Methods: The LATAM subset of this descriptive, observational, real-world study prospectively enrolled consecutive pts with surgically-resected stage IA-IIIB (AJCC 8th edi.) non-squamous NSCLC from Mar 2021-Oct 2022. Primary endpoint was *EGFRm* prevalence and secondary endpoints were *EGFRm* subtypes, clinico-demographics and treatment patterns. Association between *EGFRm* and clinico-demographic factors was assessed by Fisher's exact test with Monte Carlo.

Results: 80 pts were enrolled with mean±SD age of 66.5±9.7 yrs; 67.5% females and 57.5% never smokers. All pts had adenocarcinoma. Pathological stage (PS) distribution was PS I 66.3%, PS II 20.0% and PS III 13.8%. Most pts (61.3%) had right lung involvement and 85.0% were pN0. *EGFRm* prevalence was 39.5% (30/76) with similar rates in males and females (39.1% vs 39.6%; Table). *Exon-19* deletions (36.7%) and 21-*L858R* (30.0%) accounted for two-thirds of mutations. 4 of 11 (36.4%) pts with *EGFRm* were found to be PD-L1 positive. *EGFRm* rate in never smokers was significantly higher than in current and former smokers (51.2% vs 24.2%, p=0.017). 76.3% underwent only surgical resection. Of 44 PS IB-IIIB pts, 31.8% received systemic adjuvant therapy (AT), mostly platinum-based chemotherapy. Per logistic regression analysis age ≥60 years had increased odds of *EGFRm*, while smokers had decreased odds of *EGFRm* (both p<0.05).

Table: 1279P *EGFRm* in the LATAM cohort

Characteristics		N=80, n (%)	Comparison of mutation rate		
			EGFRm (N=30)	*EGFR wild type* (N=46)	Mutation Rate (%)
Age (years)	<60	21 (26.3)	05	14	26.3
	60-80	53 (66.3)	21	31	40.4
	>80	06 (7.5)	04	01	80.0
Gender	Female	54 (67.5)	21	32	39.6
	Male	26 (32.5)	09	14	39.1
Smoking history	Current	03 (3.8)	01	01	50.0
	Former	31 (38.8)	07	24	22.6
	Never	46 (57.5)	22	21	51.2[a]
Family history of lung cancer	No	72 (90.0)	28	40	41.2
	Yes	03 (3.8)	01	02	33.3
PS (AJCC 8th edi.)	I	53 (66.3)	19	31	38.0
	II	16 (20,0)	07	08	46.7
	III	11 (13.8)	04	07	36.4

Note: Four pts failed *EGFR* test [a]By smoking history (current and former vs never; p=0.017) Countries: Argentina, Chile, Colombia, Costa Rica, Dominican Republic, Mexico and Peru

Conclusions: The LATAM subset shows a *EGFRm* prevalence of 39.5%. Despite ASCO guidelines recommending AT in PS IB-IIIB, only about 32% received it. Our results are important for guiding *EGFR* testing and informing treatment strategies in LATAM with recent and upcoming approvals of targeted and immune-therapies.

1280P Comprehensive characterization of human lung squamous cell carcinoma identifies high TFRC expression as a mark of poorly immunogenic tumours

M. Gutiérrez Pérez[1], J. Ramos Paradas[1], D. Gomez Sanchez[1], R. Garcia Lujan[2], J. Zugazagoitia[3], N. Carrizo[1], A.B. Enguita[4], E. Conde Gallego[4], E.M. Garrido-Martin[5], A.C. Ucero[1], L. Paz-Ares[6]

[1]Translational Oncology, Instituto de Investigación Sanitaria Hospital 12 de Octubre (i+12), Madrid, Spain; [2]Pneumology, Hospital Universitario 12 de Octubre, Madrid, Spain; [3]Medical Oncology Dept., Hospital Universitario 12 de Octubre, Madrid, Spain; [4]Pathology, Hospital Universitario 12 de Octubre, Madrid, Spain; [5]Cell Biology, PharmaMar S.A., Colmenar Viejo, Spain; [6]Medical Oncology Department - Edificio Maternidad, Hospital Universitario 12 de Octubre, Madrid, Spain

Background: Lung squamous cell carcinoma (LUSC) is an aggressive tumour that accounts for 30% of all lung cancers with a 5-year survival rate of around 30%. The accumulation of CNVs and mutations on tumour suppressor genes explain the lack of directed therapies. Combination with immunotherapy in LUSC shows better efficacy than chemotherapy alone, but responses are below 50% after biomarker-based patient selection. Since tumour immunity determines the efficacy of immunotherapy, a better characterization of the immune landscape in LUSC could improve patient selection and treatment success. Altogether, this highlights the importance of identifying more precise molecular markers, as well as novel targets for LUSC treatment.

Methods: 98 early-stage patient samples Multiparametric study: Clinical annotations, targeted DNA and RNA sequencing. Immunohistochemistry (IHC): CD8, CD4, CD20,

TFRC, ferritin. Total iron staining (Turnbull Blue and Tirmann-Schmelzer methods). In vitro assays in LUSC cell lines CRISPR-KO and lentiviral-mediated overexpression of TFRC. Crystal violet. Western blot. Indirect immunofluorescence.

Results: The multiparametric analysis identified an amplification on TFRC gene in 30% of the patients associated to a transcriptional upregulation of tumour progression genes and a downregulation of immune-related genes. The reduction of immune cell infiltration according to IHC results further supported the immune-cold profile of these tumours. TFRC genomic amplification in tumour cells was translated into higher mRNA and protein levels in patient samples, which finally led to an accumulation of iron, suggesting a functional role of this copy number gain. In addition, iron positive samples showed decreased immune cell infiltration, especially CD8 T cells. While *in vitro* cell growth of LUSC cell lines was not affected by TFRC overexpression, it was significantly reduced in TFRC knockout cells.

Conclusions: Alterations in TFRC in LUSC patients have functional impact in both the tumour and the immune cells, pointing at TFRC as a potential biomarker of tumour immunity and a therapeutic target.

1281P Effect of Fra-2 expression on tumour immunogenicity and prognosis in KRAS-mutant lung adenocarcinoma

A.C. Ucero[1], M. Gutiérrez Pérez[1], A. Zazo[1], L. Bakiri[2], E.F. Wagner[2], L. Paz-Ares[1]

[1]Translational Oncology and Lung Cancer Unit - Physiology and Medicine Department, Hospital Universitario 12 de Octubre, Universidad Complutense, CNIO-H12o Lung Cancer Unit and Ciberonc, Madrid, Spain; [2]Department of Laboratory Medicine and Department of Dermatology, Institute of Cancer Research - Medical University of Vienna, Vienna, Austria

Background: Targeted therapies are available for lung adenocarcinoma (LUAD); however, more than 50% of patients either cannot benefit from them or become resistant, highlighting the need for alternative strategies. Our project focuses on FRA-2 (encoded by FOSL2 gene), a member of the AP-1 family that can act downstream of KRAS and EGFR pathways, two of the predominant genetic alterations observed in LUAD. Computational analyses of public databases have revealed a correlation between high FOSL2 expression and poor survival in KRAS-mutant LUAD. Consistently, tumour cell expression of Fra-2 has been found to correlate with shorter survival and higher tumour burden in a genetically engineered mouse model of LUAD driven by KRasG12V mutation and Tp53 loss.

Methods: Cell viability was assessed in primary tumour cells with Fra-2 gain- and loss-of-function, cultured from *KRasG12V/Tp53*-knockout mouse tumours. We prospectively collected fresh samples of resected LUAD tumours from patients with complete clinical and molecular annotations (N=27; 9 KRASmut), which were subjected to characterization by flow cytometry and IHC.

Results: In vitro analyses of primary tumour cells confirmed that overexpression of Fra-2 increases tumour cell viability. However, the absence of Fra-2 did not affect cell growth, suggesting that in vivo observations in Fra-2-deficient tumours could depend on anti-tumoral mechanisms that are extrinsic to tumour cells. In LUAD patients, the percentage of tumour cells expressing FRA-2 correlates with FRA-2 expression in immune cells as well as in cancer-associated fibroblasts (αSMA). FRA-2 also tends to show a positive correlation with proliferation (KI-67) and a negative correlation with T cells. A more detailed analysis by flow cytometry revealed that FRA-2 expression was related to an increased tumour density of regulatory T cells and decreased PD-1 expression, particularly in KRAS mutant tumours.

Conclusions: Our results suggest that FRA-2 could play a significant role as a mediator in the tumorigenic effects driven by KRAS mutations in LUAD, by promoting both tumour cell proliferation and immune evasion. These findings provide a new therapeutic opportunity in a clinically relevant setting.

Background: Determining the Programmed death-ligand 1 (PD-L1) expression status may help identify patients who will benefit from immune checkpoint inhibitor in perioperative treatment for early-stage non-small cell lung cancer (NSCLC). We evaluate the concordance of PD-L1 expression between biopsies and matched surgical specimens as part of a multicenter prospective genomic screening study in LC-SCRUM-Advantage/MRD.

Methods: Patients with preoperative untreated resectable clinical stage I to III NSCLC were eligible for this study. PD-L1 Tumor Proportion Score (TPS) was assessed in patients with operable NSCLC on both lung biopsies before surgery and matched surgical specimens after surgery, by using a 22C-3 Immunohistochemistry assay.

Results: Between August 2022 and April 2023, a total of 181 patients were enrolled in LC-SCRUM-Advantage/MRD. Of 62 evaluable patients at this analysis, 33(53%)/17(28%)/12(19%) had stage I/II/IIIA disease and 46 (74%) had adenocarcinoma histology, 54 (85%) were diagnosed by bronchoscopic biopsy before surgery. The success rate of PD-L1 TPS analysis in biopsy specimens was 98%, and median turnaround time was 7 days (quartile range, 3-13). In biopsy specimens, PD-L1 TPS was observed in 34 (56%), 17 (28%), and 9 (16%) cases for the cutoff values $<$1%, 1-49%, and $\geq$50%, respectively. On the other hand, all surgical specimens were successfully analyzed, PD-L1 TPS was observed in 22 (48%), 15 (32%), and 9 (20%) cases for the cutoff values $<$1%, 1-49%, and $\geq$50%, respectively. The overall concordance rate of PD-L1 TPS between biopsy specimen and matched surgical specimen was 74% (35/47). The concordance rate at a cut-off value of $<$1%/1-49%/$\geq$50% PD-L1 TPS were 91% (20/22), 53% (8/15), and 67% (6/9). The breakdown of discordant in PD-L1 TPS 1-49% between biopsy and matched surgical specimens, 86% (6/7) was TPS $<$1% in biopsy specimens.

Conclusions: PD-L1 TPS demonstrated a high concordant rate between biopsy and matched surgical specimens in patients with early-stage NSCLC. However, PD-L1 TPS 1-49% concordance rate is relatively low and may be underestimated, especially in biopsy specimens.

1283P Predicting PD-L1 expression using [18F]FDG PET/CT in early stage non-small cell lung cancer (NSCLC)

D.J. Hughes[1], E. Josephides[2], R. O'Shea[1], T. Manickavasagar[1], C. Horst[1], S. Hunter[3], P. Taniere[4], D. Nonaka[5], J. Spicer[2], V. Goh[1], A. Bille[2], E.M. Karapanagiotou[3], G. Cook[1]

[1]Cancer Imaging Department, King's College London, London, UK; [2]School of Cancer and Pharmaceutical Sciences, King's College London, London, UK; [3]Guy's Cancer Centre, Guy's and St. Thomas' NHS Foundation Trust, London, UK; [4]Cellular Pathology Department, Queen Elizabeth Hospital - University Hospitals Birmingham NHS Foundation Trust, Birmingham, UK; [5]Department of Histopathology, Guy and St Thomas NHS Foundation Trust - St Thomas' Hospital, London, UK

Background: Advances in the management of early stage NSCLC include the introduction of PD-1/PD-L1 checkpoint inhibitors. PD-L1 is an important biomarker but its role in early NSCLC remains unclear. PD-L1 is also closely associated to glucose transporter 1 (GLUT1) expression and the correlation of metabolic parameters measured using [18F] FDG-PET/CT has been demonstrated in advanced disease. Our aim was to investigate the association of [18F] FDG-PET/CT metabolic parameters with PD-L1 expression in a cohort of patients with resected early stage NSCLC.

Methods: We conducted a retrospective analysis of 210 patients with node-positive early stage resected NSCLC. DAKO 22C3 PD-L1 immunohistochemistry was performed on primary tumour and positive nodes and scored according to tumour proportion score (TPS) of $<$1, 1-49, or $\geq$50%. [18F]FDG PET/CT was analysed using semi-automated techniques for max, mean and peak standardised uptake values (SUV), metabolic tumour volume (MTV), total lesion glycolysis (TLG) and SUV heterogeneity index (HISUV).

Results: Patients were predominantly male (57%), median age 70 years, a majority had non-squamous NSCLC (68%), and were current smokers (89%). Stage T2(a-b) disease was common (48%) and most had negative primary PD-L1 expression (TPS $<$1%; 53%). Mean SUVmax scores of the primary tumour ($n = 210$; $p = 0.02$) and nodes ($n = 50$; $p = 0.03$) increased according to PD-L1 TPS. There were similar trends for mean SUVmean and SUVpeak values in the primary and nodes across all TPS groups. SUVmax, mean and peak scores were all significantly ($p<0.05$) associated with PD-L1 positivity using a $<$or $\geq$1% threshold. However, ROC analysis demonstrated only moderate separability with AUCs ranging 0.58 - 0.73. No statistically significant differences of mean MTV, TLG and HISUV scores were found between TPS groups.

Conclusions: This study demonstrated the association of standard [18F]FDG PET/CT metabolic parameters of SUVmax, SUVmean and SUVpeak with PD-L1 expression in early NSCLC. However, the sensitivity/specificity of these measurements for predicting PD-L1 positivity using the $<$ or $>$1% threshold was poor. Future prospective studies are warranted to determine the association, predictive role, and clinical utility of these metabolic measurements.

1284P Lung cancer among patients with chronic obstructive pulmonary disease: A Danish 10-year observational study of the overlapping population

M.B. Henriksen[1], L.H. Jensen[2], O. Hilberg[3], T.F. Hansen[4], C.L. Brasen[5]

[1]Department of Oncology, Vejle University Hospital, Vejle, Denmark; [2]Department of Oncology, Danish Colorectal Cancer Center South, University Hospital of Southern Denmark, Vejle Hospital, Vejle, Denmark; [3]Department of Internal Medicine, Sygehus Lillebaelt - Vejle Sygehus, Vejle, Denmark; [4]Oncology, Vejle Hospital, University of Southern Denmark, Odense, Denmark; [5]Department of Immunology and Biochemistry, Vejle Hospital, University Hospital of Southern Denmark, Vejle, Denmark

Background: Lung cancer (LC) is the leading cause of cancer-related death worldwide, and up to five times more likely to occur in smokers with chronic obstructive pulmonary disease (COPD) than those with normal lung function. In this study, we investigated the overlap between patients registered with COPD and patients examined on suspicion of LC over a 10-year period in the Region of Southern Denmark.

Methods: The National Registry of COPD and the Danish LC Registry delivered data on patients with COPD and LC respectively. The cohort referred for LC diagnostics was defined by assigned classification codes provided from the Health Care Classification System.

Results: During the study period, 25,647 patients were registered with COPD during hospitalizations, or from outpatient clinics. Among these, 5.030 patients (20%) were referred to LC diagnostics, and 1,551 were diagnosed with LC. This corresponds to a LC incidence of 6% among all patients with COPD, and 31% among COPD patients referred for LC diagnostics. COPD patients referred for LC diagnostics were generally more affected by COPD compared to the group of not referred for LC diagnostics. Referred patients collected more COPD related medication (6 of 7 medicaments), performed worse in terms of lung function (FEV1% 48% vs. 50%), suffered from a higher grade of dyspnea (71% vs. 57% MRC 3-5) and experiences a higher rate of exacerbations (42% vs. 31% with 2-3 exacerbations) compared to COPD patients not referred to LC diagnostics ($p<0.05$ for all). Among all patients who underwent LC diagnostics, COPD patients displayed a higher prevalence of LC compared to the non-COPD patients (31% vs. 29%, $p<0.005$). LC patients with COPD were more likely to be stage I-II compared to the non-COPD LC population (39% vs. 24%, $p<0.05$).

Conclusions: This study reveals a substantial overlap between patients with COPD and patients undergoing LC diagnostics (20%). It suggests that patients more affected by COPD are more likely to undergo LC diagnostics, and LC patients with COPD are more likely to be diagnosed in early stages. It underlines the overrepresentation of LC patients among patients with COPD, and emphasizes the need to address these patients specifically once initiating a screening program.

1285P Lung cancer in never smokers (LCINS): Clinicopathological characteristics and treatment outcomes from a university cancer centre in London

C. Gousis[1], E. Josephides[2], H. McGrath[1], K. Ryanna[3], G. Santis[3], A. Bille[1], D. Smith[1], S. Ahmad[1], S. Ghosh[1], S. Gennatas[1], E.M. Karapanagiotou[1], J. Spicer[4], A. Georgiou[1]

[1]Guy's Cancer Centre, Guy's and St. Thomas' NHS Foundation Trust, London, UK; [2]School of Cancer and Pharmaceutical Sciences, King's College London, London, UK; [3]St Thomas' Hospital, Guy's and St. Thomas' NHS Foundation Trust, London, UK; [4]Comprehensive Cancer Centre, King's College London, London, UK

Background: The patient (pt) characteristics, risk factors, and treatment outcomes of LCINS remain poorly understood. We present data from a large UK-based bespoke LCINS clinical database.

Methods: We retrospectively collected data from electronic records and analysed outcomes of LCINS pts treated at Guy's Cancer Centre, South East London, from 2010 until 2021.

Results: 483 pts were included, which accounted for 7% of all lung cancer pts. Median age was 67 years (range 25-95), 68% of pts were female (versus 43% in smokers); 50% White, 22% Black, 16% Asian, 2% mixed race, and 10% unknown (versus 72%, 5%, 2%, 2%, 18% in smokers). 8% of pts had asthma, 2% previous tuberculosis, 1% COPD, 1% interstitial lung disease, while 7% had passive smoking and 5% known asbestos exposure. 49% were overweight. 21% of pts had a history of other cancers and 5% a

first-degree family history of lung cancer. Most (64%) pts presented with stage IV disease, and 16%, 6%, and 15% with stage I, II, and III respectively. Most (80%) pts had adenocarcinoma, 9% squamous cell, and 4% small cell. 50% of pts had a driver genetic aberration, although genetic testing varied dependent on histological subtype and year of diagnosis. The commonest were *EGFR*, *ALK*, *KRAS*, and *ROS1* aberrations found in 48%, 11%, 8%, and 5% of pts tested for each gene respectively. Out of the 174 (36%) pts with stage I-III disease, 57% had curative surgery, 39% radical (chemo) radiotherapy, and 22% adjuvant chemotherapy (CT). Of all 376 metastatic pts (64% de novo and 14% relapsed), 38% had brain metastases. A total of 81%, 45%, and 23% of metastatic pts had 1, 2, and 3 lines of systemic therapy respectively. In the 1st -line setting, 47% had a tyrosine kinase inhibitor (TKI), 40% CT, and 6% CT-immunotherapy (IO). Overall, 53% of the metastatic pts had a TKI, 52% CT, and 16% IO at any treatment line. The median overall survival was 9.2, 4.0, 3.3, and 1.4 years for stage I, II, III, and IV disease respectively.

Conclusions: LCINS spans all age groups and ethnic backgrounds. Most pts are female with limited respiratory comorbidities. Pts present with advanced adenocarcinoma with a high incidence of brain metastases and driver genetic aberrations. Strategies to improve earlier stage diagnosis in LCINS are urgently needed.

1286P Real-world outcomes in stage I-III resectable non-small cell lung cancer (NSCLC): THASSOS-INTL study

T. Goksel, et al.

Pulmonary Medicine and Ege Translational Pulmonary Research Center, Ege University - Faculty of Medicine, Izmir, Turkey

Late withdrawal

1287P Comparing the cost-effectiveness of perioperative immunotherapy strategies in non-small cell lung cancer

B. Muthusamy[1], E.C. Zabor[2], N.A. Pennell[1]

[1]Hematology and Medical Oncology, Taussig Cancer Center-Cleveland Clinic, Cleveland, OH, USA; [2]Quantitative Health Sciences, Cleveland Clinic, Cleveland, OH, USA

Background: Over the course of a year, the FDA approved both adjuvant atezolizumab and neoadjuvant nivolumab plus chemotherapy for resectable non-small cell lung cancer based on positive results from the IMPOWER010 and Checkmate-816 studies respectively. In this analysis, the cost-effectiveness (CE) of these two different treatment methods was evaluated in several clinical scenarios and indirectly compared.

Methods: CE was defined as the incremental cost effectiveness ratio (ICER), a measure of the cost difference per quality adjusted life years gained (QALY). Markov models were constructed to calculate the ICER of both neoadjuvant nivolumab plus chemotherapy versus neoadjuvant chemotherapy and adjuvant atezolizumab versus standard of care (SOC) (surveillance +/- chemo). For the neoadjuvant nivolumab method, CE was assessed in the intention to treat population (all stage IB-IIIA) and the PD-L1≥1% group. CE of adjuvant atezolizumab was evaluated for the stage II-IIIA PD-L1≥1% and PD-L1≥50% groups. Each of these four clinical scenarios were divided into three sub-scenarios based on the use and assumed effectiveness of immunotherapy (IO) at recurrence in the experimental arms: 1. No IO at recurrence. 2. IO at recurrence but ineffective. 3. IO at recurrence and effective.

Results: The ICERs are in the following table. Probabilistic sensitivity analyses confirmed the results of all primary analyses.

Table: 1287P

IO status at Recurrence	Neo Nivo		Adj Atezo	
	Stage IB-IIIA, any PD-L1	Stage IB-IIIA, PD-L1≥1%	Stage II-IIIA, PD-L1≥1%	Stage II-IIIA, PD-L1≥50%
No IO	−$86,599	−$95,405	−$20,112	−$39,641
Ineffective IO	−$57,250	−$87,387	$34,051	−$24,670
Effective IO	−$103,924	−$100,339	−$58,101	−$42,318

Conclusions: In eleven of twelve scenarios, the experimental arms were less costly and more effective than the SOC. Only adjuvant atezolizumab used in PD-L1≥1% patients with ineffective IO at recurrence resulted in a cost increase per QALY gained as compared to SOC. Neoadjuvant nivolumab is a more cost-effective treatment strategy than adjuvant atezolizumab even when adjuvant atezolizumab is limited to patients with a PD-L1≥50%, likely due to shorter duration of treatment with nivolumab. Further analyses can be done to confirm CE with publication of final overall survival results.

1288P Neoadjuvant therapy with anti-PD-1/PD-L1 plus platinum-base chemotherapy for resectable stage II-III non-small cell lung cancer: A systematic review and meta-analysis of randomized clinical trials

M.I. Dacoregio[1], C.E.D.R. Castro[2], I.F. Michelon[3], C. Stecca[4], M. Silveira Vilbert[5]

[1]Medicine, Universidade Estadual do Centro Oeste, Guarapuava, Brazil; [2]UnB - Universidade de Brasília - Faculdade do Gama (FGA), Brasilia, Brazil; [3]Medicine Department, UCPEL - Universidade Católica de Pelotas, Pelotas, Brazil; [4]Medical Oncology Department, Center of Oncology of Parana, Curitiba, Brazil; [5]Department of Clinical Oncology, UHN - University Health Network - Princess Margaret Cancer Center, Toronto, ON, Canada

Background: Neoadjuvant chemotherapy (CT) has limited benefit over surgery alone for resectable non-small cell lung cancer (NSCLC). Recent trials have shown promising results for combining immune checkpoint inhibitors with platinum-doublet chemotherapy (ICI plus CT).

Methods: We conducted a systematic review and meta-analysis of randomized controlled trials (RCTs) that compared neoadjuvant ICI plus CT versus CT alone in patients with resectable NSCLC. We searched PubMed, Scopus, and Cochrane Library databases, as well as the ASCO, ESMO, and AACR websites. We used a fixed effects model for analysis and assessed heterogeneity with I^2 statistics.

Results: We included six RCTs with 2,471 patients, of whom 75% were male, 47% had non-squamous, and 53% had squamous cell carcinoma (SCC). The median age was 63.3 years (ranged from 29 to 88). After neoadjuvant therapy, 84% of patients in the ICI plus CT group underwent surgery compared to 81% in the CT group (p=0.16); R0 resection was reported in 78% versus 67% of patients (p<0.01), respectively. We found a significantly higher pathologic complete response (risk ratio [RR] 5.81 [95%CI 4.26-7.92]) and major pathologic response (RR 3.57 [3.09-4.55]) in patients who received ICI plus CT than those in the CT group. Treatment with ICI plus CT provided a greater benefit of event-free survival (EFS) (HR 0.59 95%CI 0.51-0.67 p<0.00001) and overall survival (HR 0.66 95%CI 0.53-0.82 p=0.0002)compared to CT alone. ICI plus CT improved EFS regardless of PD-L1 expression, type of platinum CT, or histology. Patients with PD-L1 ≥1% achieved considerably better EFS than those with PD-L1 <1% (HR 0.40 vs 0.76, p<0.0001). Subgroup analysis showed EFS benefit for all stages (IB and II, IIIA, and IIIB). Treatment-related adverse events grades 3 or 4 were seen in 36% of patients in the intervention arm and 32% of the control arm (p=0.05).

Conclusions: Neoadjuvant therapy with anti-PD-1/PD-L1 plus CT provided significantly higher pathologic response, EFS, and OS compared to CT alone for resectable stage II-III NSCLC patients. More mature data from the trials are awaited to confirm these findings.

Background: Lung cancer is a highly fatal cancer with poor prognosis and management despite recent therapeutic advancements. However, Artificial Intelligence (AI) presents an opportunity to leverage multiple omics datasets to create accurate predictive models for better lung cancer care. These models can be used individually or integrated into multi-omics Digital Human Avatars (DHAs) to assist in clinical decision-making and revolutionize care and research. DHAs combine various omics-based variables with clinical factors for a comprehensive understanding of the disease, enabling personalized treatment decisions to improve patient outcomes. Introducing DHAs in clinical practice can help uncover previously unexplored links among variables and significantly enhance the understanding of lung cancer.

Trial design: Trial design: The LANTERN study is a three-year, multicenter observational clinical study funded by ERA PerMed JTC2022 that aims to develop predictive models for the diagnosis and histological characterization of lung cancer, as well as personalized treatments and feedback data loops for preventive health strategies and quality of life management. The study involves a consortium of five European institutions and will collect multi-omics data from 600 non-small cell lung cancer patients, including demographic and physiological data, medical history, clinic functional and lab data, histo-pathological, immunological and genomic data, radiomics and quantitative imaging data, and IoT-derived data. The study will develop a dedicated database for all omics domains considered and perform a comprehensive molecular characterization and genomic profiling of tumor samples. The second phase of the project will focus on building multivariate models trained through advanced ML and AI techniques. Finally, the developed models will be validated to test their robustness, transferability, and generalizability, leading to the development of Digital Human Avatars (DHAs). The LANTERN study is committed to allowing the reuse of research data according to the FAIR principles and hopes that this model will eventually be utilized in clinical routine to personalize the strategy of care in lung cancer patients.

Background: Adjuvant (adj) or neoadjuvant (neoadj) immunotherapy has been recently approved for the treatment of resectable early stage Non-Small Cell Lung Cancer (NSCLC), and further advances are needed. The combination of neoadj Durvalumab (D), an anti-PD-L1, combined with chemotherapy (CT) and adj D (AEGEAN) in early-stage NSCLC has recently demonstrated promising safety and efficacy. CD39 is an extracellular ectonucleotidase highly expressed in the tumor microenvironment (TME) that, sequentially with CD73, contributes to the production of adenosine (Ado), via hydrolysis of Ado triphosphate (ATP). IPH5201 is a blocking anti-CD39 monoclonal antibody that may promote antitumor immunity by accumulating immunostimulatory ATP released by CT-treated tumor cells and reducing immunosuppressive Ado levels in the TME. Moreover, IPH5201 improved the efficacy of CT+D in preclinical models. In a phase 1, IPH5201 + D was well tolerated and pharmacodynamically active.

Trial design: MATISSE is a phase II multicenter (France, Poland, Greece, Hungary, USA), single arm study (NCT05742607) sponsored by Innate Pharma, evaluating IPH5201 + D + CT in treatment-naive pts with resectable (stage II to IIIA) NSCLC. Up to 70 pts will receive neoadj IPH5201 + D in addition to platinum-doublet CT for 4 cycles followed by surgery within 40 days. Pts will thereafter receive adj IPH5201+D every 4 weeks for up to 12 cycles post-surgery or until recurrence or unacceptable toxicity. The primary objectives are to assess antitumor activity of neoadj treatment based on pathological complete response (pCR) and safety. The secondary objectives are to assess efficacy in terms of event free survival, disease free survival, feasibility of receiving the planned surgery, major pathological response, objective response rate, overall survival, pharmacokinetics and immunogenicity. Assessment of exploratory biomarkers is also planned. A Safety Review Committee will conduct evaluations on an ongoing basis and two interim analyses will be performed.

Clinical trial identification: IND:162253; NCT05742607; EudraCT: 2022-001903-42.

Background: To assess the possibility and safety of a boost delivery up to74 Gy, based on lung tumour early response to on-treatment FDG-PET /CT (42 Gy), in inoperable patients with stage III non-small-cell lung cancer (NSCLC)treated with concomitant radio-chemotherapy (RCT).

Methods: 158 patients were prospectively included in a multicentre phase II-III study. Patients were randomized into two groups: patients from arm A (experimental) with residual metabolism on FDG-PET2 at 42 Gy received a radiation boost (74 Gy), while patients without residual uptake on FDG-PET2 at 42 Gy and patients in arm B (standard) received a standard radiotherapy (RT) dose (66 Gy). Local control rate (LCR %), median overall survival (OS, months), and progression-free survival (PFS) were analysed for three years after the end of RCT. FDG-PET parameters were measured at baseline (PET1), 42 Gy (PET2), and 6 months post-RCT (PET3). All patients were evaluated with the RECIST 1.1 criteria. The main objective was the LCR at 1 year after RCT.

Results: Patient demographic characteristics and FDG-PET parameters were similar between the two arms (A vs. B). The mean age was 62.3 years; 53.2% of lesions were stage IIIA and 45.6% were stage IIIB. The mean radiation dose was 71.65 Gy for experimental arm and 66 Gy for standard arm ($p < 0.001$). The median follow-up time was 45.1 months. The LCR at 1 year after RCT was 77.6% [95% CI: 67.6% – 87.6%] in arm A and 71.2% [95% CI : 60.8% - 81.6%] in arm B. The median OS and the PFS (months) were respectively NR [95% CI: 40.9 – NR] in arm A and 43.3 [95% CI: 33.4 - NR] in arm B, and 22.3 [95% CI: 14.8 – 33.7] in arm A and 12.3 [95% CI : 9.4 – 23.3] in arm B. Using multivariate analysis, ΔSUVmax > 66% ($p < 0.01$), Δ metabolic tumoral volume (MTV) > 100% ($p = 0.04$) between PET1 and PET3, and the boost realization ($p = 0.05$) were the only predictors of PFS. There were less acute or late toxicity in boost radiation arm.

Conclusions: Boost at 74 Gy based on interim FDG-PET is feasible and safe during thoracic RCT, without acute or late toxicity. Boost administration, ΔSUVmax, ΔMTV seem to be prognostic factors in patients with stage III inoperable NSCLC.

Background: Chemoradiotherapy followed by durvalumab consolidation therapy is standard care for patients with unresectable locally advanced non-small cell lung cancer (LA-NSCLC). However, it remains unclear about the clinical significance of durvalumab after chemoradiotherapy in patients with LA-NSCLC a performance status (PS) of 2 or aged ≥75 years.

Methods: Daily low-dose carboplatin (30 mg/m^2) was administered to patients 1 h before radiotherapy for the first 20 fractions. Radiotherapy for all patients consisted of 60 Gy administered as 30 fractions. Durvalumab at a dose of 10 mg/kg was intravenously administered every 2 weeks for up to 12 months after chemoradiotherapy. The primary endpoint was the progression free survival rate (PFS) of 12 months from the initiation of durvalumab administration. The secondary endpoints included the rate of therapeutic completion, PFS, overall survival (OS), objective response rate (ORR), and safety.

Results: Of 86 patients who underwent induction chemoradiotherapy from September 2019 to October 2021, 61 (70.9%) received durvalumab consolidation therapy. A total of 61 patients (50 males, 11 females; median age 78y; range 55-89y) was eligible for the further analysis. The PS was 0, 1, and 2 in 28 (45.9%), 27 (44.3%), and 6 (9.8%) patients. Regarding PD-L1 expression, 14 (22.9%), 17 (27.9%), 17 (27.9%), and 13 (21.3%) patient displayed levels of ≥50%, 1–49%, <1%, and unknown, respectively. The PFS rate of 12 months from durvalumab start was 51.0% (90% confidence interval [CI], 39.9 to 61.1). Therefore, the current study met the primary endpoint. The ORR after chemoradiotherapy and durvalumab consolidation was 47.0% and 57.4%, respectively. The median PFS and OS were 12.3 and 28.1 months, respectively. The rate of therapeutic completion for durvalumab was 26.2%. The most common treatment related adverse event of grade 3 or 4 was pneumonitis (6.6%). One patient died because of grade 5 interstitial pneumonitis.

Conclusions: Durvalumab consolidation after daily carboplatin with radiotherapy was effective and tolerable for LA-NSCLC vulnerable patients.

Clinical trial identification: jRCTs031190070.

Background: Since patients with unresectable stage III NSCLC who are unfit for chemotherapy (CHT) due to age or frailty receive radiotherapy (RT) only, they do not have the opportunity to benefit from durvalumab consolidation after radiochemotherapy, raising the concern of undertreatment. Synergistic effects are expected when combining restored anti-tumor immune response elicited by immune checkpoint inhibition with an RT-induced increase in immunogenicity. The latter could be further boosted by hypofractionated RT, which might also be more practicable for the patient.

Methods: TRADE-hypo (NCT04351256) is an open-label, allocated phase II trial addressing safety and efficacy of durvalumab (1.500 mg Q4W, max. 12 months) combined with either hypo- (55 Gy = 20 x 2.75 Gy, "HYPO") or conventionally fractionated thoracic RT (60 Gy = 30 x 2 Gy, "CON") in previously untreated NSCLC stage III patients unfit for CHT (planned n=88). A safety stop-and-go phase (6+6 design) in the HYPO-arm addressed the potential higher pneumonitis risk. An interim futility analysis was planned with 18 response-evaluable patients in each arm (after RT start, $\geq$1 dose durvalumab, $\geq$1 response assessment (RECIST1.1), futility rule $\leq$ 8 responses).

Results: By 11/2022, a total of 38 patients were enrolled (n=13 in HYPO, n=25 in CON). In the HYPO-arm, 2 pneumonitis grade $\geq$3 events occurred, resulting in permanent recruitment stop in this arm as per protocol. In the CON-arm, benefit-risk evaluation remained favorable, and the trial continued with recruitment into this arm only. Interim futility analysis was conducted in the CON-arm only and was positive with 11/18 patients achieving tumor response (5 stable, 2 progressive disease).

Conclusions: An increased risk for pneumonitis was found in the HYPO-arm during the safety phase, leading to recruitment stop in this arm and continuation of TRADE-hypo with only the CON-arm. Interim futility analysis for the CON-arm was positive suggesting a benefit for the novel combination of durvalumab and thoracic RT for patients not suitable for CHT. Additional safety, efficacy, and biomarker data are expected for 05/25.

Clinical trial identification: NCT04351256; EudraCT: 2019-002192-33.

Background: The best timing of starting durvalumab after completion of concurrent chemoradiation (CCRT) for patients with unresectable stage III non-small cell lung cancer (NSCLC) has not been identified. The study was conducted to evaluate the efficacy and safety of durvalumab administered immediately after completion of CCRT in patients with unresectable stage III NSCLC.

Methods: This study was a prospective, single-arm, multicenter, phase II clinical trial. Eligible Patients with ECOG PS 0,1, and age $<$ 75 years old were enrolled and received definitive CCRT (2 cycles of platinum-based doublet chemotherapy with 60 Gy/30 Fr radiotherapy) followed by durvalumab (every 2 weeks for up to 12 months) from the next day (up to 5 days) after last radiation. The primary endpoint was 1-year progression-free survival (PFS) rate from registration as assessed by an independent review committee (IRC). Safety, objective response rate, 1-year PFS from start of durvalumab, PFS, 2-year PFS rate, 1-year and 2-year OS, and OS from registration and start of durvalumab were also evaluated. The efficacy according to the PD-L1 expression level was investigated as exploratory analysis. We present the updated final results of safety, efficacy and exploratory analysis.

Results: From January 2020 to August 2020, 50 patients were enrolled from 16 institutions and 47 patients were evaluable for efficacy and safety. Forty-two patients received durvalumab consolidation. PD-L1 expression levels were confirmed in 40 patients (tumor proportion score $\geq$ 50% in 19 patients, 1-49% in 11 patients, and $<$1% in 10 patients). The 1-year PFS rate from registration by IRC was 75.0% (60% CI: 69.0 to 80.0). Median PFS from registration was 20.8 months (95% CI: 14.9 to not reached), 2-year PFS rate was 48.6%, median OS was not reached, and 2-year OS rate was 84.5%. No unexpected adverse events and treatment-related deaths were observed. The 2-year PFS rate and 2-year OS was 40.0% and 80.0% for PD-L1-negative patients.

Conclusions: Our data support the efficacy and safety of durvalumab administered immediately after completion of CCRT for patients with unresectable stage III NSCLC.

1295P Prospective trial of immuno-(chemo)therapy prior to resection, definitive chemo-radiotherapy, or palliative therapy in patients with borderline resectable or oligometastatic non-small cell lung cancer (KOMPASSneo)

M. Faehling[1], K. Lehrach[2], S. Fallscheer[1], B. Schwenk[1], S. Kramberg[1], J. Sträter[3], S. Eschmann[4], M. Hdetzel[5], R. Sätzler[2], F. Heinzelmann[6]

[1]Klinik für Kardiologie und Pneumologie, Klinikum Esslingen, Esslingen am Neckar, Germany; [2]Thoraxchirurgie, Klinikum Esslingen, Esslingen am Neckar, Germany; [3]Lungenpathologie, Institut für Pathologie, Esslingen am Neckar, Germany; [4]MVZ Nuklearmedizin, Marienhospital Stuttgart, Stuttgart, Germany; [5]Pneumologie, Krankenhaus vom Roten Krezz, Stuttgart-Bad Cannstatt, Germany; [6]MVZ Strahlentherapie, Klinikum Esslingen, Esslingen am Neckar, Germany

Background: Recent trials of immuno-(chemo)therapy (IO) prior to resection in locally advanced NSCLC report high rates of pathological response. However, primarily irresectable patients and oligometastatic patients were excluded from most studies. Moreover, there is no data on chemo-radiotherapy (CRT) after immuno-(chemo) therapy in patients who are primarily not amenable to CRT. Induction IO may enable more NSCLC patients to receive curative treatment.

Methods: We enrolled 86 patients with borderline resectable NSCLC including 22 patients with oligometastatic disease into a prospective real-world trial of induction IO followed by morphologic and metabolic reassessment and multidisciplinary board-guided curative treatment (resection [preferred] or CRT) or palliative therapy.

Results: 81 patients (94%) received curative treatment (38 resections, 43 CRT). 21 (55%) of resected patients had a major pathological response including 15 (39%) with pathological complete response. In curatively treated patients, there were 25 recurrences (31%) and 18 tumor-related deaths (22%): 6 recurrences (16%) and 1 death in resected patients, and 19 recurrences (44%) and 17 deaths (40%) in CRT-patients. There were 2 treatment-related deaths (postoperative sepsis, pneumonitis after CRT). The table shows survival of the whole population and oligometastatic patients (median follow-up 19.3 months).

Conclusions: In patients with borderline resectable NSCLC including oligometastatic disease, induction immuno-(chemo)therapy resulted in a high rate of curative treatment with promising survival. Resected patients achieved a high rate of prognostically favorable pathological response. Induction IO should be considered both for patients with stage II − III disease and for patients with oligometastatic disease.

1296P Neoadjuvant camrelizumab and apatinib in patients with resectable non-small-cell lung cancer: One-year update from a phase II trial

W. Guo[1], L. Zhao[1], J. Zhao[1], S. Wang[2], X. Tao[3], L. Li[4], Y. Mao[1], F. Tan[1], Y. Gao[1], N. Wu[3], J. Ying[4], Q. Xue[1], N. Li[2], S. Gao[1], J. He[1]

[1]Department of Thoracic Surgery, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China; [2]GCP Center, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China; [3]PET-CT Center, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China; [4]Department of Pathology, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China

Background: Our phase 2 trial was the first to report the efficacy and safety of neoadjuvant chemo-free regimen with camrelizumab and apatinib in patients with resectable non-small-cell lung cancer (NSCLC), showing promising pathologic responses and manageable toxicity. Here, we aimed to report 1-year event-free survival (EFS) and updated safety data from the above trial.

Methods: Treatment-naïve patients with histologically confirmed resectable stage IIA-IIIB NSCLC (stage IIIB, T3N2 only) and ECOG performance status of 0 or 1 received three cycles of camrelizumab (200 mg, i.v., q2w) and apatinib (250 mg, orally, qd, for 5 days followed by 2 days off), followed by surgery after 3-4 weeks. This analysis including EFS (a prespecified secondary endpoint) and updated safety was performed after an extended follow-up from the preliminary analysis.

Results: Between November 9, 2020 and February 16, 2022, 78 patients were enrolled and treated. With a median follow-up of 19.4 months (95% CI 18.0-20.5), the median EFS was not reached (95% CI 23.2-not reached). The 6- and 12-month EFS rates were 89.4% (95% CI 79.8-94.5) and 82.3% (95% CI 71.4-89.3), respectively. The EFS rates at 6 months and 12 months in the subgroups are presented in the Table. Seventy-one (91.0%) of the 78 patients experienced at least one treatment-related adverse event (TRAE) of any grade, of which

Table: 1295P

Definitive Treatment	n	PFS				OS			
		Median (months)	HR	CI	p	Median (months)	HR	CI	p
Whole population	**86**								
Curative	81	30.4	0.0001 (vs. palliative)	0.00002 to 0.0002	<0.0001	43.3	0.13 (vs. palliative)	0.018 to 0.95	0.045

1297P An open-label, prospective phase II study of tislelizumab in combination with chidamide as consolidation therapy in locally advanced, unresectable, stage III NSCLC

Y. Hu, F. Zhang, T. Li, Z. Hu, X. Han, Z. Ma, L. Wang, H. Tao

Department of Medical Oncology, Chinese PLA General Hospital (301 Military Hospital), Beijing, China

Background: The PACIFIC trial established consolidation therapy with PD-L1 inhibitor as standard of care for patients with unresectable, stage III NSCLC and no disease progression after definitive chemoradiotherapy (CRT). PD-1 antibodies may synergize with HDAC inhibitors by inducing and activating NK cell and cytotoxic T cell (CTL) -mediated cellular immunity in previous studies. It is worth exploring new regimens to further improve survival for this population.

Methods: This was an open-label, prospective study. Patients with histologically or cytologically documented stageIII,locally advanced, unresectable NSCLC without progression following definitive platinum-based concurrent chemoradiation therapy (2～4 cycles) were enrolled. After cCRT, patients received Tislelizumab 200 mg Q3W intravenously and Chidamide 30 mg twice weekly orally. The primary endpoint was safety. Secondary endpoints include 6-month and 12-month PFS rates、OS and ORR. Tumor response was assessed using RECIST V1.1.

Results: At the data cut-off April 22, 2023(median follow-up time, 23.6m), 19 patients were enrolled, mean-aged was 66.3 years (range: 53-78). Patients received combination consolidation therapy for a median of 6.37 months. Adverse events of any cause and grade occurred in 68.4% (13). 3 patients (16.7%) had Grade≥3 TRAEs. The most common Grade≥ 3 TRAEs were pneumonitis (10.5%). The confirmed ORR was 84.2% (95%CI:60.4%-96.60%). The DCR was 100%. Median PFS was 20.5 months (95% CI: 4.37m-NA), and 6-month and 12-month PFS rate were 65.7% (95%CI:38.8%-83.0%) and 58.4% (95%CI:31.5%-77.8%), respectively.

Conclusions: Tislelizumab combined with Chidamide showed encouraging antitumor activity and a favorable safety profile as consolidation therapy for locally advanced, unresectable stage III NSCLC. Further sample and longer follow-up are required to obtain more accurate results.

Table: 1297P Incidence of TRAEs

TRAEs (N=19)	Any Grade, n (%)	≥Grade 3, n(%)
Pneumonitis	7 (36.8%)	2 (10.5%)
Liver injury	5 (26.3%)	0
Nausea/emesis	5 (26.3%)	0
Alopecia	4 (21.1%)	0
Hypothyroidism	2 (10.5%)	0
Myelosuppression	2 (10.5%)	0
Hepatitis	1 (5.3%)	1 (5.4%)
Myocarditis	1 (5.3%)	1 (5.4%)
Neurotoxicity	1 (5.3%)	1 (5.4%)

Maria della Misericordia, Udine, Italy; [2]Pulmonary Diseases Department, Maastricht University Medical Center (MUMC), Maastricht, Netherlands; [3]Radiation Oncology, UMCG - University Medical Center Groningen, Groningen, Netherlands; [4]Department of Radiation Oncology (MAASTRO), Maastro Clinic, Maastricht, Netherlands; [5]Department of Radiation Oncology, ASU FC - Azienda Sanitaria Universitaria Friuli Centrale, Udine, Italy; [6]Pulmonary Diseases, Zuyderland Medical Center, Heerlen, Netherlands; [7]Department of Medical Physics, ASU FC - Azienda Sanitaria Universitaria Friuli Centrale, Udine, Italy

Background: Concurrent chemo-radiotherapy (CCRT) followed by adjuvant Durvalumab (D) is standard of care for fit patients (pts) with unresectable stage III NSCLC. We aimed to assess whether intensity modulated proton therapy (IMPT), compared to intensity modulated photon therapy (IMRT), can reduce hematological toxicity and whether it affects D treatment.

Methods: Retrospective data completion and analysis of a 4-center prospectively collected series of pts with stage III NSCLC receiving CCRT between 06.16-12.22, staged with FDG-PET-CT and brain imaging. Main exclusion criteria: previous cancer diagnosis and thoracic RT.

Results: 271 pts were enrolled (IMPT: n=71, IMRT: n=200). All pts received platinum-based chemotherapy (CT). Median age: 66 years, 36% had a squamous NSCLC, 41% had stage IIIA NSCLC, 89% had a WHO Performance Status (PS)=0/1, 65% had PDL-1 positive and 76% received q21 CT (no differences between IMPT and IMRT). The incidence of lymphopenia grade≥3 (G≥3) was 66.7% and 47% in the IMRT and IMPT arm respectively (p=0.032, OR 2.2, 95% CI: 1.03-4.9). In a multivariable logistic model including WHO PS, type and schedule of CT, age and gross tumor volume, IMRT remained significantly associated with higher risk of lymphopenia G≥3 (adjusted OR=2.6, 95% CI: 1.1-6.2, p=0.029). The incidence of anemia G≥3 during CCRT in the IMRT and IMPT arm was 26% and 8.5% respectively (adjusted OR=4.9, 95% CI: 1.9-12.6, p=0.001). Spearman's correlation coefficient between anemia G≥3 and body mean dose (BMD) was 0.052 (p=0.001). IMPT significantly reduced BMD compared to IMRT (p=0.04). IMPT was associated with a lower rate of PS≥2 at day 21 and 42 after CCRT (13.4% vs. 26%, p=0.039, OR 0.44 and 24% vs. 39%, p=0.024, OR 0.49, respectively). Pts treated with IMPT had higher probability of receiving adjuvant D (74% vs 52%, adjusted OR 0.35, 95% CI: 0.16-0.79, p=0.012). In the multivariable logistic model (including age and PS) IMPT was the only predictive factor for receiving D within 42 days (72% vs 51%, adjusted OR 0.4, 95% CI: 0.16-0.95, p=0.04).

Conclusions: IMPT can reduce severe lymphopenia and anemia in pts with unresectable stage III NSCLC. Pts treated with IMPT have a better PS after CCRT and they are more likely to receive adjuvant durvalumab.

1299P The role of radiotherapy in extensive-stage small cell lung cancer after durvalumab-based immunochemotherapy: A retrospective study

L. Chen[1], F. Tong[1], Y. Kong[2], R. Zhang[1], P. Ding[1], S. Zhang[1], Y. Wang[1], R. Zhou[1], X. Pu[2], B. Chen[2], F. Liang[3], Q. Tan[1], Y. Xu[4], L. Wu[2], X. Dong[1]

[1]Thoracic Oncology Department, Cancer Center, Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, China; [2]Department of Thoracic Medical Oncology, Hunan Cancer Hospital, Changsha, China; [3]Department of Biostatistics, Zhongshan Hospital affiliated to Fudan University, Shanghai, China; [4]Chemoradiotherapy Department, Zhongnan Hospital Wuhan University, Wuhan, China

Background: The purpose of this study was to evaluate the safety and efficacy of subsequent radiotherapy after first-line durvalumab plus chemotherapy in extensive-stage small cell lung cancer (ES-SCLC).

Methods: A total of 122 patients with ES-SCLC from three hospitals during July 2019 to December 2021 were retrospectively analyzed. Inverse probability of treatment weighting (IPTW) analysis was performed to address potential confounding factors. We primarily evaluated the progression-free survival (PFS) and overall survival (OS) in association with radiotherapy.

Results: After IPTW analysis, 49 patients received durvalumab plus chemotherapy with subsequent radiotherapy (Durva+EP+RT) and 72 patients received immunochemotherapy (Durva+EP). The median OS was 17.2 *vs* 12.3 months (hazard ratio (HR): 0.38; P=0.020), respectively, and the median PFS was 8.9 *vs* 5.9 months (HR: 0.56; P=0.030), respectively. Thoracic radiation therapy (TRT) resulted in longer OS (17.2 *vs* 14.7 months) and PFS (9.1 *vs* 7.2 months) compared to radiotherapy directed to other metastatic sites. Among patients with oligo-metastasis, radiotherapy also showed significant benefits, with a median OS of 17.4 *vs* 13.7 months and median PFS of 9.8 *vs* 5.9 months compared to no radiotherapy. Continuous durvalumab treatment beyond progression (TBP) prolonged OS compared to patients without TBP, in both the Durva+EP+RT (NA *vs* 15.8 months, HR: 0.48) and Durva+EP groups (12.3 *vs* 4.3 months, HR: 0.29). Grade 3 or 4 adverse events occurred in 13 (26.5%) and 13 (18.1%) patients, respectively, in the two groups; pneumonitis was mostly low-grade.

Conclusions: Addition of radiotherapy after first-line immunochemotherapy significantly improved survival outcomes with manageable toxicity in ES-SCLC.

Kliniken Essen-Mitte gGmbH, Essen, Germany; [3]Dept. of Internal Medicine 3, Klinikum Nuernberg Nord, Nürnberg, Germany; [4]Department of Medical Oncology, University Hospital Essen Westdeutsches Tumorzentrum, Essen, Germany; [5]Pulmonology Dept., University Hospital Ulm, Ulm, Germany; [6]Department of Hematology and Oncology, Universitätsklinikum Frankfurt (Johannes-Wolfgang Goethe-Universität), Frankfurt am Main, Germany; [7]Department of Hematology and Clinical Oncology, Universitätsmedizin Göttingen, Goettingen, Germany; [8]Department of Internal Medicine II, Hospital Martha-Maria Halle-Doelau, Halle, Germany; [9]Department of Thoracic Oncology, Franziskus-Hospital Harderberg - Niels-Stensen-Kliniken GmbH, Georgsmarienhütte, Germany; [10]Department of Infectious Diseases and Pneumonology, Universitätsklinik Charité - Campus Virchow Klinikum, Berlin, Germany

Background: Despite recent advances in treatment of locally advanced non-small cell lung cancer (NSCLC) most patients suffer from relapse following treatment with chemoradiotherapy and consolidative Durvalumab. To date, no treatment standards have yet been established in current guidelines. As well, there is a paucity of data regarding effectiveness of different treatment options in relapsed/refractory (r/r) NSCLC. Here, we present preliminary data on treatment and outcome of r/r NSCLC patients in a real word setting.

Methods: So far, in this analysis we assessed patients from 10 German lung cancer centers undergoing treatment for r/r NSCLC between 06/2017 and 05/2023. Primarily, overall survival (OS) and progression-free survival (PFS) was estimated in this cohort and compared to historical outcomes. In addition, both different treatment options and OS/PFS were compared between subgroups. Last follow up will be assessed by June 30, 2023.

Results: N = 122 patients were retrospectively evaluated. Median OS from initial lung cancer diagnosis was 25.8 months (20.6 − 30.9) for the entire patient cohort. Following diagnosis of r/r disease median OS and PFS was 11.7 months (9.2 − 14.2) and 6.4 months (5.2 − 7.6), respectively. In relation to all patients undergoing systemic therapy as first -line treatment (70.5%), choice of systemic agents varied, with checkpoint inhibitors (with or without chemotherapy, 34.9%) most commonly administered, followed by platinum- (30.2%) or single agent-based chemotherapy (27.9%) and targeted therapies (7.0%). Interestingly, patients treated with targeted therapy or checkpoint inhibitor-based therapy benefited in terms of overall survival compared with patients who received chemotherapy alone.

Conclusions: Patients suffering from r/r disease represent a distinct patient population showing a dismal prognosis. However, choice of first-line therapy might affect overall survival. Besides improving early detection of NSCLC recurrence prospective clinical trials are warranted to further guide treatment.

1301P A prognostic clinical and circulating biomarker model to identify futile chemo-radiotherapy (CRT) in stage III NSCLC

R.D.W. Vaes[1], L. Hendriks[2], R. Houben[1], J. Degens[3], F. Cortiula[4], D. De Ruysscher[1]

[1]Department of Radiation Oncology (MAASTRO), Maastro Clinic, Maastricht, Netherlands; [2]Department of Pulmonary Diseases, Maastricht University Medical Center (MUMC), Maastricht, Netherlands; [3]Department of Pulmonary Diseases, Zuyderland Medical Center, Geleen, Netherlands; [4]Department of Medical Oncology, University Hospital of Udine, Udine, Italy

Background: CRT followed by adjuvant Durvalumab (D) is standard of care for fit patients (pts) with unresectable stage III NSCLC. However, most pts will not benefit from the CRT part of the treatment. We aimed to build a prognostic model to identify pts who may not benefit from CRT without D.

Methods: Pts with stage III NSCLC treated with curative intent CRT (platinum-doubled and chest RT to a dose of 60-66 Gy) were identified from the prospective biobank project (2003-2019; NCT01084785). No pts received immunotherapy or targeted agents, neither in the primary treatment, nor for recurrence. Clinical parameters included age, sex, performance status (PS), stage (UICC 8), BMI; circulating biomarkers were GM-CSF, IFNα2a, IFNγ, IL-10, IL-12p70, IL-1β, IL-2, IL-6, IL-8, TNF-α, IFNβ, IL-1α, IP10, MCP1, PD-L1. Cut-off points were based on maximum Log-Rank statistic (with correction for multiple testing). Overall survival (OS) was calculated from start of RT. Significance level alpha was set at 0.05.

Results: 342 pts were included: mean age 64.7 ± 9.4 yrs; 62.3 % male; PS 0: 36.3 %, 1: 50.8 %, 2 or more: 12.9 %; stage: IIIA: 42.7 %; IIIB: 45.0 %, IIIC: 12.3 %. Median follow-up was >10 years. Median OS was 1.8 years (95 % CI 1.46-2.20), the 1-, 2- and 5-year OS 65.8 %, 48.5 % and 27.5 %. In multivariate analysis, higher age (p=0.003), male gender (p=0.043), PS 2 or higher (p=0.036), stage IIIB (p=0.003) or stage IIIC (p<0.001), higher IL6 (p<0.001) and higher circulating PD-L1 (p=0.001) were significant for poorer OS. The best cut-offs for IL-6 and PD-L1 were 3.39 pg/ml and 155.52 pg/ml, respectively. The multivariate prognostic model had an AUC = 0.78 (95 % CI 0.73-0.84) for 1-year OS and 0.76 (0.71-0.81) for 2-year OS. Pts in the best prognostic group (below threshold for IL6 and PD-L1; 34.4 % of total) had a median OS of 44 months, in the intermediate group (above threshold for one biomarker; 41.8 % of total) a median OS of 20 months and in the worst group (both markers above threshold; 23.6 % of total) a median OS of 8 months.

Conclusions: This easy to apply multivariate model for OS, which includes IL6 and circulating PD-L1, may identify pts with a poor OS after standard CRT without immunotherapy. These pts may benefit from alternative treatments without platinum-based chemotherapy and RT.

Background: In locally advanced non-small cell lung cancer (LA-NSCLC), durvalumab as consolidation therapy following definitive chemoradiotherapy (CRT) was established as the standard of care. Given the heterogeneity of patients with LA-NSCLC, the present study evaluated the efficacy and safety of durvalumab in a real-world, multi-center observational study.

Methods: 111 patients with LA-NSCLC, whose disease had not progressed following CRT and receiving ≥1 dose of durvalumab as part of the expanded access program (EAP) in Thailand and outside EAP were included. In addition to descriptive statistics, the survival probability was determined using the Kaplan-Meier method.

Results: A total of 78 patients from 12 centers participating in the Thailand National Lung Cancer Registry Network were enrolled. The median age was 63 years, 73% were men, 73% had non-squamous and 21.6% of patients with non-squamous histology had epidermal growth factor receptor mutation (EGFRm). Only 14% of patients had been tested for programmed death-ligand 1 (PD-L1) and 54.5% had PD-L1 expression. Most patients (89%) received concurrent CRT and carboplatin/paclitaxel was the most common chemotherapy used. 91.2% received a RT dose ≥60 Gy with a median time of durvalumab initiation from the end of RT being 42 days. Overall, 46 patients (59%) completed the 12-month treatment with a median of 24 cycles. Median follow-up time was 34.5 months (range 7—58) with 2-year PFS and OS of 64.2% and 83.3%, respectively. No significant differences in PFS were detected for EGFRm vs. wild-type *EGFR* (EGFRwt), but the median PFS was 39 months for EGFRm vs. 27 months for EGFRwt. Immune-related AEs (irAEs) of any grades and grade ≥3 were reported in 41% and 10.3%, respectively. Pneumonitis was the most frequent irAEs (18%), and 6.4% were grade ≥3, leading to discontinuation in 6/78 patients (7.7%).

