 and CTD-2291D10.4 were highly over expressed (>10 fold) in the patients while PCAT18, CRNDE, and RP11-620J15.3 showed mild overexpression (2 to 5 fold increase). The expression of these lncRNAs were also increased in Peer and CCRF-CEM cell lines. Finally, expression correlation analyses using weighted gene co-relation analysis of T-ALL selected lncRNAs and mRNAs suggested that lncRNAs LINC01221, LINC00977, CTD-2291D10.4 may play a possible role in lymphocyte activation and cell.

Conclusions: These results showed that several lncRNAs are aberrantly expressed in T-ALL patients and play potential roles in T-ALL development, and can be useful for diagnostic and/or prognostic purposes in pediatric T-ALL. This study provides the keystone to future clinical studies determining the theragnostic value of the characterized long non-coding transcriptome panorama in a clinical setting for childhood patient management.

850P A zebrafish model of MYC-driven acute myeloid leukemia reveals that neutrophil resistance to oncogenic transformation depends on their ability to promote PP2A-mediated MYC proteasomal degradation

Background: Acute Myeloid Leukemia (AML) is the most common acute leukemia in adults. The origin can be found in chromosomal translocations as well as in accumulated mutations in genes involved in hematopoietic proliferation and differentiation. Despite being considered a heterogeneous malignancy, AML possesses many genetic aberrations, including the overexpression of MYC and the downregulation of PP2A, both essential regulators of cell proliferation, apoptosis, and differentiation, and they, directly and indirectly, regulate each other's activity. We have generated a zebrafish model of MYC-driven AML to rapidly test the effects of different drugs in tumor development.

Methods: After the generation of a transgenic zebrafish line expressing the human MYC under the control of the neutrophils-specific promoter lysozyme (*lyz:hMYC*), we checked the expansion of neutrophils in whole larvae and the colonization of the adult hematopoietic organ. We investigated the effects of chemical manipulation of PP2A activity on neutrophil expansion and on MYC phosphorylation and degradation. Single-cell RNA sequencing analysis has been performed to shed light into the mechanisms of PP2A/proteasomal-mediated degradation of oncogenic MYC in AML.

Results: *In vivo* imaging of whole larvae revealed a robust expansion of neutrophils in zebrafish larvae which expressed MYC from 3 to 8 days post-fertilization (dpf). Surprisingly, the neutrophil number gradually returned to normal levels from 10 dpf onwards, coinciding with degradation of MYC. Pharmacological inhibition of the proteasome resulted in the stabilization of MYC protein and further expansion of transformed neutrophils. Similarly, inhibition of PP2A phenocopied the effects of proteasome inhibition. Otherwise, pharmacological activation of PP2A prevented neutrophil expansion and increased phosphorylation of S62 and T58 of MYC, suggesting a critical role PP2A in MYC proteasomal degradation.

Conclusions: Our results show that PP2A critically regulates MYC degradation in neutrophils preventing their oncogenic transformation. In addition, the zebrafish model of AML is a unique tool for chemical screening.

851P Characterization of a zebrafish model of MYC-driven acute myeloid leukemia

A.M. Luciano[1], J.F. Rodriguez-Vidal[1], M. Fernández-Lajarín[2], M.L. Cayuela- Fuentes[2], D. Garcia-Moreno[2], V. Mulero-Mendez[1]

[1]Department of Celular Biology and Histology, UM-University of Murcia, Murcia, Spain; [2]IMIB-Arrixaca, Hospital Clínico Universitario Virgen de la Arrixaca e IMIB-Arrixaca, Murcia, Spain

Background: Acute myeloid leukemia (AML) is a clonal malignancy of the stem cell precursors of the myeloid lineage associate with uncontrolled proliferation and impaired differentiation of hematopoietic stem cells. Among the different genes found amplified in AML, the oncogene MYC is one of the prognostic factors with an impact of AML. Albeit MYC is a well know factor associated with the uncontrolled proliferation of AML, the mechanism that led to the oncogenesis established by MYC are not well known. Zebrafish has recently emerged as a valid model organism to study cancer development because of its genetic accessibility.