Conclusions: Durvalumab after definitive CRT showed a promising outcome and was well-tolerated in this real-world study. Although a high prevalence of EGFRm is noted in this region, favorable PFS outcomes were observed regardless of *EGFR* mutation status.

1303P Immune-modulating effects on tumor draining lymph nodes following neoadjuvant chemoradiotherapy combined with immunotherapy in patients with T3-4N0-1 NSCLC

E.B. Ulas[1], A. Vrijmoet[2], S. Koomen[3], I. Houda[1], C. Dickhoff[4], I. Bahce[1], S. Senan[5], T.D. de Gruijl[6], M. Fransen[1], F. van Maldegem[3], T. Radonic[2], F. Schneiders[5]

[1]Department of Pulmonary Medicine, Amsterdam UMC - Vrije University Medical Centre (VUmc), Amsterdam, Netherlands; [2]Department of Pathology, Amsterdam UMC - Vrije University Medical Centre (VUmc), Amsterdam, Netherlands; [3]Department of Molecular Cell Biology and Immunology, Amsterdam UMC - Vrije University Medical Centre (VUmc), Amsterdam, Netherlands; [4]Department of Cardiothoracic Surgery, Amsterdam UMC - Vrije University Medical Centre (VUmc), Amsterdam, Netherlands; [5]Department of Radiation Oncology, Amsterdam UMC - Vrije University Medical Centre (VUmc), Amsterdam, Netherlands; [6]Department of Medical Oncology, Amsterdam UMC - Vrije University Medical Centre (VUmc), Amsterdam, Netherlands

Background: The addition of neoadjuvant immunotherapy to chemoradiotherapy (CRT) prior to surgical resection was investigated in locally advanced non-small cell lung cancer (NSCLC) patients (INCREASE trial, NTR-NL8435). Tumor-draining lymph nodes (TDLN) play a key role in the immune response against tumors and are often part of the healthy surrounding tissue exposed to radiotherapy. This study investigated the immune-modulating effects of neoadjuvant immunotherapy and CRT on TDLN in T3-4N0-1 NSCLC patients.

Methods: Resected TDLN were collected from: (i) participants in the INCREASE trial who received neoadjuvant ipilimumab/nivolumab combined with CRT (n=25), and (ii) a control cohort of matched NSCLC patients treated with standard CRT induction therapy (n=25). TDLN were selected based on radiation dose received [low (<5 Gy), intermediate (20-30 Gy) or high dose (50-60 Gy)] and stained with duplex immunohistochemistry for CD8/Ki67, PD1/FOXP3 and CD8/cleaved caspase-3. Hotspot areas were then manually analyzed.

Results: Higher counts of proliferating CD8 T-cells were observed within TDLN in all three categories of radiation exposure in the INCREASE cohort compared to control patients (p=<0.0001, p=0.02, p=<0.0001 for low, intermediate and high dose), as well as higher counts of activated PD-1+ Tregs (p=<0.0001 for all nodes). Furthermore, higher numbers of Ki67+ CD8 T-cells and PD-1+ Tregs were observed with increasing radiation dose (INCREASE high-dose vs low-dose, p=0.0095 for CD8 T-cells and p=0.0298 for Tregs). No relationship was observed between radiation dose exposure and the induction of apoptosis by cleaved caspase-3 in CD8 T-cells.

Conclusions: Higher rates of proliferating CD8 T cells and activated PD-1+ Tregs in TDLN were seen when immunotherapy was added to induction CRT in T3-4N0-1 NSCLC patients, suggesting the enhanced priming of effector CD8 T-cells, accompanied by a simultaneous increase in Tregs. High radiation dose led to an increase of CD8 T-cells and Tregs in the INCREASE cohort. Further analyses with spatial transcriptomics and quantitative pathology imaging is needed to reveal spatial positioning of PD-1+ Tregs in relation to proliferating CD8 T-cells.

1304P A structured multidisciplinary approach for diagnosing immune-related pneumonitis in patients undergoing adjuvant durvalumab for stage III non-small cell lung cancer

I. Smesseim[1], O. Mets[2], H.M.A. Daniels[3], I. Bahce[4], S. Senan[5]

[1]Thoracic Oncology, NKI-AVL - Netherlands Cancer Institute/Antoni van Leeuwenhoek Hospital, Amsterdam, Netherlands; [2]Radiology, Amsterdam UMC - Vrije University Medical Centre (VUmc), Amsterdam, Netherlands; [3]Pulmonary Medicine, Amsterdam UMC - Vrije University Medical Centre (VUmc), Amsterdam, Netherlands; [4]Pulmonary Diseases Dept, Amsterdam UMC - Vrije University Medical Centre (VUmc), Amsterdam, Netherlands; [5]Radiation Oncology Department PK-1, Amsterdam UMC - Vrije University Medical Centre (VUmc), Amsterdam, Netherlands

Background: In inoperable stage III NSCLC, the standard of care is chemoradiotherapy and adjuvant durvalumab (IO) for 12 months. Pneumonitis is the commonest toxicity leading to IO discontinuation. Failure to distinguish between radiation-induced changes, IO pneumonitis and infection can lead to unnecessary IO discontinuation. We investigated use of a structured multidisciplinary review of CT-scans, radiation dose distributions and clinical symptoms for the diagnosis of IO pneumonitis.

Methods: An ethics-approved retrospective study was conducted at an academic medical center for stage III NSCLC patients treated with chemoradiotherapy and adjuvant IO between 2018-2021. A thoracic radiologist reviewed baseline and follow-up chest CT-scans, systematically scored radiological features suspected for pneumonitis using a published classification system (Veiga C, Radioth Onc 2018), and had access to the radiation dose distributions. Next, two thoracic oncologists reviewed each patients' case record, CT-scans and radiation fields. A final consensus diagnosis incorporating views of expert clinicians and the radiologist was made. IO pneumonitis was diagnosed only when both the radiologist and pulmonologists were in agreement.

Results: Among the 45 included patients, 14/45 (31.1%) had a pneumonitis scored in patient records. IO was discontinued in 11/45 cases (24.4%). Review by the radiologist led to a diagnosis of IO pneumonitis only in 6/45 patients (13.3%). Review by thoracic oncologists led to a diagnosis of IO pneumonitis in only 4/45 patients (8.9%). In addition, a suspicion of an immune-related pneumonitis was rejected in 3 separate patients (6.7%), after the thoracic oncologists had reviewed the patient's radiation fields.

Conclusions: In patients treated using the PACIFIC regimen, multidisciplinary assessment of CT-scans, radiation doses and patient symptoms, resulted in fewer diagnoses of immune-related pneumonitis (8.9%). In contrast, routine clinical assessment by treating pulmonary oncologists led to discontinuation of IO in 24.4% of patients. This highlights the need for multidisciplinary review in order to avoid inappropriate cessation of adjuvant IO.

Clinical trial identification: IRB00002991.

Background: For patients who show downstaging of lung cancer following targeted therapy, salvage surgery can be considered. Resection of regrowing pulmonary masses can also be performed to acquire a tumor specimen. The aim of this study is to evaluate the prognosis of patients who have undergone prior tyrosine kinase inhibitor (TKI) treatment and later lung surgery.

Methods: The deidentified data of NSCLC patients admitted to eight university hospitals affiliated with the Catholic University of Korea were obtained from the Clinical Data Warehouse (CDW) database. Forty patients who had prior targeted therapies and later received surgical resection were evaluated for the study. The primary endpoint was overall survival, defined as the time between surgical resection and death or censoring. The secondary endpoint was postoperative progression-free survival.

Results: Of 40 patients diagnosed with adenocarcinoma. 36 (87.8%) received prior EGFR TKI treatment, while 4 (9.8%) received ALK TKI treatment. At the time of TKI initiation, 31 (77.5%) were staged as IV, and 9 (22.5%) were staged as III. Salvage surgery was performed in 18 patients (45.0%), and 22 (55.0%) underwent resection for biopsy purposes. At the time of resection, tumor burden was unchanged in 7 patients (17.5%), significantly regressing in 12 patients (30.0%), and increasing in 21 patients (52.5%). Among the 28 patients with EGFR mutations from resected tumor specimens, 9 (32.1%) exhibited the T790M mutation. Next-generation sequencing of the resected samples identified mutations such as MET amplification and TP53. Only one postoperative complication, atrial fibrillation, was observed. Patients with poor preoperative ECOG (Eastern Cooperative Oncology Group) scores had significantly worse 1-year and 2-year survival rates (P=0.014 and P=0.011, respectively). There was a significant difference in 6-month PFS rates between groups stratified by pleural invasion levels (PL0-3) (P=0.029). Furthermore, patients with T790M mutation showed a trend towards improved PFS (P=0.052).

Conclusions: Lung surgery following targeted therapies is safe and can be used to predict the prognosis of patients with initially unresectable NSCLC.

1307P The Biocartis Idylla GeneFusion Assay (RUO) for lung cancer testing: The experience of testing over 5000 tumours in routine practice

L. Robertson[1], P. Taniere[2], M. Smith[2], M. Lockwood[2], K. Charles[2], A. Iqbal[2], B. O'Sullivan[2], S. Diaz-Cano[2]

[1]Molecular Pathology, Queen Elizabeth Hospital - University Hospitals Birmingham NHS Foundation Trust, Birmingham, UK; [2]Molecular Pathology Diagnostic Service, Queen Elizabeth Hospital - University Hospitals Birmingham NHS Foundation Trust, Birmingham, UK

Background: Lung non-small cell carcinoma molecular profiling is challenging due to the number of alterations to assess, the small size of the samples and the quick turnaround required in order to offer patients the optimal treatment. We implemented the Biocartis Idylla™ GeneFusion Assay (RUO) two years ago for ALK, ROS1, RET and MET exon 14 testing. The assay is designed to specifically target 17 fusions variants in ALK, 13 in ROS1 and 7 in RET gene. This provides specific detection of 93% of ALK, 98% of ROS1 and 85% of RET fusion events as reported on COSMIC. We report on our experience on over 5000 cases tested over 2 years.

Methods: We prospectively tested lung cancer samples on the Idylla™ Platform as part of routine lung profiling locally and from over 60 UK hospitals. Tissue requirements were 1 - 3 x 5 µm sections; tumour burden was assessed on an HE stain prior to running the assay to ensure minimum 10% tumour content. Sections are loaded into the Idylla™ Cartridge; run time 180 mins; interpretation is via automated analysis using pre-defined cut offs within the Idylla™ software. Fusions (ALK, ROS1, RET) and MET ex 14 rearrangement are called with corresponding Cq values alongside internal DNA and RNA controls. Manual interrogation of the amplification curves is possible through the Idylla™ Explore software, if required.

Results: We have tested over 5000 tumours so far.

Table: 1307P Rate of positivity (ROP) and rate of failure (ROF) for GeneFusion assay

TEST	DETECTED	NOT DETECTED	INVALID	TOTALS	ROP (%)	ROF (%)
ALK Specific	66	4803	410	5394	1.3	7.6
ROS Specific	18	4845		5394	0.4	
RET Specific	24	4843		5394	0.5	
GEN - MET exon 14	106	4759		5394	2.1	

Conclusions: Our data shows a level of detection of ALK, ROS1, RET, MET exon14 as expected from published data. We had almost 100% of concordance with ALK and

ROS1 immunostaining. Test failure was due to either poor quality of RNA or insufficient material to pass QC metrics. More importantly, the assay allows testing to be successfully completed in samples unsuitable for NGS due to low tumour burden. In conclusion, the Idylla™ GeneFusion Assay offers a rapid, sensitive and specific method for lung sample profiling in routine practice.

1308P Diameter threshold for lung nodules at low-dose CT screening: Chinese population screening experience

Y. Wenjun[1], W. Fu[2], C.C. Li[3], W. Liang[4], J. He[5]

[1]Oncology, Guangzhou Medical University, Guangzhou, China; [2]Thoracic Surgery and Oncology, National Center for Respiratory Medicine, Guangzhou, China; [3]Thoracic Oncology Dept., Guangzhou Medical University, Guangzhou, China; [4]Thoracic Oncology, The First Affiliated Hospital of Guangzhou Medical University, Guangzhou, China; [5]Thoracic Surgery and Oncology, The First Affiliated Hospital of Guangzhou Medical University, Guangzhou, China

Background: High false positive rates in LDCT screening are an important concern. The study aims to explore the diagnostic performance of different diameter thresholds for various lung nodules to reduce unnecessary follow-up LDCT scans and the waste of medical resources.

Methods: Participants were recruited from the "Guangzhou Lung-Care Project" at the First Affiliated Hospital of Guangzhou Medical University in China between 2017 and 2021. The average transverse diameter of lung nodules was measured by semi-automatic segmentation. Positive outcomes were divided into two groups: outcome 1-lung cancer diagnosis with AAH/AIS, and outcome 2-lung cancer diagnosis without AAH/AIS. We calculated the area under the receiver-operating characteristic curves (AUCs), sensitivity, specificity, positive prediction rate(ppv) and negative prediction rate (NPV) to evaluate the diagnostic performance of lung cancer under each threshold between 5mm to 10mm.

Results: In the first year after LDCT screening, 126 cases of lung cancer (including 13 cases of AAH/AIS) were diagnosed among the participants of 11,705 (5,425 men and 6,280 women; median age 59). Increase the average transverse diameter threshold from 5 to 7mm in all lung nodules (solid, part-solid, non-solid), and gradually increase the AUC in outcome 1 (0.766 to 0.825) and outcome 2 (0.78 to 0.839). From 7 to 10mm, the AUC in outcome 1 (0.825 to 0.764) and outcome 2 (0.839 to 0.778) is gradually reduced. In the outcome 2, when the diameter threshold was increased from 5mm to 8mm, the specificity (60.06% to 90.82%) and ppv (6.57% to 19.02%) increased significantly, the sensitivity was reduced (94.02% to 76.07%). When the diameter threshold was increased from 8mm to 10mm, the sensitivity was significantly reduced (76.07% to 60.68%) and specificity (90.82% to 94.88%) and ppv (19.02% to 25.13%) increased slightly. There is no obvious difference between outcome 1 and outcome 2 in the above indicators.

Conclusions: Our study demonstrates that setting a diameter threshold of 8mm for LDCT screening of lung nodules achieves better overall diagnostic performance, reducing false positives and unnecessary follow-up scans while minimizing medical resource waste.

1309P Immune exhaustion in tumor-free lymph nodes of non-small cell lung cancer (NSCLC) patients is associated with performance status and survival

L. Sellmer[1], A. Bogler[1], J. Kovacs[2], J. Walter[1], R. Kiefl[1], D. Kauffmann-Guerrero[1], T.A. Bolt[1], C. Schneider[2], A. Tufman[1]

[1]Respiratory Medicine and Thoracic Oncology, LMU Klinikum der Universität München, Munich, Germany; [2]Thoracic Surgery, LMU Klinikum der Universität München, Munich, Germany

Background: Tumor-draining lymph nodes are crucial in initiation and maintenance of antitumoral immune activity. Immune cell exhaustion in these lymph nodes is associated with low therapeutic efficacy and poor prognosis. The effect of different markers of immune exhaustion on patients' performance status and survival is not yet fully understood.

Methods: Expression profiling of 770 immune-related genes in N1 and N2 tumor-free lymph nodes was performed using the PanCancer IO 360 panel by NanoString Technologies. We analysed the association between immune exhaustion data and performance status and survival using Student's t-test and Cox regression.

Results: We performed immune transcriptomics on tumor-free lymph nodes of 16 stage II/III NSCLC patients. Patients with worse performance status (ECOG 1/2 vs. 0) showed increased levels of immune dysfunction as measure by increased Tumor Immune Dysfunction and Exclusion (TIDE) scores ($p=0.05$). In particular, ECOG score was associated with increased levels of immune exhaustion marker IDO1 ($p=0.02$). IDO1 ($HR= 1.003$, $p=0.02$) and LGALS9 ($HR= 1.011$, $p=0.001$) expression in N1 and expression of CD276 ($HR= 1.005$, $p=0.01$) in N2 lymph nodes were associated with worse survival.

Conclusions: Our data confirm the relevance of immunological exhaustion in lymphatic tissues of NSCLC patients. Increased IDO1 expression is associated with higher ECOG score and worse survival and needs to be further investigated.

Background: Tumor-associated inflammation suggests that anti-inflammatory medication could be beneficial in cancer therapy. Loratadine, an antihistamine, has demonstrated improved survival in certain cancers. This study investigates loratadine's anticancer mechanisms in lung cancer. Tumor-associated inflammation suggests that anti-inflammatory medication could be beneficial in cancer therapy. Loratadine, an antihistamine, has demonstrated improved survival in certain cancers. This study investigates loratadine's anticancer mechanisms in lung cancer.

Methods: A retrospective cohort of 4,522 lung cancer patients from 2006 to 2018 was analyzed to identify non-cancer drug exposures associated with prognosis. Cellular experiments, animal models, and RNAseq data analysis were employed to validate findings and explore the antitumor effects of loratadine.

Results: The retrospective study revealed a positive association between loratadine use and improved lung cancer survival. Cellular assays showed that moderate loratadine doses induced apoptosis, cellular senescence, and reduced epithelial-mesenchymal transition (EMT). Interestingly, high loratadine doses triggered pyroptosis and interacted with apoptosis through caspase-8. Animal models indicated that loratadine impeded tumor growth in C57BL/6 mice but not in nude mice xenografts, suggesting potential immune response involvement in apoptosis and pyroptosis.

Conclusions: Loratadine use is linked to enhanced survival in lung cancer patients, potentially due to its role in modulating cell death, inflammatory, and immune responses by regulating the interplay between apoptosis and pyroptosis via caspase-8. Further research on other antihistamines and their immune response to tumors is warranted.

1311P Understanding the basis for intrinsic resistance to KRASG12C inhibitors

A. Santos Ramos[1], D. Gómez Sánchez[1], P. Plaza Expósito[1], L. Paz-Ares[2], I. Ferrer Sánchez[1]

[1]H12O - CNIO Lung Cancer Unit, Instituto de Investigación Sanitaria Hospital 12 de Octubre (i+12), Madrid, Spain; [2]Medical Oncology Department - Edificio Maternidad, Universidad Compultsense de Madrid, Madrid, Spain

Background: Lung cancer is the leading cause of cancer-related deaths worldwide. KRAS is the most frequent mutated oncogen in lung adenocarcinoma (LUAD), but it has been recognized as undruggable for many years. KRASG12C inhibitors (KRASG12Ci), are being tested in clinical trials and have revealed promising results in LUAD patients. With these results, two KRASG12Ci have been approved for the treatment of LUAD patients by the FDA, which marks the first approved targeted therapy for KRAS-mutated tumors. While these therapies hold great promise, they face the same limitation as other targeted therapies, the therapeutic potential of these inhibitors can be impaired by resistance. Deciphering intrinsic resistance mechanisms to KRASG12Ci is of prime relevance to predict which patients may benefit from these therapies and to propose therapeutic alternatives.

Methods: The efficacy of two different KRASG12Ci was tested in different KRASG12C-mutated models, *in vitro* in a panel of 8 LUAD cell lines and 7 PDX-derived organoids (PDXDO) models and *in vivo* in a panel of 7 patient-derived xenografts (PDX) models. Thus, we define the intrinsic and resistance models, and compare the genomic (WES) and transcriptomic (WTS) data to find a signature that defines the intrinsic resistance to each drug.

Results: Among the 8 LUAD cell lines, we found 3 very sensitive cell lines and 2 intrinsic resistant ones. Among the 7 PDXDO models, we found 4 sensitive models and 3 intrinsic resistant ones. And among the PDX models we found two very sensitive models and two intrinsic resistant ones. These ratios are representative of what was found among patients in clinical trials. Comparative transcriptomic analysis from sensitive and intrinsic resistant models showed different basal levels of expression and/or activation of downstream signaling pathways of KRAS, ARF or PLC and of various receptors such as ERBB, FGFR or IGF-1R.

Conclusions: 1) We found a transcriptomic signature that define the intrinsic resistance, characterized by a greater basal expression and/or activation of some RTKs and signaling pathways. 2) We identificate some molecular alterations which could be responsible of the intrinsic resistance and could acts as predictive biomarkers and/or serve as therapeutic targets in combination with KRASG12Ci.

Background: Eftilagimod alpha (E), a soluble LAG-3 protein, acts as an MHC class II agonist triggering activation of antigen-presenting cells (APC). Subsequently downstream T-cells (e.g. CD4/CD8) are recruited, possibly leading to stronger anti-tumor responses than with pembrolizumab (P) alone, especially in tumors non-overexpressing PD-L1. We hereby report initial overall survival (OS) results of the 1st line non-small cell lung carcinoma (NSCLC) cohort in TACTI-002.

Methods: Patients (pts) with measurable 1st line metastatic NSCLC unselected for PD-L1 were recruited. Primary endpoint (EP) was objective response rate (ORR) by iRECIST. Secondary EPs included OS, ORR by RECIST 1.1, duration of response (DoR), progression free survival (PFS), safety & biomarkers. Pts received 30 mg E SC q2w for 8 cycles (1 cycle= 3 weeks) & then q3w up to 1 yr with P 200 mg IV q3w up to 2 yrs. Imaging was done q9w & assessed by investigator. PD-L1 was centrally assessed (22C3). The study was powered (80%) with a 1-sided alpha of 2.5% to detect an ORR increase from 23% (historical results for P) to 35%.

Results: From Mar 2019-Nov 2021, 114 pts enrolled using modified Simon's two-stage design. Median follow up of 20.4 mo (cut-off Mar 31, 2023). Median age was 67 (44—85) & 74% were male. ECOG PS was 0 & 1 in 37% & 63% of pts. Pts had squamous (35%) or non-squamous (63%) carcinoma. All PD-L1 subgroups were represented; 77.8% had TPS <50%. Pts received median 9 (1—35) P & 13 (1—22) E doses. Median (m) OS unselected for PD-L1 was 22.6 mo (52.6% events) & mDoR was 21.6 mo. Onset of responses was quick (median: 2.1 mo). Comparable results by RECIST 1.1. Efficacy by PD-L1 shown in the table. Safety was presented prior at SITC 2022.

Table: 1312MO

Efficacy parameter	ORR, % [95% CI] by iRECIST	mPFS, mo [95% CI] by iRECIST	mOS, mo [95% CI]
ITT (N=114); PD-L1 unselected	40.4 [31.3—50.0]	6.6 [4.6—9.8]	22.6 [14.9—35.0]
By PD-L1 TPS (N=90)			
≥1% (N=58)	48.3 [35.0—61.8]	11.2 [6.3—16.6]	25.0 [12.1—38.8]
<1% (N=32)	31.3 [16.1—50.0]	4.2 [2.1—6.2]	15.5 [7.4—19.8]
1—49% (N=38)	44.7 [28.6—61.7]	9.3 [4.4—15.7]	23.4 [9.3—35.5]
≥50% (N=20)	55.0 [31.5—76.9]	16.3 [4.0—43.9]	38.8 [8.1—38.8]

Conclusions: E + P shows encouraging OS results in line with excellent ORR, PFS and DOR in 1st line NSCLC overall and in all PD-L1 subgroups. This combination warrants further late-stage clinical investigation.

1313MO Safety and preliminary efficacy of AZD7789, a bispecific antibody targeting PD-1 and TIM-3, in patients (pts) with stage IIIB–IV non-small-cell lung cancer (NSCLC) with previous anti-PD-(L)1 therapy

B. Besse[1], A. Italiano[2], S. Cousin[2], G. Ruiter[3], E. Felip[4], E. Castanon Alvarez[5], S.S. Ramalingam[6], C.D. Rolfo[7], D.R. Spigel[8], D. Andrew[9], S. Cho[10], T. Collins[9], A. Hansen[10], G. Hawkins[9], R. Kurek[9], N. Ceaicovscaia[10], M. Petruzzelli[9], E.J. Dean[9], A. Sacher[11]

Background: AZD7789 is a monovalent, bispecific, humanised IgG1 that blocks PD-1 and T cell immunoglobulin and mucin domain 3 (TIM-3), receptors that regulate antitumour T cell activity and myeloid activation. Dual blockade of PD-1 and TIM-3 may overcome or delay anti-PD-(L)1 resistance. Here we report dose escalation results from a phase 1/2a, first-in-human, multicentre, open-label trial of AZD7789 monotherapy in pts with stage IIIB–IV NSCLC with ≥1 prior line of systemic therapy including ≥1 anti-PD-(L)1 agent.

Methods: Eligible pts were ≥18 yr old with ECOG PS 0–1. Dose cohorts ranged from 2–2000 mg IV Q3W: 2–225 mg in an accelerated titration design, and 750–2000 mg using mTPI-2. The primary objective was safety, including dose-limiting toxicities (DLTs). Secondary/exploratory objectives included efficacy, pharmacokinetics (PK), PD-1 receptor occupancy (RO), and immunogenicity. Data cutoffs were 13 Feb 2023 for safety and 11 Jan 2023 for efficacy.

Results: In total, 39 pts received AZD7789 2–2000 mg; median age 66 yr, 56% male, 36% PD-L1 status <1%, 33% PD-L1 1–49%, and 28% PD-L1 ≥50%, and 80% had acquired resistance to prior anti-PD-(L)1 therapy (≥6 mo of treatment exposure). Treatment emergent AEs (TEAEs) occurred in 82% of pts and were Grade (Gr) ≥3 in 23%. The most common TEAE was increased blood creatinine (18%); no TEAE led to discontinuation. Treatment related AEs (TRAEs) occurred in 41% of pts; the most common was asthenia (8%). There were no DLTs or Gr ≥3 TRAEs. On-treatment scans were available for 19 pts: 7 had stable disease, including 2 with unconfirmed partial responses, 11 had progression, and 1 was not evaluable. Target lesion shrinkage was observed in 8 pts. PK was generally dose proportional, with $t_{½}$ ~7 days; antidrug antibodies had limited impact on PK. Doses ≥225 mg led to durable PD-1 RO >90% on peripheral T cells. As of 13 Feb 2023, 24 pts remained on AZD7789; updated data will be presented.

Conclusions: AZD7789 has manageable safety and shows preliminary efficacy at tolerable doses. Evaluation is ongoing in immunotherapy-naive pts with NSCLC and pts with acquired resistance to immunotherapy.

Clinical trial identification: NCT04931654; June 18, 2021.

Background: Once targeted therapies and platinum-based chemotherapy (PBC) become ineffective in patients (pts) with advanced/metastatic (a/m) NSCLC with AGAs, few treatments with limited benefit are available. Dato-DXd is an antibody-drug conjugate composed of a TROP2 directed monoclonal antibody covalently linked to a highly potent cytotoxic payload via a stable, tumor-selective, tetrapeptide-based cleavable linker. We report primary results from the global, open-label, phase 2 TROPION-Lung05 trial (NCT04484142) evaluating Dato-DXd in pts with a/m NSCLC with AGAs progressing on or after ≥1 AGA-specific therapy and PBC.

Methods: Dato-DXd 6 mg/kg was given every 21 days to pts with a/m NSCLC, ECOG status 0 or 1, and ≥1 documented AGA in *EGFR*, *ALK*, *ROS1*, *NTRK*, *BRAF*, *MET* exon 14 skipping, or *RET*. The primary endpoint was confirmed objective response rate (cORR)

by blinded independent central review (BICR). Secondary endpoints included duration of response (DOR) and disease control rate (DCR) by BICR, and safety.

Results: A total of 137 pts received ≥1 dose and had a median age of 61.0 y; 71.5% had ≥3 prior lines of therapy for a/m NSCLC; 56.9% had *EGFR* mutations. As of 14 Dec 2022, 85.4% discontinued therapy, 63.5% had disease progression, and 49.6% died. Median pt duration on study was 15.2 months (mo); cORR was 35.8%, DCR, 78.8%, and median DOR, 7.0 mo; similar response was seen in pts with *EGFR* mutations (Table). The most common grade ≥3 TEAEs were stomatitis (9.5%), anemia (5.8%), and increased amylase (5.8%).

Table: 1314MO Primary results (N = 137)

Efficacy[a]	
cORR, n (%) (95% CI)	49 (35.8) (27.8-44.4)
Complete response	4 (2.9)
Partial response	45 (32.8)
cORR in pts with *EGFR* mutation	34 (43.6)
DCR, n (%)	108 (78.8)
Median DOR in confirmed responders, months	7.0
Safety, n (%)	
Grade ≥3 TEAEs	65 (47.4)
Serious TEAEs	34 (24.8)
TEAEs associated with:	
Dose reduction	30 (21.9)
Drug discontinuation	13 (9.5)
Death	2 (1.5)[b]
Adjudicated drug-related ILD	
Grade 1/2	4 (2.9)
Grade ≥3	1 (0.7)[c]

[a]By BICR. [b]Two cases associated with disease progression, unrelated to study drug by investigator. [c]One grade 3 reported event, with death due to disease progression by investigator and adjudicated grade 5 ILD.

Conclusions: Dato-DXd showed encouraging antitumor activity, with a clinically meaningful and durable response, in heavily pretreated pts with NSCLC with AGAs. The safety profile was manageable and consistent with prior safety observed with Dato-DXd. These data support inclusion of pts with AGAs in the TROPION-Lung01 study (NCT04656652).

Clinical trial identification: NCT04484142.

Background: *NRG1* fusions are rare oncogenic drivers of NSCLC and other solid tumors. These chimeric proteins bind HER3, leading to HER2/HER3 heterodimerization and oncogenic transformation. Zenocutuzumab (MCLA-128; Zeno) is a bispecific antibody that overcomes HER3-mediated NRG1 signaling in NRG1+ cancer. Zeno is

being evaluated in the ongoing pivotal phase 2 eNRGy study and early access program (EAP). Updated NRG1+ NSCLC data are presented.

Methods: Patients (pts) with advanced NRG1+ NSCLC determined by NGS, previously treated with or not candidate for standard therapy, age $\geq$ 18 y, ECOG PS $\leq$ 2, and measurable (RECIST v1.1) or evaluable disease were enrolled. Zeno (750 mg IV Q2W) was administered until disease progression or unacceptable toxicity. Tumor imaging was conducted Q8W. The primary endpoint is investigator-assessed objective response rate (ORR) per RECIST v1.1. Secondary endpoints include duration of response (DOR) and safety.

Results: As of 01 Feb 2023, 85 pts with NRG1+ NSCLC (78 eNRGy/7 EAP) were enrolled. Efficacy was assessed in 65 pts who received $\geq$ 1 dose of Zeno and were enrolled by 01 Aug 2022 to allow for the opportunity for $\geq$ 6 months (mo) follow-up and met the criteria for the primary efficacy population. The median age was 64 y (range 32-86), 65% were female, 29%/63%/5% pts had ECOG PS 0/1/2 (missing 2 pts). Most were Asian (52%) or White (37%), 77% had visceral metastases, 98% had adenocarcinoma histology, and 1 pt had non-measurable disease. Common fusion partners were *CD74* (52%) and *SLC3A2* (23%). Pts received a median of 2 prior systemic therapies (range 0-6), 78% with platinum-based chemotherapy; 12% were treatment naïve. In the 64 pts with measurable disease, the confirmed ORR was 34% (22/64; 95% CI 23-47). 50/64 (78%) pts had target lesion reduction. Median DOR was 12.9 mo with responses ongoing in 11/22 (50%) pts. Kaplan-Meier estimate of 6-mo DOR rate was 79%. Among 85 pts treated with Zeno, Grade $\geq$ 3 individual AEs irrespective of causality occurred in $<$ 4% pts. No pt discontinued Zeno for a treatment related AE.

Conclusions: In this updated analysis, Zeno provides robust and durable efficacy in advanced NRG1+ NSCLC, with a well-tolerated safety profile.

Clinical trial identification: NCT02912949.

Background: BL-B01D1 is a first-in-class novel antibody drug conjugate (ADC) consisting of an EGFRxHER3 bispecific antibody bounded to a novel TOP-I inhibitor payload via a cleavable linker. We now report updated safety/efficacy results from the NSCLC patients (pts) of the BL-B01D1 phase I study.

Methods: This study enrolled pts with locally advanced or metastatic NSCLC and tested doses of 2.5, 3.0, and 3.5 mg/kg administered on D1D8Q3W, as well as doses of 5.0 and 6.0 mg/kg administered on D1Q3W.

Results: As of Mar 31st, 2023, 114 NSCLC pts who failed standard treatment were enrolled and received at least one dose of BL-B01D1. The most common TRAEs (>10%, all grade/≥ G3) were anemia (59%/25%), leukopenia (59%/28%), neutropenia (51%/32%), thrombocytopenia (48%/23%), nausea (36%/<1%), vomiting (34%/2%), alopecia (27%/0%), decreased appetite (24%/<1%), asthenia (23%/0%), mouth ulceration (21%/0%), diarrhea (20%/<1%), hypophagia (19%/0%), hypokalemia (15%/0%), hypoalbuminemia (12%/0%), rash (11%/0%). No ILD was observed. 88 pts were evaluable for efficacy (at least 1 post-baseline tumor assessment), mPFS for EGFRmut and EGFRwt NSCLC was 6.9 (4.3, ∼) and 5.2 (3.9, ∼) months, respectively, although these results are still considered immature. The study is currently ongoing and further updates regarding DoR, mPFS, and other results will be provided during the meeting.

Table: 1316MO

	NSCLC (EGFRmut) (n=38)[1]	NSCLC (EGFRwt) (n=50)[2]
Median prior treatment line (range)	3 (1-7)	2 (1-8)
Best overall response, n		
PR	24	22
SD	10	25
PD	4	3
ORR[3], % (95% CI)	63.2% (46.0-78.2)	44.0%(30.0-58.7)
DCR, % (95% CI)	89.5% (75.2-97.1)	94.0% (83.5-98.8)

[1]All had prior EGFR TKI, 89% (34/38) had prior 3rd-generation EGFR TKI and 74% (28/38) had prior platinum-based chemotherapy (PBC). [2]All had prior PBC, 90% (45/50) had prior anti-PD-1/L1 and PBC. [3]During 12/2022∼01/2023, 9 pts (4 EGFRmut, 5 EGFRwt) had skipped at least 25% of the planned doses due to COVID-19 during 1st and 2nd tumor assessments.

Conclusions: BL-B01D1 demonstrated encouraging efficacy in heavily pretreated metastatic/locally advanced NSCLC, especially in pts with EGFRmut. The observed toxicity is deemed acceptable.

Clinical trial identification: NCT05194982.

1317MO Updated study results of pelcitoclax (APG-1252) combined with osimertinib in patients (pts) with EGFR-mutant non-small cell lung cancer (NSCLC)

Y. Ma[1], H. Zhao[1], Y. Zhao[2], Y. Cheng[3], J. Cui[4], G. Liu[5], D. Xiong[6], J. Zhang[5], L. Xu[7], J. Yu[5], L. Men[7], E. Liang[8], D. Yang[5], L. Zhang[1], Y. Zhai[9]

[1]Department of Medical Oncology, State Key Laboratory of Oncology in South China, Collaborative Innovation Center for Cancer Medicine, Sun Yat-sen University Cancer Center, Guangzhou, China; [2]Department of Medical Oncology, Henan Cancer Hospital/Affiliated Cancer Hospital of Zhengzhou University, Zhengzhou, China; [3]Department of Medical Thoracic Oncology, Jilin Cancer Hospital, Changchun, China; [4]Department of Oncology, The First Hospital of Jilin University, Changchun, China; [5]Clinical Research, Ascentage Pharma (Suzhou) Co., Ltd., Suzhou, China; [6]Preclinical Research and Biomarkers, Ascentage Pharma (Suzhou) Co., Ltd., Suzhou, China; [7]Biostatistics, Ascentage Pharma (Suzhou) Co., Ltd., Suzhou, China; [8]Preclinical Research and Biomarkers, Ascentage Pharma Group, Inc., Rockville, MD, USA; [9]Clinical Research, Ascentage Pharma Group, Inc., Rockville, MD, USA

Background: Investigational agent pelcitoclax is a dual BCL-2/BCL-xL inhibitor that enhances antitumor effects of epidermal growth factor receptor tyrosine kinase inhibitor (EGFR-TKI) osimertinib in preclinical models. In pts with TKI-naïve *EGFR*-mutant NSCLC, pelcitoclax plus osimertinib was well tolerated and showed preliminary efficacy (Zhang L et al. *J Clin Oncol* 2022). Here, we provide updated safety and efficacy results of this combination therapy.

Methods: The recommended phase 2 dose of pelcitoclax was established at 160 mg weekly plus osimertinib 80 mg daily. After completion of dose escalation and 2 dose expansions, pts were divided into 3 cohorts by treatment line: Cohorts 1 and 2 (EC-1 and EC-2) included pts with disease resistant to first- and third-generation EGFR-TKIs, respectively; Cohort 3 (EC-3) included pts whose disease was previously untreated with EGFR-TKIs.

Results: As of February 16, 2023, 64 pts (median age, 56 years; 54% female) were treated with pelcitoclax plus osimertinib. Among them, 8 were in EC-1, 29 in EC-2, and 27 in EC-3. Among 26 efficacy-evaluable pts in EC-3, 20 partial responses (PRs [76.9%]) were observed. For pts with *TP53* and *EGFR*-positive mutations in EC-3, 13/16 (81.3%) PRs were observed, and the median progression-free survival (range) was 16.39 (8.11-NR) months. Preliminary biomarker data from pts in EC-2 suggested that high BCL-xL expression was associated with antitumor efficacy. A total of 64 (100%) pts in all cohorts experienced treatment-related adverse events (TRAEs), which were grade ≥ 3 in 12 (18.8%). Common TRAEs included increased aspartate aminotransferase (70.4%) and alanine aminotransferase (59.3%), reduced platelet counts (33.3%), increased serum amylase (25.9%), and increased blood creatinine (22.2%).

Conclusions: Based on these findings, pelcitoclax plus osimertinib is of potential clinical interest to improve outcomes of pts with *TP53*- and *EGFR*-mutant NSCLC. Further studies are needed to elucidate the role of pelcitoclax when combined with osimertinib in treating this pt population. Internal study: APG1252NC101; CT.gov: NCT04001777.

Clinical trial identification: NCT04001777.

Background: ABBV-637 is an antibody-drug conjugate consisting of an epidermal growth factor receptor (EGFR)—targeting antibody and BCL-X_L inhibitor. Preclinical data demonstrate potent antitumor activity of ABBV-637 plus OSI in mutant EGFR NSCLC through reactivation of the apoptotic pathway.

Methods: This phase 1 dose escalation and expansion study (NCT04721015) explored the safety and preliminary efficacy of ABBV-637 as second- (2L) and third-line (3L) combination therapy with OSI. Enrolled adults had relapsed/refractory (RR) NSCLC with EGFR mutation, ECOG 0—1, and prior response and subsequent disease progression on OSI. Enrolled patients being treated at 2L and 3L had no inclusion/exclusion criteria for specific targetable mutations. ABBV-637 (12 or 20 mg/kg) was dosed IV Q4W; OSI (80 mg) was given daily in 28-day cycles. Endpoints included the rates of treatment-emergent adverse events (TEAEs), objective response (ORR), disease control (DCR), and best overall response. Disease- and drug-related biomarkers were evaluated.

Results: Forty-two patients were treated; median age was 65 (range: 44—79), and 64% had ≥2 prior lines of therapy. Median duration of ABBV-637 treatment was 113 days (range: 28—288). Most common TEAEs were increases in aspartate (38%) and alanine aminotransferase (33%), nausea (33%), and fatigue (21%). The ORR was 14% in 3L cohorts and 10% in 2L (Table). DCR was 73% and 65% in 3L and 2L, respectively. In 2L, confirmed responders did not have targetable bypass alterations.

Table: 1318MO

Characteristic	Total (N=42)

*Based on RECIST 1.1; †dose escalation (3L; n=5); ‡dose expansion (3L; n=17); §dose expansion (2L). 2L, 2nd-line therapy (post osimertinib alone); 3L, 3rd-line therapy (post osimertinib and platinum chemotherapy).

Conclusions: ABBV-637 plus OSI showed clinical activity and a manageable safety profile in patients with RR NSCLC. Biomarker data suggest that response to ABBV-637 plus OSI may be enriched by excluding patients with targetable bypass mechanisms; ongoing research is needed to confirm association of mutation and patient selection.

Clinical trial identification: NCT04721015.

Editorial acknowledgement: AbbVie and the authors thank the participants, study sites, and investigators who participated in this clinical trial. Medical writing support was provided by Vasileios Stamou, PhD, of Fishawack Facilitate Ltd, part of Fishawack Health, funded by AbbVie.

Background: For patients (pts) with *EGFR*-mutated NSCLC after failure of EGFR TKI and platinum-based chemotherapy (PBC), available therapies provide limited benefit. CNS metastases occur in the majority of these pts and portend a poor prognosis. HER3-DXd (patritumab deruxtecan) is an antibody-drug conjugate consisting of a fully human monoclonal antibody to HER3 attached to a topoisomerase I inhibitor payload via a stable tetrapeptide-based cleavable linker. In the phase 2 HERTHENA-Lung01 trial (NCT04619004), HER3-DXd showed promising efficacy and a manageable safety profile in pts with advanced *EGFR*-mutated NSCLC following an EGFR TKI and PBC. Pts with stable brain metastases (treated or untreated) were included. We report an exploratory analysis of intracranial efficacy.

Methods: In pts (N=225) treated with HER3-DXd 5.6 mg/kg IV Q3W, intracranial responses were assessed by blinded independent central review of cranial CT/MRI (CNS BICR; per CNS RECIST) at baseline, every 6 wk to wk 24, every 12 wk thereafter.

Results: 95 pts had brain metastases at baseline; 23 had measurable target lesions and 72 only had nontarget lesions. Pts had a median of 3 (range, 1-11) prior systemic therapies in the advanced setting. As of 21 Nov 2022, median study duration was 13.1 (range, 9.0-20.5) mo, median treatment duration was 4.2 (range, 0.7-14.7) mo. CNS BICR confirmed objective response rate (cORR) was 20% (Table; in pts with no prior radiotherapy to the brain, cORR was 37%). Median duration of response was 8.5 mo. 60% of pts had a CNS best objective response of SD and 14% had PD. In pts with target lesions, 15/23 had a reduction in the sum of diameters (cORR, 22%).

Table: 1319MO

CNS BICR	All pts (N=95)	Prior local CNS-directed radiotherapy		
		<6 mo from start (n=36)	≥6 mo from start (n=29)	None (n=30)
cORR, n (%) [95% CI][a]	19 (20.0) [12.5-29.5]	5 (13.9) [4.7-29.5]	3 (10.3) [2.2-27.4]	11 (36.7) [19.9-56.1]
CR, n (%)[b]	15 (15.8)	3 (8.3)	2 (6.9)	10 (33.3)
PR, n (%)	4 (4.2)	2 (5.6)	1 (3.4)	1 (3.3)
SD/non-CR/non-PD, n (%)	57 (60.0)	25 (69.4)	20 (69.0)	12 (40.0)
PD, n (%)	13 (13.7)	5 (13.9)	4 (13.8)	4 (13.3)
NE, n (%)	6 (6.3)	1 (2.8)	2 (6.9)	3 (10.0)
DOR, median (95% CI), mo	8.5 (8.1-NE)	NE (NE-NE)	8.1 (2.8-NE)	8.4 (5.8-NE)

CR, complete response; DOR, duration of response; NE, not evaluable; PD, progressive disease; PR, partial response; SD, stable disease. [a] CR + PR. [b] 11 pts with CR only had nontarget lesions

Conclusions: HER3-DXd demonstrated efficacy in *EGFR*-mutated NSCLC CNS metastases, with durable responses. These data add to the growing body of evidence that systemic treatment is feasible in pts with brain metastases and support further investigation of HER3-DXd in this context.

Clinical trial identification: NCT04619004.

Background: BAY 2927088, an oral, reversible, potent tyrosine kinase inhibitor, has anti-tumour activity against *EGFR* and *HER2* mutations, including ex20ins, in preclinical models. Here we report preliminary safety and efficacy of BAY 2927088 in pts with *EGFR*- or *HER2*-mutant NSCLC.

Methods: This is an ongoing, open-label, multicentre, first-in-human, phase I trial. Eligible pts must have advanced NSCLC with an *EGFR* and/or *HER2* mutation and disease progression after ≥1 systemic treatment. BAY 2927088 is orally administered daily in 21-day cycles and follows a Bayesian adaptive dose-selection model. Backfill is concurrent and includes escalation doses found to be safe and potentially efficacious. The primary objectives of the study are safety, tolerability, pharmacokinetics and maximum tolerated dose. Secondary objectives include the overall response rate (ORR) and the recommended phase II dose. Data cut-off was 18 August 2023.

Results: A total of 76 pts from the dose-escalation/backfill phases were evaluable for safety. 59% were female, median age 60 (range 35-81) years, and 72% never smokers. 97% of pts had received ≥1 systemic anti-cancer treatment. *EGFR* and *HER2* ex20ins mutations were present in 18% and 26% of pts, respectively. Five dose-limiting toxicities were reported in 5 pts. Overall, 87%/25% of pts had drug-related any-grade/grade 3-4 treatment-emergent adverse events (TEAEs). No pts had drug-related TEAEs leading to treatment discontinuation. The most common drug-related TEAEs were diarrhoea (75%, mainly grade 1-2), paronychia (25%) and dry skin (22%). The ORR was 26% overall (18/69, including 4 unconfirmed partial responses [uPR]). Of note, the ORR was 60%, including 1 complete response, 8 PR and 3 uPR, in 20 evaluable pts with *HER2* ex20ins mutant disease.

Conclusions: In an early phase I analysis of pts with *EGFR*- or *HER2*-mutant NSCLC, BAY 2927088 demonstrated a manageable safety profile up to 60 mg daily. In pts with *HER2* ex20ins mutant disease, BAY 2927088 showed encouraging preliminary antitumour activity. These results warrant further investigation of BAY 2927088 in pts with NSCLC.

Clinical trial identification: NCT05099172.

Background: ~20% of pts with HER2m NSCLC have BM at metastatic diagnosis. T-DXd is the first HER2-directed therapy for pts with pretreated, advanced HER2m NSCLC. We report post hoc pooled analyses of T-DXd efficacy/safety in this population with vs without baseline (BL) BMs from DESTINY-Lung01 (DL-01) and DESTINY-Lung02 (DL-02).

Methods: Pts with and without BMs were evaluated from the DL-01 (data cutoff [DCO], Dec 3, 2021) HER2m cohort (6.4 mg/kg; 35 and 56 pts) and the DL-02 (DCO, Dec 23, 2022) cohorts treated with T-DXd 5.4 mg/kg (32 and 70 pts) or 6.4 mg/kg (19 and 31 pts); 6.4 mg/kg arms were pooled. Pts with stable BL BMs (asymptomatic; not requiring treatment) were eligible. Tumor assessments were performed every 6 weeks (MRI/CT). Systemic objective response rates (ORRs), duration of response (DoR), sites of progression, and treatment-emergent adverse events (TEAEs) were determined in pts with and without BL BMs. Intracranial (IC)-ORR, IC-DCR, and IC-DoR were analyzed in pts with measurable and nonmeasurable BL BMs.

Results: 31% and 38% of pts given T-DXd 5.4 mg/kg and 6.4 mg/kg, respectively, had detectable BL BMs, among whom 46.9% and 55.6% had untreated BMs. Systemic ORRs were similar (Table). IC-ORRs were 25.0% (5.4 mg/kg) and 18.5% (6.4 mg/kg) with complete IC responses in 4 and 1 pts. In pts with BL BMs, IC progression occurred in 13/32 and 20/54 pts on T-DXd 5.4 mg/kg and 6.4 mg/kg, respectively; in pts without BL BMs, 1/70 and 8/87 had IC progression. Generally similar safety outcomes were seen in pts with vs without BMs, with a trend of higher rates of grade ≥3 TEAEs in pts with BMs (64.5% vs 47.1% [5.4 mg/kg]; 75.9% vs 63.2% [6.4 mg/kg]).

Conclusions: T-DXd showed IC activity in pts with metastatic HER2m NSCLC, some with complete IC responses. The presence of BL BMs did not impact systemic response among pts treated with T-DXd.

Table: 1321MO Efficacy summary

	T-DXd 5.4 mg/kg (DL-02)		T-DXd 6.4 mg/kg (DL-01/DL-02 pooled)	
	BM n = 32	Non-BM n = 70	BM n = 54	Non-BM n = 87
Confirmed systemic ORR, n (%)	15 (46.9)	35 (50.0)	27 (50.0)	51 (58.6)
DCR, n (%)	29 (90.6)	66 (94.3)	50 (92.6)	80 (92.0)
DoR, median, months	4.6	16.8	7.2	14.1
IC-ORR,[a] n (%)	8 (25.0)	–	10 (18.5)	–
CR	4 (12.5)	–	1 (1.9)	–
PR	4 (12.5)	–	9 (16.7)	–
SD	18 (56.3)	–	31 (57.4)	–
PD	3 (9.4)	–	4 (7.4)	–
IC-DCR,[a] n (%)	26 (81.3)	–	4 (7.4)	–
IC-DoR, median, months	9.2	–	4.4	–

[a]IC response per modified RECIST v1.1; all measurable brain lesions were considered target lesions. Nonmeasurable BL BMs only: 18/32 (5.4 mg/kg); 24/54 (6.4 mg/kg).

Clinical trial identification: NCT03505710; NCT04644237.

1322MO Insights into tumour dissemination and progression using longitudinal Imaging and ctDNA in the TRACERx lung cancer study

[1]Cancer Metastasis Laboratory, University College London Cancer Institute, London, UK; [2]Department of Medical Physics and Biomedical Engineering, UCL - University College London, London, UK; [3]Oncology, UCL Cancer Institute - Paul O'Gorman Building, London, UK; [4]Clinical Trials, Cancer Research UK & University College London Cancer Trials Centre, London, UK; [5]Lung Cancer Centre of Excellence, Cancer Research UK, London, Yorkshire, UK; [6]Cancer Evolution and Genome Instability Laboratory, Francis Crick Institute, London, UK

Background: Longitudinal imaging and circulating tumour DNA (ctDNA) can map tumour growth and patterns of metastatic spread on a lesion-by-lesion level. In this study, we investigated the role of ctDNA as a biomarker in monitoring tumour growth in 102 metastatic lung cancer patients enrolled in the TRACERx study, tracking volumetric dynamics of 341 metastases.

Methods: Patients were categorised based on total volume growth rate: Slow >100mm3/day, Stable <100mm3/day and Rapid >600mm3/day. Individual metastases within patients were categorised into 'High' and 'Low' growth rate based on the median growth rate for all lesions across the cohort. In addition, RNAseq data from 122 regions belonging to 44 metastases mapped to imaging at autopsy were analysed in 13 patients enrolled in the PEACE study. For 28 patients, ctDNA was used to track 200 clonal or subclonal mutations in 214 plasma samples to assess total disease burden and metastatic subclones.

Results: Growth rate correlated with number of lesions at relapse and overall survival (OS). Median OS was 55.0, 25.4 and 8.5 months for Slow, Stable and Rapid classes respectively ($p<0.001$). Gene set enrichment analysis demonstrated enrichment in signalling pathways associated with cell proliferation when comparing the gene expression patterns between 'high' and 'low' growth rate lesions. Early postsurgical ctDNA detection was associated with higher ctDNA shedding at disease relapse. Total ctDNA tracked with tumour volume in the post-relapse setting, and patients with extrathoracic relapse showed higher ctDNA shedding. For eight patients in the PEACE cohort, we assessed the subclonal composition of ctDNA, tracking lesions with specific subclones detected at autopsy. These subclones were mapped to metastatic lesions measured on imaging. ctDNA subclonal fraction tracked with changes in tumour volume upon treatment response and subsequent progression. For all eight patients' lesion-specific subclones could be detected from day 1 post-surgery prior to detection by radiological imaging.

Conclusions: Our results demonstrate that ctDNA can accurately reproduce observed patterns of metastatic growth on imaging, suggesting it can be used in the detection and monitoring of metastatic disease.

Clinical trial identification: The TRACERx study (NCT01888601) is a prospective observational cohort study and PEACE (NCT03004755) is a national research autopsy programme, both approved by independent research ethics committees (13/LO/1546 and 13/LO/0972/AM05, respectively).

1323MO Immune evasion across space and time in patients with lung cancer enrolled in the PEACE autopsy study

S. Hessey[1], W.K. Liu[1], O. Pich[2], A. Huebner[3], A. Bunkum[1], C. Richard[1], C. Puttick[2], C. Lombardelli[1], D. Moore[4], N. McGranahan[3], S. Zaccaria[5], C. Hiley[2], C. Swanton[2], M. Jamal-Hanjani[1]

[1]Cancer Metastasis Laboratory, University College London Cancer Institute, London, UK; [2]Cancer Evolution and Genome Instability Laboratory, Francis Crick Institute, London, UK; [3]Cancer Genome Evolution Laboratory, University College London Cancer Institute, London, UK; [4]Pathology, University College London Cancer Institute, London, UK; [5]Computational Cancer Genomics Laboratory, University College London Cancer Institute, London, UK

Background: Checkpoint inhibitors (CPIs) improve survival of patients with metastatic non-small cell lung cancer (NSCLC). However, in many patients the duration of response is limited, and some patients derive no benefit at all. Among key determinants of CPI response are genomic alterations that impair the anti-tumour immune response. In primary NSCLC these alterations are common. However, due to challenges collecting metastasis samples, the prevalence and distribution of these alterations across metastases within patients, and how this impacts response to CPI is not known.

Methods: The PEACE autopsy study in tandem with the TRACERx study enables multiregion tumour sampling from diagnosis of NSCLC to death, allowing immune evasive capacity to be tracked across space and time. We performed exome sequencing on 84 primary tumour regions and 320 metastases from 21 patients recruited to these studies. Mutations and copy number alterations were called with our bioinformatic pipeline and used to infer tumour clones in each sample, their phylogenetic relationship and metastatic migration history. The neoantigen landscape and genomic alterations in genes involved in immune evasion ('IE alterations') were then characterised in each clone.

Results: We find IE alterations are frequent in metastases and emerge via distinct evolutionary paths. In a subset of patients, immune evasive primary tumour clones seed metastases, giving rise to metastases with poor T cell infiltrate that share IE alterations with the primary. In others, primary tumour seeding clones do not harbour IE alterations. Compared to patients with shared IE alterations, these patients' metastases have higher T cell infiltrate and acquire more metastasis unique IE alterations after seeding. Measuring the radiological growth of individual metastases in 7 of these patients treated with CPIs in the DARWIN II trial, we observe homogenous

progression of metastases in patients with shared IE alterations, while patients with metastasis unique IE alterations exhibit heterogeneous metastasis growth rates.

Conclusions: When IE alterations occur in relation to metastatic seeding dictates the distribution of immune evasive capacity across metastases, which impacts metastasis growth during CPI therapy.

Clinical trial identification: PEACE - NCT03004755, TRACERx - NCT01888601, DARWIN II - NCT02314481.

Legal entity responsible for the study: UCL Clinical Trials Centre.

Funding: The PEACE study and TRACERx study are funded by Cancer Research UK (grants C416/A21999 and C11496/A17786, respectively). The PEACE study is additionally supported by funding from the Rosetrees Trust (grant A2204). A subset of patients in this work were treated with immunotherapy on the DARWIN II study, which is an academic study sponsored by UCL funded by funded by Hoffman La Roche.

Background: Up to 50% of patients (pts) with non-small cell lung cancer (NSCLC) develop central nervous system (CNS) metastases (mets), which are a major source of mortality in NSCLC. Lazertinib (laz), a CNS-active 3rd-generation (gen) tyrosine kinase inhibitor (TKI) targeting mutant epidermal growth factor receptor (EGFR), improved progression-free survival (PFS) vs the 1st-gen TKI gefitinib (gef) in the LASER301 study. Here, we compared laz vs gef among LASER301 pts with CNS mets.

Methods: In the phase 3 LASER301 study (NCT04248829), treatment (tx)-naïve pts with EGFR-mutated advanced or metastatic NSCLC were randomized 1:1 to laz (240 mg/day) or gef (250 mg/day). Pts with symptomatic/unstable CNS mets were excluded. If tx was required for pts with asymptomatic/stable CNS mets, radiation and/or surgery, and steroids were completed >2 weeks before randomization. Magnetic resonance imaging was performed at screening, every 6 weeks for 18 months (mo), then every 12 weeks relative to randomization, using the same modality at each follow-up. Endpoints assessed by blinded independent central review and RECIST v1.1 included intracranial PFS (iPFS), intracranial objective response rate (iORR), intracranial duration of response (iDoR), and depth of intracranial response.

Results: Of 393 pts in LASER301, 45 (23%) receiving laz and 41 (21%) receiving gef had measurable and/or non-measurable baseline (BL) CNS mets. BL characteristics were balanced between groups, with most pts having 1−3 CNS lesions (laz: 91%, gef: 83%). Median BL target lesion size was 20.0 mm (laz) and 16.0 mm (gef). Median iPFS in the laz group was 28.2 mo (95% confidence interval [CI]: 14.8, 28.2) vs 8.4 mo (6.7, not reached [NR]) in the gef group (hazard ratio: 0.42; 95% CI: 0.20, 0.89; P=0.02). iORR was higher for the laz (n=17, 94%) vs gef (n=11, 73%) group. At data cutoff, median iDoR in the laz group was NR (8.3, NR) vs 6.3 mo (2.8, NR) in the gef group. The median best change from BL in CNS target lesion size was -57% and -47% for laz (n=17) and gef (n=14), respectively. No new safety signals were identified from LASER301.

Conclusions: In pts with BL CNS mets, laz significantly improved iPFS vs gef with more durable responses. Laz has the potential to improve CNS outcomes in NSCLC.

Clinical trial identification: NCT04248829.

Background: Sunvozertinib (DZD9008) is a rationally designed, irreversible EGFR inhibitor targeting *EGFR* mutations with wild-type EGFR selectivity. Primary analysis of two ongoing pivotal studies (WU-KONG1 [NCT03974022] and WU-KONG6 [NCT05712902 & CTR20211009]) have demonstrated promising efficacy and safety of sunvozertinib in advanced NSCLC patients with *EGFR* Exon20 insertion mutations (exon20ins) in $\geq 2^{nd}$ line settings. Herein, we reported preliminary results of sunvozertinib in treatment naïve *EGFR* exon20ins NSCLC.

Methods: NSCLC patients with *EGFR* exon20ins who did not receive prior systemic anti-cancer therapy were enrolled into two ongoing studies: WU-KONG1, a multinational phase I/II study; and WU-KONG15 (NCT05559645), a phase II investigator-initiated study. Sunvozertinib was administered orally at 200 mg or 300 mg QD until discontinuation criteria were met. Efficacy analysis included patients with at least one post-treatment tumor assessment according to RECIST 1.1 by independent review committee (IRC).

Results: As of February 21, 2023, a total of 28 patients were included in the efficacy analysis (200 mg, n = 19; 300 mg, n = 9). Median age was 67 years, and 75.0% (21/28) were female. Baseline ECOG PS was 0 or 1. Majority of patients (96.4%, 27/28) had metastatic diseases at study entry, with 21.4% (6/28) having > 3 metastatic sites and 32.1% (9/28) having baseline brain metastasis (BM). The most frequent mutation subtypes included 769_ASV (39.3%, 11/28), 770_SVD (10.7%, 3/28) and others. By IRC, 20 patients achieved tumor response, with a best objective response rate (ORR) of 71.4% (200 mg, 68.4%; 300 mg, 77.8%). Median duration of response has not been reached. Safety findings were consistent with results of previous sunvozertinib studies. The most common TEAEs included diarrhea, CPK increase, and skin rash. Majority of the AEs were of CTCAE grade 1 or 2, and clinically manageable.

Conclusions: In the 1st line setting, sunvozertinib as monotherapy demonstrated promising anti-tumor efficacy and acceptable safety profile in NSCLC patients with *EGFR* exon20ins. A phase III, multinational, randomized study (WU-KONG28, NCT05668988) is ongoing to compare sunvozertinib to chemotherapy as 1st line treatment for *EGFR* exon20ins NSCLC.

Clinical trial identification: NCT03974022, NCT05559645.

Background: Advanced Non-small cell lung cancer (NSCLC) patients with epidermal growth factor receptor (EGFR) mutations are at an increased risk of developing central nervous system (CNS) metastases, which can lead to significant morbidity and mortality. Although osimertinib is the recommended first-line treatment in this population, its efficacy in treating CNS metastases has been poorly studied.

Methods: ORBITAL is a multicenter phase II trial investigating the efficacy and safety of osimertinib 80 mg/d in EGFR-mutated NSCLC patients with leptomeningeal metastases (cohort 1) or patients with brain metastases who have not received prior EGFR-Tyrosine kinase inhibitor or radiation therapy (cohort 2). The primary endpoint was objective response rate (ORR) at 6 months, secondary endpoints included progressionfree survival (PFS), overall survival (OS), CNS ORR and CNS PFS. Brain magnetic resonance imaging (MRI) was performed every 6 weeks during first year and then every 8 weeks.

Results: 53 patients were included (8 patients in cohort 1 and 45 patients in cohort 2, 70% were female and 62% never smokers). Median age was 68 years. EGFR mutations were mostly del19 (60.4%) and L858R (30.2%). The number of previous lines of therapy was ≥1 in 75% of patients in cohort 1 and 11.1% in cohort 2. The median follow-up time was 11.2 months in cohort 1 and 19.8 months in cohort 2. ORR at 6 months was 37.5% (n=3/8, CI95%: 4.0%-71.0%) in cohort 1 and 60% (n=27/45, CI95%: 45.7%-74.3%) in cohort 2. Median PFS was 7.4 months [CI95%: 2.7-NR] (12-month PFS: 21.4%) and 12.6 months [CI95%: 6.9-26.2] (12-month PFS: 52.2%), in cohort 1 and 2 respectively. Median OS was 7.4 months [CI95%: 2.7-NR] (12-month OS: 46.9%) and 30.3 months [CI95%: 15.6-NR] (12-month OS: 74.7%), in cohort 1 and

2 respectively. In cohort 2, CNS ORR at 6 months was 57.8% (n=26/45, CI95%: 43.3%-72.2%) and CNS PFS was NR [CI95%: 9.7-NR]. Safety /tolerability were as expected with no new safety signal.

Conclusions: Osimertinib demonstrated clinically meaningful responses in patients with EGFR-mutated NSCLC against both leptomeningeal and brain metastases. Safety profile was acceptable and manageable. Tumour and blood samples will be analysed for exploratory biomarkers.

Clinical trial identification: EudraCT: 2019-002805-23.

Background: The results of the FLAURA study established osimertinib as the new first-line (1L) standard of care for patients with the two 'common' types of epidermal growth factor receptor mutation-positive (EGFR+) advanced non-small-cell lung cancer (aNSCLC). Uncommon EGFR mutations (non-exon 19 del and L858R) occur in up to 20% of patients; however, the efficacy of osimertinib in this population is not well understood. To date, small prospective studies, retrospective case series, and case reports have signaled that osimertinib has a role in the treatment of patients with uncommon EGFR mutations.

Methods: This is a multicentered Canadian phase II investigator-initiated study of (cohort A) osimertinib in the third-line (3L) rechallenge of patients with EGFR+ aNSCLC, following 1L treatment with osimertinib and 2L therapy with platinum pemetrexed chemotherapy; and (cohort B) 1L osimertinib in patients with uncommon EGFR mutations (exon 20 insertions are not permitted). Cohort B has a planned accrual of 85 patients. The primary endpoint is objective response rate (ORR) in 3L osimertinib rechallenge; 1L ORR in patients with uncommon mutations is a key secondary endpoint. The OCELOT study, NCT04335292, is continuing to enroll participants.

Results: 74 patients have been accrued to date, including 35 in Cohort B. At the time of preparation, 22 had evaluable disease. The most frequent 'uncommon' EGFR mutation was G719X (n=11), followed by L861X (n=8) and S768I (n=5). The confirmed ORR was 45% and disease control rate (DCR) was 77%. Confirmed ORR/DCR for evaluable patients with G719X (n=11), L861X (n=3) and S768I (n=5) mutations were 45%/73%, 100%/100%, and 60%/100%, respectively. Updated data including ORR, progression free survival, time to treatment failure and 1-year over survival rate will be presented. Safety and toxicity profile is consistent with published data on osimertinib.

Conclusions: Osimertinib appears to be highly active and well tolerated in patients with the more frequent 'uncommon' EGFR mutations (G719X, L861X, and S768I). The OCELOT study will be the largest study to date of 1L osimertinib in patients with EGFR+ aNSCLC harboring uncommon mutations.

Clinical trial identification: NCT04335292.

1328P Analysis of data from the AENEAS study assessing the third-generation epidermal growth factor receptor (EGFR) tyrosine kinase inhibitor (TKI), aumolertinib, and virtual comparison with osimertinib

M. LaRose[1], M. Zhou[1], S. Lu[2], H. Wei[3], S.E. Bates[1], L. Schwartz[4], A.T. Fojo[1]

[1]Division of Hematology/Oncology, Columbia University Irving Medical Center, New York, NY, USA; [2]Department of Oncology, Shanghai Chest Hospital, Shanghai Jiao Tong University, Shanghai, China; [3]Department of Oncology Medicine, Hansoh Pharma Group Co., Ltd., Shanghai, China; [4]Department of Radiology, MSKCC - Memorial Sloan Kettering Westchester, New York, NY, USA

Background: TKIs targeting the EGFR revolutionized care of patients (pts) with non-small cell lung cancer (NSCLC) harboring EGFR mutations. Resistance to 1st/2nd-generation EGFR TKIs inevitably develops, with clone(s) harboring T790M EGFR mutations emerging in 50–70% of cases. 3rd-generation EGFR TKIs active against T790M and common EGFR-activating mutations are in development; only osimertinib and aumolertinib have regulatory approvals.

Methods: We have described a novel approach for assessing treatment efficacy using measurements of tumor burden to estimate rates of growth and regression of tumors designated ***g*** and ***d***, respectively. Data from thousands of pts with diverse tumors have shown ***g*** is inversely correlated with OS. We analyzed data from the randomized phase III AENEAS study comparing aumolertinib with gefitinib.

Results: 94% of the data could be analyzed; notably more pts than included for the primary PFS endpoint. Tumor growth reflected in a detectable ***g*** was found in 89% of both arms, including many not scored as progression. Superiority of aumolertinib was evident in statistically slower ***g*** values [and longer tumor doubling times, TDT] for aumolertinib [***g*** = 0.0006/day (0.0005-0.0011); TDT 1155 days] than gefitinib, [***g*** = 0.0012/day (0.0007-0.0020); TDT, 578 days], p<0.0001. Aumolertinib was superior in slowing ***g*** in tumors with Ex19del alterations compared to L858R mutations [p=0.0018], and superior to gefitinib in slowing ***g*** in tumors with Ex19del alterations [p<0.0001] just missing significance for L858R mutations [p=0.0687] – possibly due to smaller number of pts. Aumolertinib slowed ***g*** in non-smokers compared to smokers [p=0.0066] and superior to gefitinib in slowing ***g*** in non-smokers [p<0.0001]. Finally, ***g*** values with aumolertinib were comparable to published osimertinib values.

Table: 1328P Median *rate of tumor growth (g)* by line and type of therapy

Line of therapy	Type of therapy	N	Median *g*/day	Tumor Doubling Time
Data from USFDA Analysis [Gong, ASCO 2020]				
Front	Mono 1stGen EGFRi*	237	0.0012/day	578 days
Front	Osimertinib	243	0.0007/day	990 days
Data from analysis of AENEAS study				
Front	Gefitinib	215	0.0012/day	578 days
Front	Aumolertinib	214	0.0006/day	1155 days

*1st generation EGFR inhibitors, gefitinib or erlotinib

Conclusions: Like osimertinib, aumolertinib is a highly effective third-generation EGFR-TKI.

Background: Alterations in FGFR1-4 genes have oncogenic capability with sensitivity to kinase inhibition in several solid tumours and hematological malignancies. FGFR alterations occur in approximately 2% of non-small cell lung cancer (NSCLC) patients (pts), predominantly with squamous cell histology (sqNSCLC). We present results of a study evaluating the efficacy of the selective FGFR1-4 inhibitor erdafitinib in pts with FGFR-altered NSCLC.

Methods: NSCLC pts were screened within the national Network of Genomic Medicine for FGFR mutations/translocations. Molecular eligibility was based on available preclinical and clinical data to FGFR alterations and assessed by a study specific molecular board. Pts were treated with erdafitinib in 3 cohorts: High confidence activating FGFR translocations (1), high confidence activating FGFR mutations (2) and low confidence activating FGFR alterations (3). The primary objective was the best confirmed overall response (OR) on erdafitinib in the cohorts 1 and 2 assessed by RECIST 1.1 every 8 weeks. Pts were treated until disease progression or unacceptable toxicity. Tumor samples and blood were collected before treatment and at disease progression. Sample size calculation was based on Simon's two-stage minimax design. Evidence of efficacy was defined as 1/8 OR in the first and 4/15 ORs in the second stage for cohort 1 and 2 separately.

Results: Between 7/2019 and 9/2022, 26 pts were enrolled, 4 pts failed screening. The majority of pts were male (77%) and had sqNSCLC (73%). All pts were current or previous smokers. Of 22 pts on erdafitinib, 7 were in the cohort 1, 8 in the cohort 2 and 7 pts in the cohort 3. FGFR3-TACC3 fusions were the most frequent genetic alterations. In the cohort 1, two pts achieved partial response (PR). However, one PR remained unconfirmed (uPR). The best response in the cohort 2 was stable disease. The most observed adverse events of any grade were hyperphosphatemia in 50% and diarrhea in 45% of pts.

Conclusions: According to the first stage results of the two-stage Simon's design, erdafitinib showed preliminary efficacy in NSCLC with FGFR translocations. Further molecular, pharmacological and clinical data are needed to evaluate the efficacy of FGFR inhibition in NSCLC, especially in pts with FGFR mutations.

1330P Updated results of the efficacy and safety of KN046 (a bispecific anti-PD-L1/CTLA-4) in patients with metastatic non-small cell lung cancer (NSCLC) who failed prior EGFR-TKI(s)

C. Zhou[1], A. Xiong[2], J. Fang[3], X. Li[4], Q. Xie[5], Q. Yu[6], L. Han[7], Z. Ma[8], J. Shi[9], B. Wang[10], M. Ji[11], G. Yang[12], T. Xu[13], M. Xu[13], Q. Liu[13], N. Wang[13], X. Yan[13]

[1]Department of Medical Oncology, Shanghai Pulmonary Hospital, Shanghai, China; [2]Thoracic Oncology, Shanghai Pulmonary Hospital, Shanghai, China; [3]Oncology, Peking University Cancer Hospital and Institute, Beijing, China; [4]Oncology Department, The First Affiliated Hospital of Zhengzhou University, Zhengzhou, China; [5]Oncology, Fuzhou Pulmonary Hospital of Fujian, Fuzhou, China; [6]Oncology, Guangxi Medical University Affiliated Tumor Hospital, Nanning, China; [7]Oncology, Xuzhou Central Hospital/The Fourth People's Hospital of Xuzhou, Xuzhou, China; [8]Oncology, Henan Cancer Hospital/Affiliated Cancer Hospital of Zhengzhou University, Zhengzhou, China; [9]Oncology, Linyi Cancer Hospital, Linyi, China; [10]Oncology, Xuzhou Mining Group General Hospital/The Second Affiliated Hospital of Xuzhou Medical University, Xuzhou, China; [11]Oncology, The First People's Hospital of Changzhou, Changzhou, China; [12]Oncology, The Second People's Hospital of Weifang, Weifang, China; [13]Medical Department, Jiangsu Alphamab Biopharmaceuticals Co., Ltd., Suzhou, China

Background: KN046 is a novel bispecific antibody that inhibits both PD-L1/PD1 and CTLA-4/CD80/CD86 pathways. We previously showed the efficacy and safety of KN046 plus chemotherapy in advanced NSCLC with EGFR sensitivity mutation who progressed after tyrosine kinase inhibitor(s) (TKIs) from Cohort D of the phase II trial. Here, we report the updated survival and safety data.

Methods: This is an open-label, multi-center, multiple cohorts, single arm study to evaluate the efficacy, safety and tolerability of KN046 in NSCLC. Subjects with EGFR sensitizing mutation (Ex19del or L858R), who had failed from prior EGFR-TKI(s) without platinum-based chemotherapy were enrolled. All subjects enrolled received KN046 5 mg/kg Q3W combined with chemotherapy (Pemetrexed, 500 mg/m^2, Q3W

and carboplatin AUC5, Q3W), until disease progression, intolerable toxicity and other discontinuation criteria. Primary endpoint was objective confirmed response rate (ORR) per RECIST version 1.1.

Results: From Jan 7, 2020 to Dec 17, 2021, 26 patients with metastatic NSCLC were enrolled. The median follow-up was 17.8 months (95% CI, 13.0, 19.5) at the data cutoff of Jul 30, 2022. The ORR was 26.9% (7/26, 95% CI, 11.6 , 47.8%), DCR was 84.6% (22/26, 95% CI, 65.1, 95.6%) with 7 PR and 15 SD. The CBR was 38.5% (10/26, 95% CI, 20.2, 59.4%). The mPFS was 5.5 months (95% CI, 4.2, 6.8) and the mOS was 20.2 months (95% CI, 11.5, -). Grade 3 or higher TRAEs occurred in 15 (57.7%) of the 26 patients due to chemotherapy or KN046. The most common grade 3 or higher TRAEs were infusion reaction (5/26 [19.2%]), decreased platelet count (4/26 [15.4%]) and anemia (3/26 [11.5%]).

Conclusions: KN046 demonstrated encouraging OS benefit and a favorable safety profile in advanced NSCLC with EGFR sensitivity mutation who progressed after EGFR-TKI(s). Further study is warranted to confirm the clinical results.

Clinical trial identification: NCT03838848.

1331P Resistance mechanisms in EGFR-mutated advanced non-small cell lung cancer (aNSCLC) patients (pts) treated with first-line osimertinib (osi) and monitoring plasma mutational load: Preliminary results of REM study

L. Bonanno[1], A. Ferro[1], L.C. Bao[2], G.M. Marinato[2], A. Padovan[3], E. Zulato[3], S. Frega[1], A. Dal Maso[1], G. Pasello[2], S. Indraccolo[2], V. Guarneri[2]

[1]Medical Oncology 2, Veneto Institute of Oncology IOV - IRCCS, Padua, Italy; [2]Department of Surgery, Oncology and Gastroenterology, University of Padova, Padua, Italy; [3]Immunology and Molecular Oncology Unit, IOV - Istituto Oncologico Veneto IRCCS, Padua, Italy

Background: The ongoing REM trial is a translational prospective multicenter Italian study aiming to monitor *EGFR*-mutated pts through liquid biopsy and explore potential mechanisms of primary and acquired resistance.

Methods: *EGFR*-mutated aNSCLC pts receiving first-line osi are prospectively enrolled. Plasma samples are collected before starting treatment (T0), after 10 (T1) and 28 days (T2) and at the time of radiological/clinical progression (T3). *EGFR* mutations (mut) in plasma are analyzed by real-time polymerase chain reaction (RT-PCR) and by next-generation sequencing (NGS). A semiquantitative index (SQI) is given by the RT-PCR, related to the amount of EGFR mut cell-free DNA (cfDNA) present in plasma sample. Change from baseline in EGFR SQI is considered as a difference from baseline to different time-points (T0—T1 and T0—T2).

Results: Since August 2022, 34 pts were included (data cut-off March 2023): mainly females (N=24, 70.6%) and never smokers (N=23, 67.6%); median age at diagnosis was 70.5 years (IQR 67-77). The majority of pts had a common*EGFR* mut (exon 19 deletion: N=18, 52.9%; L858R mut N=12, 35.3%). The objective response rate was 70.6% (95% CI, 52.5-84.9), while survival data were immature at time of analysis. The concordance between tissue and plasma was 76.5% (95% CI, 58.9-89.3). A higher tumour burden (defined as 3 or more metastatic sites at diagnosis) was related to higher SQI at T0 (OR 3.12, 95% CI: 2.70-12.81, p=0.004). Clearance of plasma *EGFR* mut at T2 was detected in 20 out of 26 pts (76.9%). A correlation between change in EGFR SQI and response rate was found: a decrease of baseline EGFR SQI (T0-T2) >=50% was associated with increased probability of reaching an objective response (OR: 13.5, 95% CI: 1.1- 165.9, *p*=0.042). Two pts experienced radiological progression at first assessment and both had no clearance at T2.

Conclusions: *EGFR* mut monitoring 10 days after the start of first-line osi has the potential to be used as predictive marker in order to personalize treatment of *EGFR*-mutated aNSCLC pts. Updated results including NGS analyses at T0 and correlation of co-mutations in cfDNA with outcome will be presented at the Conference.

1332P Efficacy and safety of gefitinib plus bevacizumab versus gefitinib monotherapy in patients with EGFR L858R mutant non-small cell lung cancer (NSCLC): A randomized, open-controlled, single-center trial

J. Wang[1], X. Zhao[1], K. Xiong[2], C. Liu[2], X. Wu[1], H. Wang[3], H. Yu[1], S. Sun[1], Z. Hu[1], Y. Lin[1], Y. Zhang[1], B. Yu[1], Z. Wu[1]

[1]Department of Thoracic Medical Oncology, Fudan University Shanghai Cancer Center, Shanghai, China; [2]Geneseeq Research Institute, Nanjing Geneseeq Technology Inc., Nanjing, China; [3]Medical Oncology, Fudan University Shanghai Cancer Center, Shanghai, China

Background: Dual inhibition of epidermal growth factor receptor (EGFR) and vascular endothelial growth factor pathways may be a potential therapeutic strategy for EGFR mutant NSCLC. This study was conducted to assess the efficacy and safety of gefitinib (Gef) plus bevacizumab (Bev) for EGFR L858R mutation-positive NSCLC.

Methods: 80 patients were randomly assigned to receive either Gef at 250 mg/day alone (group G, n = 39) or with Bev at 7.5 mg/kg every 3 weeks (group GB, n = 41). The primary endpoints were safety and progression-free survival (PFS), and the secondary endpoint was objective response rate (ORR). Genomic biomarkers and resistance mechanism were investigated.

Results: There was a significant reduction in the risk for progression in the group GB compared with the group G (HR = 0.49) with the median PFS (mPFS) of 15.1 vs. 8.2 mon (P =0.0031). The ORR was significantly higher in group GB than in group G (90.2% vs. 59.0%, P = 0.005). Adverse events were similar between two groups (85.4% vs. 70.7%, P=0.27). ctDNA status at 43 days after treatment initiation (D43) was associated with PFS, which was longer in patients with ctDNA negative (-) at D43 than those with ctDNA positive (+) at D43 in both groups (17.0 vs. 12.2 mon, P=0.008 in group GB; 10.2 vs. 4.3 mon, P<0.001 in group G). In 67 patients with matched baseline (BS) and D43 plasma samples, patients were divided into three groups: BS ctDNA- and D43 ctDNA- for type A, BS ctDNA+ and D43 ctDNA- for type B, and BS ctDNA+ and D43 ctDNA+ for type C. In type B, ORR was significantly higher in the group GB than in group G (100% vs. 64.7%, P=0.008). Type B had a comparable PFS with type A, both significantly longer than type C in both groups (mPFS 19.1, 18.8 and 11.2 mon for type A, B and C, P=0.016 in group GB; 15.9, 10.2 and 4.7 mon for type A, B and C, P<0.001 in group G). Post-progression samples from the group G showed a trend toward to higher frequency of T790M mutations compared with the group GB (70.6% vs. 38.5%, P=0.13).

Conclusions: Combined therapy of gefitinib with bevacizumab exhibited a significant improvement in PFS in patients with EGFR L858R mutant NSCLC. The post-treatment ctDNA and dynamic change were potential biomarkers of efficacy.

Background: Insertion mutations within exon 20 of both EGFR and HER2 are oncogenic drivers and are most commonly found in NSCLC. EGFR exon 20 insertion mutations occur in 4-10% of all EGFR-mutated NSCLC. Brain metastases are present in approximately one-third or more of these cases but are not addressed by available therapies directed against these mutations. ORIC-114 is a highly selective, brain penetrant, orally bioavailable, irreversible inhibitor designed to selectively target EGFR and HER2 with high potency against exon 20 insertion mutations, making it a promising therapeutic candidate to address the unmet medical need of having both meaningful systemic as well as CNS antitumor activity.

Methods: ORIC-114-01 (NCT05315700) is an ongoing i3+3 dose escalation (Part I), followed by dose optimization (Part II), and dose expansion (Part III) study in patients with advanced solid tumors harboring an EGFR or HER2 alteration who have exhausted available treatment options, including patients with active brain metastases. Primary objectives are safety/tolerability and pharmacokinetics of ORIC-114. Part I will determine the provisional RP2Ds and/or MTD for optimization in Part II and, subsequently, the optimal RP2D for Part III. Secondary endpoints will evaluate antitumor activity by RECIST v1.1, including intracranial responses in patients presenting with brain metastases at baseline.

Results: As of 03 April 2023, 32 patients received ORIC-114 across 8 dose levels administered QD or BID. The most common TRAEs reported in $\geq$10% of pts were rash (34%), stomatitis (28%), paronychia (25%), diarrhea (19%), dermatitis acneiform (16%), mucosal inflammation (13%), and pruritis (13%). The vast majority of these events were mild (G1) to moderate (G2) in severity with no MTD reached. Grade 3 TRAEs occurred in 6 patients, all of which resolved with dose modifications; there were no Grade $\geq$4 TRAEs. Early evidence of both systemic and intracranial antitumor activity was observed.

Conclusions: ORIC-114 has demonstrated an acceptable safety profile and preliminary antitumor activity, including in the CNS, at doses predicted to be active. Enrollment is ongoing and updated data will be presented.

Clinical trial identification: NCT05315700.

Background: SMARCA4 deficient (SMARCA4d) non-small cell lung cancer (NSCLC) has a poor prognosis. The activity of first line immune-checkpoint blockers (ICB) or chemo-ICB and the potential impact of co-mutations is scarcely explored in patients with SMARCA4d NSCLC.

Methods: This is a monocentric, retrospective study evaluating patients with advanced NSCLC, screened for SMARCA4 alterations and treated with first line chemo-ICB or ICB alone. SMARCA4d was defined as loss of BRG1 in immunohistochemistry or the presence of deleterious *SMARCA4* in liquid or tissue biopsies assessed by next-generation sequencing. Progression-free survival (PFS), overall survival (OS) and the impact of co-mutations (*STK11, KEAP1*) were compared between patients with or without SMARCA4d.

Results: A total of 128 patients were included: 36 with SMARCA4d (12 in IHC, 31 in NGS, 7 both) and 92 without SMARCA4d (control group). Patients with SMARCA4d had a median age of 57 years, were male in 64% cases and smokers in 94% cases, similar to the control group. Histology type was adenocarcinoma in 53% versus 82% ($p<0.001$) in control, with more cases of undifferentiated or large cell neuroendocrine carcinoma in the SMARCA4d group. TMB value was 13 vs 5 mut/Mb ($p<0.001$), median PD-L1 expression was 0 vs 5% ($p=0.3$) in SMARCA4d versus control, with no differences in immune blood counts. *STK11* and *KEAP1* mutations were frequently co-mutated with SMARCA4d (53% vs 26%, $p=$ 0,01; 37% vs 13%, $p=$ 0,01, respectively. The median PFS under ICB+/- chemotherapy was 4.0 months (CI 95% 2.87- 7.7) vs 7.37 months (CI 95% 6.53-11.3) ($p=$ 0.005) in SMARCA4d versus control, and the median OS was 9.3 months (CI 95% 7.0 — NR) vs 27.6 months (CI 95% 27.3 - NA) ($p<$ 0.0001), respectively. In patients with *STK11/KEAP1* mutations, median OS was 7 months (95% CI 5-NR) versus 13.3 months (95% CI 10.5-35.8) ($p=0.19$) in SMARCA4 and control, respectively.

Conclusions: SMARCA4d seems to negatively impact survival outcomes and the efficacy of ICB, despite high TMB. Novel treatments are rapidly needed.

1335P Phase Ib study to evaluate the safety and tolerability of osimertinib with ipilimumab in EGFRm NSCLC

S. Puri[1], S. Patel[1], K. Kerrigan[1], A. Chalmers[1], S. George[2], P. Hammon[2], E. Loertscher[3], H. Lee[4], K. Boucher[4], W. Akerley[1]

[1]Medicine/ Hematology and Oncology Department, The Huntsman Cancer Institute at the University of Utah, Salt Lake City, UT, USA; [2]Clinical Trials Office, The Huntsman Cancer Institute at the University of Utah, Salt Lake City, UT, USA; [3]Medical School, St George's University School of Medicine, Grenada, West Indies; [4]Population Health Sciences, University of Utah, Salt Lake City, UT, USA

Background: Osimertinib (Osi) is an oral epidermal growth factor receptor (EGFR) tyrosine kinase inhibitor (TKI) indicated in the 1st line treatment of EGFR mutated(m) metastatic NSCLC (mNSCLC). Although the combination of Osi with PD-1/PD-L1 inhibitors is prohibitive due to excessive toxicity, combinations with other immune checkpoint inhibitors, such as CTLA4 inhibitor Ipilimumab (Ipi), remain largely unexplored. In a phase 1 trial, we evaluated the combination of EGFR TKI erlotinib and Ipi in EGFRm mNSCLC. The study was closed due to gastrointestinal dose-limiting toxicities (DLTs), but we observed unprecedented improvement in survival (median OS 42.3m). Based on this observation, we designed a phase 1 trial of Osi with Ipi in EGFRm mNSCLC. Here we present results from the dose escalation phase.

Methods: This is a single-center, phase 1B trial. Eligible pts required a stable dose of 1st line Osi (40 or 80mg/day) for >/= 28 days w/o disease progression. The trial was initiated with cohort1(C1), Osi daily + Ipi 3mg/kg/3 wk with a safety run of 6 pts and planned expansion at this dose if <=1/6 pts experience DLTs, but de-escalation to cohort 2 (C2), Osi daily + Ipi1mg/kg/3wk if >/= 2/6 pts experience DLTs. C2 would be expanded if <= 1/6 pts experienced DLTs, and trial would be closed if >/= 2/6 pts experience DLTs. The study's primary objective was to determine the tolerability (NCI CTCAEv5) of Osi + Ipi. Key secondary endpoints are ORR, PFS, and OS.

Results: 10 pts (4 C1;6 C2) were enrolled between 9/2020-3/2022. The majority of pts were never smoker, female 80%, white 100% with an ECOG of 1. 3 DLTs (1 G3 thromboembolic event, 2 G2 diarrhea) were observed in the 2/4 pts in C1, hence de-escalation C2 enrolled 6 additional pts. Most common all-grade TRAEs were diarrhea in 60% (6/10), fatigue, nail changes and rash (40%, 4/10 pts) each. G3-4 TRAEs were infrequently observed with G3 hepatitis, diarrhea, anorexia, and weight loss in 10% (1/10) pts each. Most G3 TRAEs were observed in C1. 1/6 pts (17%) experienced G3 weight loss in C2. C2 dose was selected for dose expansion (8 additional pts accrued to date).

Conclusions: In EGFRm NSCLC pts the combination of Osi with Ipi (1mg/kg/3wk) was safe and tolerable. This dose is currently undergoing additional evaluation in the dose expansion cohort.

Clinical trial identification: NCT04141644.

Background: Given the broad application of 3rd generation tyrosine kinase inhibitors (TKI) as standard 1st line treatment for EGFR+ NSCLC, small cell transformation (SCT) as a mechanism of adaptive resistance is seen more frequently. Little is known about optimal treatment strategies and prognosis is generally poor in this subset of patients.

Methods: We conducted a retrospective study on the efficacy of different treatment strategies: platinum-based chemotherapy alone (C) vs. immune checkpoint inhibitors in combination with C (ICI+C) vs. tyrosine kinase inhibitors in combiation with C (TKI+C) in patients with EGFR+ NSCLC and SCT treated at 19 centers in Europe and the United States.

Results: Of a total of 40 patients, 16 received ICI+C, 9 TKI+C, and 15 C alone as first treatment after SCT. Median time from TKI initiation to SCT was 22 months. Half of the patients (48%) presented with brain metastases at the time of SCT. Overall response rate was 54% for ICI+C, 60% for TKI+C, and 46% for C alone. Median progression-free survival (PFS) was 5 months (95% confidence interval [CI] 3.2-6.8) for ICI+C, 6 months (CI 3.6-8.4) for TKI+C, and 4 months (CI 3.4-4.6) for C alone. Median overall survival (OS) from first SCT treatment was 18 months (CI 8.9-27.1) for ICI+C, 11 months (CI 9.8-12.1) for TKI+C, and 8 months (CI 5.3-10.6) for C alone. EGFR L858R subtype was associated with improved OS (Hazard ratio 0.31 [CI 0.11-0.85]). The impact of follow-up therapies will be presented at the conference.

Table: 1336P

	C	ICI + C	TKI +C
ORR (CI)	46%	54%	60%
PFS (months, CI)	4 (3.4-4.6)	5 (3.2-6.8)	6 (3.6-8.4)
OS (months, CI)	8 (5.3-10.6)	18 (8.9-27.1)	11 (9.8-12.1)
	Hazard ratio 0.44 (CI: 0.18-1.08)		

Conclusions: Although limited by its retrospective nature, our data suggest that combination therapies, ICI+C in particular, might be superior to C alone in EGFR+ NSCLC with SCT.

Background: Dacomitinib, a second-generation, irreversible tyrosine kinase inhibitor of epidermal growth factor receptor (EGFR), provided statistically significant progression-free survival improvement over gefitinib in treatment-naive patients with advanced *EGFR* mutation−positive non-small cell lung cancer (NSCLC) in a global phase 3 study (ARCHER 1050; NCT01774721). Here, we report interim analysis of ARIA, a non-interventional study of dacomitinib's real-world (RW) utilization and associated clinical outcomes in Asian patients with advanced *EGFR* mutation−positive NSCLC.

Methods: This longitudinal, multicenter cohort study collected prospective and retrospective data from patients with advanced *EGFR* mutation−positive NSCLC who were treated with first-line (1L) dacomitinib based on routine practices and their best interest. Study objectives were to describe patient demographics and clinical characteristics, treatment patterns of dacomitinib use, and RW outcomes of 1L dacomitinib.

Results: 300 patients from China (n=262), India (n=24), and Malaysia (n=14) were enrolled and included in the analysis. Starting dose was 30 mg once daily (QD) in 159 patients (53%), 45 mg QD in 138 (46%), and other doses in 3 (1%). As of Jan 31, 2023, 81 patients (27.0%) had dose decreases, 13 (4.3%) dose increases, 35 (11.7%) interruptions, and 107 (35.7%) permanently discontinued dacomitinib. Six (2.0%) permanent treatment discontinuations were due to treatment-related toxicities. 1L dacomitinib safety and treatment outcomes are shown in the table.

Table: 1337P Safety and treatment outcomes of 1L dacomitinib

ITT population	Total (N=300)
Duration of 1L dacomitinib treatment, median (IQR), months	13.1 (11.8)
Patients with any TRAEs, n (%)	121 (40.3)
Most common TRAEs, n (%)	
Rash	74 (24.7)
Diarrhea	65 (21.7)
Paronychia	43 (14.3)
TTF, median (95% CI),[a] months	21.4 (17.3-35.9)
rwPFS, median (95% CI),[a] months	25.3 (20.1-NR)

1L, first line; IQR, interquartile range; ITT, intention to treat; NR, not reached; rwPFS, real-world progression-free survival; TRAE, treatment-related adverse event; TTF, time to treatment failure. [a] Calculated using the Kaplan-Meier method to obtain 95% confidence interval.

Conclusions: To our knowledge, this is the largest RW study conducted for dacomitinib. Interim analysis shows efficacy of 1L dacomitinib; safety data in the RW setting were generally consistent with dacomitinib's known safety profile. These results support 1L dacomitinib use in patients with advanced *EGFR* mutation−positive NSCLC.

Background: Lazertinib, an irreversible third-generation EGFR tyrosine kinase inhibitor (TKI), has shown high blood-brain barrier (BBB) penetration in preclinical studies. In this study, we present cerebrospinal fluid (CSF) pharmacokinetic (PK) study from a phase II trial investigating lazertinib and pemetrexed in epidermal growth factor receptor (EGFR) mutant non-small cell lung cancer (NSCLC) patients with leptomeningeal metastases (LMs).

Methods: This is a single-arm, phase II study that enrolled patients with cytologically confirmed LM and EGFR-mutation. Patients were administered lazertinib at a daily dose of 240mg along with pemetrexed at a dose of 500mg/m^2 every 3weeks. The primary endpoint was post-LM overall survival (OS). Secondary endpoint included PK studies. To evaluate the through concentration of lazertinib, plasma and CSF samples were collected serially before the start of the 2nd and 3rd cycles. The concentration ratio of CSF to free plasma (FP) was analyzed.

Results: CSF and plasma PK samples were available from 32 patients. All the patients had previously failed treatment with 1st or 2nd generation EGFR TKIs. At the second cycle, the median CSF concentration was 1.05 ng/ml (range, 0.13-17.8 ng/ml), and the median plasma concentration was 213.2 ng/ml (range, 59.0-934.1 ng/ml). There was a correlation between the concentration of lazertinib in CSF and FP (r=0.38; P=0.032), with a mean CSF/FP concentration of 0.77 and a median CSF/FP concentration ratio of 0.5 (range: 0.09-6.0). At the third cycle, the median CSF concentration was 1.04 ng/ml (range, 0.07-139.0ng/ml), and the median plasma concentration was 212.3 ng/ml (range, 48.3-803.7 ng/ml). The mean CSF/FP concentration was 0.71, and the median CSF/FP concentration ratio was 0.45 (range: 0.09-4.28) at the third cycle.

Due to short follow-up time, there was no significant difference in CSF/FP concentration ratio and survival.

Conclusions: These results suggest that lazertinib had a promising CSF/FP concentration ratio in patients with EGFR-mutant NSCLC with LMs. Given its high potency for penetrating the BBB, lazertinib may be a therapeutic option for LMs from a pharmacokinetic perspective.

1339P Real-world experience of dacomitinib in mEGFR Advanced NSCLC: A single centre experience

B. Biswas, S. Ganguly, J. Ghosh, S. Roy, A. Bhattacharjee, R. Bakshi

Medical Oncology Department, TMC - Tata Medical Center, Kolkata, India

Background: Dacomitinib, an irreversible tyrosine kinase inhibitor of epidermal growth factor receptor (EGFR), is approved in advanced non-small cell lung cancer (NSCLC) with mutated EGFR. Literature on real world experience of dacomitinib is lacking, especially in patients (pts) with brain metastasis and uncommon EGFR mutation.

Methods: This is single centre retrospective study of EGFR mutated advanced NSCLC pts treated with dacomitinib between July'19 and Feb'23. Clinicopathologic features, treatment details, toxicity and treatment outcome were recorded.

Results: Total 111 pts were treated with median age of 62 years (range: 39-82). ECOG performance status (PS) was 1 in 65 pts, 2 in 37 pts and 3 in 9 pts. 42 (38%, n=96) pts had brain metastasis and 21 pts received WBRT. Type of mutations was Del 19 in 66 pts, L858R in 35 pts, G719X in 4 pts, G719X and S768I in 2 pts, L861Q in 2 pts, and Del 19 + L858R, Exon 20ins + L858R in one patient each. Starting dose of dacomitinib was 45 mg in 43 pts and 30 mg in 68 pts (61%). Intracranial response (n=27) was − CR in 2 pts, PR in 18 pts, SD in 5 pts, and PD in 2 pts. 41 out of 52 pts underwent re-biopsy on progression, 17 pts had EGFR T790M mutation and 3 had small cell transformation. After a median follow-up of 19 months (95 CI: 14.4-23.2), the median PFS was 21.5 months (95% confidence interval [CI]: 18.7 − 26.2) and median overall survival (OS) was 31.2 months (95 CI: 23.4 − not reached). PFS was inferior in pts with brain metastases (p=0.003) and 30 mg starting dose (p=0.004), but not OS and neither with type of mutation or dose modification. 81(73%) pts had any grade of toxicity and 53 pts (47%) had any grade 2 & 3 toxicity. Total 25 pts (23%) required dose modification (Table).

Table: 1339P

Variables	Groups	HR	P
Progression-free survival			
Brain metastases	Absent (n=54)	1	
	Present (n=42)	2.9	0.003
	Not known (n=15)	1.4	0.53
Type of mutation	Del 19 (n=69)	1	
	L858R (n=34)	1.6	0.12
	Uncommon mutation (n=8)	1.5	0.47
Starting dose of dacomitinib	30 mg (n=68)	1	
	45 mg (n=43)	0.9	0.004
Dose modification	Not required (n=88)	1	
	Required (n=23)	0.6	0.14
Overall survival			
Brain metastases	Absent (n=54)	1	
	Present (n=42)	1.6	0.22
	Not known (n=15)	0.8	0.7
Type of mutation	Del 19 (n=69)	1	
	L858R (n=34)	1.5	0.32
	Uncommon mutation (n=8)	1.6	0.48
Starting dose of dacomitinib	30 mg (n=68)	1	
	45 mg (n=43)	1	0.8
Dose modification	Not required (n=88)	1	
	Required (n=23)	0.9	0.9

Conclusions: To best of our knowledge, this is largest real-world study of dacomitinib in mEGFR advanced NSCLC. Dacomitinib is active in pts with brain metastasis, uncommon EGFR mutation, in patients with poor PS, and at 30 mg starting dose. Dacomitinib showed very good PFS with manageable safety profile.

1340P Propensity score matching analysis for osimertinib versus comparator first-generation EGFR tyrosine kinase inhibitors as first-line treatment in patients with advanced EGFR-mutated non−small cell lung cancer: A Chinese, multicenter, real-world cohort study

D. Zhang[1], X. Liu[1], F. Shen[2], D. Zhao[3], Y. Shi[1], H. Zhang[1], J. Liu[1], X. Gao[1], M. Chen[4], J. Zhao[4], W. Zhong[1], Y. Xu[4], M. Wang[4]

[1]Department of Respiratory and Critical Care Medicine, Peking Union Medical College Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Beijing, China; [2]Department of Respiratory Medicine, Shanxi Hospital affiliated to Cancer Hospital, Taiyuan, China; [3]Department of Respiratory and Critical Care Medicine, The Second affiliated Hospital of Anhui Medical University, Hefei, China; [4]Pulmonary and Critical Care Medicine, PUMCH - Peking Union Medical College Hospital/Beijing Xiehe Hospital - Dongdan Campus, Beijing, China

Background: The phase 3 FLAURA trial compared osimertinib with either erlotinib or gefitinib in the first-line treatment of EGFR-mutant lung adenocarcinoma and showed longer PFS, OS and a similar safety profile. However, the efficacy and safety of osimertinib as a first-line treatment still need to be investigated in a real-world setting.

Methods: 1556 patients with EGFR-mutated non−small cell lung cancer (NSCLC) who received osimertinib or a first-generation EGFR tyrosine kinase inhibitor (TKI) as first-line treatment were identified from the CAPTRA-Lung database. 1:2 propensity score matching (PSM) was used to adjust for clinical bias. Progression-free survival (PFS) and overall survival (OS) were compared using Kaplan-Meier analysis. Cox proportional hazards regression was used to identify factors associated with progression and survival.

Results: 202 patients receiving osimertinib and 404 patients receiving first-line EGFR TKIs were enrolled. The objective response rate (ORR) was 63.4% vs. 48.0% (P<0.001) and the disease control rate (DCR) was 95.5% vs. 96.8% (P=0.443) in the osimertinib arm and the comparator arm separately. Median progression-free survival was 19.4 months (95% confidence interval [CI], 14.3 to 24.4) in the osimertinib arm and 10.9 months (95% CI, 9.3 to 12.5) in the comparator arm (hazard ratio for progression, 0.47; 95% CI, 0.38 to 0.59; P < 0.001). Median overall survival was 40.5 months (95% CI, 27.1 to 54.0) versus 34.3 months (95% CI, 30.6 to 38.0) in the osimertinib and comparator groups, respectively (hazard ratio for death, 0.76; 95% CI, 0.58 to 1.00; P = 0.045). Most adverse events were mild and there were no treatment-related deaths. Patients treated with osimertinib showed a similar safety profile to the comparator EGFR TKIs.

Conclusions: In the real-world setting, osimertinib also demonstrated longer PFS, OS and a similar safety profile to comparator EGFR TKIs when given as first-line treatment to NSCLC patients.

Background: The aim of PISCES study is to assess the molecular testing, treatment patterns and clinical outcomes among Chinese patients progressed on first-line (1L) EGFR-TKI monotherapy in real-world setting.

Methods: This prospective study enrolled *EGFR* mutant, locally advanced or metastatic NSCLC patients progressed on 1L EGFR-TKI monotherapy from May 2020 to May 2021 in 16 Chinese hospitals. The treatment patterns and clinical outcomes were recorded.

Results: 292 patients received 1L EGFR-TKI monotherapy were enrolled. 93.8% (274/292) of patients received first/second generation (1/2G) EGFR-TKI and 6.2% (18/292) received third generation (3G) EGFR-TKI. 74.8% (205/274) of patients who progressed on 1L 1/2G EGFR-TKI underwent genetic testing, and 47.8% (98/205) of them were T790M positive (T790M+). 91.8% (90/98) of T790M+ patients received 3G EGFR-TKI as 2L therapy. Among the 107 patients with T790M negative (T790M-), 47.8% (51/107) received 3G EGFR-TKI, 25.2% (27/107) received chemotherapy and 8.4% (9/107) received prior 1/2G EGFR-TKI plus local therapy as 2L therapy. Among 18 patients progressed on 1L 3G EGFR-TKI, half (9/18) of them received chemotherapy, 27.8% (5/18) switched to another 3G EGFR-TKI. The overall median PFS (mPFS) of patients who had received 2L treatment was 9.1 months (95%CI, 7.6-11.2). The mPFS of patients receiving 2L 3G EGFR-TKI, prior 1/2G EGFR-TKI plus local therapy, and chemotherapy was 10.5 months (95%CI, 8.7-13.7), 10.2 months (95%CI, 5.3-19.2) and 5.5 months (95%CI, 3.3-8.6), respectively. Among those receiving 2L 3G EGFR-TKI treatment, T790M+ patients achieved significantly longer mPFS compared to T790M- patients (13.7 vs 7.6 months, P=0.012). For patients with T790M-, the mPFS was comparable (7.6 vs 5.5 months, P=0.07) when received 3G EGFR-TKI and chemotherapy as 2L therapy.

Conclusions: Most patients progressed on 1L EGFR-TKI monotherapy underwent genetic testing in Chinese real-world setting. The vast majority of T790M+ patients received 3G EGFR-TKIs treatment. Although almost half of T790M- patients received 3G EGFR-TKI as 2L therapy, these patients achieved suboptimal clinical outcome.

Clinical trial identification: NCT04207775.

1342P Effect of the timing of intervention in craniocerebral radiotherapy on prognosis of patients with EGFR-mutant lung adenocarcinoma with brain metastasis

G. Deng, J. Li, Z. Li

Shandong Cancer Hospital affiliated to Shandong University, Ji Nan, China

Background: The probability of brain metastasis (BMs) in lung cancer patients with epidermal growth factor receptor (EGFR) mutation is always high. Craniocerebral radiotherapy is the cornerstone for the treatment of BM, which plays an indispensable role together with EGFR-TKI. However, the timing of intervention in craniocerebral radiotherapy has always been a controversial issue. The purpose of this study was to evaluate the efficacy of craniocerebral radiotherapy in patients with EGFR mutant lung adenocarcinoma BM before and after EGFR-TKI resistance.

Methods: A total of 217 patients with advanced non-small cell lung cancer (NSCLC) and EGFR mutations were enrolled in this retrospective cohort study. Propensity score matching (PSM) was conducted using a nearest-neighbor algorithm (1:1) to adjust for demographic and clinical covariates. The patients were divided into two groups according to the timing of craniocerebral radiotherapy intervention.: before EGFR-TKI resistance and after EGFR-TKI resistance. Intracranial progression-free survival (iPFS) and overall survival (OS) were calculated. Kaplan—Meier analysis was used to compare iPFS and OS between the two groups. Brain radiotherapy included WBRT, local radiotherapy, and WBRT+Boost.

Results: The median age at diagnosis was 54 years (range: 32—81 years). Most patients were female (65.9%) and non-smokers (77.4%). Eighty-nine pairs of patients were matched using PSM. The median iPFS for before EGFR-TKI resistance (n=46) and after EGFR-TKI resistance (n=46) was 17.9 and 9.5 months, respectively(P=0.0376). The median OS for before EGFR-TKI resistance (n=89) and after EGFR-TKI resistance (n=89) was 36.9 and 42.1 months, respectively(P=0.6626).

Conclusions: In *EGFR*-mutant lung adenocarcinoma patients with BM, craniocerebral radiotherapy before EGFR resistance is beneficial to the prolongation of iPFS in patients, but this prolongation does not translate into the benefit of OS.

1343P Amivantimab as a salvage strategy post TKI (osimertinib/mobocertinib) in EGFRm NSCLC

B.J. Krayim[1], W. Kian[1], N. Heching[1], A.A.R. Salhab[2], N. Asna[1], D. Kahala[1], L.C. Roisman[1], N. Peled[1]

[1]Helmsley Cancer Center, Shaare Zedek Medical Center, Oncology Institute, Jerusalem, Israel; [2]Radiotherapy Department, Hadassah University Hospital - Ein Kerem, Jerusalem, Israel

Background: Amivantamab is a dual EGFR and MET inhibitor that has been approved for EGFR exon 20 mutations. Osimertinib-treated EGFRm patients may progress through cMET amplification. In such circumstances, amivantamab may be a salvage therapy. Here, we present 13 patients who received amivantamab on top of their previous EGFR TKI for disease progression (Group A - common EGFRm+ & Group B - EGFR Exon20+).

Methods: A retrospective case series study at Shaare Zedek Medical Center between October 2021 and March 2023 of patients who received amivantamab on top of previous EGFR TKI on progression outside of clinical trial after local IRB approval. The study aim to present safety as well as preliminary efficacy. Patient records served as the basis for data collection, PET-CT or CT scans were used to assess systemic response, and for followup. ORR was defined by RECIST 1.1.

Results: 13 pts, 4 male 9 female, median age 65 years (range 45-73). 9 had common mutation (Group A) and 4 uncommon (Group B). 8 group A pts had osimertinib as last line, one afatinib while in Group B 3 pts had mobocertinib, and 1 had poziotinib. Amivantamab was administered on top of previous line in all pts (Table). The objective response rate (ORR) was 37.5% in group A and 25% in group B. Median duration of therapy (mDOT) was 2.3 months in group A and 5.5 months in group B (long — rank p value 0.38), The median progression-free survival was 4.7 months in both groups. Safety profile was driven mainly by amivantamab where grade $\geq$3 toxicity was nausea, diarrhoea, and skin rash (mainly scalp). 16% patients had a grade 3 infusion reaction.

Conclusions: Incorporating amivantamab to prior EGFR TKI treatment appears to be a feasible option, although osimertinib stands out as the most well-tolerated TKI with clinical efficacy. Further studies should aim to identify patient subgroups and confirm these findings through prospective analysis.

1344P A real-world (rw) observational study of long-term survival (LTS) and treatment patterns after first-line (1L) osimertinib in patients (pts) with epidermal growth factor receptor (EGFR) mutation-positive (m) advanced non-small cell lung cancer (NSCLC)

J. Nieva[1], P.S. Karia[2], P. Okhuoya[3], M. Berktas[3], R.J-B. Salomonsen[2], L. Servidio[4], J. Chapaneri[5], K. De Silva[6], E. Martin[7], F. Griesinger[8]

[1]Medical Oncology, University of Southern California - Norris Comprehensive Cancer Center, Los Angeles, CA, USA; [2]Oncology Outcomes Research, AstraZeneca, Gaithersburg, MD, USA; [3]Oncology Outcomes Research, AstraZeneca, Cambridge, UK; [4]Global Medical Affairs, AstraZeneca, Gaithersburg, MD, USA; [5]Global Medical Affairs, AstraZeneca, Cambridge, UK; [6]Center of Oncology Data Excellence, AstraZeneca, Cambridge, UK; [7]Oncology Biometrics, AstraZeneca, Cambridge, UK; [8]Oncology Department, Pius Hospital, University Medicine Oldenburg, Oldenburg, Germany

Background: Osimertinib, a third-generation, irreversible, central nervous system-active, EGFR tyrosine kinase inhibitor (TKI) that selectively inhibits EGFR-TKI sensitising and EGFR T790M resistance mutations, is the preferred 1L treatment for EGFRm advanced NSCLC. We present results from the US cohort of a global rw observational study of LTS and treatment patterns after 1L osimertinib in advanced EGFRm NSCLC.

Methods: Adults with stage IIIB—IV EGFRm NSCLC who initiated 1L osimertinib monotherapy between Apr 2018—Mar 2020 were identified from the Flatiron Health database. Primary endpoints: overall survival (OS), time to next treatment or death (TTNTD) and treatment patterns; secondary endpoints: baseline characteristics and time to treatment discontinuation (TTD; a rw progression-free survival [PFS] surrogate). OS, TTNTD and TTD were also assessed in a subset of pts aligned with the FLAURA trial (NCT02296125) inclusion criteria (FLAURA-like cohort). Endpoints were reported descriptively.

Results: Among 773 pts, median age was 70 yrs (interquartile range [IQR] 61—78), 68% were female, 59% were White, 54% had no/unknown smoking history, 64% had ECOG PS 0 or 1 and 89% had Exon 19 deletion or L858R EGFR mutations. With a median follow-up of 24 mos (IQR 10—36), median OS, TTNTD and TTD (95% confidence interval [CI]) for all pts were 29.8 mos (27.2—32.1), 18.5 mos (17.0—21.3) and 16.3 mos (15.0—18.1), and for the FLAURA-like cohort (n=453) were 33.3 mos (30.0—37.2), 22.3 mos (18.5—25.2) and 19.4 mos (16.4—23.0), respectively. Overall, 39% of pts received subsequent therapy (Table).

Table: 1344P

Subsequent therapy received, n (%)	All pts (N=773)
Yes	299 (39)
No	
Remained on 1L osimertinib	173 (22)
Discontinued 1L osimertinib	50 (6)
Died	251 (32)
Therapy received	
2L therapy	**(n=299)**
IO + CT	74 (25)
Osimertinib + CT	47 (16)
CT	39 (13)
1G or 2G EGFR-TKI	33 (11)
IO	28 (9)
Other	78 (26)
3L therapy	**(n=138)**
IO + CT	24 (17)
Osimertinib + CT	15 (11)
CT	28 (20)
1G or 2G EGFR-TKI	14 (10)
IO	11 (8)
Other	46 (33)

Percentages have been rounded to the nearest whole number and may not sum to 100%. 1G, first-generation; 1L, first-line; 2G, second-generation; 2L, second-line; 3L, third-line; CT, chemotherapy; EGFR-TKI, epidermal growth factor receptor-tyrosine kinase inhibitor; IO, immunotherapy; pts, patients.

Conclusions: In a large rw cohort of pts with EGFRm advanced NSCLC treated with 1L osimertinib, median OS and TTD were consistent with median OS and PFS in FLAURA (Ramalingam NEJM 2020 ; Soria NEJM 2018), reinforcing the effectiveness of osimertinib in the real world.

1345P Preclinical activity of ORIC-114, a highly selective, brain penetrant, irreversible kinase inhibitor, against atypical mutations in EGFR

M.R. Junttila[1], R. Warne[1], C. Repellin[1], L. Sambucetti[1], J. Chang[2], S. Kim[3], H.Y. Kim[3], D.G. Shin[3], D.H. Park[3], R. Patel[4], E. Chow Maneval[4], P.S. Multani[4], A. Daemen[5], L. Friedman[6]

[1]Biology Dept., ORIC Pharmaceuticals, Inc., South San Francisco, CA, USA; [2]DMPK, ORIC Pharmaceuticals, Inc., South San Francisco, CA, USA; [3]Voronoi Inc., Incheon, Republic of Korea; [4]Clinical Development, ORIC Pharmaceuticals, Inc., San Diego, CA, USA; [5]Translational Medicine Department, ORIC Pharmaceuticals, Inc., South San Francisco, CA, USA; [6]Research Dept., ORIC Pharmaceuticals, Inc., San Diego, CA, USA

Background: EGFR mutations are oncogenic drivers commonly found in non-small cell lung cancer (NSCLC). Patients with atypical mutations in EGFR have a worse prognosis than those with classical mutations and need effective therapies. In addition to exon 20 insertion mutations in EGFR, another related category of atypical mutations are P-loop and alpha C-helix compressing (PACC) mutations, the majority of which lack approved therapies. ORIC-114 is a brain penetrant, orally bioavailable, irreversible small molecule inhibitor designed to selectively target EGFR and HER2 with strong potency against exon 20 insertion mutations, making it a promising therapeutic to potentially address this unmet medical need, including in NSCLC patients with active central nervous system (CNS) metastases. We further explored the potential of ORIC-114 in other atypical mutations in EGFR and herein report the preclinical results.

Methods: To comprehensively characterize the potential of ORIC-114, biochemical and isogenic cell assays were developed for a variety of atypical mutations in EGFR, including primary and acquired PACC mutations, and assessed for potency. Additional in vivo analysis was performed to further assess free unbound exposures in brain.

Results: ORIC-114 is a potent inhibitor of PACC mutants with low to sub nanomolar activity across most atypical mutations assessed in both biochemical and cell-based assays. The potency on PACC mutants is similar to the potency on exon 20 insertion mutations in EGFR. In addition, ORIC-114 was found to be highly brain penetrant in the setting of an intact blood-brain-barrier in dogs, with high unbound brain-to-plasma partition coefficient Kp,uu,brain of 1.5.

Conclusions: ORIC-114 demonstrated best-in-class properties including high free unbound exposure in brain, exquisite selectivity across the kinome, and potent activity across atypical mutations in EGFR, including PACC mutations and exon 20 insertion mutations. ORIC-114 is a promising therapy for NSCLC patients with atypical mutations in EGFR, including those with active CNS metastases, and is currently being evaluated in a global clinical trial (NCT05315700).

Clinical trial identification: NCT05315700.

1346P Efficacy and safety of high dose furmonertinib combined with intrathecal injection in EGFR-mutated advanced NSCLC patients with LM progressed on osimertinib

X. Li, X. Zheng, J. An, Y. Hua, X. Ding, H. Shi, W. Xu, Y. Li, L. Zhou

Department of Oncology, Beijing Tiantan Hospital, Capital Medical University, Beijing, China

Background: We observed that leptomeningeal metastases (LM) occurred more in patients with site-specific resistant to osimertinib than first-generation EGFR-TKI, while these patients lacked of effective therapy. Furmonertinib 160 mg has been demonstrated encouraging efficacy in EGFR-mutated advanced NSCLC with central nervous system (CNS) metastases. This retrospective study aimed to evaluate the efficacy and safety of high dose furmonertinib combined with intrathecal injection methotrexate (MTX) or pemetrexed (PEM) in EGFR-mutated NSCLC patients with LM site-specific resistance to osimertinib.

Methods: Patients confirmed EGFR-mutated advanced NSCLC with LM progressed on osimertinib or other third-generation TKIreceived furmonertinib 160 mg or 240 mg combined with intrathecal injection MTX or PEM until disease progression. The primary endpoint was central nervous system progression-free survival (CNS PFS), and secondary endpoints were LM response rate according to RANO criteria, PFS, overall survival (OS) and safety.

Results: This retrospective study analysed the efficacy and safety of 23 EGFR-mutated advanced NSCLC patients with LM at Beijing Tiantan Hospital between June 2021 and April 2023. The median age was 63 years (range: 41-78) , ECOG PS$\geq$2 65.2%, 82.6% patients had received other third-generation EGFR-TKI previously, all patients were adenocarcinoma. The median follow-up time was 8.2 months (range: 0.9-14.1), the median CNS PFS was 10.8 months, LM response was observed in 6 (31.6%) of 19 patients with available data. The median PFS was 10.8 months, the median OS was NR. The CSF tumors cells decreased from baseline was observed in 14 (73.7%) of 19 patients with available data, and the CSF tumor cells clearance was observed in 6 (31.6%) patients. Neurologic function was improved in 18 (90.0%) of 20 patients. The most common treatment-related adverse events (TRAEs) were dry skin (17.4%) and elevated AST/ALT (17.4%). Nograde 3 or higher TRAEs observed.