Methods: After the generation of a transgenic zebrafish line expressing the human MYC under the control of the neutrophils-specific promoter lysozyme (*lyz:hMYC),* we proceeded with FACS analysis of adult whole kidney marrow (WKM) of *lyz:hMYC* fish. Immunohistochemical analysis (IHC) of whole zebrafish was made to check the infiltration of cells and possible metastasis. May-Grunwald stain was made to check the kidney marrow population. Gene expression profile of WKM was performed to check the expression of genes associated with *myc* and its patthway. We conducted a Metagenomic analysis on possible variations in the intestinal microbiota associated with the disease causing its progression.

Results: FACS analysis of lyz:hMYC zebrafish revealed the expansion of myeloid cells with a significant reduction of erythroid cells, associated with anemia. The IHC analysis of whole lyz:hMYC zebrafish showed infiltration of myeloid cells into different organs confirming that those cells can proliferate unconditionally and metastasise. May-Grunwald analysis showed a higher number of blast cells unable to differentiate towards mature granulocytes in lyz:hMYC zebrafish than in their wild type siblings. The gene expression profile of WKM demonstrated the overexpression of exogenous MYC and of endogenous myc, suggesting a positive auto-regulation of MYC. Metagenomic analysis revealed that the gut microbes of AML fish were significantly altered with the possibility to be associated the progression of AML.

Conclusions: The model developed here is an excellent tool to further understand the mechanisms involved in MYC-induced AML and the relevance of gut microbiota on this disease.

852P c-MAF-driven metabolic reprogramming mediates H3K27 hyperacetylation to regulate super enhancer-associated genes

P.S. Chong[1], W.-J. Chng[2], J. Lim[1]

Background: Overexpression of transcription factor c-MAF is found in about 50% of multiple myeloma cases, and associated with the prognostically unfavorable t(14;16) translocation subtype. Genetic alterations can modify the epigenome through metabolite availability that act as substrates in histone modifications, but how this translates into specificities in gene regulation is unclear.

Methods: We integrated a multi-omics approach using metabolome profiling to characterize the metabolic phenotype and RNA-sequencing to identify key metabolic genes as a means to uncover novel associations involved in the distinct reprogramming of t(14;16) metabolism.

Results: Here, we report a novel involvement of c-MAF in metabolically-driven histone acetylation, including the superenhancer mark H3K27ac, through altering acetyl-CoA metabolism. To sustain high levels of acetylation, c-MAF acquired the metabolic flexibility to utilize glutamine in addition to glucose, feeding into the tricarboxylic acid (TCA) cycle as acetyl-CoA sources. Loss-of-function studies indicated that c-MAF is important for citrate-derived acetyl-CoA and H3K27ac levels through metabolic enzymes citrate synthase (CS) and ATP-citrate lyase (ACLY). Furthermore, blocking citrate export from mitochondrial via CRISPR/Cas9 targeting of SLC25A1 reproduced the reductions in H3K27ac. Silencing of c-MAF also displayed defective mitochondrial oxidative phosphorylation attributed to reduced metabolic flux through TCA cycle and downregulation of electron transport chain complex I/II expression, without affecting mitochondrial DNA content. To identify c-MAF-regulated superenhancer genes, we overlapped our previously published H3K27ac ChIP-seq dataset on t(14;16) MM cell lines with c-MAF RNA-seq data. We found signal enrichment of H3K27ac at ZC3H3 locus responsible for its transcriptional upregulation, and knockdown of ZC3H3 inhibited cell growth specifically in the t(14;16) subtype.

Conclusions: Altogether, we demonstrated a non-canonical c-MAF role in epigenetics that is connected to its altered metabolic state, and suggest metabolic disruptions as a new therapeutic direction in t(14;16) myeloma.