Conclusions: High dose furmonertinib combined with intrathecal injection showed encouraging efficacy in EGFR-mutated advanced NSCLC patients progressed on osimertinib or other third-generation TKI.

Background: Osi is designed to have better central nervous system (CNS) efficacy than other epidermal growth factor receptor tyrosine kinase inhibitors (EGFR-TKIs). However, 21% and 24% of pts treated in 1st or 2nd line develop CNS progression, mainly consisting of BM. A possible reason may be pharmacological failure of osi, due to low $C_{min,SS}$ and intracranial levels. However, data on osi $C_{min,SS}$ and BM related outcomes in Caucasians is lacking.

Methods: Retrospective study in three Dutch hospitals, collecting osi $C_{min,SS}$ from pts treated with osi 80 mg once daily for *EGFR*+ aNSCLC. Pts with parenchymal BM at start of osi were allocated to the BM-cohort and those without known BM to the no-known-BM-cohort. Pts were further allocated into subgroups based on osi $C_{min,SS}$ (low, middle or high). The primary outcome in both cohorts was cumulative incidence of BM development and progression.

Results: 173 pts were included, 28% had BM at osimertinib initiation (BM-cohort). In both cohorts, most pts were female (71% BM-cohort and 69% no known BM-cohort) and approximately half of the pts received osi in 2nd line (49% BM-cohort and 51% no known BM-cohort). Median follow-up was 22.8 months and at data cut-off 39% of pts still used osi without progression of BM. In the BM-cohort, 18 out of 49 pts (37%) experienced BM progression. Competing risk analysis showed a cumulative incidence of BM progression of 20% (95% CI 2.6 − 49.0), 31% (95% CI 10.6 − 53.9) and 31% (95% CI 10.8 − 54.5) after 12 months for the $C_{min,SS}$ low, middle and high subgroups respectively and 20% (95% CI 2.6 − 49.0), 52% (95% CI 23.8 − 74.2) and 57% (95% CI 24.9 − 79.7) after 20 months for the corresponding subgroups. In the no-known-BM-cohort, 4% developed BM during osi and no differences were found between the $C_{min,SS}$-subgroups.

Conclusions: This study suggests no relationship between plasma blood osi trough levels ($C_{min,SS}$) and cumulative incidence of BM development and progression in pts with *EGFR*+ aNSCLC.

Background: Lazertinib, a third generation, highly mutant-selective, irreversible EGFR TKI, has demonstrated efficacy in locally advanced or metastatic *EGFR*-mutated NSCLC as front line and later line treatment with a manageable safety profile at the dose of 240 mg/day. Paresthesia, an uncommon adverse event (AE) for EGFR TKIs, was reported in 33% and 39% of patients receiving lazertinib in the LASER201 (NCT03046992) and LASER301 (NCT04248829) studies. We performed an integrated analysis of these studies to characterize the clinical features of paresthesia and related AEs, and examined the effect of lazertinib dose reduction (DR) on drug exposure, safety and clinical efficacy.

Methods: Patients treated with lazertinib 240 mg/day in the LASER201 and LASER301 studies were included in the analysis (332 patients). Lazertinib plasma trough concentrations at steady state (C_{trough}) were measured at doses of 240 mg/day and 160 mg/day (post-DR). Efficacy outcomes including PFS were compared in patients with and without DR for any reason in LASER301.

Results: Paresthesia and related AEs including hypoesthesia and neuropathy were reported in 160 (48%) of 332 patients. Most AEs were of CTCAE grade 1 or 2 without serious AEs. Paresthesia leading to DR was infrequent (22 patients; 7%). Median time to paresthesia onset was 105 days (range: 2—799); time to DR due to paresthesia was 252.5 days (range: 64—1135). Median post-DR C_{trough} levels in DR patients were similar to those in non-DR patients (post-DR: 168.5 ng/mL; non-DR: 177.9 ng/mL). In the LASER301 study, DR occurred in 42 of 196 patients assigned to 240mg/day lazertinib. Median PFS was similar in patients with and without DR: 18.0 months (95% CI: 14.8—not reached) for DR patients vs 23.3 months (95% CI: 16.7—26.1) for non-DR patients. In the LASER201 study, 12 of 76 T790M-positive patients experienced DR due to any cause. Of 13 patients in the LASER301 study with paresthesia leading to DR, AE severity decreased in 9 patients (63%) after DR to 160mg/day, including complete AE resolution in 1 patient.

Conclusions: Most paresthesia and related AEs were grade 1 or 2 and DR due to paresthesia was infrequent. Lazertinib DR to 160 mg/day may alleviate paresthesia severity without compromising clinical outcomes.

Clinical trial identification: LASER 201 study, phase 1/2 NCT03046992; LASER 301 study, phase 3 NCT04248829.

1349P Continuing osimertinib in combination with chemotherapy after osimertinib failure reduces CNS progression in patients with EGFR-mutated NSCLC and CNS metastases

M. Li[1], K. Mok[2], L.L. Chan[1], K.W.C. Lee[1], H.H.F. Loong[1], K.C. Lam[2], F. Mok[2], Y.M. Lau[2], O. Chen[2], J. Ng[2], B. Lam[2], A. Chen[2], W. Wong[2], T.S.K. Mok[1]

[1]Clinical Oncology, The Chinese University of Hong Kong, Hong Kong, China; [2]Clinical Oncology, Prince of Wales Hospital, Hong Kong, China

Background: Central nervous system (CNS) metastases are common among patients with epidermal growth factor receptor mutation positive (EGFRm) non-small cell lung cancer (NSCLC). Chemotherapy (ChT) is the standard treatment for patients with metastatic EGFRm NSCLC patients failing osimertinib but has limited CNS activity. The role of continuing osimertinib concurrently with ChT after osimertinib failure for CNS control is uncertain.

Methods: This retrospective study included patients with metastatic EGFRm NSCLC who progressed on osimertinib and received ChT from 01/11/2017 to 17/03/2023. Primary endpoint is comparison of time to CNS progression between patients treated with osimertinib plus ChT versus ChT alone after progression on osimertinib. Time to CNS progression was defined from the starting date of ChT to radiological progression of CNS metastases. Hazard ratios and 95% confidence interval were estimated by Cox regression.

Table: 1349P

Total population	OSIM+ (n=33)	OSIM- (n=147)	Hazard Ratio (95% CI)	P value
Median PFS — months (95% CI)*	6.2 (5.5-6.8)	4.8 (4.2-5.4)	0.72 (0.48-1.09)	0.12
CNS progression — no. (%)	**7 (21)**	**33 (22)**	**0.74 (0.33-1.68)**	**0.88**
Patients with known CNS metastases	**(n=30)**	**(n=52)**		
Median PFS — months (95% CI)*	6.2 (5.6-6.7)	4.8 (4.1-5.5)	0.62 (0.38-1.00)	0.05
CNS progression — no. (%)	**6 (20)**	**24 (46)**	**0.32 (0.13-0.81)**	**0.02**
Salvage WBRT — no. (%)	2 (7)	11 (21)	0.24 (0.05-1.08)	0.06

*CNS/systemic progression or death PFS, progression free survival

Results: A total of 180 patients were analyzed. Median age was 62 (34-80). 28 (16%) received osimertinib as first-line treatment. 33 patients continued osimertinib with ChT (OSIM+) and 147 patients received ChT alone (OSIM-). Prior to starting ChT, 30/33 (91%) and 52/147 (35%) patients had known CNS involvement, among which 8 and 27 had received prior whole brain radiotherapy (WBRT), in the OSIM+ versus OSIM- arms respectively. In the total population, osimertinib plus ChT did not reduce risk of CNS progression. In patients with known CNS metastases, osimertinib plus ChT significantly reduced CNS progression. Numerically fewer patients in the OSIM+ arm received salvage WBRT.

Conclusions: Continuing osimertinib concurrently with ChT after osimertinib failure may reduce CNS progression in patients with known CNS metastasis, and the risk of being subjected to WBRT. Future prospective study is warranted to address this issue.

1350P Survival benefits of local treatment (LT) for brain metastases (BMs) in patients (pts) with EGFR-mutant non-small cell lung cancer (EGFR-mt NSCLC) treated with osimertinib

T. Tozuka[1], R. Noro[1], H. Mizutani[2], F. Kurimoto[3], T. Hakozaki[4], K. Hisakane[5], T. Naito[6], S. Takahashi[7], N. Taniuchi[8], C. Yajima[9], Y. Hosomi[4], T. Hirose[5], Y. Minegishi[6], T. Okano[7], K. Kamio[8], T. Yamaguchi[9], M. Seike[1]

[1]Department of Pulmonary Medicine and Oncology, Graduate School of Medicine, Nippon Medical School, Tokyo, Japan; [2]Department of Thoracic Oncology, Saitama Cancer Center, Saitama, Japan; [3]Respiratory Disease Center, Fukujuji Hospital, Japan Anti-Tuberculosis Association (JATA), Tokyo, Japan; [4]Department of Thoracic Oncology and Respiratory Medicine, Tokyo Metropolitan Cancer and Infectious Diseases Center Komagome Hospital, Bunkyo-ku, Japan; [5]Department of Pulmonary Medicine and Oncology, Nippon Medical School Tama Nagayama Hospital, Tokyo, Japan; [6]Department of Respiratory Medicine, Mitsui Memorial Hospital, Tokyo, Japan; [7]Department of Respiratory Medicine, Nippon Medical School Chiba Hokusoh Hospital, Inzai, Japan; [8]Department of Pulmonary Medicine, Nippon Medical School Musashikosugi Hospital, Kanagawa, Japan; [9]Department of Respiratory Medicine, Tokyo Rinkai Hospital, Tokyo, Japan

Background: Osimertinib is a standard treatment for pts with EGFR-mt NSCLC and is highly effective for BMs. It is unclear whether upfront LT for BMs prolong survival of pts with EGFR-mt NSCLC. The aim of this study was to reveal the survival benefit of upfront LT for BMs in pts with EGFR-mt NSCLC treated with osimertinib.

Methods: We conducted a multicenter (9 centers in Japan), retrospective cohort study of consecutive pts with EGFR-mt NSCLC who had BMs before the initiation of osimertinib between August 2018 and October 2021. Pts with meningitis were excluded. We divided all pts into two groups: pts who received upfront LT for BMs followed by osimertinib (Upfront LT group) and pts who received osimertinib without upfront LT (Osimertinib alone group). Overall survival (OS) and central nervous system progression free survival (CNS-PFS) between the two groups were compared. Inverse probability treatment weighting (IPTW) analysis with propensity scores was performed to adjust for potential confounding factors.

Results: A total of 121 pts was enrolled: median (range) age 72 (40—89) years; 83 (69%) female; 92 (76%) ECOG PS 0—1, 29 (24%) PS 2—4; 116 (96%) adenocarcinoma; EGFR status 57 (47%) 19del, 64 (53%) L858R; number of BMs 37 (31%) single, 84 (69%) multiple; median (range) maximum size of BMs 10 (1—51) mm; Symptoms of BMs 26 (21%) yes, 95 (79%) no; 45 (37%) upfront LT, 76 (63%) osimertinib alone. IPTW-adjusted Kaplan-Meier curves showed that OS of pts in the upfront LT group was significantly longer than that of pts in osimertinib alone group (median, Not reached (NR); 95% CI, NR—NR versus median, 31.2 months; 95%CI, 21.7—33.2; p=0.021). IPTW-adjusted HR for OS was 0.37 (95%CI, 0.16—0.87). IPTW-adjusted HR for CNS-PFS was 0.36 (95%CI, 0.15—0.87).

Conclusions: These results suggest that upfront LT for BMs followed by osimertinib may improve survival for pts with EGFR-mt NSCLC despite the high CNS activity of osimertinib.

1351P Efficacy of early stereotactic body radiotherapy to the primary lung lesion in patients with NSCLC harboring sensitive EGFR mutations treated with first-line EGFR-TKIs

D. Tao[1], H. Lei[2], J. Tan[1], D. Yang[1], Y. Jiang[1], W. Zhou[1], Y. Wang[1], Y. Wu[1]

[1]Department of Radiation Oncology, Chongqing University Cancer Hospital, Chongqing, China; [2]Chongqing Cancer Multi-omics Big Data Application Engineering Research Center, Chongqing University Cancer Hospital, Chongqing, China

Background: The addition of consolidative stereotactic body radiotherapy (SBRT) improved the survival for EGFR-mutated NSCLC treated with EGFR-TKIs. However, the optimal timing of SBRT remains unclear. The current study aimed to investigate the clinical outcome of the early and delayed SBRT to primary lung lesions in patients with EGFR-mutated NSCLC treated with first-line EGFR-TKIs.

Methods: The patients with EGFR-mutated advanced (stage IIIB-IV) NSCLC who were suitable to receive SBRT for the primary lung tumors after first-line EGFR-TKIs treatment were enrolled. The early SBRT group was defined as patients who received SBRT for their primary lung lesions at the maximal response of TKIs treatment. The delayed SBRT group was defined as patients who received SBRT after the occurrence of oligoprogression in the primary lung tumor. The primary endpoints were progression-free survival 1 (PFS1, time from the start of first-line EGFR-TKIs treatment to disease progression) and PFS2 (time from the start of first-line EGFR-TKIs treatment to disease progression after SBRT). Overall survival (OS) and adverse effects (AEs) were secondary endpoints. A two-sided P value of 0.05 was considered statistically significant.

Results: One hundred and eighty-four patients were screened, and 34 patients were eligible for enrollment in this study. The median age of the entire cohort was 61 years (range, 37—67 years), and 22 (64.7%) patients were male. Eighteen patients (52.9%) were non-smokers. Of the 34 eligible patients, 19(55.9%) received early SBRT to lung primary tumor and 15(44.1%) received delayed SBRT to lung primary tumor. The early

SBRT group had a significantly longer median PFS1 than the delayed SBRT group (30.0 months vs. 9.0 months, $P < 0.001$). The median PFS2 in the early SBRT and delayed SBRT groups were 42.0 and 33.0 months, respectively ($P = 0.521$). The median OS of both groups has not been reached. No severe toxicities (≥grade 3) were recorded.

Conclusions: Early SBRT to the primary lung lesion significantly improved PFS and is a new potentially effective and tolerable treatment option for patients with advanced NSCLC who had stable disease during first-line EGFR-TKIs treatment.

1352P Plasma metabolic signatures uncover therapeutic response and prognosis of third-generation EGFR-TKI treatment in patients with NSCLC

R. Gao[1], N. Lou[2], L. Zhang[1], X. Han[3]

[1]*Department of Medical Oncology, Chinese Academy of Medical Sciences and Peking Union Medical College - National Cancer Center, Cancer Hospital, Beijing, China;* [2]*Clinical Laboratory, Chinese Academy of Medical Sciences and Peking Union Medical College - National Cancer Center, Cancer Hospital, Beijing, China;* [3]*Clinical Pharmacology Research Center, CAMS-PUMC - Chinese Academy of Medical Sciences and Peking Union Medical College - Dongdan Campus, Dongcheng-qu, China*

Background: Advanced *EGFR* T790M-mutant non-small cell lung cancer (NSCLC) inevitably develops resistance to third-generation EGFR tyrosine kinase inhibitors (EGFR-TKIs) therapy. Metabolic reprogramming supports EGFR-TKI resistance, while thorough metabolomics clinical studies are limited.

Methods: Here, we enrolled 202 NSCLC patients from phase I and IIa clinical studies and characterized responsive metabolic features of third-generation EGFR-TKI by metabolomics, genomics and proteomics.

Results: The most frequent concurrent driver gene mutations were *TP53*, *RB1,* and *PIK3CA and* non-driver gene *PIK3CG*. Shorter progression-free survival (PFS) was related to *PIK3CG* (HR=3.55, P=0.06) or *RB1* (HR=2.56, P=0.05) mutations and *RB1* mutation was also correlated with shorter overall survival (OS) (HR=3.08, P=0.012). Baseline plasma metabolites revealed responder (R) featured by elevated glycerophospholipid and non-responder (NR) characterized by increased unsaturated fatty acids. *RB1* and *PIK3CG* mutations were positively correlated with unsaturated fatty acids and negatively associated with glycerophospholipids. Moreover, the circulating metabolic landscape implicated two distinct metabolic subtypes (C1 and C2), suggesting that subtype C2 with worse OS was characterized by *PIK3CG* mutation and higher unsaturated fatty acids. Proteomics revealed C1 harbored increased levels of biosynthesis of fatty acid, fatty acid degradation, and fatty acid metabolism pathways compared to the C1 subtype. In vitro experiments, Orlistat combined with BPI-7711 had reduced IC50 (508.08nM) in comparison with BPI-7711 alone (1328nM). Furthermore, we confirmed that exogenous fatty acids promoted cell viability upon BPI-7711 treatment (IC50=1704nM versus 1328nM) through decreasing EGFR expression. Meanwhile, fatty acids downregulated FASN and upregulated CPT1A expression, which may reduce the de nove synthesis of fatty acids and influence fatty acid oxidation.

Conclusions: This study revealed the metabolic landscape of advanced T790M-mutant NSCLC patients, providing the potential guide of personalized third-generation EGFR-TKI treatment and therapeutic target for overcoming resistance.

1353P Effect of TP53 co-mutation in non-small cell lung cancer (NSCLC) with driver mutations

J. Feng[1], K. Hueniken[2], Z. Fan[1], E. Faour[1], L. Corke[1], N. Leighl[1], G. Liu[1], P. Bradbury[1], A. Sacher[1], L. Eng[1], T. Stockley[3], M-S. Tsao[1], F.A. Shepherd[1]

[1]*Medical Oncology, UHN (University Health Network) - Princess Margaret Cancer Centre, Toronto, ON, Canada;* [2]*Biostastics, UHN (University Health Network) - Princess Margaret Cancer Centre, Toronto, ON, Canada;* [3]*Laboratory Medicine Program, UHN - University Health Network, Toronto, ON, Canada*

Background: *TP53* variants are common in NSCLC and have been reported as predictive of response and prognostic of poor outcome in *EGFR*-mutant NSCLC. The impact of *TP53* co-mutation in NSCLCs carrying rarer driver mutations with approved targeted treatments is unclear.

Methods: Records of 236 patients with rare driver mutation positive NSCLC at Princess Margaret Cancer Centre were reviewed. Associations between *TP53* status, baseline demographics and outcomes (response [ORR], survival [OS], progression-free survival [PFS]), were investigated. ORR (to first-line targeted therapy only) was compared via Fisher's exact test. OS and PFS were compared by Kaplan-Meier estimates, and Cox regression adjusted for stage at diagnosis with wildtype (WT) as reference.

Results: *TP53* variants were found in 88/236 (37%; table) with two+ driver mutations in 22 (9%). There were no significant demographic differences between *TP53*-mutated (MUT) and WT except for smoking status (never smokers 58% *TP53-MUT v* 70% *TP53*-WT, p=0.002). ORR to first-line targeted treatment was 54% vs 71% in the *TP53*-MUT and WT cohorts, respectively (p=0.09). More patients with *TP53*-MUT cancer had progressive disease (PD) as best response (27% *v* 8%, p=0.005). Median PFS was 19.6 mos for *TP53*-MUT (95% CI 14.4-24.3) *v* 42.7 mos for WT (CI 31-72.9) (stage-adjusted hazard ratio (aHR) 2.35, CI 1.62-3.39; p<0.001). Median OS was significantly shorter in the *TP53*-MUT cohort at 20.9 mos (CI 17.3-30.7) compared to 66.4 mos (CI 54.8-not reached) (aHR 3.30, CI 2.20-4.95; p<0.001). In a subset with fusion mutations (*ALK*, *ROS1*, *RET, NRG1*), we saw similar trends in ORR (67% *TP53*-MUT *v* 88% WT, p=0.11), PFS (aHR 2.83, CI 1.52-5.27; p=0.001), and OS (aHR 5.00, CI 2.42-10.33; p<0.001).

Table: 1353P

	***TP53* wildtype (n=148) N (%)**	***TP53* mutated (n=88) N (%)**	**p value**
Median age (range)	62.1 (31.8, 91.0)	64.8 (22.0, 90.0)	0.40
Female sex	91 (61%)	49 (56%)	0.46
Never smoker	99 (70%)	49 (58%)	0.06
Adenocarcinoma	141 (95%)	83 (94%)	0.99
Stage at diagnosis I/II III IV	32 (22%) 31 (21%) 85 (57%)	16 (18%) 15 (17%) 57 (65%)	0.54
Brain metastases at any time	49 (36%)	31 (37%)	0.90
Driver mutations ALK BRAF V600E EGFR exon 20 ins Uncommon EGFR HER2 exon 20 ins HER2 oncogenic SNV KIT MET exon 14 skip NRG1 RET ROS1 Multiple	44 6 3 3 27 4 0 18 2 10 15 16	9 1 5 3 21 6 1 17 0 6 8 11	
Response to first line targeted treatment CR PR SD PD Non-evaluable	n=100 1 (1%) 64 (65%) 19 (19%) 8 (8%) 8 (7%)	n=49 0 22 (45%) 6 (12%) 13 (27%) 8 (14%)	0.005

Conclusions: *TP53* co-mutation with multiple rare driver mutations is predictive of poor response to targeted treatments and prognostic of shorter OS and PFS in NSCLC.

1354P Beyond the common mutation: Examining chemotherapy success in uncommon EGFR mutations

C-C. Lin[1], P-L. Su[2], B. Lin[3]

[1]*Internal Medicine Dept., NCKU - National Cheng Kung University, Tainan City, Taiwan;* [2]*Internal Medicine Department, NCKUH - National Cheng Kung University Hospital, Tainan City, Taiwan;* [3]*Chest Medicine, NCKUH - National Cheng Kung University Hospital, Tainan City, Taiwan*

Background: Some prospective studies have shown that second-generation tyrosine kinase inhibitors (TKIs) provide better control in patients with non-small-cell lung cancer (NSCLC) with uncommon epidermal growth factor receptor (EGFR) mutations. However, studies comparing second-line chemotherapy efficacy between NSCLC patients with common and uncommon EGFR mutations remain rare. This retrospective study compared treatment outcomes in these patients.

Methods: Patients with EGFR-mutated advanced-stage NSCLC who received first-line EGFR-TKIs in a tertiary referral center were retrospectively reviewed between January 2010 and August 2022. Patients with a negative T790M test at disease progression who received second-line chemotherapy were enrolled. Progression-free (PFS)and

overall (OS) survival were compared between advanced NSCLC patients with common and uncommon EGFR mutations using Kaplan−Meier and log-rank tests.

Results: Total 209 (54.8%) patients had a negative T790M mutation test and received second-line chemotherapy, of which 192 (92.3%) had a common EGFR mutation (exon 19 deletion or exon 21 L858R substitution), and 17 (8.2%) had an uncommon EGFR mutation. Patients in the common EGFR mutation group had significantly longer PFS than those in the uncommon EGFR mutation group (4.57 vs. 2.57 months, $p = 0.031$). While patients in the common EGFR mutation group had longer OS than those in the uncommon EGFR mutation group, the difference was nonsignificant (12.53 vs. 9.70 months, $p = 0.501$). A Cox proportional hazard regression analysis controlling for potential confounding factors indicated that an uncommon EGFR mutation was an independent prognostic factor for PFS(hazard ratio [HR] = 2.15, 95% confidence interval [CI]: 1.27−3.64).Being male was only the independent poor prognostic factor for OS (HR = 1.64, 95% CI: 1.22−2.21).

Conclusions: To our knowledge, this is the first study investigating the impact of EGFR mutation subtypes on second-line chemotherapy efficacy. This study suggests that patients with uncommon EGFR mutations have poorer chemotherapy responses and shorter survival than those with common EGFR mutations. The development of new treatment strategies for these patients remains an unmet need.

1355P Evaluation of the role of variant allele frequency in EGFR mutated non-small cell lung cancer treated with first line osimertinib

M. Brambilla[1], D. Lorenzini[2], M. Occhipinti[1], S. Manglaviti[1], T. Beninato[1], L. Mazzeo[1], L. Agnelli[2], R. Leporati[1], C. Zanella[1], A.G. Leone[1], G. Fotia[1], A. Prelaj[3], G. Lo Russo[1], I. Grande[1], E. Tamborini[2], F. Perrone[2], M. Ganzinelli[1], G. Pruneri[4], F.G.M. De Braud[1], C. Proto[1]

[1]Medical Oncology Department, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy; [2]Pathology Department, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy; [3]Department of Medical Oncology, Fondazione IRCCS - Istituto Nazionale dei Tumori, Milan, Italy; [4]Pathology Department, Fondazione IRCCS - Istituto Nazionale dei Tumori, Milan, Italy

Background: The efficacy of Osimertinib (Osi) in advanced EGFR mutated non-small cell lung cancer (aNSCLC) is associated to type of EGFR mutations (EGFRm) and line of treatment, while the impact of cell clonality is still controversial. We aimed to evaluate the effect of variant allele frequency (VAF), as a surrogate of clonality, in the first line treatment with Osimertinib in EGFR mutated aNSCLC.

Methods: We retrospectively collected data of 60 aNSCLC harbouring a common EGFRm (Ex19dels or Ex21 L858R) treated with at least one cycle of first-line Osi from January 2019 to September 2022 at Fondazione IRCCS Istituto Nazionale Tumori of Milan. Next Generation Sequencing analyses were performed at baseline. According to median VAF (mVAF), patients were divided into two subgroups (VAFhigh > mVAF and VAFlow < mVAF). Differences in median progression free survival (mPFS), objective response rate (ORR) and disease control rate (DCR) between subgroups were analysed. Fisher's exact test was used to compare proportions. Survival was estimated through Kaplan-Meier method and compared by Cox-proportional Hazard model.

Results: In our cohort, mVAF was 0,39. Baseline characteristics were equally distributed between subgroups. With a median follow up of 14,2 months (mo), mPFS in the overall population was 17 mo (0.95 CI 12,2-30,1). No statistically differences in mPFS were found according to mVAF (HR 1,34, 15 mo 0.95CI [11,8-NA] vs 20,9 mo 0.95CI [11,9-NA], p=0.45, in VAFlow and VAFhigh, respectively). Similarly, mVAF did not impact on DCR and ORR (92,3% vs 96,6%, p=0,922 and 65,5% vs 65,4%, p=1 in VAFhigh vs VAFlow, respectively). Finally, no differences were observed between the two subgroups in terms of clinical characteristics associated with worse prognosis (presence of brain metastasis, number of metastatic sites and TP53 comutation).

Conclusions: Our study suggests that EGFR mVAF has a low impact in predicting the benefit of first-line Osi. Further investigations in a larger cohort and with a longer follow up, including a more comprehensive analysis of the genomic landscape, may help in clarifying the role of VAF in predicting the clinical outcomes to Osi.

Clinical trial identification: NCT05550961.

1356P 10-year survivors treated with tyrosine kinase inhibitor for advanced non-small cell lung cancer

Y. Tanaka, S. Umemura, E. Sugiyama, T. Sakai, H. Izumi, Y. Zenke, S. Matsumoto, K. Yoh, K. Goto

Department of Thoracic Oncology, National Cancer Center Hospital East, Kashiwa, Japan

Background: The development of tyrosine kinase inhibitors (TKI) has led to the emergence of long-term survivors in advanced non-small cell lung cancer (NSCLC), with a part of them surviving more than 5 years. However, no studies have examined the 10-year survivor in patients (pts) with advanced NSCLC receiving TKI. This study aims to clarify characteristics of the 10-year survivors.

Methods: We have retrospectively reviewed the clinico-genomic findings of advanced or recurrent NSCLC pts with driver oncogene who received TKIs at the National Cancer Center Hospital East between 2002 and 2012. We defined pts who survived more than 10 years as the long survivor group and others as the non-long survivor group.

Results: The analysis included 387 pts. The survival rate at the 5- and 10-year were 21% and 7%. 27 pts (7%) were in the long survivor group and 360 pts (93%) were in the non-long survivor group. The types of driver alterations were as follows: 358 EGFR mutations, 24 ALK fusions, 4 ROS1 fusions and 1 RET fusion. A comparison analysis between long survivor and non-long survivor showed that the median age was 60 (range 23-89) vs. 64 (range 25-84) (P = 0.005); female was 22 (81%) vs. 213 (59%) (P = 0.02); ECOG-PS 0-1 was 27 (100%) vs. 334 (93%) (P = 0.24) ; never smoker was 18 (67%) vs. 195 (54%) (P = 0.23); fusion genes were 5 (19%) vs. 24 (7%) (P = 0.04). Among EGFR-mutated pts, there were no differences in the fraction of EGFR mutation subtypes between the two groups. The proportion of deaths from non-lung cancer including cardiovascular disease and other site of cancer after 5 and 10 years was 7% and 33%, and pts survived longer than 10 years had a higher proportion of deaths from non-lung cancer compared to the others (P = 0.01).

Conclusions: 10-year survivors had characteristics of younger age, female, and with fusion alterations, while there are no difference EGFR subtype. Despite achieving 5-year survival, two-thirds did not achieve 10-year survival. The increase of deaths from non-lung cancer in the long-term survivor, emphasizing the importance of monitoring and managing cardiovascular and other cancer complications.

1357P Bevacizumab improved prognosis for advanced EGFR mutant lung adenocarcinoma with brain metastasis receiving cerebral radiotherapy

Y. Zhou[1], J. Li[2], Z. Li[2]

[1]Shandong Cancer Hospital and Institute, Shandong First Medical University and Shandong Academy of Medical Sciences, Jinan, China; [2]Shandong Cancer Hospital and Institute, Shandong First Medical University and Shandong Academy of Medical Sciences, Shandong Cancer Hospital affiliated to Shandong University, Jinan, China

Background: Cerebral radiotherapy can reduce recurrence and improve overall survival (OS) in patients with brain metastasis (BM) from Epidermal growth factor receptor (EGFR)-mutant lung adenocarcinoma. Bevacizumab (Avastin), an anti-Vascular endothelial growth factor (VEGF) monoclonal antibody, angiogenesis inhibition and alleviates blood-brain barrier (BBB) damage and brain edema through its blocking VEGF. However, whether bevacizumab combined with cerebral radiotherapy can further increase the efficacy and improve the prognosis of patients is unclear. This study aimed to evaluate the effect of bevacizumab on OS in BM patients with EGFR mutation-positive non-small cell lung cancer (NSCLC) undergoing cerebral radiotherapy.

Methods: A total of 178 patients with EGFR-mutant lung adenocarcinoma and BM who received cerebral radiotherapy met the inclusion criteria for this retrospective study, including 70 patients in the bevacizumab treatment group and 108 in the non-bevacizumab group. The Kaplan-Meier method was used for survival analysis. Univariate and multivariate analyses were performed to identify EGFR-mutated BM prognostic factors for these patients. Cerebral radiotherapy included whole-brain radiotherapy (WBRT), local radiotherapy, and WBRT + Boost.

Results: At the end of the last follow-up period, 176 patients (74.3 %) had died, and the median OS was 33.25 months. We observed a significant difference in the median OS between the bevacizumab and non-bevacizumab groups (45.8 months vs 32.0 months, P =0.007). Patients treated with bevacizumab after cerebral radiotherapy had a longer median OS than patients treated with bevacizumab before cerebral radiotherapy (59.4 months vs 33.7months, P=0.0198).

Conclusions: Bevacizumab could improve OS in BM patients with EGFR mutation-positive NSCLC receiving cerebral radiotherapy. This improvement was more obvious after cerebral radiotherapy, possibly as a result of bevacizumab alleviating radiation brain necrosis caused by brain radiotherapy.

Background: Promising clinical activity has been reported in the INSIGHT 2 study of tepotinib (TEP) + osimertinib (OSI) in patients (pts) with *EGFR*m NSCLC with *MET* amplification (*MET*amp) progressing on OSI, with an ORR of 43.9% (95% CI: 33.9, 54.3) and a mDOR of 9.7 months (5.6, ne). TEP monotherapy has been extensively studied in *MET*ex14 skipping NSCLC (N=313) and is generally well tolerated, with low discontinuation rates due to treatment-related AEs (TRAEs; 14.7%). The most common TRAE is peripheral edema (67.1%, Grade 3 11.2%). Our aim is to further characterize the safety profile of TEP in combination with EGFR TKIs.

Methods: TEP 500 mg (450 mg active moiety) was administered in combination with OSI 80 mg (INSIGHT 2; NCT03940703) or gefitinib (GEF) 250 mg (INSIGHT; NCT01982955) QD until disease progression, intolerable toxicity, or withdrawal. To manage AEs, each drug could be dose reduced but if discontinuation was needed, both drugs were stopped. AEs were graded by NCI-CTCAE v5.0.

Results: As of Sep 26, 2022, 187 pts with *EGFR*m NSCLC (65% <65 yrs, 62% female, 72% Asian, 70% nonsmokers, 75% ECOG PS 1) had received TEP + EGFR TKI: 129 +OSI and 58 +GEF. TRAEs were mostly Grade 1—2 and included diarrhea, peripheral edema, and paronychia (Table). TRAEs leading to dose reduction of TEP (≥3 pts) were decreased appetite, peripheral edema, and nausea. There were few discontinuations due to TRAEs (≥2 pts: peripheral edema and pneumonitis). Two deaths considered to be treatment related (due to pneumonitis and dyspnea) occurred in pts receiving TEP+OSI.

Conclusions: TEP in combination with an EGFR TKI was well tolerated in these pts with progressive disease post-first-line therapy, and reflects the safety profile of the individual compounds. Lower incidence of peripheral edema in pts with *EGFR*m NSCLC versus *MET*ex14 skipping NSCLC may be due to younger age and/or the EGFR TKI combination. TEP+OSI provides a potential chemotherapy-sparing oral targeted therapy option for patients with *EGFR*m *MET*amp NSCLC that has developed resistance.

Background: Osimertinib is the standard of care in Epidermal Growth Factor Receptor (EGFR)-mutated advanced Non-Small-Cell Lung Cancer (NSCLC). The MELROSE study, a multicentric phase II trial (NCT03865511) was designed to identify resistance mechanisms in treatment-naive EGFR-mutated NSCLC patients receiving osimertinib. We have evaluated the impact of *TP53* mutations on the response to osimertinib.

Methods: The MELROSE trial enrolled 150 patients with EGFR-mutated (exon 19 deletion, n=88; L858R mutation, n=62) NSCLC. All patients received osimertinib. Tumor assessment was performed every 3 months, with brain and thoracoabdominal CT-scan. Tumor tissues collected at diagnosis were analyzed by next generation sequencing (QIAseq targeted DNA custom panel, QIAGEN). Anti-p53 antibodies were quantified in plasma using the automated Elecsys anti-p53 immunoassay (Cobas, Roche).

Results: Primary analysis of the whole cohort (data cutoff on April 4, 2023) showed a median PFS of 17.4 months (95% CI: 14.9-21.8). Tumor *TP53* genotyping was successfully performed for 116 patients. *TP53* mutations were detected in tumors of 74 patients (63.8%). Most mutations were present on exons 5 (n=14), 6 (n=13), 7 (n=12) and 8 (n=18). The presence of a *TP53* mutation was associated with a reduced median PFS (16.4 months) as compared to wild type tumors (27.5 months; p=0.0034; HR 2.15; 95% CI: 1.29-3.60). Anti-p53 antibodies were detected at baseline in the plasma of 17.8% of the patients tested (26/146). The presence of antibodies was strongly associated with the existence of a *TP53* mutation (p=0.001). Patients presenting detectable anti-p53 antibodies at baseline had a significantly lower median PFS (16.4 months) as compared to patients not presenting antibodies (20.0 months; p=0.034; HR 1.72; 95% CI: 1.04-2.83).

Conclusions: The existence of a *TP53* gene mutation in patients' tumor significantly impacted their PFS, suggesting that future clinical trials should include *TP53* genotyping at randomization. Baseline quantification of anti-p53 antibodies could also be used to early identify a fraction of patients presenting a *TP53* alteration, and identify patients who may benefit less from osimertinib treatment.

Clinical trial identification: NCT03865511.

1360P Updated patient-reported outcomes from the CROWN study: Analyses in first-line ALK+ patients with (w) and without (w/o) baseline brain metastases (BMs) and w or w/o central nervous system adverse events (CNS AEs)

G. Liu[1], Q. Zhou[2], B.J. Solomon[3], H. Le[4], A. Reisman[5], D. Thomaidou[6], F. Toffalorio[7], J. Mazieres[8]

[1]Medical Oncology Department, Princess Margaret Cancer Centre, University of Toronto, Toronto, ON, Canada; [2]Guangdong Lung Cancer Institute, Guangdong Provincial People's Hospital (Guangdong Academy of Medical Sciences), Southern Medical University, Guangzhou, China; [3]Medical Oncology, Peter MacCallum Cancer Centre, Melbourne, VIC, Australia; [4]Global Health Economics and Outcomes Research, Pfizer, New York, NY, USA; [5]Research and Data Sciences Center, Pfizer, New York, NY, USA; [6]Global Medical Affairs Department, Pfizer, Athens, Greece; [7]Global Product Development - Oncology, Pfizer, New York, NY, USA; [8]Thoracic Oncology Department, Toulouse University Hospital, Toulouse, France

Background: Lorlatinib (LOR) demonstrated superior systemic and intracranial efficacy and favorable patient-reported outcomes (PROs) compared with crizotinib in the phase 3 CROWN study. Here we report PROs from the 36-month follow-up analysis in LOR-treated patients (pts) w and w/o baseline BMs and w or w/o CNS AEs.

Methods: Post hoc descriptive quality of life (QoL) analyses using the EORTC QLQ-C30 and QLQ-LC13 were presented for data up to cycle 38 (data cutoff: Sep 20, 2021). Longitudinal mixed-effect models evaluated score changes from baseline; clinically meaningful improvements (CMIs) were defined as a ≥10-point change.

Results: Of 148 LOR pts, 37 had baseline BMs while 111 did not (PRO completion rate, ≥95.6%). Pts w baseline BMs had lower scores than those w/o BMs on all functioning domains. Global QoL generally improved regardless of baseline BM status, although there was a trend for greater QoL improvement in pts w baseline BMs vs those w/o: pts w baseline BMs had CMIs starting from cycle 2, whereas pts w/o BMs did not have CMIs until cycle 38. Cognitive and emotional functioning scores remained stable over time regardless of baseline BM status. For cognitive functioning, pts w BMs had small numerical improvements over time (0.6 to 4.2) while pts w/o BMs had small numerical deteriorations (−2.7 to −6.6). For emotional functioning, CMIs were more frequently observed longitudinally in pts w baseline BMs. CNS AEs in LOR pts were evaluated by the EORTC QLQ-C30 cognitive and emotional functioning PRO domains. Emotional functioning scores generally improved over time, independent of presence or absence of CNS AEs. Slight declines in cognitive functioning scores over time in pts w or w/o CNS AEs were not clinically meaningful.

Conclusions: These updated PRO results from the CROWN study continue to show the benefit of LOR in the first-line setting in *ALK*+ pts. Both pts w or w/o baseline BM continue to maintain/improve global QoL, emotional functioning, with generally no significant deterioration in cognitive functioning. Pts w or w/o CNS AEs had similar longitudinal patterns in PRO domains.

Clinical trial identification: NCT03052608.

Background: BFAST (NCT03178552) is an ongoing global, open-label, multicohort study assessing the activity of therapies in patients (pts) with advanced/metastatic NSCLC harbouring actionable genetic alterations identified in ctDNA via NGS. In a previous analysis of the BFAST *ALK*+ NSCLC cohort, a high overall response rate (ORR) was reported in pts treated with alectinib. We present updated data with longer follow-up, and exploratory correlative ctDNA and biomarker analyses.

Methods: Pts aged ≥18 years with treatment-naïve stage III/IV NSCLC had comprehensive genomic profiling via NGS on ctDNA at screening. Pts with *ALK* fusions (*ALK*+) received alectinib 600 mg twice daily. Primary endpoint: investigator (INV)-assessed ORR; key secondary endpoints: INV-assessed progression-free survival (PFS), duration of response (DOR), overall survival (OS), safety. Blood samples for exploratory analyses were collected every 2 cycles during treatment, and at disease progression if feasible.

Results: The cohort included 87 *ALK*+ pts; median survival follow-up was 52.0 months (range 2.6—62.6). At data cutoff (24 Feb 2023), 34 (39.1%) pts remain on alectinib. Median PFS data for the overall population and per subgroup are presented in the table. In the overall population, ORR was 89.7% (95% CI 81.3—95.2); median DOR was 35.1 months (95% CI 24.8—49.7); 48-month OS rate was 58.3% (95% CI 47.8—68.7). Most pts (93%) had complete clearance of ctDNA (no *ALK* fusion reads) by Cycle 3 Day 1. Pts without *ALK* clearance had poor PFS (7.1 months; 95% CI 5.6—NE). No new safety signals were identified.

Conclusions: BFAST is the first trial with mature clinical data using prospective blood-based NGS screening of *ALK* to select pts for treatment with alectinib. PFS data were consistent with the ALEX study. Concurrent *TP53* mutation and high baseline ctDNA levels were associated with poorer prognosis; ctDNA clearance was associated with better outcomes.

Table: 1361P

Patient subgroup (*ALK*+)	N (% of total population)	Median PFS, months (95% CI)
Overall population	87 (100)	33.0 (20.5—44.2)
TP53 co-mutation vs *TP53* wild type	38 (44) vs 49 (56)	18.7 (12.6—36.9) vs 39.5 (29.4—NE)
Baseline cTF ≥1% vs <1%	47 (54) vs 40 (46)	18.4 (14.5—40.5) vs 41.5 (31.5—NE)
Baseline cTF ≥10% vs <10%	13 (15) vs 74 (85)	12.7 (7.4—NE) vs 36.9 (29.4—51.6)
EML4 fusion partner vs other fusion partners	73 (84) vs 14 (16)	33.0 (22.2—42.0) vs 33.3 (5.4—NE)
ctDNA: no clearance vs clearance*	5 (6) vs 66 (93)	7.1 (5.6—NE) vs 36.8 (29.4—51.5)

*N=71 patients with Cycle 3 Day 1 data. cTF, composite tumour fraction; NE, not estimable

Clinical trial identification: NCT03178552.

1362P Association of baseline (BL) anaplastic lymphoma kinase (ALK) fusion detected by circulating tumor DNA (ctDNA) with clinical features and outcomes in the phase III ALTA-3 trial

C. Aggarwal[1], A. Barakat[2], X. Tong[3], A. Krueger[2], B. Hupf[4], R. Fram[5], S. Vincent[2]

[1]Division of Medical Oncology, Department of Medicine, University of Pennsylvania, Abramson Cancer Center, Philadelphia, PA, USA; [2]Oncology Cell Therapy Precision and Translational Medicine, Takeda Development Center Americas, Inc., Lexington, MA, USA; [3]Statistics and Quantitative Sciences, Takeda Development Center Americas, Inc., Lexington, MA, USA; [4]Oncology Statistics, Takeda Development Center Americas, Inc., Lexington, MA, USA; [5]Clinical Science, Takeda Development Center Americas, Inc., Lexington, MA, USA

Background: In ALTA-3 (NCT03596866), treatment with brigatinib and alectinib showed similar efficacy in patients (pts) with *ALK*+ NSCLC. We report the results of an exploratory correlative pooled analysis of the association of BL *ALK* fusion status, as detected by ctDNA, with clinical features and outcomes in ALTA-3.

Methods: ALTA-3 was a randomized, open-label study of brigatinib 180 mg once daily (7-day lead-in at 90 mg) vs alectinib 600 mg twice daily in pts with advanced *ALK+* NSCLC after progression on crizotinib. For this analysis, *ALK* fusion detection in plasma at BL by ctDNA sequencing was correlated with clinical features (tumor size, target lesion number, organ site involvement, smoking status) and outcomes (median progression-free survival [mPFS; estimated by Kaplan-Meier methods]). ctDNA sequencing was conducted retrospectively with AmoyDx (Chinese pts) and Resolution Bio ctDx™ next-generation sequencing panels. Tumor size was represented as sum of the longest diameter (SLD) of target lesions (RECIST v1.1 criteria). Association between *ALK* status and clinical features was estimated by odds ratios (OR).

Results: Of 248 pts in ALTA-3, ctDNA from plasma collected at BL from 232 pts was sequenced. *ALK* fusions were detected in 78 (*ALK* ctDNA+) and not detected in 154 (*ALK* ctDNA−). *ALK* ctDNA− pts had longer mPFS compared with *ALK* ctDNA+ pts (mPFS 22.5 vs 11.1 months, respectively; hazard ratio 0.48; 95% confidence interval [CI] 0.32−0.71; P=0.0002). *ALK* ctDNA− pts were more likely to have SLD less than or equal to the median (39 mm) compared with *ALK* ctDNA+ pts (OR 0.32, 95% CI 0.17−0.59). *ALK* ctDNA+ status was associated with >1 (median) BL target lesion (OR 0.27, 95% CI 0.14−0.50) and >3 (median) involved organ sites (OR 0.40, 95% CI 0.21−0.73). Smoking status did not impact ctDNA detection of *ALK* fusion status or outcomes.

Conclusions: Detectable BL *ALK* fusion by plasma ctDNA is an indicator of poor prognosis and is associated with increased tumor size, number of metastases, and organ site involvement. *ALK* fusion detection using BL ctDNA could be a surrogate for disease burden and may identify pt populations for escalation strategies in the future.

Clinical trial identification: NCT03596866.

1363P Genomic heterogeneity of ALK rearrangements and acquired resistance pathways in ALK+ Advanced non-small cell lung cancer (NSCLC) treated with upfront alectinib: Preliminary results of GALILEO project

E. Vita[1], F. Monaca[2], J. Russo[2], A. Stefani[2], Q. Zhang[3], M. Di Salvatore[2], R. Trisolini[4], F. Lococo[5], A. Cancellieri[3], G. Tortora[2], E. Bria[1]

[1]UOSD Oncologia Toraco-Polmonare, Fondazione Policlinico Universitario Agostino Gemelli - IRCCS, Rome, Italy; [2]Oncologia Medica, Fondazione Policlinico Universitario Agostino Gemelli - IRCCS, Rome, Italy; [3]Anatomia Patologica, Fondazione Policlinico Universitario Agostino Gemelli IRCCS, Rome, Italy; [4]Pneumologia Interventistica, Fondazione Policlinico Universitario Agostino Gemelli IRCCS, Rome, Italy; [5]Chirurgia Toracica, Fondazione Policlinico Universitario Agostino Gemelli IRCCS, Rome, Italy

Background: Longitudinal genomic evaluation of ALK+ ANSCLC patients treated with 1L alectinib is poorly explored in clinical practice.

Methods: GALILEO (Genomic ALteratIons and cLonal EvOlution in ALK+ NSCLC) is national observational prospective cohort study on ALK+ ANSCLC pts treated with new generation ALK-TKIs. Comprehensive genomic profiling was performed on pre-treatment FFPE tissue of ALK+ ANSCLC identified by using FISH and/or IHC. At the time of progression, DNA-based NGS was repeated on newly obtained tissue (if feasible) or blood ctDNA (FM1 CDx/Liquid®).

Results: In this preliminary analysis, 30 ALK+ ANSCLC pts who started 1L alectinib by Dec 2020 were evaluable. In pre-treatment samples, NGS identified 26 (86.6%) EML4-ALK fusion (V1: 9, V2: 2; V3: 11; NOS: 4), 6 (20%) non canonical fusions (1 alone, 5 conc. with EML4-ALK), 8 (30%) ALK Internal/Intrachromosomal rearrangements (4 intron 19, 2 exon 19, 1 intron 18, 1 C2orf44; 2 alone, 6 conc. with ALK-fusions); in one case, any ALK-alteration was detected. As the data cut-off (median FU: 37 mo.), 14 pts had radiological progression (PD). Among 11 alectinib-responder pts (CR/PR or SD > 6 mo.), 4 patients presented de-novo ALK-SNV [G1202R (50%); E1210K (25%); I1171N/T (25%)], 4 pts had no ALK-SNV (DNMT3A M+: 3 pts; SEDTD2 M+: 2 pts, TP53 M+: 2 pts), 1 pt had oncogene-switch (EGFR); 2 pts failed ctDNA-NGS (low purity). Among 8 pts who received 2L lorlatinib, we observed 3 PR in ALK SNV+ pts, 2 SD ≥6 mo. and 3 PD in pts without ALK-SNV. In post-lorlatinib NGS-assay, 2 pts had ALK-compound mutations, while 4 pts had newly off-target alterations (CDKN2A/B CDKN2B loss, NF1 deletion, DNMT3A/ARID1A/CHECK2 M+).

Conclusions: Implementation of longitudinal genomic assessment is required in order to provide an extensive overview of resistance mechanisms and clinical outcomes according to current ALK-inhibitors treatment sequences.

1364P ctDNA analysis of SAF-189s efficacy in ALK+ advanced non-small cell lung cancer (NSCLC)

J-J. Yang[1], J. Zhou[2], Y. Cheng[3], M. Li[4], Q. Zhao[5], Z-Y. Zhang[6], A. Zang[7], Y. Fan[8], Y. Zhou[9], J. Guo[10], Y. Zheng[10], Z. Wu[11], J. Sun[11], X. Xiang[12], X. Wang[13], Y-L. Wu[1]

[1]Guangdong Lung Cancer Institute, Guangdong Provincial People's Hospital and Guangdong Academy of Medical Sciences, Southern Medical University, Guangzhou, China; [2]Respiratory medicine, The First Affiliated Hospital, Zhejiang University School Of Medicine, Hangzhou, China; [3]Oncology, Jilin Cancer Hospital, Changchun, China; [4]Medical Oncology, The First Affiliated Hospital of Zhengzhou University, Zhengzhou, China; [5]Thoracic Oncology, Shulan Hospital, Hangzhou, China; [6]Oncology, The First Affiliated Hospital of Henan University of Science and Technology, Luoyang, China; [7]Oncology, North Hospital, Affiliated Hospital of Hebei University, Baoding, China; [8]Thoracic Oncology, Zhejiang Cancer Hospital, Hangzhou, China; [9]R&D, Wanbang Biopharmaceuticals, Jiangsu, China; [10]Translational Medicine, Beijing Fosun Pharmaceutical Research and Development Co., Ltd., Shanghai, China; [11]Clinical Oncology, Beijing Fosun Pharmaceutical Research and Development Co., Ltd., Beijing, China; [12]Biometrics and Data Science, Beijing Fosun Pharmaceutical Technology Development Co., Ltd., Beijing, China; [13]Global R&D Center, Shanghai Fosun Pharmaceutical Development Co., Ltd, Shanghai, China

Background: SAF-189s is a next-generation inhibitor of *ALK/ROS1* tyrosine kinase, which has been shown to have anti-tumor activity against *ALK/ROS1* fusion-positive non-small-cell lung cancer (NSCLC), including CNS activity due to its ability to penetrate the blood-brain barrier. Here we present a circulating tumor DNA (ctDNA) biomarker analysis of patients (pts) with advanced, *ALK*-rearranged NSCLC treated in phase 2a study.

Methods: Tumor tissue samples were collected from all enrolled pts for *ALK*-fusion detection by VENTANA ALK (D5F3) IHC assay. Plasma samples were collected at baseline and disease progression. Next-generation sequencing for ctDNA was done using Lung cancer 180-gene panel (Genetron). PFS was evaluated according to *ALK* alteration status.

Results: By the cut-off date of Dec 13th, 2021 (median PFS follow-up 11 mo), a total of 143 NSCLC *ALK*-fusion positive pts had been enrolled and treated with SAF-189s (80 mg, n=19; 120 mg, n=47, 160 mg, n=64; 210 mg, n=13), including 100 ALKi-naïve pts and 43 ALKi-refractory pts (received crizonitib and/or next-generation ALKi). ctDNA at baseline was tested in 143 pts with a *ALK*-fusion positivity rate of 53.8% (77/143). The main fusion partner of *ALK* was *EML4*, accounting for 93.6% (73/78). The most common fusion variants were v3 (34.5%, 27/78), v1 (28.2%, 22/78), and v2 (10.3%, 8/78). Pts with v1 variants showed a longer mPFS than v3 variants (16.5 mo vs. 13.8 mo, p=0.188). There was no significant difference in the distribution of *ALK* fusion variants between ALKi-naïve and ALKi-refractory groups. Of 25 pts who progressed with SAF-189s, two *ALK* mutations, G1202R and I1179T, were newly identified in 3 pts. I1179T has not been previously reported and is speculated to be a novel *ALK*-resistant mutation. *TP53* co-mutations were detected in 47% pts, but it was not shown to have a significant effect on outcomes. Gene co-occurrence survival analysis showed that mPFS of pts harboring *FAT3/FAT4* mutations were significantly shorter than those without *FAT3/FAT4* mutations (8.9 mo vs 16.5 mo, p=0.012).

Conclusions: Clinical utility of ctDNA was demonstrated, not only at baseline by identifying fusion types and subgroups of *ALK+* NSCLC pts that may benefit more from SAF-189s, but also at progression by tracking *ALK*-resistant mutations.

Clinical trial identification: NCT04237805.

1365P Neurocognitive adverse events related to lorlatinib in non-small cell lung cancer: A systematic review and meta-analysis

J.N. Priantti[1], F. Cezar A Moraes[2], T.M. Madeira[3], E. Moisés de Lima Santiago[4], M. Silveira Vilbert[5]

[1]Department of Internal Medicine, Universidade Federal do Amazonas - Faculdade de Medicina, Manaus, Brazil; [2]Department of Internal Medicine, UFPA - Universidade Federal do Pará, Belém, Brazil; [3]Department of Internal Medicine, UFMG - Universidade Federal de Minas Gerais, Belo Horizonte, Brazil; [4]Department of Internal Medicine, HU/EBSERH/UFMS, Campo Grande, Brazil; [5]Department of Clinical Oncology, UHN - University Health Network - Princess Margaret Cancer Center, Toronto, ON, Canada

Background: Lorlatinib (LOR), a 3rd generation tyrosine kinase inhibitor (TKI), has shown promising activity in NSCLC. However, the treatment has been associated with an increasing number of neurocognitive adverse events (NAEs). This systematic review and meta-analysis evaluated the NAEs associated with LOR therapy in NSCLC patients.

Methods: PubMed, Scopus, and the Cochrane Library were searched for clinical trials and observational cohort studies investigating LOR for NSCLC patients. NAEs were defined as the cluster terms of cognitive effects, mood effects, speech effects, and psychotic effects. Heterogeneity was examined with the I^2 statistics and random-effect model was used to pool studies.

Results: Sixteen studies were included with 1,147 patients, of whom 56% were female, 8% were Asians, 8% had a history of smoking, 62% had brain metastasis, and 1% ECOG 2 or higher. Most patients had previously received an early-generation TKI before the LOR. A pooled analysis of NAEs showed a prevalence of cognitive effects in 15.57% of overall population (95% CI 8.40 − 22.73, I2 90%), mood effects in 11.93% (95% CI 5.80 − 18.06, I2 89%), speech effects in 6.56% (95% CI 1.79 − 11.34, I2 91%), and psychotic effects in 4.15% (95% CI 1.46 − 6.83, I2 74%). In a subgroup analysis, we found higher rates of cognitive effects in clinical trials than in real-world data (23.57% vs. 9.36%, $p = 0.05$), and a significant difference was also seen in mood effects (18.64% vs. 3.70%, $p < 0.01$). NAEs were manageable with dose modification, temporary interruption, and/or concomitant medication.

Conclusions: Our study revealed that LOR is associated with cognitive, mood, speech and psychotic effects in approximately 16%, 12%, 7%, and 4% of patients, respectively. We found significant differences in the prevalence of cognitive and mood effects between clinical trials and real-world data. Additionally, all analyses had a high heterogeneity among studies. Collectively, these findings underscore the importance of educating patients and healthcare professionals regarding LOR-associated NAEs to facilitate early detection and management of NAEs, aiming to improve NSCLC patients' quality of life.

1366P Association between the adverse events and serum concentrations of lorlatinib in patients with advanced ALK-positive lung cancer

Y. Shimoda[1], T. Yoshida[2], R.A. Makihara[3], M. Torasawa[1], A. Tateishi[1], Y. Matsumoto[1], Y. Shinno[1], Y. Okuma[1], Y. Goto[1], H. Horinouchi[1], N. Yamamoto[2], Y. Ohe[1]

[1]Department of Thoracic Oncology, NCCH - National Cancer Center Hospital-Tsukiji Campus, Chuo-ku, Japan; [2]Department of Thoracic Oncology and Experimental Therapeutics, NCCH - National Cancer Center Hospital-Tsukiji Campus, Chuo-ku, Japan; [3]Department of Pharmacy, NCCH - National Cancer Center Hospital-Tsukiji Campus, Chuo-ku, Japan

Background: Lorlatinib is a third-generation anaplastic lymphoma kinase (ALK) inhibitor, has been the standard of care for untreated and previously treated patients with advanced ALK-positive non-small cell lung cancer (NSCLC). The common adverse events (AEs) of lorlatinib leading to drug discontinuation or dose reduction were hyperlipidemia, edema, and central nervous system (CNS)/ psychiatric disorders. The association between AEs and serum concentrations of lorlatinib remains unclear.

Methods: We retrospectively reviewed advanced ALK-positive NSCLC patients treated with lorlatinib between December 2018 and July 2022. The association between AEs and serum concentrations of lorlatinib was assessed at 28 days (± 14 days) after the initiation of lorlatinib using a high-performance liquid chromatography tandem mass spectrometry.

Results: Among 55 eligible patients, the median age was 54 years (range: 23−79) and the median number of treatment lines was 2 (range: 2-10). Most patients were female (29 [53%]) and performance status 0-1 (48 [87%]). Grade 3 or higher AEs occurred in 23 patients (42%) including hyperlipidemia in 18 (33%), edema in 5 (9%), and CNS/ psychiatric disorders in 4 (7%). Discontinuation or dose reduction was required in 21 patients (38%). Serum concentrations were measured in 36 patients (65%) and were significantly higher in the patients experiencing grade 3 or higher AEs than those without (462 ng/mL vs 177 ng/mL, $p<0.01$). On the other hand, there was no significant difference in progression-free survival (PFS) between the patients who had experienced the discontinuation or dose reduction within the first 6 months and those who had not (12.8M vs 5.2M, p=0.14).

Conclusions: The incidence of grade 3 or higher AEs with lorlatinib was associated with high serum concentrations at the first month of treatment. Drug discontinuation or dose reduction had no impact on PFS.

1367P Predictive clinical characteristics for body weight gain in patients treated with alectinib: Analyses of J-ALEX, ALUR, and ML29453

B.J. Sikkema[1], S.J. Baart[2], M.S. Paats[2], E.F. Smit[3], A.M. Schols[4], R.H. Mathijssen[1], E.F. van Rossum[5], A-M.C. Dingemans[2]

[1]Medical Oncology Department, Erasmus MC - Daniel den Hoed Cancer Center, Rotterdam, Netherlands; [2]Department of Respiratory Medicine, Erasmus MC Cancer Institute, Rotterdam, Netherlands; [3]Thoracic Oncology Department, LUMC - Leiden University Medical Center, Leiden, Netherlands; [4]Respiratory Medicine, Maastricht University Medical Center (MUMC), Maastricht, Netherlands; [5]Internal Medicine, Erasmus MC, Rotterdam, Netherlands

Background: Alectinib has emerged as one of the anaplastic lymphoma kinase (ALK) directed therapy of choice in patients with advanced *ALK+* non-small cell lung cancer (NSCLC). Body weight gain is a side effect reported in 12% of patients, caused by an increased amount of body fat. Baseline waist circumference has been found to be a positive predictor of the increase in visceral adipose tissue. We hypothesize that baseline body mass index (BMI) is positively associated with body weight gain.

Methods: Individual data from patients treated with alectinib were obtained via Vivli data-sharing platform. Studies with body weight data were selected. All body weight measurements during the first year of treatment were included. A mixed-effects model with random intercept was conducted to assess the trend of % change in body weight over time and to explore the effect of baseline characteristics on % change in body weight from baseline.

Results: Three prospective trials with body weight data were eligible (J-ALEX, ALUR, ML29453). All 309 patients were included in the analysis. During the first year of treatment, 2632 measurements of body weight were documented. Data from J-ALEX (n=103) was analyzed separately, as reference values for BMI differ between Japanese and Western populations. Percent change in body weight increased significantly over time in the mixed-model analyses in both J-ALEX ($\hat{\beta} = 0.48$, $p < 0.001$) and ALUR/ML29453 ($\hat{\beta} = 0.31$, $p = 0.001$). In the ALUR/ML29453 dataset there was an association between baseline albumin level and % change in body weight ($\hat{\beta} = 0.08$, $p = 0.003$). A maximum body weight gain of $\geq$ 10% during the first year was observed in 23 patients (22.3%) in J-ALEX and 31 patients (15.0%) in ALUR/ML29453.

Table: 1367P Baseline characteristics

	J-ALEX	ML29453	MO28928
	n = 103	*n = 129*	*n = 77*
Population	Japan	USA	Europe and Asia
Baseline characteristics			
Age (in years)	59 ± 14	55 ± 13	54 ± 12
Sex (M) (%)	39.8	43.4	58.4
Weight (kg)	55.9 [12.8]	70.5 [19.6]	70.0 [23.3]
Baseline BMI (kg/m^2)	21.9 [3.8]	24.1 [6.8]	25.8 [5.7]
Albumin baseline (g/L)	39 [7]	38 [6]	37 [9]

Conclusions: A significant and clinically relevant increase in body weight was observed in the first year of treatment with alectinib. Baseline BMI was not predictive for body weight gain. Informing patients before start of alectinib is strongly recommended.

Clinical trial identification: Trials included in analysis: J-ALEX trial, JO28928, JapicCTI-132316 ML29453, NCT02271139 ALUR trial, MO29759, CT02604342.

1368P LUMINATE 102: A real-world study on biomarker testing rates among patients with non-small cell lung cancer (NSCLC) across lines of therapy

C. Aggarwal[1], Q. Xu[2], S. Ng[3], R. Kamalakar[4], S.A. Crawford[2], S. Beruti[2], A. Myftiu[2], M.B. Beasley[5]

[1]Medicine - Hematology/Oncology Department, University of Pennsylvania, Philadelphia, PA, USA; [2]Global Health Economics Outcomes and Research, AbbVie Inc. - Headquarters, North Chicago, IL, USA; [3]Global Health Economics Outcomes and Research, AbbVie Inc., North Chicago, IL, USA; [4]RWE Analytics, AbbVie Inc., North Chicago, IL, USA; [5]Pathology, Mount Sinai Hospital, New York, NY, USA

Background: Molecular testing for biomarkers in patients (pts) with advanced/metastatic NSCLC (a/mNSCLC) is essential for diagnostic testing and use of targeted therapy. Testing patterns across lines of therapy (LOT) for pts with a/mNSCLC remain unclear.

Methods: This retrospective real-world study used ConcertAI Patient360™ database to assess biomarker testing patterns among adults with nonsquamous a/mNSCLC (2017—2022). Eligible pts received $\geq$1 LOT with $\geq$90-day follow-up. Biopsy and biomarker testing assessed actionable genetic alterations (*ALK, BRAF, EGFR, KRAS, NTRK, RET, ROS1*) and PD-L1 by LOT (first-, second-, third-line [1L, 2L, 3L]), test modality (IHC, FISH, CISH, NGS, PCR), and sample type (tissue/liquid).

Results: 4528 pts were included; median age 67 years and from a community setting (76%). NGS rate at 1L was 57% overall (2017—2022) and increased to 80% during 2020—2022. Testing for $\geq$1 biomarker was 85% (1L), 31% (2L), 26% (3L) (overall, 2017—2022); and 89% (1L), 37% (2L), 28% (3L) (2020—2022). *EGFR, BRAF, KRAS, RET,* and *ROS1* (Table) were mostly tested using NGS (56% at 1L vs 51% IHC, 21% FISH, and 10% PCR). Testing was most often conducted with tissue at 1L (64%) and liquid in 2L+ (41% each of tested 2L pts and 3L pts). At 2L, only 6% of pts had tissue re-biopsy, which dropped to 4% in 3L. Pts with 1L targeted therapy had higher re-testing (41% vs 25%, P<0.001) rates regardless of sample type in 2L than those who did not.

Conclusions: Tissue was most frequently used in 1L for biomarker testing by NGS for genetic alterations or IHC for PD-L1; however, tissue was not regularly re-biopsied in 2L+ settings. Biomarker testing rates drop as pts navigate through LOT. Re-testing rate is higher among pts with an actionable mutation in 1L. Standardization of biomarker testing post-1L is needed to facilitate optimal later-line treatment decisions and individualized care for pts with a/mNSCLC.

Table: 1368P

	N	Any biomarker (%)	PD-L1 (%)	*ALK* (%)	*BRAF* (%)	*EGFR* (%)	*KRAS* (%)	*METexon 14 (%)*	*NTRK* (%)	*RET* (%)	*ROS1* (%)
1L	4528	85	71	73	65	78	64	46	40	55	71
2L	1394	31	19	24	23	26	22	19	15	21	24
3L	473	26	14	20	20	22	19	16	11	18	21

Background: Brigatinib and alectinib are both next-generation ALK inhibitors (ALKi) showing efficacy in naïve and post-crizotinib ALK+ advanced non-small-cell lung cancer (aNSCLC). Real-life data on alectinib efficacy after brigatinib failure are missing.

Methods: BrigALK2 study retrospectively assessed the efficacy of brigatinib in 183 *ALK*$^+$ aNSCLC pretreated with at least one ALKi during the brigatinib French Early-Access Program (1 August 2016—21 January 2019). BrigAlec study made a focus on alectinib activity after brigatinib treatment, according to post-brigatinib treatment line in BrigALK2.

Results: 92 (50.3%) patients received $\geq$ 1 agent(s) post-brigatinib. 30 (16.4%) received alectinib: 19 (10.3%) patients were treated with alectinib immediately after brigatinib, 11 (4.9%) following at least one line of treatment. At data cut-off, median follow up was 25.5 (95% CI: 10.6-30.5) months. Median duration of brigatinib treatment (mDOT) and median progression free survival according to investigator (InvmPFS) were 13.6 (95% CI: 6.3-17.7) and 10.9 (95% CI: 6.2-20.2) months, respectively. For patients who received alectinib immediately after brigatinib, mDOT was 7.1 (95% CI: 2.1-18.2) months, mInvPFS, 4.8 (95% CI: 2.0-12.5) months and mOS, 27 (95% CI: 12.5-NR) months from the start of alectinib treatment. Response (RR) and disease control rates (DCR) were 25% and 60%, respectively. Among this subgroup, reasons for brigatinib discontinuation were toxicity and progressive disease for 5 and 14 patients, respectively. mDOT and mPFS were 18.2 (95% CI: 3.4-21.6) and 12.5 (95% CI: 3.3-17.9) months for the former and 5.7 (95% CI: 0.9-10.6) and 3.4 (95% CI: 0.9-9.2) months for the latter, respectively. For patients receiving at least one treatment between brigatinib and alectinib, with a median follow up of 13.3 (95% CI: 2.3-31.5) months, mDOT, mInvPFS and mOS were 11.7 (95% CI: 0.7-21.5), 5.0 (95% CI: 0.5-18.8) and 16 (95% CI: 2.3-NR) months, respectively. RR and DCR were 10 and 30.

Conclusions: According to our retrospective real-life study, alectinib after brigatinib treatment remains an option in metastatic *ALK*+ NSCLC, especially if brigatinib is discontinued due to toxicity.

1370P Efficacy and safety of ensartinib in ALK-positive non-small cell lung cancer patients with brain metastases: A multicenter, open-label, single-arm, phase II study

J. Chang[1], X. Wu[2], L. Guo[3], T. Zhang[3], C. Fu[1], S. Huang[3], G. Jiang[4]

[1]Department of Medical Oncology, Cancer Hospital & Shenzhen Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Shenzhen, China; [2]Department of Medical Oncology, Fudan University Shanghai Cancer Centre, Shanghai, China; [3]Department of Medical Oncology, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital & Shenzhen Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Shenzhen, China; [4]Department of Medical Oncology, Dongguan People's Hospital, Dongguan, China

Background: Brain metastases (BM) are a major cause of mortality in patients (pts) with ALK-positive (ALK+) non—small cell lung cancer (NSCLC). Here, we evaluated efficacy and safety of ensartinib, an ALK-TKI, in ALK+ NSCLC pts with BM.

Methods: This ongoing, multicenter, open-label phase 2 study enrolled locally advanced/recurrent/metastatic ALK+ NSCLC pts with BM, having $\leq$1 prior chemotherapy. Eligible pts were brain-enhanced MRI/CT-confirmed BM without CNS metastasis (except clinically stable)/risk of cerebral hemorrhage, and with $\geq$1 measurable intracranial lesion having no radiotherapy based on Response Assessment in Neuro-oncology BM (RANO-BM). Pts received 225 mg ensartinib orally once daily. Primary endpoint was intracranial objective response rate (iORR) by RANO-BM.

Results: As of Mar 24, 2023, 17 pts were enrolled. 14 pts who had $\geq$1 efficacy assessment were included in efficacy/safety analysis. Pts received ensartinib as 1st (1/14, 7%) or 2nd (13/14, 93%) -line therapy (with prior crizotinib). The iORR was 71.4% (10/14; 95% CI, 41.9%-91.6%), with median intracranial duration of response of 13.01 months (Table). The intracranial disease control rate and median intracranial progression-free survival (iPFS) were 100.0% and 13.63 months. Median PFS was 13.63 months. Overall survival was immature. Median cerebrospinal fluid/plasma concentration ratio was 1.52% in 10 pts, consistent with reported in phase I study of ensartinib. No mini mental status examination decline (>3 from baseline) events observed. Grade $\geq$3 treatment-related adverse events (TRAEs) occurred in 28.6% pts, with no grade 5 TRAEs/deaths. Most common TRAE was rash (85.7%).

Table: 1370P

	Intracranial per RANO-BM (n=14)
Best objective response, n (%)	
Complete response	2 (14.3)
Partial response	8 (57.1)
Stable disease	4 (28.6)
Progression disease	0
Not evaluable	0
Objective response rate, % (95% CI)	71.4 (41.9, 91.6)
Disease control rate, % (95% CI)	100 (76.8, 100.0)
Time to progression, months (95% CI)	13.63 (4.44, not evaluable)
Duration of response, months (95% CI)	13.01 (5.42, not evaluable)
Progression-free survival, months (95% CI)	13.63 (4.44, not evaluable)

Conclusions: Ensartinib showed promising intracranial efficacy with high blood-brain barrier penetration and a tolerable safety profile in ALK+ NSCLC pts with BM. Study is ongoing and final results will be presented in future.

Clinical trial identification: NCT03753685.

1371P First-line alectinib vs. brigatinib in advanced metastatic NSCLC with ALK rearrangement: Real-world data

Y.K. Jeon[1], S. Park[2], H.A. Jung[2], J-M. Sun[2], S-H. Lee[2], J.S. Ahn[2], M-J. Ahn[2]

[1]*Division of Medical Oncology and Hematology, Pusan National University Yangsan Hospital, Gyeongsangnam-do, Republic of Korea;* [2]*Hematology and Medical Oncology, Samsung Medical Center, Seoul, Republic of Korea*

Background: Alectinib and brigatinib are second-generation anaplastic lymphoma receptor tyrosine kinases (ALKs) that are widely used as first-line therapy for treating ALK-positive advanced non-small cell lung cancer (NSCLC). Given the lack of a head-to-head comparison of these drugs as first-line therapies, this retrospective observational study aimed to compare the real-world efficacy and safety of alectinib and brigatinib.

Methods: Patients who received alectinib or brigatinib as the first-line treatment for ALK-positive advanced NSCLC were evaluated for clinical outcomes of objective response rate (ORR), intracranial ORR, time to next treatment (TTNT), progression-free survival (PFS), overall survival (OS), and safety profiles.

Results: Of 208 patients who received either alectinib or brigatinib as a first-line treatment, 176 received alectinib and 32 received brigatinib. At the data cutoff point, the median follow-up duration was 10.6 months (95% CI: 9.7—11.5) in the brigatinib group and 24.6 months (95% CI: 19.4—29.9) in the alectinib group. The ORR was 91.9% with alectinib and 92.2% for brigatinib (p-value: 0.54, 95% CI: 0.35—7.30); the intracranial ORR rates were 94.6% and 100%, respectively. The rate of progression-free survival at 12 months was comparable between the alectinib group and the brigatinib group (84.8% vs. 84.1%, p-value: 0.93), and the median TTNT, PFS, and OS were not reached in either group. Treatment-related adverse events were usually mild, and treatment discontinuation due to adverse events was rare in both groups.

Conclusions: Alectinib and brigatinib had similar clinical benefits when used as the first-line treatment of NSCLC patients with ALK rearrangement in the real world.

Background: Repotrectinib, a next-generation ROS1 and TRK tyrosine kinase inhibitor (TKI), has shown clinical activity and manageable safety in pts with *ROS1+* NSCLC or *NTRK+* locally advanced/metastatic solid tumors in the pivotal phase 1/2 TRIDENT-1 trial (NCT03093116). This is the first report of repotrectinib efficacy by Blinded Independent Central Review (BICR), with 8.7 mo minimum follow-up in pts with TKI-naïve and -pretreated *NTRK+* solid tumors, including NSCLC, and safety in all pts treated at the recommended phase 2 dose (RP2D).

Methods: Pts with *NTRK+* solid tumors were enrolled in TKI-naïve and -pretreated cohorts. RP2D was 160 mg QD for 14 d, then 160 mg BID. Phase 2 primary endpoint: confirmed objective response rate (cORR) by BICR.

Results: At data cutoff (19 Dec 2022), median follow-up was 17.8 mo (range, 8.7—64.6) in the TKI-naïve cohort (n = 40), and 20.1 mo (8.7—69.4) in the TKI-pretreated cohort (n = 48). The table shows efficacy in pts with *NTRK+* solid tumors and subgroups of interest. NSCLC was the most common tumor (TKI-naïve, 52%; TKI-pretreated, 29%). In TKI-naïve *NTRK+* NSCLC, cORR was 62% (95% CI, 38—82) and estimated 12-mo duration of response (DOR) and progression-free survival (PFS) was 92% (95% CI, 76—100) and 64% (43—86), respectively. In TKI-pretreated *NTRK+* NSCLC, cORR was 42% (18—71) and estimated 12-mo DOR and PFS was 44% (1—88) and 23% (0—49), respectively. In all pts treated at RP2D in TRIDENT-1 (n = 426), dizziness (62%; grade ≥3, 3%) was the most common treatment-emergent adverse event (TEAE). Grade ≥3 TEAEs occurred in 51% of pts (29% treatment-related AEs). Treatment discontinuation rate due to TEAEs was 7% (3% due to treatment-related AEs).

Conclusions: In TRIDENT-1, with 8.7 mo minimum follow-up, repotrectinib showed robust responses and durable clinical activity in both TKI-naïve and -pretreated pts with *NTRK+* solid tumors, including NSCLC. Repotrectinib safety at RP2D was manageable, consistent with prior reports.

Table: 1372P Repotrectinib in *NTRK+* solid tumors

***NTRK+* solid tumors**[a]	**TKI-naïve (n = 40)**	**TKI-pretreated (n = 48)**
Efficacy, % (95% CI)		
cORR[b]	58 (41—73)	50 (35—65)
12-mo DOR	86 (71—100)	39 (16—62)
12-mo PFS	56 (40—72)	22 (8—36)
***NTRK+* solid tumors by prior TKI**[c]		
cORR,[b] % (95% CI)		
Prior larotrectinib (n = 23)	—	43 (23—66)
Prior entrectinib (n = 24)	—	54 (33—74)
***NTRK+* solid tumors with solvent front mutations**		**(n = 25)**
Efficacy, % (95% CI)		
cORR[b]	—	60 (39—79)
12-mo DOR	—	33 (7—58)
12-mo PFS	—	21 (4—39)

[a]Tumors included NSCLC (52% TKI-naïve; 29% TKI-pretreated), salivary gland cancer (8%; 17%), thyroid cancer (12%; 8%), soft tissue sarcoma (8%; 12%); others <10% each.
[b]Per RECIST v1.1.
[c]May have received 1-2 prior TKI.

Clinical trial identification: NCT03093116.

Background: Taletrectinib, a next-generation, CNS-active, ROS1 TKI with selectivity over TRKB, demonstrated high overall and intracranial response rates, prolonged PFS, activity against G2032R, and was well tolerated in TRUST-I (NCT04395677). We report interim results of taletrectinib from the pivotal phase 2 trial, TRUST-II (NCT04919811), in advanced ROS1$^+$ NSCLC pts from North America, Europe, and Asia.

Methods: TRUST-II, a multicenter, open-label, single-arm study in pts with ROS1$^+$ tumors, has 4 cohorts: 1) NSCLC: ROS1 TKI-naive, $\leq$1 line of chemotherapy (CT); 2) NSCLC: 1 prior ROS1 TKI, $\leq$1 line of CT; 3) NSCLC: $\geq$2 ROS1 TKIs, $\leq$1 line of CT; and 4) solid tumors including NSCLC if ineligible for cohorts 1-3: $\leq$3 ROS1 TKIs, $\leq$2 lines of CT. Eligible pts had ECOG PS 0—1 and could have asymptomatic or treated/controlled CNS involvement. All pts started taletrectinib at 600 mg QD. The primary endpoint is independent review committee (IRC)-assessed confirmed objective response rate ($cORR_{IRC}$); other key endpoints include investigator-assessed cORR ($cORR_{INV}$), disease control rate (DCR), time to treatment response (TTR), DoR, PFS, and safety.

Results: Interim efficacy results are from 18 pts in cohort 1 and 22 pts in cohort 2 with $\geq$2 disease assessments (39% and 59% of pts had brain metastases, respectively). $cORR_{INV}$ was 94% (17/18; 95% CI: 73, 100) in cohort 1 and 55% (12/22; 95% CI: 32, 76) in cohort 2; DCR was 100% and 91%, respectively. $cORR_{IRC}$ will be presented. In both cohorts, median TTR was 1.4 mo; median DoR was not reached. As of March 31, 2023, 72 pts were included in the safety population that received $\geq$1 dose of taletrectinib. Median duration of exposure was 3.7 mo. Overall, 90% had a treatment-emergent adverse event (TEAE), mostly grade 1—2. The most common TEAEs were increased ALT (61%) or AST (61%), and nausea (38%). No treatment-related AE (TRAE) led to discontinuation or death; 24% of pts had a TRAE leading to dose reduction.

Conclusions: In this ongoing global pivotal phase 2 study, taletrectinib demonstrated robust and consistent clinical activity with TRUST-I, including high response rates and a tolerable safety profile in both TKI-naive and TKI-pretreated pts with ROS1$^+$ NSCLC.

Clinical trial identification: NCT04919811.

1374P Survival and therapy analysis of small-scale ROS1-mutant non-small cell lung cancer (NSCLC) patients

M. Glaser[1], S. Braegelmann[1], A. Rasokat[1], L. Nogova[1], C. Wömpner[1], J. Schmitz[1], E. Bitter[1], I. Terjung[1], A. Eisert[1], R.N. Fischer[1], F. John[1], S. Michels[1], R. Riedel[1], L.V. Ruge[1], H. Scharpenseel[1], U. Siebolts[2], S. Merkelbach-Bruse[2], R. Büttner[2], J. Wolf[1], M. Scheffler[1]

[1]Department I of Internal Medicine, University Hospital Cologne, Cologne, Germany; [2]Institute of Pathology, University of Cologne, Cologne, Germany

Background: *ROS1* fusions are well treatable aberrations in NSCLC. Besides solvent-front mutations (SFM) in resistance to targeted therapy, small-scale *ROS1* mutations are largely unknown. We exploratively analyzed the clinicopathological characteristics, survival and therapy of small-scale *ROS1* mutations in NSCLC patients without activating *ROS1* fusions or SFMs.

Methods: Next-generation sequencing was performed on tissue samples from NSCLC patients within the Network Genomic Medicine. Patients with *ROS1* fusions and SFMs were excluded. We analyzed the characteristics of the patients, their survival and their response to systemic therapy.

Results: Of 10,396 patients analyzed, 101 (1.0%) patients harbored small-scale *ROS1* mutations. Most patients were male (73.3%) and smokers (96.6%). Nearly half of the patients presented with squamous-cell carcinoma (SqCC, 40.4%). Most mutations were transversions (50.5%), and 66% were in the kinase domain. Besides *TP53* mutations (65.3%), *KRAS* (22.8%), *EGFR* (5.9%), *PIK3CA* (9.9%) and *FGFR1-4* mutations (8.9%) co-occurred. In 10 (9.9%) patients, *ROS1* mutation was the only aberration detected. The median overall survival (mOS) of all stage IV patients was 10.5 months and the survival differed significantly in patients with or without *KRAS* co-mutations (9.7 vs 21.5 months, p=0.02, HR 2.6, 95% CI: 1.1-5.9). Altough not significant, the most common *KRAS* mutation in this cohort G12V (n=7/17) worsened survival (4.4 versus 9.7 months). Patients significantly benefited from treatment with immune-checkpoint blockade (21.5 vs 4.4 months, p=0.003, HR 0.14, 95% CI: 0.03-0.6). *KRAS* co-mutant patients treated with ICB only had an mOS of 8 months. In three patients with co-occurring mutations, qualifying for and having received targeted therapy (2x *EGFRmut*, 1x *MET* fusion), mOS was 23.5 months (95% CI: NA).

Conclusions: The cohort's clinical characteristics contrasted *ROS1*-fused cohorts. Co-occurrence of *KRAS* mutations led to shortened survival and patients benefited from ICB. Our data does not support the idea of *ROS1* small-scale mutations as strong oncogenic drivers in NSCLC, but rather as relevant bystanders altering the efficacy of treatment approaches.

KG, Biberach an der Riss, Germany; [7]Oncology, Boehringer Ingelheim Pharmaceuticals, Inc., Ridgefield, CT, United States of America; [8]CD&O, Boehringer Ingelheim S.A, Sant Cugat del Vallès, Spain; [9]Department of Thoracic Oncology, National Cancer Center Hospital East, Kashiwa, Japan; [10]Department of Thoracic Oncology, National Cancer Center Hospital, Tokyo, Japan

Background: The ongoing phase Ia/Ib trial determines the safety, MTD, PK, PD and preliminary efficacy of BI 1810631 in pts with HER2 aberration-positive solid tumors (NCT04886804).

Methods: Phase Ia: pts with HER2 aberration-positive advanced/unresectable/metastatic solid tumors refractory/unsuitable for standard therapy were enrolled. Pts received escalating doses of BI 1810631 BID (starting dose 15 mg) or BI 1810631 QD (starting dose 60 mg). Phase Ib will initially include pts with advanced/metastatic *HER2* TK domain mutation-positive, pre-treated NSCLC. Additional cohorts may be included. Primary endpoints: MTD based on number of pts with DLTs (phase Ia); ORR (phase Ib). Secondary endpoints: number of pts with DLTs throughout entire treatment (Tx) period and PK parameters (phase Ia/Ib); DoR, DCR, duration of disease control and PFS (phase Ib).

Results: As of 9 Mar 2023, 43 pts had been treated. Pts had NSCLC (n = 27), lung cancer (unspecified; n = 5), colorectal cancer (n = 3), or other tumors (n = 8). Most pts had a pathological HER2 mutation. Pts received BI 1810631 at 15, 30, 60, 100, 150 mg BID (n = 3/3/4/4/3) or 60, 120, 180, 240, 300 mg QD (n = 5/4/6/6/5). Median number of cycles was 4 (range 1—15). Tx is ongoing in 26 pts. To date, 4 DLTs have been observed (grade [G] 2 edema [60 mg BID], G2 diarrhea [150 mg BID], G3 anemia [60 mg QD], G3 increased ALT [180 mg QD]). The MTD has not been reached with either schedule. Tx-related adverse events (TRAEs) were reported in 28 pts (65%; BID/QD 76/58%). The most common TRAEs were diarrhea (33%; BID/QD 47/23%), increased ALT (9%; BID/QD 6/12%) and increased AST (9%; BID/QD 6/12%). Four pts (BID/QD 1/3) had grade 3 TRAEs (increased ALT [n = 3]; increased AST [n = 1]). Of 24 evaluable lung cancer patients (17 are still on Tx), 11 responded (all PRs) and 12 had SD. Two patients with other tumors (esophagus; cholangiocarcinoma) also achieved PR.

Conclusions: These preliminary data indicate that BI 1810631 is well tolerated and shows strong efficacy signals across all dose levels in pts with pretreated HER2 aberration-positive solid tumors. Recruitment into phase Ib is ongoing with the QD regimen. Updated phase 1a data, and emerging Phase1b data, will be presented.

Clinical trial identification: NCT04886804.

Background: *EGFR* exon 20 insertion mutations (*EGFR*ex20ins) can be classified as near-loop and far-loop based on their location. The underlying structural difference between near- vs. far-loop *EGFR*ex20ins and its impact on various other novel EGFR TKIs response are not well understood.

Methods: We assessed *in vitro* activity of multiple EGFR TKIs against a panel of BaF3 cells expressing *EGFR*ex20ins mutations. Molecular Dynamics (MD) modeling of near- vs. far-loop *EGFR*ex20ins, with and without binding of EGFR TKIs was performed. Clinical responses (tumor size reduction and progression free survival) were analyzed by near- vs. far-loop insertion location in ZENITH20 and EXCLAIM trials.

Results: *In vitro* testing with different *EGFR*ex20ins indicated a favorable IC_{50} for afatinib, CLN-081, and poziotinib in near-loop (A767-P772) versus far-loop (H773-R776) insertions, whereas mobocertinib had similar IC_{50} values in near- and far-loop insertions. MD modeling using free-energy calculations indicated that wildtype EGFR displayed distinct inactive and active states with a relatively high transitional energy barrier. In comparison, the near-loop (S768insSVD) exhibited multiple states separated by shallow barriers whereas the far-loop (H773insNPH) was conformationally more rigid. The differential p-loop orientation change in near- vs. far-loop insertions played an active role in TKI binding, stabilization, and selectivity. Clinical data supported the in vitro differential impact of insertion location. In the ZENITH20 trial (n=82), in pre-treated *EGFR*ex20ins lung cancer patients, poziotinib had superior activity in near-loop than far-loop tumors both on tumor size reduction (-25.9% vs. -9.8%, p=0.0014) and PFS (11.1 vs. 3.5 months, Log Rank p=0.016). In the EXCLAIM trial platinum-pretreated patients (n=76), mobocertinib demonstrated robust activity in both groups as assessed by tumor size reduction (near -38.5% vs. far -34.1%, p=0.59) and PFS (12.0 vs. 13.0, Log Rank p=0.99).

Conclusions: Preclinical and clinical data indicated that near- vs far-loop *EGFR*ex20 insertions differentially impact sensitivity to individual TKIs. Thus, knowledge of insertion location may allow for more effectively tailored TKI therapy.

Clinical trial identification: ZENITH20: NCT03318939; EXCLAIM: NCT02716116.

Background: Addition of a MEK inhibitor to a BRAF inhibitor enhances tumour growth inhibition, delays acquired resistance of the MAPK pathway in *BRAF* V600-mutated cancers. We assessed the safety and efficacy of tunlametinib (HL-085), a novel highly selective MEK1/2 inhibitor, in combination with vemurafenib in patients(pts) with advanced *BRAF*-mutated solid tumors.

Methods: In this phase I study, pts with advanced solid tumors who had progressed on or shown intolerance to standard treatment were enrolled and received escalating doses of tunlametinib combined with vemurafenib in dose-escalation phase (followed a 3 + 3 design). Patients received tunlametinib at dose levels of 0.5, 6, 9, 12, and 15 mg BID, together with vemurafenib 960 mg BID, in 21-day cycles. In dose-expansion phase, tunlametinib 12mg + vemurafenib 960mg, tunlametinib 12mg + vemurafenib 720mg and tunlametinib 9mg + vemurafenib 720mg dose groups were evaluated. The tunlametinib 9mg + vemurafenib 720mg was determined as the recommended phase 2 dose (RP2D).

Results: As of the data cut-off date on 04, Nov, 2022, a total of 72 pts with solid tumors were enrolled. The most common AE were CK elevation, anemia and rash which were predominantly grade 1/2. 33 pts with non-small cell lung cancer (NSCLC) have been evaluated for response. The objective response rate (ORR) was 60.6% (95% CI: 42.1%, 77.1%), a median duration of response (DoR) was 11.3 months (95% CI: 3.9, NE), and a median progression free survival (PFS) was 11.7 months (95% CI: 5.6, NE) . At the RP2D, ORR was 60.0% (95%CI: 32.3%, 83.7%) and mPFS was 10.4 months (95% CI: 5.6, NE). 24 pts with metastatic colorectal cancer (mCRC) at all doses, ORR was 25.0% (95%CI: 9.8%, 46.7%), mDoR was 5.5 months (95% CI: 2.9, NE), and mPFS was 6.2 months (95% CI: 4.8, 7.6). Antitumor activity was also seen in papillary thyroid carcinoma and pancreatic ductal adenocarcinoma.

Conclusions: Tunlametinib in combination with vemurafenib showed promising antitumor activity and manageable safety profile in pts with *BRAF* V600-mutated solid tumors. Further studies are ongoing.

Clinical trial identification: NCT03781219.

Background: C-MET alterations implicated as a negative prognostic factor. It can occur as exon 14 (METex14) skipping mutations, gene amplification, and protein overexpression. Vebreltinib (PLB-1001) is a potent highly selective c-MET inhibitor, which has shown promising results in pts with NGS-identified advanced METex14 skipping NSCLC in our previous phase I study. Here we present data from pts with METex14 mutation (Cohort 1) from a phase II, open-label, multicenter and multi-cohort KUNPENG study of PLB1001 conducted in locally advanced or metastatic NSCLC pts with c-MET alterations.

Methods: Eligible pts were ≥18 years of age, ECOG PS 0∼1 with stage IIIB/IV NSCLC. Pts in Cohort 1 received 200 mg of Vebreltinib twice daily (28 days as a cycle) until disease progression, death, AE leading to discontinuation or withdrawal of consent. The primary endpoint was objective response rate (ORR) assessed by blinded independent review committee (BIRC) per RECIST v1.1. Secondary endpoints included investigator-assessed (INV) ORR, disease control rate (DCR), duration of response (DoR), time to response (TTR), progression-free survival (PFS) and overall survival (OS).

Results: As of 09-Aug-2022, 113 pts were enrolled, among whom 52 pts were in Cohort 1. 32.7% (17/52) pts previously received systematic therapy for advanced or metastatic NSCLC. The primary endpoint ORR was 75% (95% CI: 61.1%∼86.0%) per BIRC, while the ORR was 77.1% (95% CI: 59.9%∼89.6%) in treatment-naïve pts and 70.6% (95% CI: 44.0%∼89.7%) in previously-treated pts. ORR per INV was 69.2% (95% CI: 54.9%∼81.3%), while the ORR was 74.3% (95% CI: 56.7%∼87.5%) in treatment-naïve pts and 58.8% (95% CI: 32.9%∼81.6%) in previously-treated pts. Per BIRC, DCR was 96.2%, median DoR was 15.9 months, median TTR was 1.0 month, median PFS was 14.1 months and median OS was 20.7 months. Among pts with baseline brain metastases (N=5), ORR was 100.0%. The most common (≥20%) TRAEs in all the 113 pts were peripheral edema (56.6%), hypoalbuminemia (22.1%) and hypoproteinemia (19.5%). Most of the TRAEs were grade 1/2.

Conclusions: Vebreltinib showed promising efficacy and favorable safety in patients with *METex*14 mutant NSCLC.

Clinical trial identification: NCT04258033.

Background: Tepotinib, a MET TKI, is approved for Tx of advanced/metastatic *MET*ex14 skipping NSCLC, after immunotherapy (IO) and/or platinum (plat)-based chemotherapy (CT) in the EU, and regardless of prior Tx in other countries including the UK and Switzerland. In the VISION trial, tepotinib showed durable activity regardless of prior Tx, including in first line (1L) (1L outcomes: ORR, 56.1%; mDOR, 46.4 mo; and mPFS, 12.6 mo). We report long-term efficacy in previously treated pts (i.e. in second [2L], second or later [2L+], and third or later [3L+] lines) and prior/post-tepotinib Tx (data cut-off: Nov 20, 2022).

Methods: Pts received tepotinib 500 mg (450 mg active moiety) QD. Primary endpoint was objective response (RECIST v1.1) by IRC. Prior/post-tepotinib Tx was investigator's choice; outcomes were reported per investigator.

Results: Of 313 pts, 149 received tepotinib as 2L+ Tx (median age, 70.8 years), including 92 in 2L (median age, 70.4) and 57 in 3L+ (median age, 71.9). Across all prior Tx lines, ORR was 28.9%, mDOR was 6.0 mo, and mPFS was 5.0 mo. Outcomes were similar across prior regimens, including plat-based CT without IO (n=99), IO monotherapy (n=59), and IO+CT (n=22; **Table**). Compared with prior Tx, tepotinib outcomes in 2L+ were greatly improved (ORR, 45.0%; mDOR, 12.6 mo; mPFS, 11.0 mo) and were consistent regardless of Tx line (2L, 3L+) or smoking history. At the data cut-off, 139 (93.3%) 2L+ pts had discontinued tepotinib, and 70/139 (50.4%) had started subsequent Tx, including plat-based CT without IO (n=16), IO monotherapy (n=22), IO+CT (n=4), and MET TKIs (n=34). Across all subsequent MET TKIs after 2L+ tepotinib, best response was PR in 2 and SD in 10 pts.

Table: 1380P

Outcomes with:	Pts receiving Tx, n	ORR, %	mDOR, mo	mPFS, mo
All Tx lines prior to tepotinib by investigator assessment*	149	28.9	6.0	5.0
Plat-based CT without IO	99	29.3	5.0	4.0
IO monotherapy	59	22.0	6.0	4.0
IO+CT	22	22.7	5.0	5.0
Tepotinib by IRC				
2L+	149	45.0	12.6	11.0
2L	92	45.7	12.6	10.9
3L+	57	43.9	10.8	11.0

*mDOR and mPFS were based on a descriptive analysis. CT, chemotherapy; DOR, duration of response; IO, immunotherapy; IRC, independent review committee; m, median; mo, months; ORR, objective response rate; PFS, progression-free survival; pts, patients; Tx, treatment.

Conclusions: Tepotinib showed clinically meaningful efficacy in 2L+, 2L and 3L+, which was far greater than with standard of care Tx in prior lines. Despite pre-tepotinib Tx, a high proportion of 2L+ pts went on to receive post-tepotinib Tx, often including MET TKIs.

Clinical trial identification: NCT02864992.

Background: The TOGETHER study was designed for flexible pooling of *MET*ex14 skipping non-small cell lung cancer (NSCLC) patient (pt) datasets to characterize real-world (rw) outcomes before approval of MET inhibitors.

Methods: Seven datasets were used to analyze rw progression-free (rwPFS) and overall (rwOS) survival in advanced NSCLC with *MET*ex14 skipping according to Kaplan-Meier. Indirect treatment comparisons (ITC) were performed with propensity score reweighting of pts who received first-line (1L) immunotherapy (IO) alone or with chemotherapy (chemo) to match the characteristics of 111 pts with positive tissue biopsies (T+) who received 1L tepotinib in the VISION study (NCT02864992; data cut: Nov 2022).

Results: As of Jan 2023, TOGETHER included 309 pts (mean [SD] age 71.1 [9.7] years, 48% male, 52% with smoking history [SM]), with 615 lines of therapy administered between 2004 and 2022. For 1L IO+chemo (n=26; mean age 66.8 [SD 12.4], 65% SM) median rwPFS in TOGETHER was 5.7 months (95% CI: 3.1, 17.5) before and 6.9 mo (95% CI: 5.7, 29.4) after weighting, compared with 15.9 mo (95% CI: 11.3 , ne) for 1L tepotinib (HR 0.52 [0.29, 0.93]; p=0.03). For 1L IO monotherapy (n=48; mean age 73.2 [SD 9.1], 67% SM), median rwPFS in TOGETHER was 3.9 mo (95% CI: 2.7, 7.1) before and 3.4 mo (95% CI: 2.0, 9.7) after weighting compared with 15.9 mo for 1L tepotinib (HR 0.37 [0.24, 0.58]; p<0.01). Although confounded by subsequent treatments, median OS was also longer for tepotinib with 29.7 mo (95% CI: 19.1, ne) compared with 22.1 mo (95% CI: 12.6, ne) for IO+chemo (HR 0.77; p=0.38) and 18.9 mo (HR 0.64; p=0.05) for IO monotherapy. Other rw 1L treatments were chemo (n=128; mean age 69.3 [SD 9.5], 55% SM) with a median rwPFS of 4.8 mo (95% CI: 4.1, 6.2), and crizotinib (n=62; mean age 74.6 [SD 11.0], 56% SM) with a median rwPFS of 7.4 mo (95% CI: 4.4, 10.9). Median rwPFS was shorter for 2L+ chemo (4.3 mo, n=95) or 2L+ IO monotherapy (3.3 mo, n=83), and longer for 2L+ crizotinib (8.1 mo, n=68).

Conclusions: This large retrospective analysis shows poor rw outcomes for *MET*ex14 skipping NSCLC pts under standard treatments prior to the uptake of novel MET inhibitors. Matched ITC suggests longer PFS and OS with 1L tepotinib compared with 1L IO+chemo or IO monotherapy.

1382P Liquid biopsies (LBx) and tissue biopsies (TBx) for identifying MET exon 14 (METex14) skipping in advanced NSCLC: Analyses from the phase II VISION study of tepotinib

C.D. Rolfo[1], A.M. OBrate Grupp[2], C. Menzel[3], R. Bruns[4], D. Juraeva[5], C. Stroh[3], A. Johne[6], P.K. Paik[7]

[1]Center for Thoracic Oncology Cancer Institute, The Tisch Cancer Institute, Icahn School of Medicine at Mount Sinai, New York, NY, USA; [2]Global Medical Affairs, Merck Healthcare KGaA, Darmstadt, Germany; [3]Companion Diagnostics & Biomarker Strategy, Merck Healthcare KGaA, Darmstadt, Germany; [4]Department of Biostatistics, Merck Healthcare KGaA, Darmstadt, Germany; [5]Oncology Bioinformatics, Merck Healthcare KGaA, Darmstadt, Germany; [6]Global Clinical Development, Merck Healthcare KGaA, Darmstadt, Germany; [7]Thoracic Oncology Service, Memorial Sloan-Kettering Cancer Center, New York, NY, USA

Background: LBx and TBx have complementary roles in detection of NSCLC driver alterations, such as METex14, which predicts efficacy of MET inhibitors. The only MET inhibitor trial to enroll based on prospective detection of METex14 in LBx and/or TBx is the VISION trial of tepotinib. We evaluated patient (pt) characteristics and outcomes according to METex14 positivity in LBx and/or TBx (data cut-off: Nov 20, 2022).

Methods: *MET*ex14 was centrally assessed in prescreening by NGS analysis of fresh LBx (Guardant360® or Archer®MET) and/or archival or fresh TBx (Oncomine Focus or Archer®MET). Pts in Japan could enroll based on local TBx RT-PCR via the LC-SCRUM program. Parallel LBx/TBx testing was recommended but not mandatory. Eligibility required LBx-positive (L+) and/or TBx-positive (T+) status.

Results: Of 313 pts, 208 (66.5%) were T+ and 178 (56.9%) were L+. L+ pts had worse baseline prognostic features than T+ pts, including more pts with ≥3 target lesions (27.5% vs 18.8%) or ECOG PS 1 (76.4% vs 72.1%), higher median sum of target lesion diameters (67.1 vs 55.2 mm) and worse health-related quality of life (mean EORTC QLQ-C30 GHS, 53.9 vs 60.1). In 180 T+ pts with matching LBx results, *MET*ex14 was detected in ctDNA (L+) in 74 (41.1%) (i.e. T+/L+) and was undetectable (L−) in 106 (58.9%) (i.e. T+/L−). ORRs were slightly higher in T+/L+ pts, but T+/L− pts had longer DOR, PFS and OS. Overall meaningful durable efficacy was seen in treatment-naive and previously treated pts (Table).

Table: 1382P

	Treatment-naive		Previously treated	
	T+/L− (n=52)	T+/L+ (n=42)	T+/L− (n=54)	T+/L+ (n=32)
ORR, % (95% CI)	57.7 (43.2, 71.3)	64.3 (48.0, 78.4)	44.4 (30.9, 58.6)	53.1 (34.7, 70.9)
mDOR, months (95% CI)	ne (10.4, ne)	19.4 (7.6, ne)	12.6 (5.1, 20.8)	9.9 (4.4, 15.4)
mPFS, months (95% CI)	22.1 (14.8, ne)	12.1 (7.8, 49.7)	13.8 (8.2, 24.9)	8.2 (5.5, 13.7)
mOS, months (95% CI)	32.7 (15.3, ne)	28.5 (14.2, ne)	20.8 (15.6, 32.5)	19.8 (10.0, 26.5)

CI, confidence interval; DOR, duration of response; m, median; ORR, objective response rate; OS, overall survival; PFS, progression-free survival.

Conclusions: Tepotinib had robust and durable activity in T+ pts with L− or L+ status. While both LBx and TBx are suitable and complementary for detecting *MET*ex14, LBx may preferentially select pts with a poorer prognosis and higher tumor load. Undetectable *MET*ex14 in baseline ctDNA may define a more favorable treatment outcome. Differences in populations identified by TBx and LBx should be considered when interpreting trial data.

Clinical trial identification: NCT02864992.

Background: Capmatinib, a selective MET inhibitor, is approved by EMA and other health authorities worldwide for the treatment of adult patients (pts) with locally advanced or metastatic non-small cell lung cancer (NSCLC) harboring *MET* exon 14 skipping (*MET*ex14) mutations. The RECAP study provided comparative evidence of capmatinib vs standard of care (SoC) in first (1L) and second line (2L) NSCLC pts with *MET*ex14 mutations (NCT05796726).

Methods: The RECAP study is a historical comparison of capmatinib pts from the GEOMETRY mono-1 study with an external control arm of SoC pts from German routine care collected via a retrospective chart review. Analyses were performed both naive and propensity score adjusted. Evaluated outcomes included efficacy endpoints such as overall survival (OS), progression-free survival (PFS), overall response rate (ORR), time to CNS progression (CNSprog) and exploratory safety endpoints.

Results: A total of 119 1L and 46 2L pts were included in the chart review and compared to 60 1L and 81 2L pts treated with capmatinib. For 1L pts, the naive comparison showed a significant benefit of capmatinib for OS (median 25.49 vs 14.59 months; HR 0.58; 95% CI 0.39-0.87; p=0.011), PFS (median 12.45 vs 5.03 months; HR 0.44; 95% CI 0.31-0.63; p<0.001) and ORR (event rate 68.3 vs 26.9%; RR 2.54; 95% CI 1.80-3.58; p<0.001). In 2L, OS, PFS and ORR showed trends favoring capmatinib with no significant results. Notably, CNSprog resulted in a significant benefit with

capmatinib in 1L and 2L. No patient developed new, symptomatic brain metastases during capmatinib treatment. Propensity score adjusted analyses showed consistent results to naive analysis. Exploratory safety endpoints indicate a manageable safety profile for capmatinib.

Conclusions: For 1L pts, clinically relevant effects of capmatinib are seen in all efficacy and safety endpoints before and after adjustment. 2L results are consistently in favor of capmatinib but are limited by low patient numbers. Overall, RECAP demonstrates the important role of capmatinib for NSCLC pts harboring *MET*ex14 mutations with significant efficacy in preventing the development of brain metastases.

1384P Phase II study of cabozantinib in patients with MET-altered lung cancers

G. Harada[1], F.C. Santini[1], R.W. Repetti[1], J. Chang[2], S.R. Yang[2], Y-T. Lin[2], K.A. Moses[1], C. Falcon[1], C.J. Wilhelm[1], M. Goldstein[1], A. Makhnin[1], M.S. Ginsberg[3], A.J. Plodkowski[3], M.G. Kris[1], A. Drilon[1]

[1]Department of Medicine, Memorial Sloan-Kettering Cancer Center, New York, NY, USA; [2]Pathology Department, Memorial Sloan-Kettering Cancer Center, New York, NY, USA; [3]Radiology Department, Memorial Sloan-Kettering Cancer Center, New York, NY, USA

Background: MET alterations occur in about 5% of lung cancers and define a subgroup associated with sensitivity to MET tyrosine kinase inhibitors (TKIs). Only type I MET TKIs have been approved for these patients. In contrast, cabozantinib is a type II multikinase inhibitor with activity against MET.

Methods: In this single-arm phase 2 trial, patients (pts) with stage IV *MET*-altered lung cancers received cabozantinib 60 mg daily until progressive disease or intolerable toxicity. A Simon two-stage minimax design was used. If at least 2 responses were observed among 16 evaluable pts, the trial would proceed to the 25-patient second stage. The primary endpoint was objective response rate (ORR).

Results: The target of 25 pts was met. Among pts evaluable to date, 19 pts (79%; 19/24) had a *MET* exon 14 alteration only (skipping mutation, n=17; *MET* fusion with exon 14 exclusion, n=2), 2 pts (8%) had *MET* amplification only, and 3 pts (12%) had a concurrent *MET* exon 14 alteration and *MET* amplification. In cases with available tissue, FACETS confirmed *MET* amplification (≥6 copies), and MET immunohistochemistry was diffusely positive (>50%) in all cases. Most pts (84%, 20/24) received a prior MET TKI (crizotinib, n=15; capmatinib, n=4; tepotinib, n=1); 16 pts (67%) and 13 pts (54%) received one or more prior lines of chemotherapy and immunotherapy, respectively. The ORR was 17% (4/24; 95% CI 6.8-35.8%; *MET* skipping mutation, n=3; concurrent *MET* skipping mutation and *MET* amplification, n=1) and the disease control rate was 71% (95% CI 50.8-85.1%; partial response, n=4; stable disease, n=13, one with *MET* D1228N). Of the 4 pts with a partial response, 2 had received crizotinib and 1 capmatinib. The median progression-free survival was 6 months (95% CI 3.9-8.8 months), and the median overall survival was 9 months (95% CI 4.0-13.5 months). The most frequent treatment-related adverse events were grade 1 and 2 palmar-plantar erythrodysesthesia (42%), fatigue (38%), and diarrhea (38%).

Conclusions: Cabozantinib was active in MET-dependent cancers. Due to its alternative type II binding mode, cabozantinib can be useful in the treatment of type I TKI resistance. As proof of concept, 3 of 4 responses were observed in patients with type I MET TKI progression.

Clinical trial identification: NCT01639508.

1385P Genomics of early progression on selpercatinib in patients with RET fusion-positive lung cancers

M.F. Chen[1], E. Rosen[2], C. Falcon[1], M. Repetto[2], S.R. Yang[3], J. Chang[3], M.G. Kris[1], N. Rekhtman[3], M. Donoghue[4], A. Drilon[1]

[1]Thoracic Oncology, MSKCC - Memorial Sloan Kettering Cancer Center, New York, NY, USA; [2]Early Drug Development, MSKCC - Memorial Sloan Kettering Cancer Center, New York, NY, USA; [3]Pathology, MSKCC - Memorial Sloan Kettering Cancer Center, New York, NY, USA; [4]MSKCC - Memorial Sloan Kettering Cancer Center, New York, NY, USA

Background: Selective RET inhibitors transformed the treatment (tx) paradigm of *RET* fusion-positive (*RET*+) lung cancers. For selpercatinib, the median progression free survival (PFS) is 22.0 months (mos) for tx naive patients and 24.9 mos for platinum doublet pretreated patients. Genomic factors associated with early versus late progression are unknown.

Methods: We analyzed data from 80 patients with *RET*+ LC identified between January 2014 and March 2023 utilizing a DNA-based hybrid capture tumor next generation tumor sequencing assay (MSK-IMPACT) and plasma ctDNA assay (MSK-ACCESS). Patients with radiologic progression (PD) on selpercatinib ≤ 3 mos from initiation were classified as "rapid progressors", >3- 24 mos as "intermediate progressors", and ≥24 months as"late progressors." Baseline and post-PD MSK-IMPACT and MSK-ACCESS specimens were evaluated. Patients with post-PD biopsies were evaluated for acquired resistance (AR) (classified as on-target (secondary *RET* mutations), off-target (non-*RET* OncoKB level 1-4), and unknown).

Results: Among 80 patients with *RET*+ LC, 63 had pre-tx tumor sequencing and 35 patients had post-tx tumor/ctDNA sequencing. 58% (n=46/80) progressed on selpercatinib. PD was classified as rapid, intermediate, and late in 9% (n=7), 35% (n=28), 14% (n=11), respectively. Acquired resistance (AR) was identified in 48% of cases. Six patients had on-target AR and 17 patients had off-target AR. Most common off-target AR included *MET* amp (9%), *KRAS* mutation (6%), *PIK3CA* mutation (6%), *CDKN2A* mutation (6%), and *FGFR1* amp (6%). There were no differences in age, gender, ethnicity, prior tx, or PDL1 status between these groups. Pre-tx *TP53*, *KEAP1*, and *ARID1A* mutations were more common in rapid and intermediate versus late PD (p=0.03, p=0.02, p=0.06). Off-target mechanisms of resistance appeared to be enriched in rapid and early progressors vs late progressors (75% vs 51% vs 25%, p=0.3).

Conclusions: *RET* fusion+ NSCLCs that progressed on selpercatinib prior to two years, an approximation of the drug's median PFS, were enriched for select co-occurring alterations (e.g., *TP53, KEAP1*, and *ARID1A* mutations) in pre-tx samples and off-target resistance in post-PD samples.

1386P Validation of MET amplification using next-generation sequencing in lung adenocarcinoma

M. Salido[1], S. Clavé[2], I. Sánchez[3], P. Rocha[4], L. Masfarre Pinto[5], N. Navarro Gorro[5], M.A. Galindo Campos[4], R. Del Rey-Vergara[4], A. Taus Garcia[5], B. Espinet[1], E. Arriola[5], B. Bellosillo Paricio[2]

[1]Molecular Cytogenetics Laboratory, Hospital del Mar - Parc de Salut Mar, Barcelona, Spain; [2]Molecular Biology Laboratory, Hospital del Mar - Parc de Salut Mar, Barcelona, Spain; [3]Pathology Department, Hospital del Mar - Parc de Salut Mar, Barcelona, Spain; [4]Cancer Research Program, IMIM - Institut Hospital del Mar d'Investigacions Mediques, Barcelona, Spain; [5]Medical Oncology Department, Hospital del Mar - Parc de Salut Mar, Barcelona, Spain

Background: *MET* gene amplification is a potential therapeutic target in lung adenocarcinoma (LUAD) currently identified by fluorescence in situ hybridization (FISH). Next-generation sequencing (NGS) has become an essential diagnostic tool for routine biomarker profiling of cancer patients, including the detection of copy number alterations (CNAs). The aim of this study was to evaluate the concordance between these two methods and identify potential limitations of NGS implementation.

Methods: Thirty cases with *MET* amplification detected by FISH were retrospectively selected from a cohort of 567 LUAD diagnosed between 2018 and 2022 (prevalence: 5.3%). Cases were classified according to the current Camidge-2021 FISH criteria as 5 low-amplified (*MET*/CEP7 ratio $\geq$1.8 to $\leq$2.2), 11 medium-amplified (*MET*/CEP7 ratio $>$2.2 to $<$4) and 14 high-amplified (*MET*/CEP7 ratio $\geq$4). Tumor area and tumor cell percentage were annotated to later evaluate complete molecular alterations by NGS using the Oncomine Precision Assay.

Results: Detection of *MET* amplification was concordant in only 16 out of 30 cases (5 cases were excluded due to insufficient DNA), and no correlation was found between *MET* copy number determined by FISH and NGS (R^2=0.346). Distribution of amplification categories was random: 2 cases showed low-amplification, 7 medium-amplification, and 7 high-amplification. Slight differences were observed between concordant and discordant cases in: *MET* enumeration (12.4 vs. 9.3 gene copies), *MET*/CEP7 ratio (4.8 vs. 3.2), tumor area (15 vs. 11mm2), and DNA concentration (12 vs. 7 ng/µl), but none of them were statistically significant. FISH results of the 9 discordant cases were reviewed and high copy number heterogeneity was observed in 7 of them and focal amplifications were observed in 2. In 7 out of 9 discordant cases, co-alterations were detected: 2 *KRAS* (p.G12C and p.Q61H), 2 *BRAF* non-V600, 2 *MET* exon 14 skipping and one *EGFR* p.L858R.

Conclusions: The detection of *MET* amplification by NGS did not show satisfactory concordance with the results obtained by FISH, likely due to the high heterogeneity in *MET* gene copy number enumeration. As a result, complementary determination by FISH is necessary, given the lack of standardized criteria for establishing CNAs positivity by NGS.

1387P Efficacy of first-line treatment options in advanced HER2-altered non-small cell lung cancer: A multi-center retrospective study

H. Sun[1], Y. Ge[1], J. Wu[1], Y. Sun[1], J. Zhang[1], Q. Cheng[1], D. Wang[1], X. Wang[1], J. Li[1], X. Fu[2], H. Sun[2], A. Gao[2]

[1]Phase I Clinical Research Center, Cancer Hospital affiliated to Shandong First Medical University, Jinan, China; [2]Department of Thoracic Radiation Oncology, Cancer Hospital affiliated to Shandong First Medical University, Jinan, China

Background: HER2 alterations are identified in 2-4% of non-small cell lung cancer (NSCLC), indicating poor clinical outcomes. Due to the deficiency of effective targeted therapies in the first-line setting, chemotherapy alone or combined with Bevacizumab, immune checkpoint inhibitors (ICIs) or both are recommended as standard options. However, the optimal therapy is still undetermined.

Methods: Stage IV NSCLC patients with HER2 alteration were retrospectively analyzed from 6 cancer centers in China between May 2017 and February 2023. All the patients received chemotherapy alone (C), chemotherapy combined with Bevacizumab (BC), chemotherapy combined with ICIs (IC), or chemotherapy combined with Bevacizumab and ICIs (IBC) as first-line strategies. The clinical outcomes were evaluated.

Results: Eighty patients with HER2 mutation (75/80) or amplification (5/80) were included, in which 10 patients received chemotherapy alone, 37 received BC, 24 received IC, and 9 received IBC treatment. Compared with chemotherapy, combination therapy significantly improved mPFS (8.47 months VS 4.97 months, p$<$0.0001). Further analysis based on different combination mode showed that, each of the combination therapeutics, including BC (mPFS 7.27 m, HR=0.31, 95% CI: 0.14-0.68, p$<$0.001), IC (mPFS 8.47m, HR=0.20, 95% CI:0.08-0.48, p=0.004) and IBC (mPFS 16.3m, HR=0.08, 95% CI: 0.02-0.25, p$<$0.001), gave beneficial PFS compared with chemotherapy. In our effort to determine the optimal combination strategy, we found IBC treatment gave longer mPFS compared with BC (HR=0.15, 95% CI: 0.04-0.50, p$<$0.001) and IC (HR=0.43, 95% CI: 0.16-1.18, p=0.092). However, the efficacy of IC and BC schemes are comparable.

Table: 1387P

Groups	Patient number	ORR, % (95% CI)	DCR, % (95% CI)	mPFS, months (95% CI)
Chemotherapy	n=10	30.0(1.60,58.4)	100(100,100)	4.97 (4.09, 5.84)
Combination	n=70	25.7(15.5,36.0)	91.4(84.9,98.0)	8.47 (7.28, 9.35)
IC	n=24	29.2(11.0,47.4)	87.5(74.3,101)	8.47 (7.15, 9.78)
BC	n=37	18.9(6.30,31.5)	91.9(83.1,101)	7.27 (6.27, 8.26)
IBC	n=9	44.4(12.0,76.9)	100(100,100)	16.3 (8.83, 23.8)
ALL	n=80	26.3(16.6,35.9)	92.5(86.7,98.3)	7.63 (6.35, 8.92)

Conclusions: Chemotherapy-based combination strategies improve patient survival compared with chemotherapy in the first-line therapy of HER2-altered NSCLC, while the IBC mode lead to the optimal PFS.

Background: *RET* fusions are found in 1−2% of patients (pts) with NSCLC. RET inhibitors (RETi) have recently been approved for *RET* fusion-positive (*RET*+) aNSCLC, but the prognostic value of *RET* fusions is unclear. This study aimed to describe the overall survival (OS) of pts with *RET*+ or *RET* wild-type (*RET*-WT: no *RET* alterations) NSCLC using real-world data from two large databases.

Methods: This was a retrospective, observational study using US-based data from 1) a nationwide Flatiron Health−Foundation Medicine NSCLC clinico-genomic de-identified database (FH-FMI CGDB) and 2) a nationwide longitudinal electronic health record-derived FH de-identified database (FH). Pts with aNSCLC diagnosed between 1 Jan 2011 and 31 Dec 2021 (CGDB) or 30 Sep 2022 (FH) with known *RET* fusion status were included. Pts with other actionable gene alterations or previous treatment with RETi or a clinical study drug in any line were excluded. The primary objective was to compare the OS of pts with *RET*-WT vs *RET*+ aNSCLC in 1) all pts (index date: date of advanced diagnosis) and 2) pts who received first-line (1L) chemotherapy plus cancer immunotherapy (index date: start of 1L therapy). Hazard ratios (HRs) for left-truncated OS (to account for immortal time from index to *RET* testing) were adjusted for confounding variables using a multivariate Cox proportional regression model.

Results: Overall, 45 (CGDB) and 60 (FH) pts with *RET*+ aNSCLC, and 5,890 (CGDB) and 16,566 (FH) pts with *RET*-WT aNSCLC were included in the analysis. Pts with *RET*+ NSCLC tended to be younger ($<$65 yrs old: 51% vs 33%), less frequently smokers (8% vs 47%), and less commonly had *KRAS* (7% vs 34%) and *TP53* (42% vs 72%) mutations than *RET*-WT pts. In CGDB and FH, there was no significant difference in OS between *RET*-WT and *RET*+ pts (Table).

Conclusions: Data from this real-world study using two large databases show that pts with *RET*+ aNSCLC do not have a different prognosis than pts with *RET*-WT aNSCLC. These data suggest that *RET* fusions have no prognostic value in aNSCLC.

Table: 1388P

Cohort	*RET* fusion status	Pts with *RET*+ or *RET*-WT NSCLC from the CGDB			Pts with *RET*+ or *RET*-WT NSCLC from the FH database		
		Events/N	Median OS (95% CI)	Adjusted[‡] HR (95% CI)	Events (n/N)	Median OS (95% CI)	Adjusted HR[‡] (95% CI)
All pts*	*RET*+	25/45	12.0 (5.2—25.1)	1.08 (0.72—1.63)	33/60	12.9 (7.1—27.2)	1.28 (0.83—1.97)
	RET-WT	4,101/5,890	7.9 (7.4—8.3)		10,958/16,566	8.7 (8.5—9.0)	
1L chemotherapy + cancer immunotherapy[†]	*RET*+	9/16	14.9 (10.6—NR)	0.93 (0.47—1.85)	6/14	7.0 (4.5—NR)	1.10 (0.49—2.45)
	RET-WT	946/1,603	10.5 (9.5—11.1)		2,647/4,572	10.3 (9.8—10.9)	

*Index: advanced diagnosis date; [†]index: start of 1L therapy; [‡]adjusted by multivariate Cox proportional regression model for multiple covariates.

1389P Efficacy of poziotinib in HER2 exon 20 insertion NSCLC patients who received prior platinum-based and HER2 targeted therapies

A. Prelaj[1], X. Le[2], C. Proto[3], C.S. Baik[4], N. Tchekmedyian[5], J. Heymach[6], G. Bhat[7], R. Cornelissen[8]

[1]Oncologia Medica Toracica Dept., Fondazione IRCCS - Istituto Nazionale dei Tumori, Milan, Italy; [2]Thoracic Head & Neck, The University of Texas MD Anderson Cancer Center, Houston, TX, USA; [3]Medical Oncology Dept., Fondazione IRCCS - Istituto Nazionale dei Tumori, Milan, Italy; [4]Medical Oncology Dept., University of Washington Seattle Cancer Care Alliance, Seattle, WA, USA; [5]Medical Oncology, City of Hope Comprehensive Cancer Center, Duarte, CA, USA; [6]Thoracic Oncology, MD Anderson Cancer Center, Houston, TX, USA; [7]Clinical Science Department, Spectrum Pharmaceuticals, Irvine, CA, USA; [8]Pulmonary medicine, Erasmus MC - University Medical Center, Rotterdam, Netherlands

Background: Poziotinib (Pozio) is an oral pan-ErbB tyrosine kinase inhibitor (TKI) of EGFR and HER2 exon 20 mutations with demonstrated clinical activity and an expected safety profile. There is an unmet medical need for patients who progressed on platinum-based (PLT) or/and HER2 targeted therapy. Pozio is being studied in a multi-cohort, global, phase 2 study (ZENITH20). Here, we present the efficacy and safety results of pozio in patients with NSCLC HER2 exon 20 mutations who previously received 2+ lines of therapies including HER2-targeted therapies.

Methods: Patients with HER2 exon 20 NSCLC who previously received 2+ lines of systemic therapy were enrolled in 2 cohorts of ZENITH20. Poziotinib was administered orally either as 16 mg QD or 8 mg BID until disease progression or toxicity. The endpoints were ORR, PFS, and DOR, evaluated by a central, independent review committee (IRC) using RECIST 1.1 and safety.

Results: 91 patients were treated with pozio (69 16 mg QD and 22 8 mg BID) as 3rd line. Of these, 35 patients (25 16 mg QD; 10 8 mg BID) had prior HER2 therapy such as trastuzumab, TDM1, and T-DXd. The median age was 63 yrs; 71% females, 60% non-smokers, and 14% had stable brain metastases at study entry. 46% had 2 lines and 54% had 3+ lines of prior therapy (median of 3). In patients who received pozio in 3rd line, the ORR was 31% (28/91) with 95% confidence interval of [22, 41] by IRC. The median DOR was 6.4 m and median PFS was 5.8 m. The efficacy was consistent independent of types and sequence of prior therapies. ORRs were 30% with PLT+any systemic therapy; 30% with PLT+docetaxel and 43% with PLT+TKI. In 35 patients that had a prior HER2 therapy, the ORR was 29%; DCR was 71%; median DOR was 5.5 m and median PFS was 5.6 m. Responses by local review were seen in 4 of 8 prior T-DXd treated patients. The most common Grade $\geq$3 AEs were rash (42%), diarrhea (31%), and mucositis (23%). 82% had dose interruptions, 74% had dose reductions, and 15% discontinued drug due to related AEs.

Conclusions: Poziotinib demonstrated clinically meaningful efficacy in patients who received prior 2+ lines of therapy including HER2 therapy. ZENITH20 study provides a large dataset in the 3rd or later line setting of HER2 exon 20 mutations in NSCLC who have very limited treatment options.

Clinical trial identification: NCT03318939.

1390P Real-world characteristics, treatment patterns and outcomes of patients with advanced HER2/ERBB2-mutant non-small cell lung cancer (NSCLC) in France and Germany

P. Christopoulos[1], N. Girard[2], L. Zhang[3], Z. Mbanya[4], K. Dunton[3], A. Ali[5], M. Berktas[6], L. Delmastro[7], A. Struebing[8], Y. Xiong[9], S. Lay-Flurrie[10], P. Hindocha[10], T. Mehdikhanova[11]

[1]Dept. of Oncology of Thoracic Tumors, Thoraxklinik Heidelberg gGmbH, Heidelberg, Germany; [2]Thorax Institute, Institut Curie, Paris, France; [3]HEOR, Daiichi Sankyo Europe GmbH, Munich, Germany; [4]Global Health Economics & Payer Evidence, AstraZeneca UK, Luton, UK; [5]Global Oncology Medical Affairs, Daiichi Sankyo Europe GmbH, Munich, Germany; [6]Global Oncology Outcome Research, AstraZeneca - City House L1 and L3, Cambridge, UK; [7]Global Medical Affairs, AstraZeneca, Cambridge, UK; [8]HEOR, Daiichi Sankyo Europe GmbH, Martinsried, Germany; [9]Real World Evidence, Daiichi Sankyo International, Basking Ridge, NJ, USA; [10]Real World Evidence, IQVIA, Livingston, UK; [11]Real World Evidence, IQVIA Ltd, London, UK

Background: HER2 mutations (HER2m) are a potential therapeutic target in 2—3% of patients with non-squamous NSCLC; however, real-world evidence on demographics and outcomes is limited. We assessed patient characteristics and treatment patterns for advanced HER2m NSCLC at a French and a German academic centre.

Methods: Adults with advanced HER2m non-squamous NSCLC were identified at Institut Curie, France (study: 1 Jan 2011—22 Apr 2022) and Thoraxklinik Heidelberg, Germany (1 Jan 2014—5 May 2022). Lines of therapy (L) and treatment pathways were characterised. Demographic/clinical characteristics were analysed by descriptive statistics; survival was assessed by Kaplan—Meier analysis. Real-world progression-free survival (rwPFS) was time between L start and earliest progression event (Germany), discontinuation due to progression (France), next L start or death.

Results: Of 55 patients with advanced HER2m NSCLC (n=17, France; n=38, Germany), the median age at diagnosis was 66 years, 63.6% were female and 74.6% had ECOG scores of 0 or 1. 48 patients (87.3%) received at least 1L, 29 (52.7%) received at least 2L and 19 (34.5%) received at least 3L. The most common regimens were carboplatin + pemetrexed (13/48, 27.1%) and carboplatin + pemetrexed + pembrolizumab (9/48, 18.8%) in 1L and pembrolizumab (6/29, 21.0%), carboplatin + pembrolizumab + pemetrexed (3/29, 10.3%) and pemetrexed (3/29, 10.3%) in 2L. The most common treatment pathway began with non-platinum-based chemotherapy or platinum-based chemotherapy in 1L (26/48, 54.2%) and immunotherapy in 2L (7/26, 26.9%) (Table). Median real-world overall survival from the start of 1L was 16.5 months (95% CI: 12.3—29.8). Median rwPFS in the 1L was 5.1 months (95% CI: 3.5—8.5).

Conclusions: Chemotherapy was the mainstay in 1L; diverse regimens were used in 2L. Poor survival suggests a need for novel therapeutic options for advanced HER2m NSCLC.

Editorial acknowledgement: Medical writing and editorial assistance were provided by Julia C. Jones (PharmD, PhD), Erica Cave (PhD), and Daria Renshaw from IQVIA, funded by the study sponsors.

1391P Capmatinib vs docetaxel as second- or third-line (2/3L) therapy in patients (pts) with METex14-mutated advanced NSCLC (aNSCLC): The GeoMETry-III trial

O.J. Juan Vidal[1], M.K. Singhal[2], R.M. Alvarez[3], F.L. Cecere[4], P-J. Souquet[5], S-W. Kim[6], A. Robeva[7], A. Jary[8], S. Glaser[8], M. Miskic[8], J. Wolf[9]

[1]Department of Medical Oncology, Hospital Universitari i Politècnic La Fe, Valencia, Spain; [2]Medical Oncology, Indraprastha Apollo Hospital, New Delhi, India; [3]Medical Oncology Department, Gregorio Marañón Hospital, Madrid, Spain; [4]Oncology Department, IRCCS Istituto Nazionale Tumori Regina Elena (IRE), Rome, Italy; [5]Department of Thoracic Oncology, University Hospital of Lyon-Sud, Pierre-Bénite, France; [6]Department of Oncology, Asan Medical Center - University of Ulsan College of Medicine, Seoul, Republic of Korea; [7]Oncology Global Drug Development, Novartis Pharmaceuticals Corporation, East Hanover, NJ, USA; [8]Oncology DU Global Drug Development, Novartis Pharma AG, Basel, Switzerland; [9]Department of Internal Medicine, Center for Integrated Oncology, University Hospital of Cologne, Cologne, Germany

Background: Capmatinib (cap), a selective MET inhibitor, is approved by multiple health authorities worldwide, including US, Japan, and EU, in *MET*ex14-mutated aNSCLC population, based on the phase 2 GeoMETry mono-1 study (NCT02414139). Here, we report the available efficacy and safety of cap vs docetaxel (doc) from GeoMETry-III trial.

Methods: GeoMETry-III is a multicenter, open-label, randomized, phase 3 trial (NCT04427072). Eligible pts included *EGFR* wild type, *ALK* rearrangement−negative, stage IIIB/IIIC or IV *MET*ex14−mutated NSCLC who have progressed on 1/2L of systemic therapy. Primary and key secondary endpoints were progression-free survival (PFS) and overall response rate (ORR) by blinded independent review committee (BIRC) assessment per RECIST v1.1, respectively. Although 90 pts were planned to be included in this study, due to slow enrollment, the study was terminated early with 22 patients enrolled.

Results: As of Feb 15, 2023, data cutoff, 22 pts were randomized 2:1 to cap (n = 15) or doc (n = 7) arms. Baseline characteristics were generally comparable between arms. The observed benefit with cap vs doc in median PFS was not statistically significant: 6.1 months vs 4.1 months; HR, 0.46; 95% CI 0.16-1.3; $P = 0.066$. Of 15 pts in cap arm, 8 had partial response (53.3%, 95% CI 26.6-78.7) vs none in doc arm (95% CI 0-41.0). Disease control rate was 73.3%; 95% CI 44.9-92.2 vs 57.1%; 95% CI 18.4-90.1, respectively. Median duration of response in cap was 9.9 months; 95% CI 2.9-NE. Five of 6 doc-treated pts crossed over to cap (at 1.4, 1.9, 6.0, 6.3, and 13.7 months from doc start due to progression), which confounded the overall survival results. No new safety signals were observed for cap. Most frequent treatment-related AEs (≥25%, any grade) in cap were peripheral edema (46.7%) and nausea (33.3%); and in doc were, alopecia (66.7%), anemia (50.0%), asthenia, conjunctivitis, lacrimation increased, onycholysis (33.3% each).

Conclusions: Overall, the numerical differences in PFS and ORR showed trends favoring cap, and together with safety, are consistent with previous results of the pivotal GeoMETry mono-1 study. The GeoMETry-III trial was terminated early due to enrollment constraints.

Clinical trial identification: NCT04427072.

Background: *MET*muts occur in 3% of NSCLC and are associated with poor survival. Despite known sensitivity of *MET*mut NSCLC to MET inhibition, no EMA approved

therapies existed for this indication before 2022. In this study, safety and efficacy of oral tyrosine kinase (TK) inhibitor crizotinib, approved for *ALK*+ and *ROS1*+ NSCLC, were evaluated in *MET*mut aNSCLC.

Methods: In DRUP (NCT0295234), cancer patients (pts) are treated with drugs outside their labeled indication, based on their molecular profile. Previously treated and treatment naïve pts with *MET*mut aNSCLC were included and treated with crizotinib 250 mg BID until disease progression or intolerable toxicity. Pts with known symptomatic, untreated brain metastases were excluded. Primary endpoints were clinical benefit (CB: RECIST v1.1 confirmed objective response (OR) or stable disease (SD) $\geq$ 16 weeks) and safety. Pts were enrolled using a Simon like 2-stage model, with 8 pts in stage 1 and if $\geq$ 1/8 pts had CB, 24 pts in stage 2.

Results: Between 09/2018 and 10/2022, 44 pts were screened, 30 started treatment and 24 were evaluable for response. Median age was 75 [IQR, 69 − 78]. ECOG performance status was 0, 1 and 2 in 6 (25%), 12 (50%) and 6 (25%) pts, respectively. 19 pts (79%) were treatment naïve, 5 (21%) had received checkpoint blockade and/or platinum based chemotherapy. 1 (4%) complete response (CR), 14 (58%) partial responses and 2 (8%) SDs $\geq$ 16 weeks were observed, with resulting OR-rate of 62% (95% CI, 41 − 81) and CB-rate of 71% (95% CI, 49 − 87). After 20.2 months median follow-up, median progression-free and overall survival were 8.3 (95% CI, 6.0 − NA) and 13.0 months (95% CI, 8.0 − NA), respectively. 23 treatment-related grade $\geq$ 3 adverse events occurred in 12/30 pts (40%) and led to treatment discontinuation in 2 (6%). The pt who achieved CR had a TK domain mutation (p.H1094Y), all others exon 14 skipping *MET*muts. Post hoc whole genome sequencing of pre-treatment biopsies of 11 pts (46%) did not reveal any biomarkers for (non-)response.

Conclusions: Crizotinib proved highly effective in pts with *MET*mut aNSCLC, with a manageable toxicity profile. Additional research is warranted to identify biomarkers for response.

Clinical trial identification: NCT0295234.

1393P Characteristics of MET gene and its relationship with TMB/MMR genes in Chinese NSCLC population

H.Y. Zhang[1], Z. Liu[2], L. Feng[2], Y. Xu[2], H. He[2], P. Luo[3]

[1]Oncology, Fuzhou Pulmonary Hospital, Fuzhou, China; [2]Department of Medicine, Zhejiang Shaoxing Topgen Biomedical Technology Co., Ltd, Shanghai, China; [4]Department of Medicine, Zhejiang Shaoxing Topgen BioPharm Technology Co., Ltd., Shanghai, China

Background: Patients with driver-gene mutations in NSCLC can benefit significantly from corresponding targeted therapy, but respond poorly to immunotherapy (such as EGFR, ALK). As a driver-gene of NSCLC, the relationship between the characteristics of MET and many immune indicators in the Chinese population is still unclear. This study aims to elucidate the characteristics of the MET gene and its relationship with immune indicators in the Chinese NSCLC population.

Methods: 732 Formalin-Fixed Paraffin-Embedded (FFPE) lung adenocarcinoma samples were collected and detected by Next Generation Sequencing 603-gene panel from July, 2021 to March, 2023 were selected from the study. The biomarkers of immunotherapy (TMB-High [$\geq$10/Mb], and MMR-related genes (MLH1, MSH2, MSH6, PMS2) were also calculated.

Results: Among the 732 subjects included in the previous detection, a total of 32 cases were detected to carry MET-related mutations. The detection rate of MET gene was 4.37%. The median age was 65 (13-97). 15% of patients belonged to exon 14 skipping type (5/32); MET amplification accounted for the least, accounting for only 6% (2/32). The top 3 of mutation frequency were Met_L221W (4/32), MET_Q1067K (2/32), and MET_F206S (2/32). The gene partners of Met co-mutation were analyzed, and the top five genes were PPP2R1A, HIST1H3G, CDKN1B, SYK, and ERBB4. In the analysis of the immune indicators of the MET mutant population and wild-type population, the Mann-Whitney U test found that among the TMB indicators, the mean value of the MET group was 8.09 with SD of 7.91, and the mean value of the un-MET group was 5.94 with SD of 4.98. MET was correlated with TMB with statistical difference (P value 0.02).We also paid attention to MET and MMR-related genes. The analysis showed that there was a significant relationship between MET group and wild-type MET group and MMR gene (p-value: 0.026).

Conclusions: In the Chinese NSCLC population, there is a correlation between MET expression and TMB, and the MET mutation will increase the TMB value. MET expression was significantly correlated with MMR-related gene mutations.

1394P Real-world experience in treatment of patients with non-small cell lung cancer with BRAF and cMET Exon 14 skipping mutations

U. Janzic[1], W. Shalata[2], A. Agbarya[3], R. Dziadziuszko[4], K. Szymczak[4], M. Jakopovic[5], G. Mountzios[6], A. Pluzanski[7]

[1]Medical Oncology Department, University Clinic of Respiratory and Allergic Diseases Golnik, Golnik, Slovenia; [2]Oncology Department, Soroka University Medical Center, Beer Sheva, Israel; [3]Oncology Department, Bnai Zion Medical Center, Haifa, Israel; [4]Department of Oncology and Radiotherapy and Early Phase Clinical Trials Centre, Medical University of Gdansk, Gdansk, Poland; [5]Respiratory Diseases Dept., KBC Zagreb - Clinic for Lung Diseases Jordanovac, Zagreb, Croatia; [6]Second Department of Medical Oncology and Clinical Trials Unit, Henry Dunant Hospital Centre, Athens, Greece; [7]Lung and Thoracic Cancer Clinic, Maria Sklodowska-Curie National Research Institute of Oncology, Warsaw, Poland

Background: BRAF and cMET Exon 14 skipping are rare mutations of NSCLC. Opposite to other alterations, the preferred treatment sequencing in 1st and 2nd line is not clear.

Methods: We created an international registry for patients (pts) with advanced NSCLC harboring BRAF and cMET exon 14 skipping mutations, diagnosed from Jan 2017 until June 2022, excluding pts enrolled in clinical trials. Clinicopathologic and molecular data were collected, and treatment patterns were recorded. Clinical endpoints according to treatment assignment were assessed using Kaplan-Meier curves and Cox regression models.

Results: Data on 58 pts from 7 centers across 5 countries were included in the final analysis. Forty patients had cMET exon 14 skipping mutation and 18 had BRAF V600E mutation. Main characteristics: median age 66.7 (range: 36.0-91.0) years, female sex (48.0%), never or past smokers (71.0%), performance status 0-1 in (84.0%), adenocarcinoma (86.2%), stage IIIC - IV at diagnosis (82.2%), bone and brain metastasis (45.0%, and 21.0%, respectively). Mutations were uniformly diagnosed by NGS in all centers. Programmed death-ligand 1 TPS was $<$1% in 18%, 1-49% in 34% and $>$50% in 48% of cases. Fifty-three and 28 pts received 1st and 2nd line treatments, respectively, among which 52.8% received targeted therapy (TT) in 1st line and 53.5% in 2nd line. Overall response rate (ORR) and disease control rate (DCR) for 1st line treatment with TT vs. other (IO +/- CT) was 55.6% vs. 21.7% (p = 0.0084) and 66.7% vs 39.1% (p =

0.04), respectively. Type of treatment in 1st line (TT vs. IO +/- CT) affected Time to Treatment Discontinuation (TTD), 11.6 m vs. 4.6 m, p = 0.006. Overall survival for the whole group was 15.4 m and was not statistically influenced by the type of treatment (19.2 m vs. 13.5 m; p = 0.83).

Conclusions: This real-world retrospective study suggests that TT in the 1st line is the preferred option for the treatment of pts with advanced NSCLC with BRAF and cMET exon 14 skipping mutations, as opposed to IO +/- CT, due to higher ORR and DCR, longer TTD and the fact that almost half of the patients did not receive 2nd line treatment. U Janzic and W. Shalata contributed equally to this study.

1396P HER2 testing pattern, characteristics of locally advanced or metastatic NSCLC patients by HER2 testing in France

D. Debieuvre[1], P. Macouillard[2], X. Quantin[3], M. Berktas[4], N. Girard[5], C. Audigier Valette[6], T. Filleron[7], S. Musilli[8], L. Bosquet[2], M. Pérol[9]

[1]Pneumology, GHRMSA, Mulhouse, France; [2]Real-World Data, Unicancer, Paris, France; [3]Medical Oncology, ICM - Institut du Cancer de Montpellier, Montpellier, France; [4]Global Oncology Outcome Research, AstraZeneca - City House L1 and L3, Cambridge, UK; [5]Pneumology, Thorax Institute, Institut Curie, Paris, France; [6]Pneumology, Hopital Sainte Musse, Toulon, France; [7]Biostatistics & Health Data Science, Institut Claudius Regaud - IUCT Oncopole, Toulouse, France; [8]Medical Affairs, AstraZeneca - Laboratoire Pharmaceutique, Rueil-Malmaison, France; [9]Medical Oncology Dept., Centre Léon Bérard, Lyon, France

Background: HER2 targeted treatment impacted the management of NSCLC patients (pts) with HER2 mutations; however, real-world data on HER2 testing in NSCLC pts is limited. This abstract aims to describe HER2 testing and characteristics of locally advanced or metastatic (LAM) NSCLC pts in France.

Methods: This is a retrospective analysis of observational data from the EpidemioStrategy and Medical Economics (ESME) Lung Cancer Database from France (NCT03848052). Patients >18 years diagnosed with LAM NSCLC from 2015 without any other previous malignancy were included in the analysis.

Results: ESME includes 22561 LAM NSCLC pts who met the eligibility criteria. Of those, 33.4% received at least 1 HER2 test and 10.3% of tested pts received >1 test. HER2 testing decreased over time (2015 27.7%, 2016 21.0%, 2017 17.1%, 2018 12.6%, 2019 9.7%, 2020 3.7%). 2.5% of tested pts had HER2 alteration. 81.4% of LAM NSCLC pts received HER2 testing after LAM NSCLC diagnosis, with a median time of 28 days from LAM NSCLC diagnosis to test result. 58.2% received first HER2 test result before 1st line treatment, and the median time to treatment start from the test result was 20 days. Primary tumor tissue was the most common sample material for HER2 testing (71.5% of pts), followed by metastasis tissue (27.4%) and blood (3.9%). Age at initial and LAM-NSCLC diagnosis were similar between HER2 tested and not tested pts. However, the HER2 tested group had a higher proportion of female pts and those ≤60 years old. Pts with ECOG PS record showed that HER2-tested pts had better performance status. HER2 tested group had higher proportion of non-squamous NSCLC (95.3% vs 69.7%) and more pts were diagnosed with de novo LAM NSCLC (80.2% vs 74.0%) and at stage 4 (84.2% vs 76.8%).

Table: 1396P Characteristics of LAM NSCLC patients by HER2 test status

	HER2 not tested (n=15301)	HER2 tested (n=7530)
Gender, female	4689 (31.2%)	3016 (40.1%)
Age at LAM diagnosis		
Year, median (min-max)	65 (24-98)	64 (21-97)
≤ 60 years, n (%)	4762 (31.7%)	2756 (36.6%)
ECOG PS at LAM diagnosis		
Score 0-1*, n (%)	1726/2858 (60.4%)	953/1391 (68.5%)
Histology		
Non-squamous, n (%)	10480 (69.7%)	7174 (95.3%)
adenocarcinoma	*8747 (58.2%)*	*6439 (85.5%)*
Squamous, n (%)	4551 (30.3%)	356 (4.7%)
Setting at LAM diagnosis		
Stage IV, n (%)	11540 (76.8%)	6339 (84.2%)
Relapse, n (%)	3908 (26.0%)	1491 (19.8%)

* based on number of pts with ECOG PS records

Conclusions: These results revealed that HER2 testing rates for LAM NSCLC pts were low and have decreased over time, with a remarkable drop in 2020 in France; and NSCLC pts with specific characteristics had higher HER2 testing rate.

Background: Antibody-drug conjugates (ADCs) may extend targeted therapy to patients (pts) whose tumors express an antigen regardless of the presence of a driver mutation. Telisotuzumab vedotin (ABBV-399), a first-in-class MET (or c-Met)-directed ADC, had promising monotherapy anticancer activity in previously treated pts with MET-overexpressing (OE), non-squamous *EGFR* wild type NSCLC (Camidge et al. JCO. 2022;40:16 suppl, 9016). Characterization of MET OE NSCLC, a novel biomarker-defined therapeutically relevant subgroup, is thus warranted. MET OE was evaluated in a real-world cohort and co-associated with mRNA expression, *MET* gene amplification (*MET*amp) and mutations, and outcomes to understand prognosis of MET OE NSCLC.

Methods: The cohort comprised treated pts with stage IV NSCLC seeking care at City of Hope National Medical Center in ≥2016 and had tissue adequate for MET immunohistochemistry (IHC). MET OE was determined using anti-MET clone SP44 IHC assay (Roche Tissue Diagnostics; positive if ≥25% cells at 3+ intensity). MET FISH, RNAseq, and whole exome sequencing were conducted. Clinical data were extracted from electronic health records, and unadjusted hazard ratios from 1L treatment initiation until death or censoring were calculated. Pts receiving targeted therapy in 1L were excluded.

Results: 84 pts were included; 77% had samples taken prior to metastatic spread. 21 (25%) were MET OE positive. MET OE was not associated with history of smoking. *MET*amp was found in 5/69 tumors evaluated (9%); of these, 2 were MET OE. Only 2 pts had *MET* mutations; neither were exon 14 skipping and one was MET OE. MET mRNA, evaluated in 58 cases, was 4-fold higher in MET OE NSCLC vs not OE. 1L regimens used were chemotherapy (52.4%), chemotherapy + immune checkpoint

inhibitor (ICI; 26.2%), or ICI (21.4%). The unadjusted hazard ratio for death in pts with MET OE NSCLC vs not OE was 2.04 (95% CI: 1.02, 4.10).

Conclusions: Pts with MET OE NSCLC had worse prognosis compared with those without MET OE, when treated with standard of care including ICI. Given the development of MET-directed ADCs, MET OE (distinct from *MET*amp) may be a future target for characterization and treatment of NSCLC.

1398P Hepatotoxicity in patients (pts) with KRASG12C-mutated non-small cell lung cancer (NSCLC) treated with sotorasib after prior immunotherapy (IO)

S.M. Ernst[1], P. de Bruijn[2], T.E. van der Horst[1], M.S. Paats[1], J.G. Aerts[1], R.H. Mathijssen[2], S.L. Koolen[2], A-M.C. Dingemans[1]

[1]Department of Respiratory Medicine, Erasmus MC Cancer Institute, Rotterdam, Netherlands; [2]Department of Medical Oncology, Erasmus MC Cancer Institute, Rotterdam, Netherlands

Background: Sotorasib after prior IO may increase the risk of immune-related toxicities. We aimed to investigate the potential association between the time interval between prior IO and sotorasib and the incidence of severe hepatotoxicity. IO levels at baseline and on-treatment sotorasib levels were also evaluated.

Methods: Pts with *KRAS*^{G12C}-mutated NSCLC treated with sotorasib were prospectively enrolled in our biomarker study (NCT05221372). On-treatment ALT/AST was collected. Severe hepatotoxicity was defined as grade $\geq$3 ALT or AST increase (CTCAE v5.0). Plasma samples were collected for IO and sotorasib concentrations. Sotorasib concentrations were measured by validated liquid chromatography-mass spectrometry to calculate trough concentrations (C_{trough}). IO concentrations will be analysed shortly.

Results: At data cut off (April 28th 2023), 90 pts were included, of which 79 (88%) received prior IO. Median time on sotorasib was 107 days (range 28 − 799). The incidence of severe hepatotoxicity was significantly higher in pts with prior IO than those without (29% vs 0%, p=0.04). Pts receiving sotorasib <6 weeks after IO (n=18) had a significantly higher incidence of severe hepatotoxicity than those with intervals of 6-12 weeks (n=24) and $\geq$12 weeks (n=37) (78% vs 25% vs 8%, respectively, p<0.001) (Table). Sotorasib concentrations of 108 samples from 46 pts were evaluable. Median C_{trough} did not differ between those with or without severe hepatotoxicity (90 versus 126 ng/mL, p=0.10).

Conclusions: IO followed by sotorasib was associated with severe hepatotoxicity, especially in pts with a short interval between treatments. No association with systemic sotorasib levels was found, further suggesting the influence of prior IO. Relation with baseline IO levels will be presented at the conference. Our results strongly suggest a minimum interval of 6 weeks between last IO course and sotorasib initiation to reduce the risk of hepatotoxicity.

Table: 1398P

	No IO (n=11)	Prior IO per interval between last IO and sotorasib (n=79)			
		$\leq$6 weeks (n=18)	6 to 12 weeks (n=24)	$\geq$12 weeks (n=37)	p-value
Any-grade hepatotoxicity	7 (64%)	14 (78%)	16 (67%)	8 (22%)	<0.001
Grade ≥3 hepatotoxicity	0 (0%)	14 (78%)	6 (25%)	3 (8%)	<0.001
Worst grade					<0.001
Grade 1	6 (55%)	0 (0%)	7 (29%)	4 (11%)	
Grade 2	1 (9%)	0 (0%)	3 (13%)	1 (3%)	
Grade 3	0 (0%)	12 (67%)	5 (21%)	2 (5%)	
Grade 4	0 (0%)	2 (11%)	1 (4%)	1 (3%)	
Treatment modification	0 (0%)	14 (78%)	7 (29%)	3 (8%)	0.003
Interruption and reduction	0 (0%)	7 (39%)	5 (21%)	2 (5%)	
Treatment discontinuation	0 (0%)	7 (39%)	2 (8%)	1 (3%)	
Days to grade ≥3 hepatotoxicity, median (range)	N/A	56 (24 − 85)	49 (25 − 91)	57 (35 − 65)	0.975

Clinical trial identification: NCT05221372.

1399P Tumor-immune microenvironment analysis of de novo and acquired KRAS-mutated non-small cell lung cancer

J. Reuss[1], N. Gandhi[2], P. Walker[2], J. Nieva[3], J.G. Bustamante Alvarez[4], J. Carlisle[5], A. Desai[6], A.M. VanderWalde[2], P.C. Ma[7], S.V. Liu[8]

[1]Oncology Department, Lombardi Cancer Center Georgetown University, Washington, DC, USA; [2]Clinical and Translational Research, Caris Life Sciences - Headquarters, Irving, CA, USA; [3]Medical Oncology, USC - University of Southern California - Norris Comprehensive Cancer Center, Los Angeles, CA, USA; [4]Medicine, West Virginia University Health Sciences Center, Morgantown, VA, USA; [5]Hematology and Medical Oncology, Winship Cancer Institute of Emory University, Atlanta, GA, USA; [6]Oncology, Mayo Clinic, Rochester, MN, USA; [7]Medicine, Penn State Hershey Medical Center, Hershey, PA, USA; [8]Medical Oncology Department, Lombardi Cancer Center Georgetown University, Washington, DC, USA

Background: With the emergence of novel *KRAS*-targeted drugs, molecular analysis of unique *KRAS* mutations in non-small cell lung cancer (NSCLC) has become increasingly relevant. Acquired *KRAS* mutations are a known resistance mechanism in driver mutation-positive (DM+) NSCLC. The impact of acquired vs. *de novo KRAS* mutations on the tumor-immune microenvironment (TIME) is unknown.

Methods: Mutation status was assessed using next-generation sequencing (Caris Life Sciences) with paired whole-exome and whole-transcriptome sequencing (Illumina NovaSeq). *KRAS*-mutated (*KRAS*mt) subgroups were defined as *de novo KRAS*mt NSCLC (*KRAS* only identified driver − DN) and DM+ NSCLC with acquired *KRAS* mutations (concurrent *KRAS*mt with other known drivers − ACQ). Immune pathway enrichment was assessed with single sample gene set enrichment analyses (SSGSEA). Hierarchical agglomerative clustering (HAC) was performed on expression of a panel of immune checkpoints to define immune low/medium/high clusters. Fisher's exact, Chi-square, and Mann-Whitney U tests were used, as appropriate, to assess statistical significance and corrected for multiple hypothesis testing (q<0.05/FDR <0.25).

Results: 6240 *KRAS*mt NSCLC cases were identified - 6186 DN, 54 ACQ. A trend ($p<0.05, q>0.05$) toward increased expression of immune checkpoints PD-L1, TIM-3, and CD86, as well as a significant enrichment of TNFα, IFNα, IFNλ, JAK-STAT, and inflammatory response signaling pathways were observed in ACQ compared to DN. HAC analysis to delineate the immune profile associated with specific *KRAS* mutations revealed that the distribution of *KRAS* mutations was significantly different among immune clusters in the DN but not the ACQ subgroup (see table).

Table: 1399P

KRAS subgroup	DN			ACQ		
Immune checkpoint expression cluster	Low (n=2708)	Medium (n=2738)	High (n=760)	Low (n=17)	Medium (n=31)	High (n=6)
G12C (%)	38.6	41.6	41.8	41.2	25.8	50.0
G12V (%)	19.4	18.7	20.8	11.8	22.6	0.0
G12D (%)	15.7	14.1	10.3	17.7	19.4	16.7
G12A (%)	6.5	6.3	7.9	11.8	6.5	0.0
G13C (%)	3.8	3.3	4.3	5.9	3.2	16.7
Q61H (%)	4.5	4.3	4.9	5.9	9.7	16.7
Other (%)	11.4	11.7	10.0	5.9	12.9	0.0

Conclusions: Differences in the TIME were observed between DN and ACQ *KRAS*mt NSCLC. *KRAS* mutation subtype frequency appeared to differ according to TIME phenotype in DN *KRAS*mt NSCLC. The clinical and therapeutic implications of these findings warrant further investigation.

Background: Sotorasib has demonstrated robust activity in phase 3 trial in pretreated NSCLC patients (pts) with KRAS G12C mutation. However, its effectiveness and safety in a real-world (RW) setting, particularly when administered after treatment with immune checkpoint inhibitors (ICI), remains to be confirmed.

Methods: Multicenter retrospective study including NSCLC pts who received at least one dose of sotorasib as part of the French expanded access program between February 2021 and April 2022. The primary objective was to evaluate real-world progression-free survival (rwPFS), and the secondary objectives included overall survival (OS) and reporting of sotorasib-related hepatic toxicity.

Results: At time of intermediate database lock a total of 313 pts with data collection completed (out of 446 included) were considered in this analysis. At time of sotorasib initiation: median age 66 years (range [39-85]), males (56%), PS2+ (30%) and smokers (95%). Brain metastases (BM) were present in 116 (37%) pts, with 53% in progression. PD-L1 expression was $<1\%$ in 33%, $\geq$ 1-49% in 35% and $\geq$ 50% in 23% of the pts. The median number of lines of treatment before sotorasib was 2.0, and the last treatment before sotorasib included ICI in 164 pts. The median follow-up time was 13.7 months (ms). Median rwPFS was 4.2 ms [95%CI 3.3;4.9], and median OS was 9.3 ms [95%CI 7.9 ;12.3]. Objective response rate (ORR) was 34.3% [95%CI 28.4; 40.1] and disease control rate (DCR) was 64.2%. Median duration of response was 3.9 ms [95%CI 2.9;5.6]. In BM, DCR was 65.9% with 18.7% of ORR. Hepatic grade 3 or 4 treatment-related adverse events (TRAEs) were reported in 7% pts, with ALAT elevation observed in 3.5% and ASAT elevation observed in 2.2% of pts. Among 263 pts who stopped treatment, 42 (16%) discontinued sotorasib due to toxicity, including hepatic toxicity (26 pts), diarrhea (14 pts) and other reasons (8 pts).

Conclusions: Our IFCT-2102 study confirms the effectiveness of sotorasib in pretreated KRAS G12C-NSCLC pts, and its safety profile is manageable with hepatic grade 3 or 4 TRAEs occurring in 7% of pts. Our findings support the use of sotorasib as a treatment option in this population.

Clinical trial identification: NCT05273047.

Background: The Kristen Rat Sarcoma (*KRAS*) activating mutation represents the most frequent oncogenic alteration in non-squamous non-small cell lung cancer (nsq-NSCLC). We aimed to describe the characteristics, treatment patterns and survival outcomes of a real-world population of advanced NSCLC according to the *KRAS* status.

Methods: From January 2011 to December 2021, we identified from the ESME database (NCT03848052) patients with a metastatic nsq-NSCLC. Patients with other druggable oncogenic alterations were excluded. Patients were grouped according to KRAS status: mutated (*KRAS*m) versus wild-type (*KRASwt*). We analyzed *KRASm* subtype prevalence, patient and tumor characteristics, treatment history, and overall survival (OS). We analyzed patients' survival outcomes according to the period of care to assess the impact of the implementation of immunotherapy as standard of care in France (available from 2017 in monotherapy and 2019 in combination with chemotherapy). Given that the proportional-hazards assumption is not verified, we used the restricted mean survival time (RMST). RMST is the average survival time until a milestone time point.

Results: We identified 6 818 patients of whom 2 916 (42.8%) were *KRAS*m. Among the *KRASm* tumors, 1272 (43.6%) were *KRAS*-G12C. According to KRAS-status (mutant vs. wild-type): 41.4% vs. 33.8% were women ($p<0.01$); 3.9% vs. 10.9% were non-smokers ($p<0.01$); 45.0% vs. 37.0% had a high PD-L1 expression (>50%; $p<0.01$), 33.5% vs. 30.8% had brain metastasis ($p=0.06$). After a median follow-up of 52.9 months (95% CI 51.2 - 55.5), median OS was 13.2 months (95% CI 12.3 - 14.1) for *KRAS*m and 15.1 months (95% CI 14.4 - 15.5) for KRASwt patients ($p<0.01$).

Table: 1401P RSMT for OS at one year according to KRAS status and period of care

	KRASwt			KRASm		
	n	RSMT 1year-OS	95% CI	n	RSMT 1year-OS	95% CI
2014-2016	1735	9.38 months	9.22 — 9.52	1029	8.90 months	8.68 — 9.09
2017-2018	1277	9.35 months	9.17 — 9.53	1012	8.93 months	8.71 — 9.13
2019-2021	767	9.33 months	9.09 — 9.55	811	9.39 months	9.15 — 9.58

Conclusions: *KRAS*m appears to be a poor prognostic factor for metastatic nsq-NSCLC. The advent of chemotherapy-immunotherapy seems to have mitigated this pejorative impact. The prevalence of high PD-L1 in the *KRAS*m tumors may explain this improvement of survival outcomes.

1402P Real-world routine KRAS testing practices in France for patients (pts) with advanced or metastatic (AM) non-small cell lung cancer (NSCLC): Data from the ESME cohort

C. Audigier Valette[1], M. Pérol[2], N. Girard[3], L. Bosquet[4], L. De Gunten[5], G. Desamericq[6], L. Tzala[7], B. Allard[8], D. Debieuvre[9]

[1]Pneumology, Hopital Sainte Musse, Toulon, France; [2]Medical Oncology, Centre Léon Bérard, Lyon, France; [3]Pneumology, Thorax Institute, Institut Curie, Paris, France; [4]Health Data and Partnerships, Unicancer, Paris, France; [5]Medical Affairs, Amgen France, Boulogne-Billancourt, France; [6]Value, Access & Policy, Amgen SAS France, Boulogne-Billancourt, France; [7]Center for Observational Research, Amgen Ltd, Uxbridge, UK; [8]Medical Affairs, Amgen France, Boulogne Billancourt, France; [9]Pneumology, GHRMSA, Mulhouse, France

Background: Sotorasib is available in France since 2019 in clinical trials and now early access program for *KRAS G12C* AM NSCLC pts who progressed after ≥1 treatment line. *KRAS* testing is recommended at metastatic stage for all non-squamous (nsq) and non-smokers squamous (sq) NSCLC. Our aim is to understand routine *KRAS* testing practices for AM NSCLC pts.

Methods: We performed a retrospective observational cohort study of AM NSCLC patients included in the Epidemio-Strategy and Medical Economics (ESME) Lung

Table: 1402P

	KRAS tested at any time (N=9714)	*KRAS* not tested (N=10467)
Male %	60.5	71.3
ECOG at AM diagnosis [1] % 0-1 ≥2	69.4 30.6	57.1 42.9
Histology at initial diagnosis % Nsq Sq	95.4 4.6	61.6 38.4
Stage at initial diagnosis [2] % Early Locally advanced Metastatic	19 9 70.1	25.8 13.1 58.4
L1 received %	86.1	75.7
EGFR testing %	93.9	20
PDL1 testing %	46.5	37.5
For nsq pts Smoking status[3] % Non-smoker Former smoker Smoker Median number of pack-years Smoker [4] Former smoker [5]	N=9271 13.9 50.7 35.5 40 35	N=6452 12.2 52.7 35.1 40 40

Pts without data in KRAS tested and KRAS not tested cohorts respectively (1) 7 835 ; 8 485 (2) 186;286 (3) 368;445 (4) 405;387 (5) 609;500

Cancer Database from 07/2015 to 10/2021. Pts were split in 4 subgroups: *KRAS* not tested; *KRAS* tested at any time of the disease; *KRAS* tested before first-line treatment (L1); *KRAS* tested after L1 and before L2. We analyzed 2 periods: 2015-2018 and 2019-2021, according to the date of AM diagnosis.

Results: 20 181 AM NSCLC pts were included. 48.1% were tested for *KRAS* at any time of the disease, without evolution between 2015-2018 and 2019-2021 (48.7% and 43.5%, respectively). Among *KRAS* tested pts (n=9714), 74.1% were tested before L1 and 23% after L1 / before L2. *KRAS* and *KRAS G12C* were positive for 37.8% and 14.7% of pts respectively. *KRAS* positive pts (n=3668) were tested on tumor (72.1%), metastasis (26.6%) and blood (3%). We described the main differences in pts characteristics overall as no difference was observed between pts tested for *KRAS* before L1 and after L1 / before L2.

Conclusions: Approximately half of AM NSCLC pts were not tested for *KRAS*, without evolution between 2015-2018 and 2019-2021.The emergence of *KRAS G12C* inhibitors should lead to an increase in AM NSCLC pts testing according to guidelines.

Background: Sotorasib showed a significant improvement of progression free survival (PFS), safety and quality of life over docetaxel in patients with KRAS p.G12C—mutated advanced non—small-cell lung cancer (NSCLC) in the CodeBreak-200 study. Here we report real-world efficacy and tolerability data from NSCLC patients who received sotorasib within the Italian expanded access program (EAP).

Methods: Sotorasib (960 mg, orally, once daily) was available on physician request for KRAS p.G12C mutant advanced NSCLC patients who were pretreated with standard regimens or unfit for approved therapies. Clinical-pathological and molecular data were collected from the Italian ATLAS real-word registry. Patients underwent CT-scan and responses were evaluated by RECIST criteria. Efficacy and tolerability outcomes have been assessed.

Results: A total of 190 advanced NSCLC patients were treated across 30 Italian centres. The overall patients' median age was 68 years old (range 32-85). Most patients were male (62%), former (49%) or current smokers (42%), with ECOG performance status 0/1 (84%) and adenocarcinoma subtype (89%). Tumor PD-L1 expression was $\geq$ 50%, 1-49% and <1% in 25%, 37% and 31% of patients, respectively. Patients had received a median of 2 (0—4) previous lines of systemic therapy, with 44% and 33% of them receiving sotorasib in 2nd and 3rd line, respectively. Overall, response rate was 26% and disease control rate 66%. Median PFS was 6.1 months (95% CI: 5.6 — 9.1). Median overall survival (OS) was 8.2 months (95% CI: 6.7-13.6) without significant differences across the main clinical subgroups [age (< 70 *vs* $\geq$ 70 years, p= 0.83), treatment line ($1^{st}/2^{nd}$*vs* $>2^{nd}$, p=0.3), brain metastases (p=0.53)]. Grade 3-4 treatment-related adverse events (TRAEs) occurred in 32 patients (17%), with no significant differences between who received or not previous immunotherapy (16% *vs* 14%, respectively). The most common TRAEs were hepatotoxicity (12%), diarrhea (3%) and asthenia (1%).

Conclusions: Real-world data from the Italian EAP confirm the activity and tolerability of sotorasib in pre-treated patients with KRAS p.G12C-mutated advanced NSCLC.

Background: Sotorasib is the first specific and irreversible KRAS G12C inhibitor that showed superiority vs docetaxel in CodeBreaK 200 phase 3 study, with a median PFS of 5.6 mos (HR: 0,66) and an acceptable safety profile for sotorasib. In France, sotorasib has been authorized before MA for patients with KRAS G12C mNSCLC who progressed after at least one treatment line. Here, we present the clinical characteristics of patients included in the cATU.

Methods: From 08/2021 to 06/2022, data from 1011 pts, of which 958 received sotorasib, were collected in 249 centers.

Table: 1404P

Variable	Results
Median age, years [Q1-Q3] *n=1011*	65.9 [58.8-72]
Male, % *n=1011*	58.7
Smoking status Non / former / current, % *n=1009*	3.6 / 79.4 / 17
Adenocarcinoma, % *n=1004*	94.8
ECOG PS, % *n=1011* 0 1 ≥2	20 58.9 21.2
PD-L1, % *n=1010* <1 [1-49] ≥50 Undetermined	40.9 30.2 21.8 7.1
KRAS testing by NGS, % *n=1010*	84.1
Brain metastases (active), % *n=1011*	29.4 (10.1)
Sotorasib therapy line 2 / 3 / ≥4, % *n=997**	53.3 / 27.1 / 19.6
Median of prior lines *n=1004*	1
First-line therapy, % *n=997* CT IO CT+IO	33.9 12.7 48.6

*39 pts didn't receive sotorasib at all 80% of patients were exposed to chemotherapy (CT) and immunotherapy (IO) before sotorasib: ∼50% simultaneously, ∼30% sequentially. 51% of patients received sotorasib directly after IO. With a median follow-up of 8.9 [0.2-17.5] mos, the median duration of treatment was 8.1 [0.1-17.5] mos. These data must be interpreted with caution because of the short follow-up period.

Results: Main characteristics of this population are presented below:.

Conclusions: Nearly 1000 pts, ineligible to clinical trials, were treated by sotorasib through French cATU, highlighting the unmet therapeutic need. The main technique to retrieve KRASG12C was NGS. Clinical characteristics are consistent with those of CodeBreaK 200 trial pts, with a relatively lower proportion of patients with PD-L1≥50%. More than half of the patients received sotorasib in 2L, reflecting conditional marketing authorization granted in Europe. Real-life data on sotorasib efficacy, safety and QoL are currently studied by academic institutions.

Background: Sotorasib is a first-in-class KRAS p.G12C-inhibitor that has entered clinical trials in pretreated patients with non-small cell lung cancer (NSCLC) in 2018. It remains unclear whether response to sotorasib and outcomes differ in a real-world setting when including patients of higher risk.

Methods: Patients with KRAS p.G12C-mutated advanced or metastatic NSCLC received sotorasib within the German multicenter sotorasib expanded access program between April 2021 to February 2022. Data on effectiveness, tolerability, and survival were analyzed in the full cohort and in subgroups of special interest such as patients with co-occurring mutations and across PD-L1 expression levels.

Results: We analyzed 173 patients who received sotorasib after a median of 2 previous treatment lines (range, 0 to 7). Every fourth patient had a poor performance status and 38% had brain metastases (BM) at the time of sotorasib initiation. The objective response rate was 38.7%. The median overall survival was 9.8 months (95% CI, 6.5 to not reached), with a 1-year mortality rate of 48.5%. Response to sotorasib was lower among patients with a positive PD-L1 expression (TPS ≥1%) and a co-occurring *KEAP1* mutation, respectively. Patients with *KEAP1* had a higher risk of 1-year real-world disease progression (HR 2.0, 0.9 to 4.2, p=0.01). Patients with poor performance status had significantly inferior 1-year overall survival (HR 2.2 ,95% CI 1.12 to 4.54, p=0.003). Other patient factors such as BM, *STK11*, and *TP53* mutations had no impact on response and survival. Subgroup analysis indicated an intracranial non-progression rate of 74.5%, with an intracranial real-world progression-free survival of 7.5 months (95% CI 3.7 to 11.4). Dose reductions and permanent discontinuation were necessary in 35 (21.5%) and 7 (4.3%) patients, respectively, mostly due to gastrointestinal toxicity including liver enzyme elevation, irrespective of whether the immediate previous treatment line contained a checkpoint inhibitor or not.

Conclusions: These first results from a real-world population in Germany confirm promising effectiveness of sotorasib for the treatment of advanced KRAS p.G12C-mutated NSCLC. Patients with co-occurring *KEAP1* mutation seem to derive less benefit.

1406P Outcomes of patients with metastatic EGFR mutant lung cancer requiring dose modifications of first line osimertinib

J.C. Wells[1], C. Ho[2], B. Melosky[2], J. Laskin[1], Y. Wang[1], M. Mullin[3], S. Sun[4]

[1]*Medical Oncology, BC Cancer Agency - Vancouver, Vancouver, BC, Canada;* [2]*Medical Oncology Department, BC Cancer Agency - Vancouver, Vancouver, BC, Canada;* [3]*Respirology, UBC - The University of British Columbia, Vancouver, BC, Canada;* [4]*Division of Medical Oncology, BC Cancer Agency - Vancouver, Vancouver, BC, Canada*

Background: Osimertinib is a standard first line treatment for advanced EGFR mutant lung cancer. While EGFR tyrosine kinase inhibitors are generally well tolerated, side effects, including diarrhea and rash, are common and often require dose modifications. The impact of osimertinib dose modification on survival outcomes is not known.

Methods: Patients with metastatic EGFR mutant lung cancer who received first line osimertinib between 2020 and 2022 were retrospectively identified using pharmacy records in British Columbia, Canada. Patient charts were reviewed to determine the incidence of dose reductions or treatment cessation of osimertinib due to toxicity. The type of toxicity leading to the treatment modification was also recorded. The median time to treatment discontinuation (mTTD) and the median overall survival (mOS) of patients requiring dose modification was compared to those who did not require modification using Kaplan Meier analysis and log rank testing.

Results: The analysis identified 311 patients and with a median follow up time of 26 months. 72 (23%) patients required a dose modification due to toxicity. At time of analysis, 52/72 (72%) of the dose modification group had stopped osimertinib vs 142/239 (60%) in the no modification group. The most frequent toxicities leading to dose reduction or cessation included diarrhea (17), skin toxicity (13), respiratory symptoms (10), anorexia (9), and cardiotoxicity (6). Pneumonitis occurred in 9 patients (3% of the study population). Twenty patients ultimately discontinued osimertinib due to toxicity. The mTTD was shorter in the dose reduction group, 14.3 months (95%CI 11.0-21.3) vs 21.9 months (95%CI 16.9-24.5) in the no reduction group (p=0.042). Second line treatment was received by 19/52 (35%) in the dose modification group and 59/145 (42%) in the no modification group. The mOS of patients requiring dose modifications was 27.6 months (95% CI 21.1-34.1), which was similar to patients not requiring dose modifications, mOS 26.8 months (95% CI 21.9-33.1), p=0.868.

Conclusions: Nearly one quarter of patients treated with osimertinib required a dose reduction or treatment cessation. Despite this, dose modifications did not lead to worse mOS.

Background: *KRAS* G12C mutation is found in 14% of NSCLC. Pts with *KRAS* G12C AM NSCLC have not been well characterized in routine clinical setting. Our objective was to describe pts with *KRAS* G12C AM NSCLC and compare them to pts with other *KRAS* and non-*KRAS* AM NSCLC.

Methods: We performed a retrospective observational cohort study of AM NSCLC pts included in the Epidemio-Strategy and Medical Economics (ESME) Lung Cancer Database and diagnosed between 2015 and 2021. Pts tested for *KRAS* mutation before first-line treatment (L1 or during the disease for pts who didn't receive any L1) were divided in 3 subgroups: *KRAS* G12C (positive *KRAS* G12C mutation), other *KRAS* (positive for *KRAS* mutation other than G12C) and non-*KRAS* (negative for all *KRAS* mutations).

Results: A total of 1073 pts carried *KRAS* G12C (15%), 1642 *other KRAS* (23%) and 4295 *non-KRAS* (61%). Among *KRAS* G12C pts, 58% were male, and the median age was 63 years. The majority (98%) had a smoking history. 68% had an ECOG PS of 0-1. 69% had *de novo* stage IV. The most frequent metastatic sites involved were bone (42%), brain (35%) and contralateral lung (27%). *STK11* appears to be the most common co-mutation (54%) when tested. When PD-L1 status was screened (43%), one third had PD-L1≥50%, and one third had PD-L1<1%. In 2015, most pts received platinum-based chemotherapy (CT) alone (89%) in 1L; this proportion decreased to 55% in 2019 given the benefit of immunotherapy (IO) combined to CT or as monotherapy. In L2, treatments were evenly used in 2015 but IO monotherapy peaked in 2018 to 65%. In L3, IO and other treatments were quite stable over time. The patient and disease characteristics were similar in other *KRAS* and non-*KRAS* pts, except a higher proportion of non-smokers (20%) and a less frequent *STK11* mutation (28%) in non-*KRAS* pts than in the 2 other groups. Treatments were similar in the 3 subgroups except the peak of IO observed in L2 in 2017 and in L3 in 2018 for other *KRAS* pts.

Conclusions: In real-world clinical practice, clinical characteristics and treatment sequences of pts with *KRAS* G12C AM NSCLC are similar to those of other *KRAS* mutations or wild-type *KRAS* pts except for the prevalence of *STK11* co-mutation and the proportion of non-smokers.

Background: Non-small cell lung cancer (NSCLC) can harbor different *KRAS* mutations. Although targeted therapy is available for *KRAS* G12C-mutant NSCLC, immune checkpoint inhibitors (ICIs) are still the first line treatment (tx) for these patients (pts). Here we aimed to assess the outcomes on ICIs for *KRAS* G12C compared to *KRAS* non-G12C-mutant pts.

Methods: This is an observational, retrospective, multicenter study in pts with *KRAS*-mutant NSCLC treated with ICIs (monotherapy or combination) between January 2017 and January 2023. Targeted sequencing was performed in most cases. Clinicopathological and molecular data were collected. We evaluated pts characteristics, tx response and survival outcomes from the beginning of ICIs in *KRAS* G12C vs non-G12C tumors.

Results: A total of 169 pts were included. NGS was performed in 105 pts, *STK11* and *TP53* were the most frequent co-mutated genes present in 4.4%/15% G12C/non-G12C (p=0.110) and 20%/35% G12C/non-G12C (p=0.143), respectively. There were no differences in median progression free survival (PFS) between G12C/non-G12C (8.8 vs 7.1 months(m) respectively p=0.727). In the multivariate analysis, PD-L1 negative tumors and ECOG ≥1 remained independently associated with worse PFS (p=0.010 and p= 0.002 respectively). Regarding overall survival (OS), harboring a G12C mutation was associated with a better OS compared with non-G12C tumors (mOS 16.2m vs 10.4m p=0.033), conversely PD-L1 negative tumors and basal ECOG of ≥1 was associated with worse OS (p= 0.002 and p<0.001 respectively).

Table: 1408P Patient's characteristics

N (%)	G12C (n=75)	Non-G12c (n=94)	p-value
Median age	62.9	63.8	0.471
Sex			0.220
Male	45 (60)	66 (70.2)	
Female	30 (40)	28 (29.7)	
Tobacco			0.203
Former	34 (45.4)	53 (56,4)	
Current	41 (54.6)	41 (43.6)	
Stage			0.630
I-III	17 (21.7)	22 (23,4)	
IV	58 (78.3)	72 (76.6)	
M1 CNS	14 (18.6)	24 (25.5)	0.381
M1 liver	14 (18.6)	20 (21.3)	0.820
ICIs treatment line			0.604
1	57 (76)	75 (80)	
≥2	18 (24)	19 (20)	
PD-L1			0.397
Negative (0%)	17 (22.7)	30 (32)	
Positive (≥0%)	58 (77.3)	64 (68)	
ECOG			0.887
0	31 (41.4)	41 (43.6)	
≥1	44 (58.6)	53 (56.4)	

Conclusions: Our work shows that patients with *KRAS* non-G12C tumors are more frequently PD-L1 negative and harbor a higher proportion of *STK11* co-mutations conditioning a worse OS on immunotherapy treatment. Innovative therapeutic strategies need to be investigated for these patients.

1409P DEnosumab in combination with PD-1 checkpoint blockade for MAINtenance therapy of KRAS-mutant advanced NSCLC after first-line immunotherapy: A prospective, single-arm, phase II trial (DEMAIN)

H-S. Li[1], H. Xu[2], J. Duan[1], Z. Wang[3], J. Zhong[3], Y-Y. Cui[4], Q. Fang[4], S-Y. Lei[1], Y. Wang[1]

[1]Medical Oncology Department, Chinese Academy of Medical Sciences and Peking Union Medical College - National Cancer Center, Cancer Hospital, Beijing, China; [2]Department of Comprehensive Oncology, Cancer Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Beijing, China; [3]Medical Oncology Department, CAMS-PUMC - Chinese Academy of Medical Sciences and Peking Union Medical College - Dongdan Campus, Beijing, China; [4]Medical Oncology Department, Affiliated Hospital of Chifeng University, Chifeng, China

Background: Currently, there is still an unmet therapeutic need for patients (pts) with *KRAS*-mutated (mut) non-small cell lung cancer (NSCLC). Preclinical models have demonstrated the potential efficacy of the receptor activator for NF-κB ligand (RANKL) inhibitor in *KRAS*-mutant NSCLC. However, no clinical trials have been conducted to confirm the efficacy and safety of RANKL inhibitor combined with PD-1 inhibitors in this subset of pts.

Methods: Eligible pts had advanced *KRAS*-mutated NSCLC and were receiving first-line PD-1 inhibitor-based therapy. Pts were treated with PD-1 inhibitor (q3w) and denosumab (120 mg, q4w) for subsequent maintenance therapy regardless of bone metastases. The primary endpoint was progression-free survival (PFS) and the secondary endpoints were objective response rate (ORR), overall survival (OS) and safety. Biological samples were retained for exploratory analysis.

Results: As of 30 March 2023, 20 pts were recruited for maintenance therapy, of which 13 (65.0%) pts had bone metastases. The median age was 65.5 (range: 40-74) years and the majority of patients were male (75.0%). Median PFS (mPFS) for the entire treatment course (mPFS1) and maintenance therapy (mPFS2) was 329 (95% CI: 277-380) days and 196 (95% CI: 145-247) days, respectively. Median OS was not reached. The most common adverse events (AEs) were dental symptoms (20%) and hypothyroidism (10%), and one (5%) pt discontinued the treatment due to grade 2 immuno-hepatitis. No grade 3-4 AEs occurred. Subgroup analysis suggested a greater survival benefit in patients with $KRAS^{G12C}$ mutation than in patients with $KRAS^{non\text{-}G12C}$ mutation (mPFS1, p=0.026; mPFS2, p=0.049). Interestingly, patients with bone metastases (mPFS1, p=0.138; mPFS2, p=0.100) appeared to benefit more than those without. Exploratory analysis (n=14) suggested that neither baseline tissue RANKL levels nor baseline blood soluble RANKL levels were associated with the survival benefit.

Conclusions: The combination of denosumab and PD-1 inhibitors demonstrated antitumor activity in the advanced *KRAS*-mutated NSCLC with a good safety profile, which warrants further investigation.

Clinical trial identification: Chinese Clinical Trial Registry (ChiCTR2100047759).

1410P Characterization of patients with advanced non-small-cell lung cancer (NSCLC) harboring KRASG12C mutation and their associated direct healthcare costs in Spanish routine clinical practice (SILK study)

N. Reguart Aransay[1], J. Sánchez[1], O.J. Juan Vidal[2], M. Aguilo Domingo[3], E. Arriola[4], C. López[2], X. Botella[3], F. Cots[4], C. Montironi[5], S. Palanca[2], E. Borràs[3], L. Masfarre Pinto[4], L. Planellas[6], A. Lloansi Vila[6]

[1]Dept. Medical Oncology, Hospital Clinic y Provincial de Barcelona, Barcelona, Spain; [2]Medical Oncology Dept., Hospital Universitari i Politècnic La Fe, Valencia, Spain; [3]Medical Oncology, Hospital Terrassa-Consorci Sanitari de Terrassa, Terrassa, Spain; [4]Medical Oncology Dept., Hospital del Mar - Parc de Salut Mar, Barcelona, Spain; [5]Pathology, Hospital Clinic of Barcelona, Barcelona, Spain; [6]Amgen - Spain, Barcelona, Spain

Background: Around 15% of patients (pts) with NSCLC harbor the $KRAS^{G12C}$ mutation. In a changing landscape of $KRAS^{G12C}$ treatment (tx), there is a need for updated real-world evidence on characteristics and outcomes of routine clinical practice. Here we present characteristics, tx patterns, outcomes, and direct healthcare costs in pts with NSCLC and $KRAS^{G12C}$ in the Spanish clinical practice.

Methods: Observational, retrospective, multicenter study in pts with newly diagnosed locally advanced (not candidate for radical tx) or metastatic NSCLC and $KRAS^{G12C}$. Pts participating in clinical trials with *RAS* inhibitors were excluded. The study collected clinical and economic data from medical records and administrative databases from 1st Jan 2016 to 9th Mar 2022 (diagnosis period: Jan 2016-Oct 2021).

Results: A total of 127 pts were included (median age 65 years, 71% male, 43%/54% current/former smokers, 82% ECOG≤2, 57% ≥2 metastatic site). PD-L1 expression was analysed in 104 pts at baseline: 19/104 (18%) pts had a PD-L1 expression <1%, 45/104 (43%) pts 1-50%, and 40/104 (39%) pts ≥50%. 94 pts (74%) received systemic tx. The most common first line tx was platinum-based chemotherapy alone (71%). Table shows progression free survival and overall survival. 124 and 103 pts had available global and disease-related (d-r) economic data, respectively. Total global cost over study period was €5,780,686 (total global mean cost per pt: €46,618) with a total pharmacological cost of €2,373,384 (mean cost per pt: €19,140). Total d-r cost was €4,245,504 (total d-r mean cost per pt: €41,218) with a d-r pharmacological cost of €2,177,712 (mean cost per pt: €21,142).

Conclusions: The real-world data confirm limited outcomes for most $KRAS^{G12C}$ pts and emphasize the high clinical and economic burden of these pts' care in an evolving tx landscape. Evaluating the impact of new and effective targeted therapies is warranted.

Background: Carcinoembryonic antigen-related cell adhesion molecule 5 (CEACAM5) expression is often higher in malignant versus normal lung tissue. Tusamitamab ravtansine (tusa rav), an antibody-drug conjugate of humanized CEACAM5 antibody linked to cytotoxic DM4, showed promising antitumor activity and safety in heavily pretreated metastatic nonsquamous non-small cell lung cancer (mNSQ NSCLC) with high CEACAM5 expression. Docetaxel ± ramucirumab (ram) every 3 weeks is standard second-line therapy for mNSQ NSCLC without targetable mutations after progression on immunotherapy ± chemotherapy.

Methods: CARMEN-LC04 is an open-label phase 2 study (NCT04394624) assessing combination tusa rav 100 mg/m^2 every 2 weeks (Q2W) + ram 8 mg/kg Q2W in patients with mNSQ NSCLC and high CEACAM5 expression (≥2+ intensity in ≥50% of tumor cells by immunohistochemistry). Patients had progression after an immune checkpoint inhibitor + platinum-based chemotherapy; patients with *EGFR* or *BRAF* mutations or *ALK/ROS* alterations had progression on targeted therapy. Primary endpoints were dose-limiting toxicity (DLT) in the first 4 weeks for Part 1 and objective response rate (ORR: confirmed complete response [CR] or partial response [PR]) per RECIST v1.1 for Part 2. Safety, disease control rate (DCR: CR + PR + stable disease), and progression-free survival (PFS) were assessed.

Results: As of April 2023, 31 total patients were treated in Parts 1 and 2. The median duration of exposure was 24.1 weeks (range, 3.9–106.0), with 6 (19.4%) patients still on treatment. No DLTs were observed (DLT-evaluable patients, n = 6). ORR was 19.4% (6/31) with 1 CR; DCR was 83.9% (26/31). Target lesion shrinkage occurred in 23/31 (74.2%) patients. Median PFS was 5.7 months (95% confidence interval, 5.4–9.1). Treatment-emergent adverse events (TEAEs) occurred in all patients; 12 (38.7%) patients had a Grade ≥3 TEAE. Seven (22.6%) patients had ≥1 corneal TEAEs: 5 (16.1%) Grade 2 and 2 (6.5%) Grade 3 as worst Grade. No treatment-emergent interstitial lung disease or toxic death was reported.

Conclusions: Tusa rav + ram showed encouraging efficacy. The safety of this combination was consistent with the safety profile of each drug, with no unexpected safety signals.

Background: A significant number of patients (pts) with advanced non-small cell lung cancer (NSCLC) do not respond to therapy with immune checkpoint inhibitors (ICI). After relapse, treatment options are limited. We have previously demonstrated in a preclinical *in vivo* model that the combination of ICI and gemcitabine (GEM) can overcome resistance to ICI or GEM alone. ORIGIN (NCT04480372) is a multicenter phase II trial of GEM and atezolizumab (ATEZO) in patients with advanced non-small cell lung cancer (NSCLC) and mesothelioma (MPM) progressing on ICI. Here we report the data of the NSCLC cohort.

Methods: Eligible pts had ECOG PS 0-2, with confirmed NSCLC stage IIIB-IV with disease recurrence or progression during or after ≥ prior line of ICI or chemo-ICI and available tissue for translational research. Pts received GEM (1000mg /m2 IV d1, 8 q3w) and ATEZO (1200 mg IV q3w). The primary endpoint (EP) was overall response rate (ORR) of the full analysis set (FAS) evaluated by independent radiological

assessment. 35 pts were needed based on a one-sided type I error of 10% and a power of 80% for H_1 ORR ≥25% compared to H_0 ORR ≤11%. Key secondary EPs were progression free survival (PFS), disease control rat (DCR) at 18 weeks, duration of response (DoR), overall survival (OS) and safety.

Results: Between 03/2021 and 10/2021 37 pts were accrued and received GEM+A-TEZO after a median of 2 prior lines of treatment (range 1-8). 36 patients were included in the FAS. Pts with ECOG PS 0, 1 and 2 were 25%, 56% and 19% resp; females represented 44% of pts and median age was 67y (48-80). At data cutoff, median follow-up was 17.6 mo. ORR was 31% (one-sided 90%CI: 20%, 95%CI: 16%-48%) and 22% of pts had stable disease. Median PFS was 4.0 mo (95% CI: 2.5-5.3), DCR at 18 weeks was 42% (95%CI: 26%-59%); median DoR was 5.2 mo (95% CI: 1.1-not reached) and median OS 8.2 mo (95% CI: 6.1-10.1). Treatment-related AEs occurred in 89% (G3-4, 59%) and led to discontinuation in 19% of pts. Extensive translational research on longitudinal blood samples is ongoing.

Conclusions: ORIGIN met its primary endpoint with an ORR of 31% in heavily pre-treated NSCLC patients with no unexpected toxicity profile of GEM or ATEZO.

Clinical trial identification: NCT04480372.

1413P Patient-reported outcomes (PROs) from a phase 2 trial of telisotuzumab vedotin (Teliso-V) in c-Met−overexpressing, EGFR wild type, non-squamous non-small cell lung cancer (c-Met OE, EGFR WT, NSq NSCLC)

S. Lu[1], J. Bar[2], N. Girard[3], Q. Xu[4], R. Sen[4], C. Ratajczak[5], S. Ng[4], S. Xia[6], D.R. Camidge[7]

[1]Lung Cancer Center, Shanghai Chest Hospital, Shanghai Jiao Tong University, Shanghai, China; [2]Institute of Oncology, Chaim Sheba Medical Center, Ramat Gan, Israel; [3]Thorax Institute, Institut Curie, Paris, France; [4]HEOR, AbbVie, Mettawa, IL, USA; [5]Oncology Development, AbbVie, North Chicago, IL, USA; [6]Statistics, AbbVie, Mettawa, IL, USA; [7]Medical Oncology, University of Colorado Denver - Anschutz Medical Campus, Aurora, CO, USA

Background: The phase 2 LUMINOSITY trial (NCT03539536) of Teliso-V monotherapy has shown acceptable safety & promising efficacy in previously treated patients (pts) with c-Met OE, *EGFR* WT, NSq NSCLC. Interim PRO data are reported.

Methods: Pts received Teliso-V (1.9 mg/kg) Q2W. PROs were assessed using the European Organisation for Research and Treatment of Cancer quality of life (QOL) questionnaires in lung cancer (LC13) & palliative cancer care (C15-PAL). Time to deterioration (TTD) beyond meaningful change threshold (MCT; ≥10 points from baseline) & mean change from baseline (mCFB) were analyzed.

Results: 59 pts were evaluated. Median no. of prior therapies was 1 (range 1−3); median follow-up was 81 d. The table shows median TTD. For cough, pain in chest, pain in other parts, & QOL domains where median TTD was not reached, mCFB analyses revealed initial trends toward improvement. Cough, pain in chest, & overall QOL improved beyond MCT in wk 41, 49, & 41, respectively; pain in other parts trended toward deterioration. mCFB analyses revealed trends toward improvement for the LC13 symptom of hemoptysis, and for alopecia, sore mouth. Peripheral neuropathy deteriorated beyond MCT; dysphagia showed no consistent time trend. For C15-PAL, mCFB trend improved for nausea and vomiting, dyspnea (improved beyond MCT in wk 41), pain, fatigue, emotional function, and insomnia over a sustained duration for ≥29 wk, then deteriorated. Appetite loss worsened initially but improved in wk 41. Constipation improved initially then trended toward deterioration in wk 41 & 45.

Conclusions: This interim analysis suggests extended TTD and trends toward improvement from baseline in key lung cancer symptoms, physical functioning, & QOL; and deterioration in peripheral neuropathy. Impact of Teliso-V monotherapy on PROs will also be assessed at LUMINOSITY trial conclusion and in the phase 3, TeliMET NSCLC-01 trial (NCT04928846).

Table: 1413P Time to deterioration in symptoms, functional domains, and QOL

Instrument	Domains	Event/N	Median TTD, wk (95% CI)
LC13	Cough	7/59	NR
	Dyspnea	22/59	33 (12, NE)
	Pain in chest	9/59	NR
	Pain in arm/shoulder	22/59	20 (12, 34)
	Pain in other parts	17/59	NR
C15-PAL	QOL	18/59	NR
	Physical function	20/59	43 (8, NE)

NE, not estimable; NR, Kaplan-Meier curve did not reach 50%.

1414P Impact of co-mutations on the prognosis of targeted therapy in EGFR-mutant advanced NSCLC: A result of real-world study

S. Pan[1], N. Wang[1], M. Tian[1], X. Song[2]

[1]The Second Clinical Medical College, Shanxi Medical University, Taiyuan, China; [2]Respiratory Department, Shanxi Provincial Cancer Hospital, Taiyuan, Shanxi, China

Background: The aim of this study was to observe the concurrent genetic profiles of EGFR-mutated advanced Chinese non-small cell lung cancer (NSCLC), as well as to analyze the effects of diverse concurrent genetic alterations on the prognosis in EGFR-mutated NSCLC treated in first-line with EGFR-TKI.

Methods: The CAPTRA-Lung (NCT03334864) database was used to retrieve 307 patients with advanced EGFR-mutated NSCLC between January 1, 2018 and January 1, 2022 in our institution. Of those, 103 patients were detected by next-generation sequencing (NGS) and the results showed other concurrent genetic alterations. We divided them into two cohorts: those who were sequenced with NGS at baseline were included in cohort 1, and those who received NGS after progression to first-line therapy were contained in cohort 2. The follow-up deadline was October 1, 2022.

Results: The following genes are found to be most frequent in the entire cohort: TP53 mutation (n = 64, 62.14%), EGFR amplification (n = 14, 13.59%), KRAS mutation (n = 13, 12.62%), PIK3CA mutation (n = 13, 12.62%), and DNMT3A mutation (n = 13, 12.62%). Most of the TP53 mutations have been identified in exons 5 (16/64), 6 (9/64), 7 (10/64), 8(9/64), etc. For KRAS mutations, G12V (4/13) and G12S (3/13) were the most common mutation types, and E545K (5/13) and H1047R (2/13) were the most frequently alterations observed in PIK3CA. Cohort 1 constituted 68 patients (mean [SD] age, 60.93 [9.051] years; 55.9% female). Multivariate analysis demonstrated that alterations in TP53 (HR 1.946, 95% CI 1.112-3.403; P = 0.020) and MET (HR 3.581, 95% CI 1.070-11.992; P = 0.039) were independently correlated to poor progression-free survival (PFS). Cohort 2 encompassed 35 patients (mean [SD] age, 56.80 [8.741] years; 71.4% female). Multifactorial analysis showed that TP53 mutation (HR 2.198, 95% CI 1.006-4.803; P = 0.048) and RB1 mutation (HR 8.798, 95% CI 1.604-48.269; P = 0.012) were independent risk factors for PFS with first-line targeted therapy.

Conclusions: This research added to the evidence that co-alterations such as TP53, MET, and RB1 are prospective prognostic biomarkers in NSCLC patients treated with EGFR-TKI.

Clinical trial identification: NCT03334864.

1416P Recurrence of infusion-related reaction (IRRs) associated to avimantamab

M.V. Sanchez Becerra[1], M. Tagliamento[2], M. Aldea[3], J. Remon Masip[4], A. Gazzah[5], D. Vasseur[6], P. Lavaud[3], M. Frelaut[2], P. Abdayem[7], M-L. Meyer[8], M.R. Ghigna[9], A. Levy[10], A. Botticella[10], S. Ponce Aix[11], F. Barlesi[2], D. Planchard[3], B. Besse[12]

[1]Medical Oncology, Gustave Roussy, Alcorcon, Spain; [2]Department of Medical Oncology, Gustave Roussy - Cancer Campus, Villejuif, France; [3]Medical Oncology Department, Institut Gustave Roussy, Villejuif, France; [4]Dept. Oncology, Institut Gustave Roussy, Villejuif, France; [5]DITEP, Institut Gustave Roussy, Villejuif, France; [6]Molecular Biology, Gustave Roussy - Cancer Campus, Villejuif, France; [7]Cancer Medicine Department, Gustave Roussy - Cancer Campus, Villejuif, France; [8]Department of Medicine, Gustave Roussy - Cancer Campus, Villejuif, France; [9]Anatomy Pathology, Gustave Roussy - Cancer Campus, Villejuif, France; [10]Radiation Oncology Department, Gustave Roussy - Cancer Campus, Villejuif, France; [11]Medical Oncology Department, Institut Gustave Roussy, Villejuif, France; [12]Cancer Medicine Department, Institut Gustave Roussy, Villejuif, France

Background: Infusion-related reaction (IRR) are a common toxicty of amivantamab, with a high incidence during the first infusion (97%). However, subsequent injections are usually not affected, unless there is a delay in treatment for several weeks. We evaluate the risk of IRR after the resumption of amivantamab, based on the duration of the free treatment interval.

Methods: This was a retrospective observational study to evaluate the recurrence of IRR in advanced non-small cell lung cancer patients treated with amivantamab and lazertinib in Gustave Roussy (2019-2023).

Results: Baseline characteristics of patients are summarized in the table. 24 patients were included, 12 (50%) presented IRR during the first infusion, and only one of them presented previous history of allergy. 9 patients had a temporary discontinuation of treatment, but only 2 had an IRR recurrence (these 2 had experienced an IRR during first cycle). Median time of treatment discontinuation was of 25.57 days for those patients without IRR recurrence and 44 days for those who presented it. Both patients with IRR recurrence had a temporary withdrawal due to another toxicity (at day 29 and 59 respectively) being of CTCAE grade 3 and 2 respectively. 5 patients (41.6%) needed corticoesteroids and 6 (50%) received antihistamines as treatment for the IRR. Only one patient required magnesium sulfate. A third IRR recurrence was experienced in both patients (grade 2 and 1 respectively), leading to permanent treatment discontinuation for one patient. None of the patients progressed to amivantamab and both are still alive.

Table: 1416P

Gender (N) Female Male	**15 9**
Median age, Years (IQR)	66 (39-81)
Molecular profile (N) EGFR exon 19 EGFR exon 20 EGFR L858R MET overexpression MET exon 14 skipping mutation	11 1 9 1 2
Median number of previous lines (IQR)	2

Conclusions: Recurrence of IRR after the first episode is frequent and must be taken into account when reintroducing amivantamab after a temporary withdrawal of $\geq$1 month. IRR recurrence does not seem to have a detrimental impact on treatment efficacy.

1417P Change in healthcare resource use and associated costs of patients with metastatic lung cancer between 2013 and 2019: An observational study from the French national claims database

C. Chouaid[1], C. Marchal[2], M. Apert[3], L. Bensimon[3], V. Guimard[4], M. Née[5], M. Belhassen[2], G. de Pouvourville[6], J-Y. Blay[7]

[1]Pneumology Department, CHI - Centre Hospitalier Intercommunal de Créteil, Créteil, France; [2]Health Economics and Outcomes Research, PELyon, Lyon, France; [3]Health Economics and Outcomes Research, MSD France, Puteaux, France; [4]Medical Affairs, MSD France, Puteaux, France; [5]Biostatistics, PELyon, Lyon, France; [6]Economy, ESSEC Business School, Cergy, France; [7]Medicine Department, Centre Léon Bérard, Lyon, France

Background: Treatment landscape in metastatic lung cancer is quickly evolving, including targeted therapies and immunotherapies. Both treatments have shown improved survival but are also associated with increased costs. This study aimed to describe the evolution of costs associated with metastatic lung cancer in France.

Methods: From the French national claims database (SNDS), a dynamic cohort of patients identified between 2013 and 2019 with metastatic lung cancer and a marker for the presence of metastases (ICD-10 code or at least one reimbursement for Bevacizumab or Pemetrexed) was constituted. Healthcare resource use was described each calendar year through the percentage of patients with at least one record for each expenditure item. The associated costs were reported monthly and estimated from the health insurance perspective. The trend over the study period for the total mean monthly cost was studied using Joinpoint software.

Results: Between 2013 and 2019, 116 686 patients with a metastatic lung cancer were identified (67.1% of men, median age of 65 years). The percentage of patients with at least one overnight hospitalization decreased from 85.2% in 2013 to 67.6% in 2019 while the use of day hospitalizations remained stable (about 40%). The percentage of patients with outpatient care increased over the study period: medical visits (from 82.6% to 88.0%), lab tests (from 74.1% to 83.5%), medical procedures (from 72.0% to 83.2%). The total mean monthly cost per patient decreased between 2013 and 2019 (from 5,683€ to 4,653€), by 2.85% per year (95%CI: -4.13 to -1.56, $p<0.0001$). An increase in drugs acquisition costs (from 1,015€ to 1,365€) and a decrease in the cost of overnight hospitalizations (from 3,110€ to 1,990€) were observed.

Conclusions: This study highlights that the increase in drugs acquisition costs has been offset by a decrease in hospitalization costs, resulting in a decrease in global management costs of patients with metastatic lung cancer in France between 2013 and 2019. These findings may be the result of French health policy and may also be related to improved disease management.

Background: Tumor Treating Fields (TTFields) are electric fields that disrupt processes critical for cancer cell survival. The randomized, pivotal LUNAR study met its primary endpoint, demonstrating significantly improved OS with TTFields/standard of care (SOC; investigator's choice immune checkpoint inhibitor or docetaxel) vs SOC in mNSCLC following platinum failure without added systemic toxicity. A prior study in glioblastoma showed that adding TTFields therapy to standard chemotherapy did not adversely affect HRQoL. Herein we report global and functional HRQoL from LUNAR.

Methods: Adults with mNSCLC progressing on/after platinum therapy were randomized 1:1 to TTFields/SOC or SOC. HRQoL was assessed at baseline (BL) and every 6 weeks (to 54 weeks) by the EORTC QLQ-C30 questionnaire. HRQoL outcomes from global health and functional scales are reported here. Scores were calculated as mean change from BL (change of $\geq$10 points considered clinically relevant). Time to deterioration (TTD) was defined as time from BL to a deterioration of $\geq$10 points without a subsequent $\geq$10-point improvement (and no death before the confirmatory assessment). TTD was estimated by Kaplan−Meier plots with medians by Greenwood's formula and comparisons by 2-sided log-rank tests.

Results: BL scores were comparable for patients receiving TTFields/SOC (n=134) vs SOC (n=136) in global health status and functioning. Overall, there were no notable differences in change from BL in these scales over time between groups. There were no significant differences between TTFields/SOC vs SOC for median TTD in global health status (4.4 vs 4.0 months, P=0.91), physical functioning (3.2 vs 4.2 months, P=0.58), role functioning (3.0 vs 2.8 months, P=0.59), emotional functioning (6.6 vs 5.7 months, P=0.96), cognitive functioning (3.7 vs 4.4 months, P=0.23), or social functioning (4.0 vs 3.9 months, P=0.66).

Conclusions: The HRQoL analysis conducted as part of LUNAR demonstrated that the TTFields device did not adversely affect the quality of life of patients receiving standard second-line therapies, supporting its incorporation into management guidelines for recurrent or progressive, platinum-refractory mNSCLC.

Clinical trial identification: NCT02973789.

1419P TACSTD2 (Trop-2) constitutes a promising antibody-drug conjugate target for patients with non-small cell lung cancer brain metastases

S. Hijazo-Pechero[1], A. Alay Badosa[2], N. Vilariño[3], J. Brenes Castro[3], L. Moliner[3], M-A. Mosteiro[3], N. Vidal[4], C. Muñoz-Pinedo[1], J. Bruna[5], E. Nadal[3]

[1]Preclinical and Experimental Research in Thoracic Tumors, IDIBELL - Bellvitge Biomedical Research Institute, L'Hospitalet de Llobregat, Spain; [2]Bioinformatics for Precision Oncology, ICO-Catalan Institute of Oncology, L'Hospitalet de Llobregat, Spain; [3]Medical Oncology, ICO-Catalan Institute of Oncology, L'Hospitalet de Llobregat, Spain; [4]Pathology, HUB-Bellvitge University Hospital, L'Hospitalet de Llobregat, Spain; [5]Neuro-Oncology, ICO-Catalan Institute of Oncology, Barcelona, Spain

Background: Brain metastases (BM) are a frequent complication in patients with non-small lung cancer (NSCLC). Treating BM is challenging as the blood-brain barrier can limit intracranial drug delivery. Data from different trials suggest that antibody-drug conjugates (ADC) can have clinically relevant intracranial activity. This study aims to characterize the gene expression of ADC targets in NSCLC-BM to guide treatment decisions.

Methods: Gene expression data from 125 BM resected from patients with NSCLC were obtained from 3 public datasets. Gene expression of 14 ADC targets (*ERBB2, ERBB3, TACSTD2, MET, GPNMB, PTK7, MSLN, CD276, TF, AXL, EGFR, SLC34A2, CEACAM5* and *ROR2)* was evaluated to identify those consistently expressed across the cohorts. Additionally, hierarchical clustering was used to stratify NSCLC-BM, in each dataset separately, based on the combined relative gene expression of the common 25% most variable genes: *MSLN, CEACAM5* and *SLC34A2*. Furthermore, association between clusters and clinical covariates was assessed for one of the datasets with available data (N=63).

Results: Gene expression evaluation showed that *TACSTD2* (Trop-2) was ubiquitously highly expressed across datasets, suggesting that *TACSTD2* could be a promising ADC target for NSCLC-BM. Contrarily, *ROR2* showed consistently lower expression and would probably not be a good candidate in NSCLC-BM. Transcriptional patterns from the 3 most variable ADC targets (*MSLN*, *CEACAM5*, and *SLC34A2*) yielded common subgroups in all datasets defined by the following expression levels (respectively): High/High/High, Low/High/High, High/Low/Low. These groups did not correlate with clinical covariates.

Conclusions: Gene expression evaluation of ADC targets in NSCLC-BM resulted in the identification of *TACSTD2* expression across all datasets. *TACSTD2* might be a promising ADC target for patients with NSCLC with BM. Further validation is warranted in terms of protein expression. Our results underscore the potential value of gene expression profiling to identify new targets and improve patient selection in the context of NSCLC-BM ADC therapy.

Background: Due to scarce publications, no specific recommendations have been published for the management of octogenarians with NSCLC. In a real-life prospective observational, multicenter study we analyze their clinical and biological characteristics, modalities of treatments by stage, overall survival (OS) and its evolution in ten years.

Methods: Between 01/01 and 12/31/2020, all patients diagnosed with a Lung Cancer (LC) in 82 participating centers, were included in a nationwide cohort (KBP-2020). Here, we report data on octogenarians with NSCLC compared to those under 80 y.o (<80). OS was calculated using the Kaplan-Meier method. Management and OS were compared to the previous cohort (KBP-2010).

Results: 8,999 LC were included in KBP-2020, 1026 (11.4%) were NSCLC over 80 y-o. Median age was 83.7, 33.7% were female, 40.0% had a PS≥2 (*vs* 21.9% in <80), 61.2% had lost weight (mean 6.8kg) at diagnosis (vs 53.2% in <80), 32.2% were non-smokers (vs 10.8 % in <80), 62.7% had an adenocarcinoma. By stage, there were 19% localized (N=188), 18.8% locally advanced (N=186) and 62.2% metastatic (N=615) disease. Biomolecular analysis was performed in 65% of cases.

Compared to KBP-2010, in octogenarians, surgery was performed in 46.3% of localized disease (*vs* 26%), thoracic radiotherapy or chemotherapy in 33.3% (vs 25.5%) and 38.9% (vs 41.5%), respectively of locally advanced disease and systemic therapy was given in 55.7% of metastatic disease (vs 52.1%). Chemotherapy, targeted therapy or immunotherapy were performed in 25.4%, 18.2% and 14.9% of metastatic patients, respectively. In 2020, median OS for all NSCLC octogenarians was 8.7 months [7.0 - 9.9] *vs* 5.0 months [4.6 - 5.8] in 2010.

Conclusions: Compared to youngest patients, octogenarians more often had a PS≥2, lost weight, were non-smokers, had an EGFR or a MET exon 14 mutation. Compared to 2010, in 2020 surgery was performed more frequently as targeted therapy and immunotherapy while chemotherapy was less often offered resulting in better OS.

1421P AI-powered intracranial tumor response predicts systemic progression with high concordance in endpoint evaluation in the phase III CROWN study

S-L. Lu[1], C. Duan[2], Y-C. Chang[3], C-H. Liang[3], P-L. Chiang[3], V. Lin[4], Y-S. Yang[5], A. Schayowitz[6], P. Selaru[7], K.D. Wilner[7], J-T. Lu[3]

[1]Radiation Oncology, NTUCC - National Taiwan University Cancer Center, Taipei City, Taiwan; [2]Worldwide Research, Development and Medical, Pfizer Inc., Cambridge, MA, USA; [3]Research and Development, Vysioneer Inc., Cambridge, MA, USA; [4]Quality Assurance and Regulatory Affairs, Vysioneer Inc., Cambridge, MA, USA; [5]Business Development and Operations, Vysioneer Inc., Cambridge, MA, USA; [6]Global Product Development, Pfizer Inc., Cambridge, MA, USA; [7]Global Product Development, Pfizer Inc., San Diego, CA, USA

Background: Imaging reading for endpoint evaluation in clinical trials presents challenges in reproducibility and accuracy, limiting the use of novel endpoints beyond human capabilities. This analysis explored the feasibility of AI-powered intracranial response assessment and uncovered novel imaging prognosticators in the phase III CROWN study.

Methods: 72 patients (40 patients in the crizotinib arm, 32 patients in the lorlatinib arm) with CNS metastases at baseline in the CROWN study (NCT03052608) underwent intracranial response assessment using MRI at screening and then every 8 weeks until disease progression. VBrain, an FDA-approved brain tumor AI, was used to generate response assessments that were compared with those performed by 2 neuro-radiologists from the blinded independent central review group for the study using modified RECIST (mRECIST). The sum of tumor diameter changes at first on-treatment tumor scan from baseline, denoted as early tumor shrinkage (ETS), was assessed with Cox's proportional hazard model to estimate drug efficacy.

Results: For target lesion measurements, AI showed a high correlation with the independent readers (Pearson correlation coefficient $\rho=0.94$). The intracranial objective response rate assessed by AI was 27.5% and 71.9% in the crizotinib and lorlatinib arms, respectively. Among 666 time-point assessments, discordance rates were 35.1% between AI and reader 1, 33.5% between AI and reader 2, and 35.7% between the 2 readers. The time to intracranial progression (iTTP) derived from AI and human readers showed no significant difference by log-rank test. AI tracked 394 tumors beyond mRECIST, with a median ETS of -41.8% for all these lesions vs -24.4% for target lesions by mRECIST. Brain-wide ETS better predicted systemic TTP (HR 0.40, [95% CI 0.21−0.76], $p<0.01$), while target-lesion ETS showed no significant difference (HR 0.59, [95% CI 0.32−1.09], $p=0.09$) by ETS categories > or <= to median ETS.

Conclusions: There was high agreement between AI and readers in lesion measurement, response assessment, and endpoint evaluations in the CROWN study. ETS leveraging all brain lesions may uncover a potential prognostic indicator of response in ALK-positive advanced NSCLC patients.

1422P Comprehensive genomic profiling (CGP) changes management and improves survival in patients with advanced non-small cell lung cancer (aNSCLC)

G. Simon[1], A. Berry[2], B. Bapat[3], J. Law[4], C. Sweetnam[4], H. Mohammed[4], A. McBratney[4], M. Izano[4], M. Scannell Bryan[4], S. Spencer[5], D. Hostin[3], B. Schroeder[3], P.G. Febbo[6]

[1]Medical, Moffitt Cancer Center, Tampa, FL, USA; [2]Biomarker Data and Lab Medicine, Syapse, San Francisco, CA, USA; [3]Global Market Access, Illumina, Inc., San Diego, CA, USA; [4]HEOR, Syapse, San Francisco, CA, USA; [5]HEOR, Illumina, Inc., Denver, CO, USA; [6]Medical, Illumina, Inc., San Diego, CA, USA

Background: Advances in therapies for patients with NSCLC require personalizing treatment based on patients' tumor genetic profiles to improve outcomes. Approaches to evaluate tumor biomarkers include a range of testing from single gene/small panel to CGP which includes hundreds of genes and signatures like TMB and MSI. This study compared actionable biomarker detection, targeted therapy receipt, and clinical outcomes in patients with aNSCLC tested with CGP vs small panels (SP).

Methods: This is a retrospective study of adult patients in the US community setting diagnosed with aNSCLC between 1/1/2015 and 12/31/2020. Patients were followed from aNSCLC diagnosis (index) until the earliest of death or study-end and (9/30/2021) categorized based on the most comprehensive testing during follow-up as SP ($\leq$52 genes) or CGP (>52 genes). Biomarker actionability was defined by OncoKB[1]: FDA recognized (Level 1), standard of care (Level 2), standard of care predictive of resistance (Level R1). Likelihood of receipt of matched therapy was assessed using logistic regression; Kaplan-Meier and Cox proportional hazards models were used to assess real- world overall survival (rwOS).

Results: Among 3,884 patients (median age 68y, 50% female, 73% Non-Hispanic White), 20% received CGP and 80% SP as the most comprehensive test. The proportion of patients with $\geq$1 actionable biomarker was significantly higher in CGP than SP (32% vs 14%; p<0.001). Of patients with actionable biomarkers, 43%(CGP) and 38% (SP) received matched therapies (p=0.20). Among treated patients: (1) CGP prior to 1st line treatment was associated with higher likelihood of receiving matched therapy (OR=3.21[95%CI: 1.98, 5.19]); (2) patients receiving CGP testing during follow-up had greater median rwOS (22 months[95%CI:18-25] vs. 15 months[95% CI:14-16]) and reduced risk of mortality (HR: 0.80[95% CI: 0.72, 0.89]) compared to SP.

Conclusions: Patients who received CGP had improved use of matched therapies and greater rwOS compared to SP. . Broader adoption of CGP may improve detection of actionable biomarkers, facilitating appropriate timely delivery of precision therapies resulting in better outcomes.

1423P Clinical impact of radiological diagnosis of lymphangitic carcinomatosis in patients with extensive non-small cell lung cancer treated with immunotherapy

A. Bolina[1], M. Sallam[2], A. Ortega Franco[3], H. Wong[4], D. Cobben[5], C. Escriu[6]

[1]Medical Oncology, University of Liverpool, Liverpool, UK; [2]Internal Medicine, Queen Elizabeth Hospital - University Hospitals Birmingham NHS Foundation Trust, Birmingham, UK; [3]Medical Oncology, Cancer Research UK Manchester Institute - The University of Manchester, Macclesfield, UK; [4]Biostatistics, The Clatterbridge Cancer Centre - Liverpool, Liverpool, UK; [5]Radiation Oncology, The Clatterbridge Cancer Centre - Liverpool, Liverpool, UK; [6]Medical Oncology, The Clatterbridge Cancer Center - Liverpool, Liverpool, UK

Background: Lymphangitic carcinomatosis (LC) is a pathological feature secondary to lymphatic or haematological spread, without an immune cell infiltrate but with radiological appearances of inflammation. Immunotherapy (IO) is now standard of care in early and late-stage non-small cell lung cancer (NSCLC). LC correlates with poor prognosis, but its effects on immunotherapy response are unknown. Here we aim to explore the predictive relevance of the radiological diagnosis of LC in patients with advanced NSCLC treated with single agent immunotherapy (SAIO) or with chemo-immunotherapy (CIO).

Methods: Demographic and clinical data of patients treated with first-line IO between January 2016 and December 2020 was retrospectively collected, and patients with LC identified using pre-treatment CT reports. A paired control arm matched for gender, age ($\leq$70 or >70), smoking status, PS, PDL1 (<1%, 1-49% and $\geq$50%), stage and treatment was used to compare clinical outcomes. Chi-square Log-Rank (Mantel-Cox) test was used to compare Progression-Free Survival (PFS) and Overall Survival (OS).

Results: A total of 484 patients had been treated with first-line SAIO or CIO, 46 (10.6%) with LC. 41 of them (89%) had non-squamous histology. 29 (63%) were treated with SIAO and 17 (37%) with CIO. Comparing tumours with LC versus the rest, PDL1 expression was <1%; 24 vs 11%, 1-49%; 9 vs 11% and $\geq$50%; 65 vs 71%. Grade 3/4 IO toxicity rates were similar (48% vs 45%). Comparing patients with LC versus a paired control population (n=73), overall response rates were 28% vs 56%, with disease progression rates of 37 vs 25%. Median PFS was 5 vs 9 months (HR 1.57, 95% C.I. 1.054 − 2.35, p=0.019) and median OS was 9 vs 17 months (HR 1.49, 95% C.I. 0.995 − 2.224, p=0.046). Brain metastases on progression were more common in patients with LC (20% vs 8%). Using univariate Cox regression analysis, PFS and OS were not influenced by the treatment received (SAIO or CIO).

Conclusions: Lymphangitis Carcinomatosis (LC) in patients with NSCLC treated with immunotherapy correlated with lower response rates, poorer PFS and OS. Addition of chemotherapy did not improve outcomes. LC may represent a pre-treatment marker of primary resistance to immunotherapy.

[1]Chest Medicine, Taichung Veterans General Hospital, Taichung City, Taiwan; [2]Cancer Prevention and Control Center, Taichung Veterans General Hospital, Taichung City, Taiwan; [3]Internal Medicine, Chung Shan Medical University Hospital Da-Ching, Taichung City, Taiwan; [4]Internal Medicine, Taichung Veterans General Hospital, Taichung City, Taiwan; [5]Institute of Medicine, Chung Shan Medical University Hospital, Taichung City, Taiwan

Background: Antiangiogenetic therapy and lung cancer, *per se*, are associated with an increased risk of thromboembolic (TE) events. We aim to evaluate the influence of TE on the outcome of advanced non-small cell lung cancer (NSCLC) patients receiving antiangiogenic therapy.

Methods: This retrospective cohort study included advanced NSCLC patients receiving antiangiogenic therapy, including bevacizumab and ramucirumab, from March 2013 to May 2021 at Taichung Veterans General Hospital. All TE were confirmed by objective image studies. We evaluated the prevalence, pattern, treatment, and outcome of TE and its influence on survival time.

Results: A total of 427 patients were included. Of them, 345 (80.8%) received bevacizumab, 24 (5.6%) received ramucizumab, and 58 (13.6%) received both. The overall prevalence of TE was 10.1% (n = 43). Deep vein thrombosis (DVT) was the most common TE (n = 20), followed by pulmonary embolism (PE) (n = 14), combined PE and DVT (n = 6), and cerebral vascular accidents (n = 3). Among them, 46.2% of DVT did not occur in the typical lower extremities. Two patients died of TE, which presented with massive middle cerebral artery territory infarction. Among patients with continuous use or reuse of antiangiogenetic therapy, 18.2% had recurrent TE events. At TE, 28 patients experienced progressive disease (TE with PD), while tumor status remained stable in another 15 patients (TE without PD). The post-TE survival of patients without and with PD was 8.9 months (95% CI 3.9-13.9) vs. 2.2 months (95% CI 0.1-4.3), P = 0.012. As compared with patients without TE (31.4 months [95% CI 27.1-35.7]), TE with PD patients experienced a significantly shorter overall survival (20.1 months [95% CI 15.5-24.6]), but TE without PD patients had comparable survival time (32.7 months [95% CI 7.4-28.1]) (P = 0006). Multivariate analysis suggested that the use of hormone analog and proteinuria independently predicted a higher TE prevalence among TE with PD patients (aOR 2.79 [95% CI 1.13=6.92]; P = 0.027) and TE without PD patients (aOR 4.30 [95% CI 1.13-16.42]; P = 0.033), respectively.

Conclusions: Owing to the different influences on the survival time and risk factors, TE with PD and TE without PD may be two different disease entities.

1425P Clinical utility of liquid biopsy for the early diagnosis of EGFR mutant advanced lung cancer in real-life setting (CLEAR)

R.M. El Sayed[1], W. Belkaid[2], C. Richard[2], X. Weng[1], R. Nassabein[1], R. Alameddine[1], F. Blanc-Durand[1], J. Roy[1], Y. Kim[3], I. Syed[3], N. Devost[3], D. Hui[3], G. Kenth[3], M. Florescu[1], B. Routy[1], M. Tehfe[1], G. Kasymjanova[4], J. Agulnik[4], N. Blais[1]

[1]Hematology/Oncology, Centre Hospitalier de l'Université de Montréal, Montreal, QC, Canada; [2]Oncology, CRCHUM - Centre de Recherche du CHUM, Montreal, QC, Canada; [3]Oncology, AstraZeneca Canada, Inc., Mississauga, ON, Canada; [4]Oncology, Jewish General Hospital McGill University, Montreal, QC, Canada

Background: Timely diagnosis with complete molecular profiling is essential in advanced lung cancer. Although tissue sampling remains the gold standard, liquid biopsies provide an alternative option for timely molecular characterization, especially for epidermal growth factor receptor (EGFR) testing in lung cancer.

Methods: All patients referred at the Centre Hospitalier de l'Université de Montréal (CHUM) with a radiological suspicion of advanced lung cancer and no known prior tumour molecular testing were prospectively screened and consented. Plasma and tissue samples were retrieved for EGFR testing and mutations were analyzed using Cobas® cell-free DNA (cfDNA). The CLEAR study evaluated plasma and tissue EGFR testing and the clinical impact on the management of suspected lung cancer patients.

Results: Between November 2019 and January 2023, a total of 312 patients were initially screened for eligibility for inclusion in the study and 7 patients were excluded for history of treated lung cancer. Median age was 68 years, 55% were female, 17% were non-smokers, and 30% were active smokers. 83% had non-small cell lung cancer and 70% of patients had stage IV disease. 8% and 10% EGFR mutations were detected by cfDNA and tissue biopsy, respectively. EGFR exon 19 deletion was the most frequent mutation, detected in 59% of patients. Median time to EGFR result was 28 days and 3 days for tissue and plasma sampling, respectively. cfDNA was 100% specific and 72% sensitive for EGFR status. Positive predictive value was 100% and the negative predictive value was 95%. Osimertinib was initiated within a median of 12 days of cfDNA results and up to 21 days before tissue results. Cranial radiotherapy was avoided in 6 EGFR-positive patients with brain metastases.

Conclusions: Early detection of EGFR mutations by cfDNA reduces time to diagnosis and accelerates therapy initiation. Cobas® assay is specific, with high positive and negative predictive values. Decreased delays to access targeted therapy can decrease improper treatment choices and alleviate complications of untreated disease while awaiting molecular results from tissue biopsies.

1426P Real-world data on next-generation sequencing using comprehensive genomic profiling assays for detecting driver oncogenes in advanced non-small cell lung cancer: Analysis with the National Database of Japan

I. Masaki[1], M. Iwasaku[1], R. Morita[2], T. Doi[2], T. Ishikawa[2], Y. Ogura[1], H. Kawachi[1], Y. Katayama[1], N. Nishioka[1], K. Morimoto[1], S. Tokuda[1], T. Yamada[1], T. Kohichi[1]

[1]Pulmonary Medicine, Kyoto Prefectural University of Medicine, Kyoto, Japan; [2]Cancer Genome Medical Center, Kyoto Prefectural University of Medicine, Kyoto, Japan

Background: Comprehensive genomic profiling (CGP) assays have been utilized with advanced solid tumor patients who have completed standard chemotherapy in Japan. These assays are expected to investigate the driver oncogenes comprehensively, especially for patients with advanced non-small cell lung cancer (NSCLC) whose driver oncogenes have not been detected at initial diagnosis. However, there are few reports on the proportion of advanced NSCLC patients with undetected driver oncogenes at initial diagnosis who have newly identified driver oncogenes using CGP assays.

Methods: We retrospectively analyzed patients with advanced NSCLC who received CGP assays between August 2019 and March 2022. Patients under the age of 20 years were excluded. We used the Center for Cancer Genomics and Advanced Therapeutics database. The driver oncogenes were defined as EGFR, ALK, ROS1, BRAF V600E, KRAS, HER2, MET exon 14 skipping, RET and NTRK. We investigated the proportion of driver oncogenes in patients with NSCLC and which were newly identified using CGP assays.

Results: A total of 986 NSCLC patients who received CGP assays were enrolled. The adenocarcinoma, squamous cell carcinoma, not other specified, other types of patients were 764 (77.5%), 128 (13.0%), 86 (8.7%), and 8 (0.8%) cases, respectively. Among all patients, 451 (45.7%) patients were detected driver oncogenes. Among 330 NSCLC patients with undetected EGFR, ALK, ROS1, and BRAF V600E at initial diagnosis, 121 (36.7%) patients had newly identified driver oncogenes. EGFR mutation was 4 (1.2%) patients of exon 19 deletion, 1 (0.3%) patient of exon 21 L858R, 12 (3.6%) patients of exon 20 insertion, and 1 (0.3%) patient of G719A. ALK and BRAF V600E were 1 (0.3%) patient, respectively. The other driver oncogenes detected using CGP assays were 23 (7.0%) patients of KRAS G12C, 40 (12.1%) patients of KRAS non-G12C, 20 (6.1%) patients of HER2 mutation, 14 (4.2%) patients of MET exon 14 skipping, and 4 (1.2%) patients of RET.

Conclusions: CGP assays are useful for identifying driver oncogenes in patients with advanced NSCLC, especially for patients whose driver oncogenes were not identified at initial diagnosis.

1427P Exploration of the value of leptomeningeal biopsy in diagnosing and treating non-small cell lung cancer with leptomeningeal metastasis

L.B. Cai

Oncology Department, Guangdong Sanjiu 999 Brain Hospital, Guangzhou, China

Background: To explore the value of ventriculoperitoneal (VP) shunting combined with leptomeningeal metastasis (LM) biopsy in diagnosing and treating driver mutation-positive non-small cell lung cancer patients with LM (NSCLC-LM).

Methods: We retrospectively analyzed 32 driver mutation-positive NSCLC-LM patients who underwent VP shunting or Ommaya reservoir implantation from June 2019 to June 2021. Pathological result of the LM biopsy, post-operative adverse events (AE), and clinical outcomes were analyzed.

Results: Of the 32 recruited NSCLC-LM patients, tumor was detected from LM biopsy from 21 patients, leading to a detection rate of 65.6% (21/32). LM sample from one patient underwent genomic profiling and was found to harbor *EGFR* rare mutations p.G719S and p.L816Q and mutated *TP53*. Median overall survival was 16.8 months (95% confidence interval [CI] 8.7-24.8) since LM diagnosis and 10.6 months (95% CI 7.2-13.9) since VP shunting or Ommaya reservoir implantation. postoperative complications included intracranial infection (1/32, 3.1%), incisional surgical site infection (1/32), perioperative mental disorders (1/32). All AEs were Grade 1 or 2 and improved upon treatment.

Conclusions: LM biopsy is safe and feasible for driver mutation-positive NSCLC-LM patients. Importantly, LM biopsy can be used to diagnose otherwise difficult cases and identify actionable genomic alterations for targeted therapy.

1428P Clinical benefit of combination chemo-immunotherapy in first-line treatment for patients over the age of 65 or 75 with metastatic NSCLC

T. Landre[1], N. Sadaoui[2], D. Bouharati[3], C. Taleb[4]

[1]UCOG Dept., Hopital René Muret - AP HP, Sevran, France; [2]Geriatric, Assistance Publique - Hopitaux de Paris AP-HP, Paris, France; [3]Geriatric Oncology, Hopital René Muret - AP HP, Sevran, France; [4]Geriatric Oncology - UCOG, Hopital René Muret - AP HP, Sevran, France

Background: Anti-PD-1/PD-L1 plus chemotherapy (CT) is considered the standard of care in first line treatment of metastatic NSCLC. However, the clinical benefit of this combination in older patients is controversial.

Methods: We performed a meta-analysis (MA) of randomized trials that compared PD-1/PD-L1 inhibitor plus CT with CT alone in first line of treatment for older patients with advanced NSCLC. Subgroups of patients over 65 and over 75 were analyzed. The outcomes included overall survival (OS) and progression-free survival (PFS). A fixed-effect model was used.

Results: We analyzed 9 trials with an anti-PD-1 (camrelizumab, cemiplimab, nivolumab, pembrolizumab, tislelizumab or toripalimab) and 6 trials with an anti-PD-L1 (atezolizumab, durvalumab or sugemalimab), including 3371 patients (41%) over the age of 65 and 212 patients (<10%) over the age of 75. Most of the patients were men (65%), PS 0/1 (98%), PD-L1+ (66%) and smokers (82%). In patients >65 years, anti PD-(L)1 +/- CT was significantly associated (hazard ratio [95% confidence interval]) with prolonged OS (0.82 [0.74-0.91]; $p = 0.0003$) and PFS (0.65 [0.60-0.72]; $p < 0.00001$) compared to CT alone. Survival benefits occurred in both anti-PD-1 and anti-PD-L1 trials. For patients over 75 years of age, OS benefit was not statistically significant (0.80 [0.58-1.09]; $p = 0.16$).

Conclusions: For patients over the age of 65 with untreated NSCLC, the anti-PD-1/PD-L1 combination with CT, compared with CT alone, is associated with significantly improved OS and PFS. Due to the low number of patients it is difficult to conclude for those over 75.

1429P Homologous recombination repair (HRR) gene mutation: A novel biomarker for precision genomics testing in advanced lung cancer

M. Nagaraj[1], K. Cawley[2], D. Siva[2], M. Ahmed[3]

[1]Internal Medicine, AIIMS - All India Institute of Medical Sciences, New Delhi, India; [2]Medical Oncology, Memorial Health System, Belpre, OH, USA; [3]Radiation Oncology, Memorial Health System, Belpre, OH, USA

Background: With the rapidly evolving targeted therapy in lung cancer, a study was done to identify a new biomarker HRR gene mutation by precision genomics-based testing and to determine its relationship with immunotherapy biomarkers.

Methods: 228 cancer patients underwent the FoundationOne CDx genetic testing for the presence of HRR gene mutation over 3 years. The HRR gene includes ATM, ARID1A, BARD1, BRCA 1/2, BRIP1, CDK12, CHEK1/2, FANCA/E/G, PALB2, PPP2R2A, RAD51B/C/D, RAD54L. PD-L1 (IHC) testing and Next-Generation Sequencing (NGS) testing were done to detect alterations in 324 genes including HRR gene mutation, microsatellite instability (MSI) and tumor mutational burden (TMB). 30 patients with advanced lung cancer who underwent the genetic testing were divided into two groups of HRR gene mutated vs HRR gene wild-type (WT) and tested for statistical significance.

Results: Among 228 cancer patients analyzed, the overall HRR gene mutation prevalence was 26.31% (N=228). In the study population of 30 patients with advanced lung cancer, the age (mean 68.9, SD 8.86 years), 43.33% males (n=13), 56.67% females (n=17), at least one HRR gene mutation was detected in 26.66% (n=8) and 73.33% (n=22) of patients were HRR gene WT. Histopathology was NSCLC in 80% (n=24) and SCLC in 20% (n=6) of patients. The difference in means of TMB (mut/Mb) between HRR gene mutated (Median=7.50, IQR 3.75-21.25) and HRR gene WT (Median=8.00, IQR 5.25-12.25) groups using the Mann-Whitney U test was not statistically significant ($P>.99$). The comparison of PD-L1 status ($P=.23$), MSI status ($P>.99$) between HRR gene mutated and HRR gene WT groups using fisher's exact test was not statistically significant.

Conclusions: The HRR gene mutation in advanced lung cancer was independent of the predictors for immunotherapy response (TMB, MSI and PD-L1 biomarkers). Further clinical trials are needed to assess the efficacy of combining poly ADP ribose polymerase (PARP) inhibitors with immunotherapy in the future.

Background: In patients with advanced non-small cell lung cancer (aNSCLC) timely therapeutic decision making is critical. In the past decade the treatment options for aNSCLC have expanded, along increased numbers of biomarkers that need to be tested, often on small and sparse material with multiple testing technologies. This may result in an undesired prolonged time to treatment and in the worst case even to non-feasible analysis. To elucidate the performance of the Idylla™ GeneFusion Assay, which simultaneously covers the biomarkers ALK, ROS1, RET and MET exon 14 skipping, a multicenter study was conducted in a routine clinical setting involving 12 clinical centers across Europe.

Methods: A total of 326 archival aNSCLC formalin fixed paraffin embedded (FFPE) samples were included. The results of the Idylla™ GeneFusion Assay were compared with the biomarker status determined earlier with routine reference methods (including FISH, IHC, RT-PCR, and NGS). A total of 179 biomarker positive cases (85 ALK, 33 ROS1, 20 RET and 41 MET exon 14 skipping) were included, making this one of the largest fusion positive datasets tested. The Idylla™ detects ALK, ROS1 and RET fusions using both fusion specific and expression imbalance detection, allowing for the detection of less common fusions not covered by the fusion specific PCR's.

Results: FFPE sample types used were 44% resected specimen, 46% tissue biopsies, 9% cytological specimen and 1% unknown. 67% of the centers used only 1 or 2 FFPE sections (5 or 10µm). The Idylla™ GeneFusion Assay demonstrated a low failure rate (0.9%). It showed also a high sensitivity/specificity, respectively for the following actionable biomarkers in NSCLC: 96.1%/99.6% for ALK, 96.5%/98.9% for ROS1, 100%/99.6% for RET and 92.5%/100% for MET exon 14 skipping.

Conclusions: Since results are available within 3 hours, the Idylla™ GeneFusion Assay technology has emerged as a highly relevant time efficient upfront screening tool in FFPE samples. Moreover, detection of potentially novel fusions based on the principle

Table: 1429P

HRR genes	(n)	Immunotherapy biomarkers	HRR gene mutated,(n)	HRR gene wild-type,(n)

Background: The national network genomic medicine lung cancer (nNGM) improves patient care of non-small cell lung cancer (NSCLC) patients by applying harmonized state-of-the-art molecular testing. Patients with actionable alterations can benefit from targeted molecular therapy options. However, systematic molecular testing frequently also leads to the discovery of mutations with no clear clinical actionability, commonly classified as variants of unknown significance (VUS). Since individual VUS are often rare, generation of evidence from clinical trials is difficult. The preclinical platform of the nNGM aims to provide functional data on VUS by combining preclinical research efforts with clinical data available from the nNGM network, thereby generating evidence for patients with VUS.

Methods: Clinicians can contact the preclinical platform with characterization requests for VUS. An expert team compiles literature data, clones the mutations into in vitro model systems, and conducts functional testing for oncogenicity and resistance mechanisms. Results are recorded in the MURIPEDIA knowledge data base, and correlation of predicted treatment sensitivity and clinical response informs a self-learning, evidence-generating system. The service is integrated with individual and collaborative research activities of the contributing groups for the systematic generation of preclinical evidence and includes computational methods for driver detection, and the setup of organoid biobanks as the groundwork for future patient-derived in vitro models.

Results: A total of 32 on-demand requests have been processed by scientists from the preclinical platform. Specialized in vitro testing with a turnaround time of 6 − 12 weeks is available for VUS occurring in EGFR, FGFR1, FGFR2, FGFR3, FGFR4, ROS1, or BRAF. From 19 requests concerning VUS of EGFR with no prior available data, 6 novel EGFR in vitro drivers were identified and profiled.

Conclusions: The nNGM preclinical platform offers a comprehensive on-demand characterization service for VUS in NSCLC patients supporting the concept of knowledge-generating patient care in the nNGM.

1432P Tumor stage shift in lung cancer during the COVID-19 pandemic: A real-world data study of the Network Oncology Registry

A. Thronicke[1], B.S. Matthes[2], C. Grah[3], P. Grabowski[2], F. Schad[2]

[1]Network Oncology, Research Institute Havelhöhe at Hospital Gemeinschaftskrankenhaus Havelhöhe, Berlin, Germany; [2]Interdisciplinary Oncology and Palliative Care, Hospital Gemeinschaftskrankenhaus Havelhöhe, Berlin, Germany; [3]Lung Cancer Center, Gemeinschaftskrankenhaus Havelhöhe, Berlin, Germany

Background: Lung cancer patients are vulnerable towards severe COVID-19 outcomes due to multiple risk factors such as smoking, older age or certain cancer treatments. During the COVID-19 pandemic the lung cancer care was significantly altered. As increasing data point towards a shift towards the diagnosis of more advanced tumors during the pandemic in lung cancer patients we evaluated cancer stages I-IV in lung cancer, especially NSCLC patients, newly diagnosed between 2018 and 2022 in a certified German lung cancer center.

Methods: Demographic data as well as tumor-related data were retrieved from the network oncology registry and evaluated retrospectively at the time of diagnosis. The study has been approved by the ethics committee of the Medical Association Berlin (Eth-27/10).

Results: In total 1118 lung cancer patients were included in the registry study. Comparing lung cancer patients from single pandemic years to the pre-pandemic year 2018, a significant 6.9% (p=0.02) drop of stage II lung cancer diagnoses was seen in 2022. Furthermore, when looking at NSCLC patients, significant tumor stage shifts were observed during 2021 and 2022: while the proportion of stage IV diagnosed NSCLC patients increased by 10.7% (p=0.03) during 2021, the proportion of stage II NSCLC decreased by 8.2% (p=0.01) in the following year compared to the pre-pandemic year 2018. No significant shifts were observed for SCLC patients. Finally yet importantly, a 12% decline of lung cancer diagnoses in 2021 and a 17.2% decline in 2022 was documented when comparing with diagnoses in 2018.

Conclusions: COVID-19-related delays and patient's reluctance have led to clinically meaningful decreases of lung cancer diagnoses in a certified German lung cancer center. Additionally, a significant increase of stage IV NSCLC diagnosis (2021) and a significantly decreased diagnosis of stage II lung cancer, particularly NSCLC tumors (2022), during the COVID-19 pandemic were observed. The implication of these results on the cancer care, patient's health-related quality of life and the lung cancer mortality will need to be urgently evaluated in the near future.

1433P CNS efficacy of atezolizumab, bevacizumab, carboplatin and paclitaxel in patients with non-small cell lung cancer and actionable mutations

M. Rathbone[1], C. O'Hagan[1], A. Khan[2], T. Cook[2], S. Rose[2], J. Heseltine[3], M. Howell[2], H. Wong[4], C. Escriu[5]

[1]School of Medicine, University of Liverpool, Liverpool, UK; [2]Medical Oncology, The Clatterbridge Cancer Centre - Liverpool, Liverpool, UK; [3]Medical Oncology Department, The Clatterbridge Cancer Center - Wirral, Metropolitan Borough of Wirral, UK; [4]Biostatistics, The Clatterbridge Cancer Centre - Liverpool, Liverpool, UK; [5]Medical Oncology, The Clatterbridge Cancer Center - Liverpool, Liverpool, UK

Background: Prospective and retrospective data support the use of Atezolizumab in combination with Bevacizumab, Carboplatin and Paclitaxel (ABCP) in patients with extensive non-small cell lung cancer with EGFR mutations after exhausting oral targeted therapy. The atezo-brain study showed CNS efficacy of upfront atezolizumab and platinum doublet in patients without EGFR or ALK alterations and untreated brain

metastases (CNS mPFS 6.9 months). The clinical impact of ABCP in patients with brain metastases and EGFR or ALK alterations remains unknown. Here we aimed to quantify the clinical impact of ABCP in our patient population with actionable mutations and brain metastases.

Methods: Patients with actionable mutations and CNS disease treated at the Clatterbridge Cancer Centre with ABCP between 2019 and 2022 were identified. All patients had been consistently selected, monitored, and documented by the same team. Data was collected retrospectively. Progression-free survival (PFS) and Overall Survival (OS) were quantified from day 1 of cycle 1.

Results: 19 patients had brain metastases at baseline, with an average age of 59 (range 32-77). 4 had ALK translocations, 2 had rare EGFR mutations and 13 had common EGFR mutations. 4 patients had received brain radiotherapy. 13 patients had asymptomatic brain metastases and 7 patients had well-controlled CNS symptoms. They all had an average of 11 cycles of treatment (median 7). Disease control was achieved in 14 patients (74%) with partial response in 9 of them (47%). There was a 94% concordance in intracranial vs extracranial response. All patients with CNS symptoms experienced a subjective improvement after an average of 13 days, although one patient was then noted to have CNS progression on brain MRI at week 9. The median PFS was 5.71 months (CNS mPFS 6.79 months) and the median OS was 11.21 months. Grade 3-4 toxicity leading to treatment modification occurred in 10 patients (53%), but none leading to treatment discontinuation.

Conclusions: Our data indicates CNS efficacy of ABCP regardless of the actionable mutation or previous CNS treatment, with frequent and quick responses. This supports the use of ABCP in patients with actionable mutations and untreated brain metastasis.

1434P Machine learning features derived from spatial interaction of immune cell families are associated with survival in NSCLC patients post-immunotherapy

S. Arabyarmohammadi[1], G. Corredor[1], M. Lopez de Rodas Gregorio[2], K. Schalper[3], A. Madabhushi[1]

[1]Biomedical Engineering, Emory University, Atlanta, GA, USA; [2]Pathology and Medical Oncology, Yale University School of Medicine, New Haven, CT, USA; [3]Pathology and Medical Oncology, Yale School of Medicine - Interventional Radiology Yale Cancer Center, New Haven, CT, USA

Background: The spatial architecture of B and T cells in the tumor microenvironment (TME) is known to be associated with treatment response in cancer patients. However, more complex spatial statistics to characterize the interaction of more than two immune cell types could further inform our understanding of tumor response to immunotherapy (IO). In this work we sought to evaluate quantitative metrics of higher order spatial relationships between multiple (>2) cell types to better characterize and predict overall survival (OS) in NSCLC patients.

Methods: The study included quantitative immunofluorescence images of pre-IO tumor biopsy specimen of 135 NSCLC patients from five centers with OS information. To predict OS, a set of 223 image features that characterize the spatial interplay of different cell types (CD4+, CD20+, CD8+, tumor, and stroma) in the TME were extracted. First, every nucleus belonging to each immune cell family was detected using an image analysis program (MATLAB) to identify the cell's expression, subsequently the cell coordinates were recorded. The algorithm then identifies each triplet of distinct cells in proximity of each other to form spatial triangles. Features relating to the density, neighborhood, and proximity of nuclei were subsequently extracted. A risk score (RS) was then computed for each patient using the least absolute shrinkage and selection operator. To predict OS, the Cox regression model was trained on 100 patients (St) and validated on 35 patients (Sv). The discriminative ability of the features was assessed using Kaplan-Meier and log-rank tests.

Results: The RS was significantly associated with OS in both St (HR: 1.76; 95% CI = 1.09 - 2.85; P = .02), and Sv (HR: 2.8; 95% CI= 1.18−6.68; P=.01). RS based risk stratification showed greater accumulation of tumor, CD4 T cells, and CD20 B cells in very close proximity of each other in low-risk patients, compared to high-risk patients.

Conclusions: Machine learning derived features describing the higher order spatial relationships between tumor, CD20 B cells, and CD4 T cells were found to be associated with OS in NSCLC patients treated with IO. Additional, independent multi-site validation of these findings is warranted.

Background: SNF-CLIMEDIN aims to provide comprehensive care to advanced NSCLC patients through 3 pillars: clinical, molecular and digital. Molecular profiling is not yet reimbursed. In the era of new therapies remote support tools are needed.

Methods: In this prospective randomized non-interventional study in 200 NSCLC patients receiving standard 1st line therapy, 161 genes are analyzed via NGS. Clinicians report Adverse Events (AEs) in a study database; patients record AEs in a digital platform and are randomized to receive (investigational) or not (control) educational and supportive content. The impact of digital support on QoL is evaluated.

Results: This unplanned interim analysis studied 100 patients from 15 HeCOG centres. The Table shows clinical and molecular characteristics. The most common 1st line therapy was IO-chemo (80%). PR was 32%, SD 31%, 1-yr OS 64%, med PFS 5 months and med OS 8 months. Clinicians reported fatigue, haematological, liver and skin toxicities as the commonest gr3-4 AEs, while patients in the platform most often reported fatigue, cough, nausea, diarrhoea and anorexia. More AEs were reported in the platform than in the study database (89% vs 68% of patients, $p<0.05$). Platform use was higher in the investigational arm and rural areas. Patient-reported AE improvement was 78.4% (80.8% investigational vs 75.8% control). Most pts reporting AEs at least twice had ≥50% improvement. QoL and socio-demographic correlations with digital platform use will be presented.

Table: 1435P

Clinical			Molecular
Age median	68 yrs		
Characteristic	%	Aberration	%
Male	80	TP53	59
Smoker	85	KRAS	27
Residence Urban	85	STK11	12
Live with Family	82	SMARCA4	10
Pensioners	59	EGFR	6
>High school education	73	BRAF	6
ECOG PS 0-1	97	PIK3CA	5
De Novo mets	88	PTEN	5
Adenocarcinoma	66	BRCA1/2, ATM	9
PDL-1 (+)	56	NOTCH	9
		MYC	5

Conclusions: The study provides prospective evidence on NSCLC patients' clinical and molecular profiles, treatment patterns and outcomes. Digital education and support led to increased AE reports and improvements, especially in the investigational arm.

Socio-demographic factors influenced platform engagement, highlighting the significance of digital initiatives for patient-centered NSCLC care.

1436P Prospective study utilizing ctDNA genome-wide copy number variations for longitudinal monitoring of patients with advanced non-small cell lung cancer

P. Han[1], Q. Liu[2], J. Zhou[2], H. Tang[3], F. Xie[3], Y. Zhang[3], S. Jia[3]

[1]Department of Respiratory and Critical Care Medicine, Chongqing Three Gorges Medical College, Chongqing, China; [2]Department of Respiratory and Critical Care Medicine, Chongqing Three Gorges Center Hospital, Chongqing, China; [3]Translational Medicine, Huidu (Shanghai) Medical Technology Co., Ltd., Shanghai, China

Background: Non-small cell lung cancer (NSCLC) is the most common type of lung cancer. While the development of targeted therapies has led to significant improvements in NSCLC patient outcomes, resistance can develop over time. Hence, there is need for reliable methods to monitor treatment response and identify tumor relapse. Circulating tumor DNA (ctDNA) in plasma has emerged as a promising biomarker for NSCLC, which can be used for longitudinal tumor monitoring.

Methods: The study recruited 69 patients with advanced NSCLC and collected their blood samples at the baseline. Patients were treated with targeted therapies tailored to their biomarker profiles. Blood samples were collected approximately every three months until disease progression, and were delivered to a central laboratory for ctDNA analysis. The study applied PredicineSCORE, a low-pass whole-genome sequencing (LP-WGS) assay, to monitor disease progression during treatment.

Results: In this ongoing study, baseline blood samples from 69 enrolled patients were tested, of whom 12 patients had longitudinal blood samples tested at multiple follow-up time points. Using the ctDNA assay, gene copy variants related to NSCLC were detected at baseline, including copy gain of EGFR (n=11), PIK3CA (n=10), KRAS (n=9), AKT3 (n=8), AKT2 (n=7), ERBB2 (n=7), and copy loss of TP53 (n=8), FAT1 (n=7), BAP1 (n=7), BRCA2 (n=7), and RB1 (n=6). The assay also measured the genome-wide copy number burden (CNB) levels in plasma samples as an approach for treatment monitoring. Among the 12 patients whose longitudinal samples were tested, 7 were observed to have a CNB decrease during treatment, which was correlated with their clinical response. Notably, the study also found that 2 patients had an increase in CNB, preceding the clinical detection of disease progression.

Conclusions: Next-generation sequencing (NGS)-based ctDNA tests using plasma have demonstrated remarkable molecular profiling capabilities in advanced NSCLC patients. PredicineSCORE-based LP-WGS assays performed in the study have revealed the copy number burden profiles of NSCLC, which provides potential biomarkers for longitudinal monitoring of treatment response and disease progression.

1437P Clinical and economic burden of tissue re-biopsy (TRB) vs. tissue followed by liquid biopsy (TFLB) in metastatic non-small cell lung cancer (mNSCLC) patients

N.M. Engel-Nitz[1], A. Shah[2], J. Apple[2], S. Aslam[1], L. Le[1], M. Terpenning[3]

[1]HEOR, Optum, Eden Prairie, MN, USA; [2]HEOR, AstraZeneca Pharmaceuticals LP, Gaithersburg, MD, USA; [3]Private individual, Eagle, ID, USA

Background: Tissue biopsy (TIB) is the gold standard for biomarker testing in mNSCLC patients. Although TIB is common, it is associated with potential invasive procedure-related complications. Liquid biopsies are used when tissue is unavailable or insufficient for testing. Studies suggest that TFLB has comparable diagnostic accuracy to TIB for detecting genetic alterations in mNSCLC patients. Liquid biopsies are increasingly used to genotype a tumor in a less invasive manner. This study compared TIB-related complications and healthcare costs with TRB vs. TFLB in mNSCLC patients.

Methods: US administrative claims were assessed retrospectively for patients diagnosed with mNSCLC between July 2016 to June 2021 to identify adult Medicare Advantage or commercially insured patients with ≥2 biopsy claims, and whose first biopsy was tissue-based. The second biopsy defined the cohorts: TRB or TFLB. To control for possible confounding factors, study cohorts were matched 1:1 using propensity-scores (PSM).

Results: The study comprised 470 patients post-PSM, each group had 235 patients. TFLB had a lower TIB-related complication rate and associated healthcare costs compared with TRB (Table). Furthermore, mean number of complication-related healthcare visits were lower for TFLB than TRB group; outpatient visits (0.51 v 1.12, p=0.002), inpatient stays (0.45 v 0.67, p<0.001) and inpatient days (3.49 v 6.60, p=0.002).

Table: 1437P Comparison of outcomes between study cohorts

	TFLB (N = 235)	TRB (N = 235)
TIB-related complications (%)*	65.1	84.7
Pneumothorax*	17.5	46.0
Prolonged air leak >5 days*	1.3	11.9
Hemorrhage	14.0	18.3
Infection*	23.0	31.9
Thrombotic complications	13.2	8.5
Cardiovascular complications	38.7	42.1
Death	0.4	2.6
Mean [SD] TB complication-related healthcare costs - US$		
Medical costs*	8,494 [15,706]	19,741 [30,641]
Office visits*	20 [71]	51 [219]
Outpatient visits	251 [1,672]	336 [1,562]
Emergency room visits	119 [590]	85 [358]
Inpatient stays*	8,076 [15,338]	18,918 [30,012]
Other medical costs	29 [148]	352 [3622]

*P-value <0.05

Conclusions: The analysis suggests that TFLB, compared with traditional TRB, is a method that carries less economic burden and fewer TIB-related complications to detect actionable genetic mutations during mNSCLC diagnostic work-up.

Background: Outcomes for patients (pts) with squamous non-small cell lung cancer (NSCLC) treated with immunotherapy are generally poorer than pts with non-squamous NSCLC and have fewer treatment options. We report an exploratory subgroup analysis of pts with squamous NSCLC who were treated with cemiplimab from two phase 3 clinical trials.

Methods: EMPOWER-Lung 1 (NCT03088540) and EMPOWER-Lung 3 (NCT03409614; part 2) included pts with squamous or non-squamous advanced NSCLC without EGFR, ALK or ROS1 aberrations. In EMPOWER-Lung 1, pts with ≥50% programmed cell death-ligand 1 (PD-L1) were randomized 1:1 to first-line (1L) cemiplimab monotherapy or platinum-doublet chemotherapy (chemo). In EMPOWER-Lung 3, pts irrespective of PD-L1 level were randomized 2:1 to 1L cemiplimab + chemo or placebo + chemo.

Results: In both trials, ∼43% of pts had squamous histology. In EMPOWER-Lung 1, at median follow-up of 37.1 mo, for squamous pts treated with cemiplimab vs chemo, median overall survival (OS) was 22.7 vs 13.5 mo (HR: 0.51; 95% CI: 0.37, 0.69), and median progression-free survival (PFS) was 8.3 vs 5.9 mo (HR: 0.44; 95% CI: 0.32, 0.59). The objective response rate (ORR) was 43.9% vs 22.1%, and the median duration of response (DOR) was 16.0 mo (95% CI: 10.4, 33.0) vs 4.3 mo (95% CI: 4.2, 6.1), respectively. In EMPOWER-Lung 3 part 2, at a median follow-up of 28.4 mo, for squamous pts treated with cemiplimab + chemo vs placebo + chemo, median OS was 22.3 vs 13.8 mo (HR: 0.61; 95% CI: 0.42, 0.87), and median PFS was 8.2 vs 4.9 mo (HR: 0.56; 95% CI: 0.41, 0.78). ORR was 46.6% vs 26.9%, and the median DOR was 13.8 mo (95% CI: 11.0,18.2) vs 11.3 mo (95% CI: 4.2, 21.4), respectively. Patient reported outcomes and safety results will be described for both studies in the presentation.

Table: 1438P

	EMPOWER-Lung 1† Squamous	EMPOWER-Lung 3 Part 2 Squamous
	Cemiplimab (n=123) vs chemo (n=122)	Cemiplimab + chemo (n=133) vs placebo + chemo (n=67)
OS, median, mo	22.7 vs 13.5	22.3 vs 13.8
OS HR (95% CI)	0.51 (0.37, 0.69)	0.61 (0.42, 0.87)
PFS, median, mo	8.3 vs 5.9	8.2 vs 4.9
PFS HR (95% CI)	0.44 (0.32, 0.59)	0.56 (0.41, 0.78)
ORR, %	43.9 vs 22.1	46.6 vs 26.9
DOR, median (95% CI), mo	16.0 (10.4, 33.0) vs 4.3 (4.2, 6.1)	13.8 (11.0,18.2) vs 11.3 (4.2, 21.4)

†PD-L1 ≥50% population. Data cutoff dates: EMPOWER-Lung 1: 4 Mar 2022; EMPOWER-Lung 3 Part 2: 14 June 2022.

Conclusions: Subgroup analysis with long-term follow up data from two large phase 3 studies demonstrate improved clinical benefit of cemiplimab as 1L monotherapy or in combination with platinum-doublet chemo over chemo alone in pts with squamous NSCLC.

Clinical trial identification: NCT03088540; NCT03409614.

Background: Preclinical data have shown a synergistic effect of radiotherapy (RT) combined with immunotherapy. However, the effect of combining RT with immunotherapy remains unknown for advanced NSCLC with brain metastases (BMs). This study aimed to assess the preliminary efficacy and safety of brain RT combined with camrelizumab plus platinum-based chemotherapy as first-line treatment in NSCLC patients (pts) with BMs.

Methods: Treatment-naïve pts with NSCLC and BMs were adults who had no known EGFR/ALK/ROS1 alterations and had at least one measurable intracranial and extracranial lesions per RECIST 1.1. Eligible pts received camrelizumab (200 mg) and platinum-based chemotherapy intravenously every 3 weeks for 4-6 cycles after stereotactic radiosurgery or whole-brain RT. Subsequently, pts without disease progression received maintenance treatment with camrelizumab ± pemetrexed every 3 weeks up to 24 months, or until disease progression or intolerance. The primary endpoint was 6-month progression-free survival (PFS) rate.

Results: Between May 6, 2020 and April 25, 2023 (data cutoff), 65 pts were enrolled and treated. The primary endpoint 6-month PFS rate was 70.2% (95% CI 56.3-80.4). With a median follow-up of 11.2 months (95% CI 9.0-17.0), the median PFS was 8.7 months (95% CI 7.5-15.7), and median overall survival was 21 months (95% CI 15.1-NE). Of the 65 pts, 49 (75.4%) pts had a confirmed partial response and 14 (21.5%) had stable disease, with the overall objective response rate (ORR) and disease control rate of 75.4% (95% CI 63.1%-85.2%) and 96.9% (95% CI 89.3%-99.6%). The intracranial ORR was 81.5% (95% CI 70%-90.1%). Adverse events (AEs) of any grade occurred in 64 (98.5%) of the 65 pts, and grade 3 or 4 AEs were observed in 32 (49.2%) pts, with the most common being neutrophil count decreased (14 [21.5%]) and white blood cell count decreased (11 [16.9%]). No treatment-related deaths occurred.

Conclusions: The combination of brain radiotherapy, camrelizumab and platinum-based chemotherapy showed promising efficacy and manageable toxicity for treatment-naïve advanced NSCLC with BMs.

Clinical trial identification: NCT04291092 First posted: March 2, 2020; Last update posted: September 10, 2021.

Background: Treatment options in 2L metastatic NS NSCLC remain limited with modest outcomes to date. AXL, a receptor tyrosine kinase, mediates resistance to immune- and chemotherapy (CT) and is a poor prognostic biomarker in NSCLC. Bemcentinib (bem), a highly selective oral AXL inhibitor, potentiates the immune-checkpoint inhibitor (ICI) effect in pre-clinical models, providing a strong scientific rationale for the bem+pembro combination in this patient population (PP).

Methods: BGBC008 is a ph2 open-label, single-arm study of bem+pembro in 2L NS NSCLC: ICI-naïve patients (pts) (cohort A), CT-naïve pts (cohort B) and pts with prior CT+ICI (cohort C). Primary endpoint was objective response rate (ORR); secondary endpoints included safety, progression-free survival (PFS) and overall survival (OS). Exploratory analyses assessed PD-L1 (by TPS) and AXL (by H-score) status impact on outcomes.

Results: The study enrolled 99 safety-evaluable pts; median age 65 years (range 39-86); 90 pts were efficacy-evaluable (EE). Most common adverse events were gastrointestinal disorders (G $\leq$2) in >20% of pts and transient liver enzyme increase (G $\leq$3) in 10% pts. Median (m) OS and mPFS were 13 and 6.2 months (mths), respectively. AXL status impacted mOS: 14.8 vs 9.9 mths (p=0.029) for AXL >5 vs AXL $\leq$5, respectively. No difference in mOS (10.6 vs 12.4 mths) or mPFS (6 vs 7 mths) in PD-L1+ (TPS$\geq$1) vs PD-L1- (TPS<1) pts, respectively. The ORR of 11.1% in all EE pts and 21.9% in pts with AXL >5 favourably aligns with therapies in 2L NSCLC. Median OS and mPFS in KRAS mutated ($KRAS^{MT}$) (n=20) and KRAS wild-type ($KRAS^{WT}$)(n=36) were 14.1 vs 10.0 mths (p=0.49) and 9.8 vs 3.8 mths (p=0.009), respectively. The mOS and mPFS for the PD-L1- (n=6) and PD-L1+ (n=11) $KRAS^{MT}$ pts were 18 vs 11.4 mths (p=0.017) and 17.3 vs 6.1 mths (p=0.09), respectively.

Conclusions: Bem+pembro was well tolerated and efficacious compared to historical controls. Survival benefit was observed in pts with AXL >5, regardless of prior therapy or PD-L1 status. The promising efficacy signal observed in $KRAS^{MT}$ pts warrants further validation.

Clinical trial identification: NCT03184571.

1441P Atezolizumab and bevacizumab (atezo + bev) ± radiotherapy (RT) vs docetaxel (doc) in checkpoint inhibitor (CPI)−experienced metastatic NSCLC (mNSCLC): Results from the phase Ib/II MORPHEUS-lung study

F. Ghiringhelli[1], E. Felip[2], A. Zer[3], L. Greillier[4], A. Greystoke[5], N. Al-Sakaff[6], H-J. Helms[7], J.P. Pintoffl[6], S. Rahalkar[8], F.L. Lim[9], B.C. Cho[10]

Hoffmann-La Roche Ltd, Basel, Switzerland; [7]Product Development Data and Statistical Sciences, F. Hoffmann-La Roche Ltd, Basel, Switzerland; [8]Product Development Safety, Roche Products Limited, Welwyn Garden City, UK; [9]Barts Cancer Institute, Queen Mary University of London, London, UK; [10]DAAN Cancer Laboratory, Yonsei Cancer Center, Seoul, Republic of Korea

Background: The MORPHEUS platform was designed to accelerate development of novel cancer immunotherapy combinations across tumour types. The adaptive design of these global, open-label, randomised, phase Ib/II studies allows a single control arm to be compared with multiple experimental arms and provides the flexibility to open new arms or close existing arms. We report interim analysis results from the MORPHEUS-Lung study in CPI-experienced patients (pts) with mNSCLC.

Methods: Cohort 2 (C2) of MORPHEUS-Lung is enrolling pts with *EGFR/ALK* WT mNSCLC that has progressed on prior platinum and a CPI (anti−PD-L1/PD-1) given concurrently or sequentially. The primary endpoints are investigator-assessed ORR (RECIST v1.1) and safety. Secondary endpoints include PFS and OS. Biomarkers are also being explored. C2 pts with non-squamous mNSCLC randomised to the atezo +

Table: 1441P

	Atezo + bev n=40	Doc (control) n=32
Response, n (%)		
Confirmed ORR	7 (18)	5 (16)
DCR	26 (65)	18 (56)
Median survival (95% CI), mo[a, b]		
PFS	6.9 (4.3, 8.3) HR 0.77 (95% CI:	4.5 (3.4, 5.9) 0.44, 1.34)
OS	13.7 (8.5, NE) HR 0.99 (95% CI:	18.6 (7.0, 21.0) 0.50, 1.94)
Pts with ≥1 AE, n (%)		
Grade 3-5	16 (40)	19 (59)
Worst Grade: 4	0	4 (13)
Worst Grade: 5	0	1 (3)[c]
Tx related	31 (78)	31 (97)
Serious	12 (30)	8 (25)
Leading to withdrawal from any treatment	2 (5)	5 (16)

NE, not estimable. [a]Per RECIST 1.1. [b]Median survival follow-up: atezo + bev, 8.5 mo; doc, 7.2 mo. [c]Grade 5 pneumonia considered by the investigator to be tx related.

bev, atezo + bev + RT or doc (control) arms were included in the analysis. Data from the atezo + bev + RT arm will be presented at the meeting along with updated data for the atezo + bev and doc arms.

Results: At data cutoff (24 Aug 2022), the efficacy and safety populations included 72 pts (atezo + bev, n=40; doc, n=32). The median age was 63 y, 72% of pts (n=52) were male and 81% (n=58) had PD-L1+ NSCLC per local testing. Confirmed ORR was 18% (n=7) and 16% (n=5) in the atezo + bev and doc arms, respectively (Table); 1 pt (3%) had a complete response (atezo + bev). Gr 3-5 AEs occurred in 40% (n=16) and 59% (n=19) of pts in the respective arms (Table). Tx-related Gr 4/5 AEs only occurred in the doc arm.

Conclusions: MORPHEUS-Lung interim analysis results suggest that atezo + bev is a potential tx option for CPI-experienced pts with mNSCLC. No new safety signals were identified, and AEs were consistent with the known safety profiles of the individual agents. Atezo + bev was tolerable, with fewer Gr 3-5 AEs and tx withdrawals than with doc.

Clinical trial identification: NCT03337698.

Background: NSCLC is a disease of the elderly, but frail and older patients (pts) are underrepresented in clinical trials with scarce data to guide treatment.

Methods: DURATION (NCT03345810) was a phase 2 trial conducted in 31 German centers between 12/17-01/22. 201 older or frail stage IV NSCLC pts (age $\geq$70 years and/or Charlson Comorbidity Index $>$ 1 and/or performance status (PS) ECOG $\geq$ 2) were stratified to receive mCTX or dCTX according to the modified Cancer Aging Research Group score (mCARG $>$3 or $<$3, respectively), and subsequently randomized between 4 cycles of CTX and 2 cycles of CTX followed by D. Primary endpoint was the rate of treatment-related grade III/IV adverse events (AEs).

Results: The median follow-up was 36.8 months (mo) with 17% of pts censored. Median age was 76 years (range 56-90), 59 pts (30%) had an ECOG PS $\geq$2 and 112 pts (56%) a CCI $>$1. The PD-L1 tumor proportion score was 0%, 1-49% and $>$50% in 42%, 50% and 8% of pts, respectively. The rate of grade III/IV AEs was 34%, 34%, 24% and 29% for dCTX , dCTX-D, mCTX-D and mCTX respectively (p=0.68). Treatment-related deaths were reported in 1% (n=2, dCTX-D and mCTX). 2nd-line treatment (proportion anti-PD-1/PD-L1) was administered in 57% (43%), 42% (12%), 31% (16%), 38% (22%) cases after dCTX, dCTX-D, mCTX-D and mCTX, respectively. In the modified per-protocol (PP) population (including pts treated until cycle 3, excluding pts with major protocol deviations), the median overall survival (OS) was 14.3 vs 11.1 mo for dCTX and dCTX-D (HR 1.2, p=0.46) and 10.2 vs 8.3 mo for mCTX-D and mCTX (HR 0.7, p=0.25). Pts with mCARG $\leq$3 had significantly longer OS compared to patients with mCARG $>$3 in the PP population (11.0 mo vs. 5.3 mo in median, HR 2.10, p$<$0.001).

Conclusions: The mCARG score stratified older or frail pts with advanced NSCLC for safe treatment conductance on dCTX, resulting in longer OS without increased toxicity compared to mCTX. The rate of grade III/IV-AEs did not exceed 34% and treatment-related mortality was $\leq$ 1% in both strata. Immature data show a numerical OS advantage for mCTX-D compared to mCTX, which may be related to the low rate of 2nd-line treatment $<$ 40% in these most frail cases.

Clinical trial identification: NCT03345810.

1443P Patient-reported outcomes (PROs) with cemiplimab plus chemotherapy (CEMI + CHEMO) for first-line treatment of advanced non-small cell lung cancer (aNSCLC): PD-L1 level subgroups in EMPOWER-Lung 3

M. Gogishvili[1], T. Melkadze[2], A. Baramidze[3], T. Makharadze[4], X. He[5], G. Gullo[5], P. Rietschel[5], R.G.W. Quek[5]

[1]Medical Oncology, High Technology Medical Centre, University Clinic Ltd, Tbilisi, Georgia; [2]Oncology and Hematology Dept, Todua Clinic, Tbilisi, Georgia; [3]Department of Clinical Trials, Todua Clinic, Tbilisi, Georgia; [4]Oncology, LTD High Technology Hospital Med Center, Tbilisi, Georgia; [5]Department of Medical Oncology, Regeneron Pharmaceuticals, Inc., Tarrytown, NY, USA

Background: In EMPOWER-Lung 3 (NCT03409614), a Ph 3 double-blind randomised 2:1 trial, CEMI + CHEMO (n=312) vs placebo (PBO) + CHEMO (n=154) was evaluated as 1st-line treatment for aNSCLC with any PD-L1 expression level. OS and PFS across PD-L1 level subgroups <1%, 1–49% and ≥50% were previously reported. Exploratory analyses were conducted to evaluate PROs across these subgroups.

Methods: PROs were assessed using the EORTC QLQ-C30 and QLQ-LC13 questionnaires. A longitudinal mixed-effect model for repeated measures analysis was used to compare treatment groups for global health status (GHS)/quality of life (QoL) and all functional and symptom scales. Time to definitive clinically meaningful deterioration (TTD) was compared between treatment groups; comparisons were made using a stratified log-rank test and proportional hazards model.

Results: Significant delays in TTD favouring CEMI + CHEMO vs PBO + CHEMO was observed in pain and alopecia across PD-L1 subgroups. Significant delays in TTD favouring CEMI + CHEMO was observed in cognitive functioning and haemoptysis in PD-L1 <1%; in physical, role and emotional functioning and symptoms of fatigue, nausea/vomiting, dyspnoea and dysphagia in PD-L1 1–49%; and in role functioning and symptoms of dyspnoea, coughing, haemoptysis and sore mouth in PD-L1 ≥50%. CEMI + CHEMO resulted in significant favourable differences vs PBO + CHEMO in overall change from baseline in pain symptoms in both PD-L1 <1% and 1–49%. Statistically significant overall change from baseline favouring CEMI + CHEMO was also observed in cognitive functioning in PD-L1 <1%; in emotional functioning in PD-L1 1–49%; and in symptoms of coughing and alopecia in PD-L1 ≥50%. The differences in overall change from baseline and delay in TTD for GHS/QoL numerically favoured CEMI + CHEMO vs PBO + CHEMO across all PD-L1. No analyses yielded statistically significant PRO results favouring PBO + CHEMO on any QLQ-C30 or QLQ-LC13 scale.

Conclusions: Across PD-L1 subgroups in patients with aNSCLC, CEMI + CHEMO resulted in significant overall improvement and delayed TTD in multiple patient-reported functioning and cancer-related and lung cancer–specific symptoms.

1444P Sintilimab with two cycles nab-paclitaxel / platinum as first line therapy for advanced squamous non-small-cell lung cancer: The final analysis and biomarker results

H. Wang[1], M. Zhang[1], G. Zhang[1], Y. Niu[1], G. Zhang[2], Y. Ji[3], X. Yan[1], Q. Wang[4], X. Jing[5], J. Wang[6], Z. Ma[1]

[1]Medical Oncology Department, Henan Cancer Hospital/Affiliated Cancer Hospital of Zhengzhou University, Zhengzhou, China; [2]Medical Oncology Department, Xinxiang Central Hospital, Xinxiang, China; [3]Medical Oncology Department, The First Affiliated Hospital of Xinxiang Medical University, Xinxiang, China; [4]Medical Oncology Department, Nanyang Second People's Hospital, Nanyang, China; [5]Medical Oncology Department, Pingdingshan First People's Hospital, Pingdingshan, China; [6]Medical Oncology Department, Anyang Cancer Hospital, Anyang, China

Background: PD-1 antibody combined with 4-6 cycles platinum-based chemotherapy has been the standard 1st line treatment for recurrent or advanced squamous (sq)-NSCLC. This study evaluated the effect and safety of sintilimab plus 2 cycles nab-paclitaxel/carboplatin for treatment-naïve stage IIIB-IV sq-NSCLC.

Methods: This is a single arm, multi-center, phase II study, advanced sq-NSCLC patients received sintilimab (200mg, IV) with nab-paclitaxel / carboplatin every 3 weeks for 2 cycles, followed by sintilimab (200mg, Q3W) until disease progression, or unacceptable toxic effects, or up to 2 years. The primary endpoint was progression-free survival (PFS). The secondary endpoints were objective response rate (ORR), disease control rate (DCR), duration of response (DOR), overall survival (OS) and safety. Peripheral blood circulating tumor DNA (ctDNA) were measured at baseline as well after 1 cycle (C1) and 2 cycles (C2) treatment. Here we report the final analysis and biomarker results.

Results: 48 patients were enrolled, 47 received at least once treatment, 44 had at least once tumor assessment. The median PFS and OS were 10.68 months (95%CI: 6.4-17.8) and 21.9 months (95% CI: 17.0-NE). PFS rates at 12m and 24m were 38.2% and 20.4%. OS rates at 12m and 24m were 78.9% and 47.8%. The ORR and DCR were 70.5% (95%CI: 54.8-83.2) and 93.2% (95%CI: 81.3-98.6), with a median DOR of 16.5m (95%CI: 7.0-20.6). 42 patients (91.3%) experienced treatment related adverse events (TRAEs), 5 were grade3/4, the most common TRAE were anemia, α-hydroxybutyrate dehydrogenase elevated and alanine aminotransferase elevated. Patients with abnormalities in BRAC2, BRINP2, FBXW7, KIT or RB1 exhibited a poorer PFS. The clearance of ctDNA after C2 treatment was found to be an independent predictor of superior response and longer PFS. Median PFS for patients with cleared ctDNA versus those with uncleared ctDNA were 18.1m compared to 4.3m, respectively.

Conclusions: Sintilimab combined with two cycles nab-paclitaxel/carboplatin showed encouraging PFS/OS and manageable safety as first line treatment for advanced squamous NSCLC. The ctDNA clearance might be a potential predictor for the efficacy.

Background: To date, first-line pembrolizumab monotherapy (PEM) has not been compared to pembrolizumab + chemotherapy (PEM/CT) in metastatic non-small cell lung cancer (NSCLC) with PD-L1 TPS ≥50%. However, the regimen that provides the highest response rate, crucial for when a tumor response is urgently needed, is unknown. Here, we report the interim results of the PAULIEN study (NTR 8896), aiming to identify the regimen (PEM or PEM/CT) with the highest response rate.

Methods: This open label, phase 3, multicenter trial aimed to randomize (1:1) 84 patients with untreated metastatic NSCLC with PD-L1 TPS ≥50% and a high tumor burden to receive PEM (200mg fixed, 3 or 6 weekly) or PEM (200mg fixed, 3 weekly) + platinum-based chemo-doublets with either pemetrexed or paclitaxel. Pemetrexed and PEM were continued as maintenance therapy. Patients in the PEM arm received CT after progressive disease. Stratification factors included age, performance status, T-stage and histology. Co-primary endpoints were objective response rate (ORR) and disease control rate (DCR) at week 6 and 12 per RECIST v1.1. Secondary endpoints included progression-free survival, overall survival and safety. A planned interim analysis was performed (data cut-off March 1st, 2023).

Results: 50 patients were randomized to PEM (n=19) and PEM/CT (n=31). Baseline characteristics were well balanced between arms. 42 patients were radiologically evaluable of whom 17 patients received PEM and 25 patients PEM/CT. The PEM arm demonstrated an ORR at week 6 of 38% vs. 44% in the PEM/CT arm (p=0.68) and a DCR of 88% vs. 88% (p=1.0). At week 12, the PEM arm demonstrated an ORR of 74% vs. 68% in the PEM/CT arm (p=1.0) and a DCR of 93% vs. 91% (p=1.0), respectively. The incidence of grade 3-4 treatment-related adverse events was 28% (PEM) vs. 52% (PEM/CT). No treatment-related deaths occurred.

Conclusions: In this interim analysis, the tumor response rate with first-line PEM alone was comparable to that of PEM/CT in metastatic NSCLC patients with PD-L1 TPS ≥50%,. No new safety signals were observed. More data is needed to explore subgroups that may still benefit from adding chemo to PEM in this population.

Background: Rilvegostomig is a bispecific, humanised IgG1 targeting PD-1 and TIGIT, receptors that suppress antitumour T cell activity. Initial data from the first-in-human study showed favourable tolerability and early antitumour activity in patients (pts) with CPI-pretreated advanced/metastatic NSCLC. Here we report updated data from dose escalation and expansion (Parts A + B).

Methods: Pts in the initial phase of this open-label, multicentre study had stage III unresectable or stage IV NSCLC, PD-L1 tumour proportion score ≥1%, and primary or secondary CPI resistance. Part A evaluated 70−1500 mg IV Q3W; Part B evaluated the recommended phase 2 dose (RP2D). Primary and secondary endpoints included safety, tolerability, preliminary efficacy, and PK.

Results: As of 13 Apr 2023, 83 pts were enrolled (Part A, n=51; Part B, n=32). Pts were 63.9% male, median age was 63.0 yr, and 22.9% had squamous histology. Overall, 22.9% had 1 prior line of therapy, 34.9% had 2, 24.1% had 3, and 18.1% had >3. Median duration of therapy was 12.4 wk. Rilvegostomig was well tolerated (Table); RP2D was 750 mg. Four pts had confirmed partial responses (PRs) and 33 had stable disease (SD); 6-month disease control rate (DCR) was 31.3%. Median progression-free survival was 2.1 mo (95% CI, 2.0, 4.1). Updated clinical and translational data (e.g. molecular response based on ctDNA) will be presented.

Conclusions: Rilvegostomig was well tolerated and had antitumour activity in heavily pretreated pts who had progressed on CPI therapy. Further investigation is ongoing in CPI-naïve cancer patients.

Table: 1446P Safety and efficacy of rilvegostomig

Safety, n (%)	N=83
Treatment-emergent AEs (TEAEs), any grade / grade ≥3	75 (90.4) / 25 (30.1)
Treatment-related AEs (TRAEs), any grade / grade 3*	45 (54.2) / 7 (8.4)
Serious TEAEs	25 (30.1)
Serious TRAEs	6 (7.2)
AEs leading to discontinuation	3 (3.6)
Efficacy	**Evaluable pts (n=83)**
Objective response, % (95% CI)	4.8 (1.3, 11.9)
Confirmed PR	4 (4.8)
SD, n (%)	33 (39.8)
Duration of response, mo, median (range)	Not calculable (2.1, 10.3)
DCR at 9 wk, n (%)	37 (44.6)
DCR at 27 wk, n (%)	26 (31.3)
Progression-free survival, mo, median (95% CI)	2.1 (2.0, 4.1)

*No Grade 4 or 5 treatment-related AEs were reported.

Clinical trial identification: NCT04995523; 9 August, 2021.

Background: IMscin001 Part 2 met its co-primary endpoints of non-inferior drug exposure for Cycle 1 C_{trough} and $AUC_{0\text{-}21d}$ for atezo SC vs IV (Burotto ESMO-IO 2022). Efficacy, safety and immunogenicity were similar between arms at primary analysis. Here, we report updated data.

Methods: Cancer immunotherapy-naïve patients with locally advanced or metastatic NSCLC for whom platinum therapy had failed were randomised 2:1 to receive 1875 mg atezo SC or 1200 mg atezo IV q3w. Secondary endpoints were efficacy (OS, PFS, ORR, DOR), safety, immunogenicity and PROs. PROs were collected on Day 1 of Cycles 1-6 and then every second cycle until treatment discontinuation. Healthcare providers (HCPs) completed SC and SC vs IV perspective questionnaires after giving ≥3 doses of atezo SC or ≥3 doses of atezo SC and IV each, respectively.

Results: At data cut-off (16 Jan 2023; median follow-up: 9.5 mo), ≈60% of OS events had occurred. Median OS was 10.7 mo for SC vs 10.1 mo for IV; immunogenicity and safety were also similar between arms (Table). Mean PRO scores were within 10% between arms for global health status, role and physical functioning, and satisfaction with therapy. 90% (70/78) of HCPs reported that giving atezo SC was fairly easy/very easy, 85% (66/78) were satisfied/very satisfied with atezo SC and 75% (33/44) agreed that administering atezo SC could save time compared with IV.

Table: 1447P

	SC (n=247)	IV (n=124)
Median administration time (95% CI), min	7.1 (6.6, 7.4)	40.0 (37.5, 45.0)
Efficacy		
OS events, %	58	64
OS, median (95% CI), mo	10.7 (8.5, 13.8)	10.1 (7.5, 12.1)
Confirmed ORR, (95% CI), %	11.0 (7.4, 15.6)	10.5 (5.7, 17.3)
Confirmed DOR, median (95% CI), mo	15.1 (5.6, NE)	11.2 (4.2, NE)
Safety, %

AE leading to atezo discontinuation	4	7
Infusion-related reaction	0	3
Injection site reaction	4	0
Grade 1/2	4	0
Immunogenicity		
ADA incidence, %	21	14

NCT03735121. ADA, anti-drug antibody; NE, not estimable.

Conclusions: At this updated analysis, OS data were mature and similar between arms. Safety was also similar and consistent with the atezo IV profile for approved indications. ADA incidence for both arms was in the historic range for atezo IV. PROs were similar for both arms, and HCPs reported easy/very easy administration and potential time savings for atezo SC. These results support atezo SC as an alternative to IV.

Clinical trial identification: NCT03735121.

Background: The CheckMate 9LA study showed that NIVO + IPI with 2 cycles of chemotherapy (chemo) vs chemo alone significantly improved overall survival (OS) for patients (pts) with metastatic NSCLC. The FINN real-world study (NCT04794010) aims to evaluate this regimen in clinical practice in Germany.

Methods: Enrollment for the prospective, observational study is ongoing, with 90 sites and 650 pts planned in Germany. Pts ≥18 years old with metastatic NSCLC are eligible if they began first-line NIVO + IPI with 2 cycles of chemo according to the approved EMA label. During the planned ≤5-year follow-up period (from treatment [tx] initiation until death, withdrawal of consent, loss of follow-up, or end of study), assessments will be conducted per routine local clinical practice. The primary

endpoint is OS. Secondary endpoints include progression-free survival, tx duration, patient characteristics, and safety.

Results: At the interim analysis (Jan 31, 2023), 256 pts were enrolled (median follow-up duration: 5.6 months). Median (range) age was 67 (43–86) years and 60.9% were male. Other patient characteristics are presented (Table). Tx-related adverse events (AEs) of all grades occurred in 53.9% of pts, and tx-related severe AEs occurred in 17.6% of pts. There was 1 tx-related death from immune-mediated hepatitis. We will present an update of the data with longer follow-up (data cutoff July 2023).

Table: 1448P Patient characteristics* (N = 256), n (%) unless noted

Age group, years <66 66–75 >75	120 (46.9) 102 (39.8) 33 (12.9)
Smoking status Current Former Never	98 (38.3) 111 (43.4) 28 (10.9)
Eastern Cooperative Oncology Group performance status 0 1 2 3	74 (28.9) 142 (55.5) 26 (10.2) 5 (2.0)
Number of metastases, median (range)	2 (0–12)
Histology Squamous Non-squamous	89 (34.8) 163 (63.7)
Metastasis stage M1a (contralateral lung) M1b/M1c (extrathoracic metastasis)	39 (15.2) 173 (67.6)
Metastasis site Brain Liver	51 (19.9) 49 (19.1)
Radiotherapy No/yes	204 (79.7)/48 (18.8)
Surgery No/yes	208 (81.2)/44 (17.2)
Systemic therapy/chemo No/yes/unknown	217 (84.8)/33 (12.9)/2 (0.8)

*Excludes missing data.

Conclusions: The FINN study will describe patient characteristics, efficacy, safety profile, and tx patterns of first-line NIVO + IPI with 2 cycles of chemo in clinical practice in Germany. At interim analysis, pts had a manageable safety profile.

Clinical trial identification: NCT04794010.

Background: KN046 is a novel bispecific domain antibody, which blocks both PD-L1 and CTLA-4. KN046 combined with platinum-based chemotherapy as 1L treatment for NSCLC had shown promising efficacy and tolerability in the previous clinical trial. (2022 ESMO 1029P). Herein, we present the promising preliminary data of KN046 combination with axitinib as 1L treatment for NSCLC.

Methods: Eligible subjects with recurrent/metastatic NSCLC, treatment-naive and PD-L1 expression ≥1% will be enrolled and receive KN046 5mg/kg IV Q3W and axitinib 5mg orally bid. This study adopts a Simon's optimal two-stage design. In the 1st stage, 17 subjects will be enrolled, and the 2nd stage enrollment will be discontinued if objective response (CR or PR) observed in less than 5 subjects. Otherwise, 37 subjects will be enrolled in the 2nd stage. The primary endpoint is ORR. The secondary endpoints include DoR, safety, PFS and OS.

Results: As of data cut-off date (Mar 17, 2023), 22 subjects were enrolled, the median age was 64.5y (min:37, max:73), 90.9% were male. ECOG score was 0 (4.5%) and 1 (95.5%). PD-L1 expression was ≥50% in 22.7% of the subjects. 15 subjects completed at least one tumor assessment. In the efficacy analysis set, the ORR was 66.7% (10/15). The median follow-up for DoR was 4.21 m (95% CI,1.22, NE). The 3-m DoR rate was 100% (95% CI, 100.00, 100.00). The median study follow-up was 2.83 m (95% CI,0.72, 5.12). The 6-m PFS rate was 76.6 % (95% CI, 41.16, 92.28), The mPFS and mOS was not reached. The incidence of TEAE was 81.8% (18/22), of which KN046-related TRAE was 63.6% (14/22). Majority was grade 1-2. The incidence of KN046-related CTCAE Grade ≥3 TRAE was 9.1% (2/22). The most frequent TRAE was AST increased 9.1% (2/22) and ALT increased 4.5% (1/22). The incidence of irAE was 13.6% (3/22), No CTCAE Grade ≥3 irAE was found. There was no KN046-related death.

Conclusions: KN046 combined with axitinib is well tolerated and has shown very promising efficacy and safety signal in 1L treatment for advanced NSCLC. The 2nd stage of enrollment is ongoing and a phase 3 RCT is planned to further confirm the clinical benefit of KN046 and axitinb combo as a viable chemo free option for the 1st line NSCLC patient.

Clinical trial identification: NCT05420220.

1450P Addition of bevacizumab to first-line chemoimmunotherapy in NSCLC with liver metastases

M. Roulleaux Dugage[1], M. Tagliamento[2], T. Gorria[3], A. Rochand[1], L-M. Garcin[1], S. Oudard[1], C. Thibault[1], V.M. Albarran Artahona[3], J.C. Laguna Montes[3], I. Nalda Ariza[4], F.J. Muñoz i Carrillo[3], L. Aguilar[4], A. Arcocha[3], L. Lupinacci[5], C. Teixido[6], B. Besse[7], L. Mezquita[3], E. Auclin[8]

[1]Medical Oncology Department, HEGP - Hopital Europeen Georges-Pompidou - AP-HP, Paris, France; [2]Department of Medical Oncology, Gustave Roussy - Cancer Campus, Villejuif, France; [3]Medical Oncology Department, Hospital Clinic of Barcelona, Barcelona, Spain; [4]Departamento de Oncología Médica, IDIBAPS - Fundació de Recerca Clinic Barcelona - Institut d'Investigacions Biomediques August Pi i Sunyer, Barcelona, Spain; [5]Clinical Oncology Department, Hospital Italiano de Buenos Aires, Buenos Aires, Argentina; [6]Pathology Department, Hospital Clinic of Barcelona, Barcelona, Spain; [7]Cancer Medicine Department, Institut Gustave Roussy, Villejuif, France; [8]Oncology Dept., HEGP - Hopital Europeen Georges-Pompidou - AP-HP, Paris, France

Background: Liver metastases create a unique immunosuppressive microenvironment in patients with advanced non-small cell lung cancer (aNSCLC) and are associated with poorer outcomes when treated with chemoimmunotherapy, especially in non-squamous (ns-) aNSCLC.

Methods: We retrospectively analyzed data from IMpower150 and IMpower130, which included patients with ns-aNSCLC without EGFR/ALK/KRAS alterations, treated with first-line chemotherapy (CT) with/out atezolizumab (CT+IT) and/or bevacizumab (CT+IT+AA, CT+AA). Data was available on the VIVLI platform.

Results: Out of the 1,523 evaluable patients, 20.4% (n=311), 46.4% (n=707), 19.7% (n=300), and 13.4% (n=205) received CT+IT+AA, CT+IT, CT+AA, and CT, respectively. 13.9% (n=212) of the patients had liver metastases (LM). LM were associated with lower serum albumin and higher lactate dehydrogenase levels, a greater number of metastatic sites (all $p<0.001$) and poor outcomes across all treatment regimens except for patients treated with upfront CT+IT+AA (Table). In the overall population, CT+IT+AA achieved longer progression-free survival (HR for PFS: 0.74, $p<0.001$) but not overall survival (HR for OS: 0.91, $p=0.38$) compared to CT+IT. Of all included variables (age, smoking status, Lung Immune Prognostic Index (LIPI), albumin levels, ECOG performance status, and number of metastatic sites), only LM+ patients yielded substantial OS benefit of CT+IT+AA vs. CT+IT (HR for PFS: 0.44, $p<0.001$; HR for OS: 0.43, $p=0.002$, Table). No benefit of CT+AA over CT in patients with/out LM was observed.

Table: 1450P Impact of liver metastases on PFS and OS across all regimens and on response to CT+IT +/- AA

Impact of LM across regimens					
Regimen		**HR for OS (LM+ vs. LM-)**		**p-value**	
CT		1.8 (1.1-2.9)		0.02	
CT+AA		2.2 (1.5-3.3)		<0.001	
CT+IT		2.5 (1.9-3.2)		<0.001	
CT+IT+AA		1.0 (0.6-1.7)		0.94	
Addition of bevacizumab to CT+IT					
		Overall		**LM+ patients**	
		CT+IT	**CT+IT+AA**	**CT+IT**	**CT+IT+AA**
PFS	**n**	707	311	103	39
	Events	548	210	90	27
	mPFS	6.8 (6.0-7.1)	8.3 (7.7-9.9)	4.4 (3.9-5.4)	8.0 (5.7-13.4)
	6M-PFS	53.4%	67.0%	28.4%	58.3%
	p	<0.001		<0.001	
OS	**n**	707	311	103	39
	Events	336	128	74	16
	mOS	18.6 (16.3-20.5)	19.2 (16.8-NR)	8.7 (6.5-11.2)	16.8 (12.9-NA)
	12M-OS	63.6%	67.5%	36.7%	65.5%
	p	0.35		0.002	

Conclusions: LM are associated with poor outcomes in patients with aNSCLC treated with CT, CT+AA and CT+IT but not CT+IT+AA. The addition of bevacizumab to CT+IT improves outcomes (PFS and OS) in patients with liver metastases and helps correct its negative prognostic impact. The presence of liver metastasis may help in guiding treatment selection in first-line aNSCLC.

1451P Identifying long-term responders to immune checkpoint blockade: Potential utility of serum proteomic profiling in metastatic non-small cell lung cancer

R. Bach Mora[1], P. Rocha[1], L. Masfarre Pinto[1], N. Navarro Gorro[1], A. Rossell[1], S. Gonzalez[2], X. Villanova[1], M. Giner[3], I. Sánchez[3], M.A. Galindo Campos[2], R. Del Rey-Vergara[2], A. Iñañez[2], A. Taus Garcia[1], L. Moliner[4], M. Hardy-Werbin[1], S. Clave[3], B. Bellosillo Paricio[3], A. Rovira[2], J. Perera-Bel[5], E. Arriola[1]

[1]Medical Oncology Department, Hospital del Mar-CIBERONC, Barcelona, Spain; [2]Cancer Research Program, IMIM (Instituto Hospital del Mar de Investigaciones Médicas), Barcelona, Spain; [3]Pathology Department, Hospital del Mar, Barcelona, Spain; [4]Medical Oncology, ICO - Institut Català d'Oncologia - Hospital Duran i Reynals, L'Hospitalet de Llobregat, Spain; [5]MARGenomics, IMIM (Instituto Hospital del Mar de Investigaciones Médicas), Barcelona, Spain

Background: Immune checkpoint blockade (ICB) has significantly impacted the treatment landscape in non-small cell lung cancer (NSCLC). However, this benefit is restricted to a subset of patients. While these results are encouraging, it is crucial to identify those patients who benefit the most from ICB and those who are refractory. Here we investigate the potential utility of longitudinal serum proteomic profiling to identify predictive biomarkers.

Methods: We included 40 metastatic NSCLC patients who received ICB treatment at Hospital del Mar, Barcelona between 2017-2021. Patients were categorized as long-term responders (LTR, n=20) if they had maintained radiologic response for more than 2 years or non-responders (NR, n=20) if they had disease progression at first radiological evaluation. Serum protein levels were assessed longitudinally (before treatment, previous cycle 2) using the Olink® Explore 384 Oncology panel.

Results: LTR had a greater proportion of high PD-L1 expression (p=0.01). Analysis of baseline serum samples showed an increase in LTR of proteins levels related to apoptosis and autophagy (CASP8, ATG4A), TCR signaling pathway (STAT5B, CRACR2A) and myeloid differentiation (ZBTB16, ARG1) ($p<0.05$ for all proteins). Higher levels of proteins related to immunosuppression and tumorigenesis (PDCD1, TGFBR2, KLK4, KLK6) prior to the second cycle of ICB were associated with poorer response to ICB, with non-responders exhibiting significantly higher levels ($p<0.05$ for all). Gene set enrichment analysis showed that LTR had an increase in myeloid cell differentiation process, while higher levels of immunoregulatory interactions between lymphoid and non-lymphoid cells were observed in NR ($p<0.001$ for all).

Conclusions: Our findings suggest that patients with high levels of proteins related to apoptosis, autophagy, TCR signaling, and myeloid differentiation at baseline may identify LTR to ICB. Our study underscores the potential use of baseline and longitudinal assessment of serum proteomics as valuable tools for patient selection who are suitable candidates for ICB. Further studies are needed to validate these findings and establish their potential clinical utility.

1452P Factors associated with real-world (rw) outcomes among pts with metastatic NSCLC (mNSCLC) receiving select immuno-oncology (IO) regimens: CORRELATE

S.V. Liu[1], R.J-B. Salomonsen[2], I. Diaz Perez[3], A. Wang[2], L. Cai[4], J. Schmidt[5], S. Sadow[6], S. Peters[7]

[1]Medical Oncology Department, Georgetown University, Washington, DC, USA; [2]Oncology Outcomes Research, AstraZeneca, Gaithersburg, MD, USA; [3]Global Medical Affairs / Oncology Business Unit, AstraZeneca, Gaithersburg, MD, USA; [4]Oncology Biometrics, AstraZeneca, Gaithersburg, MD, USA; [5]Oncology Biometrics, AstraZeneca, Cambridge, UK; [6]Vaccines & Immunology Biometrics, AstraZeneca, Gaithersburg, MD, USA; [7]Oncology Department, Centre Hospitalier Universitaire Vaudois, Lausanne University, Lausanne, Switzerland

Background: PD-(L)1 inhibitors ± chemotherapy (CTx) have demonstrated significant survival benefit vs CTx in randomised controlled trials (RCTs) in mNSCLC. However, subgroups that may benefit less from current standard of care regimens have emerged, such as those with mutations (m) in *STK11*, *KEAP1* and *KRAS*. One aim of CORRELATE was to determine factors associated with OS and rwPFS in pts receiving 1L IO treatment (tx).

Methods: This analysis included pts from the US Flatiron Clinico-Genomic Database who had mNSCLC (progressed or *de novo*), started 1L IO tx between 1 Nov 2016 and 31 May 2021, and met eligibility criteria based on 4 RCTs for tx with a US approval in mNSCLC (KEYNOTE [KN]-024 [n=95], KN-189 [n=462], KN-407 [n=122] and

IMpower150 [n=4]). Association of pt characteristics and select 2-way interactions with OS and rwPFS were explored. Those variables that were statistically significant ($p<0.05$) were included in multivariate Cox regression models along with *STK11*, *KEAP1*, *KRAS* and PD-L1 status.

Results: Of 683 pts, 65% were aged ≥65 y, 88% white and 54% male. 21% had PD-L1 ≥50% and 34% had PD-L1 ≥1% (53% unknown PD-L1); 80% had ECOG performance status (PS) 0/1 and 90% were former/current smokers. 15%, 13% and 31% had *STK11*m, *KEAP1*m and *KRAS*m tumours, respectively. Median OS was 15.2 mo (95% CI 13.5−17.6); median rwPFS was 6.0 mo (5.6−6.8). Multivariate Cox regression showed male sex (p=0.021), lower PD-L1 expression (p=0.030), higher PS ($p<0.0001$) and multiple baseline mets ($p<0.0001$) were associated with higher risk of death; and lower PD-L1 expression (p=0.049), higher PS ($p<0.0001$) and multiple baseline mets ($p<0.0001$), with higher risk of progression/death. Pts with *STK11*m had a higher risk of death (HR 1.52 [95% CI 1.17−1.97]; p=0.002) and progression/death (1.54 [1.22−1.94]; $p<0.0001$). Pts with *KRAS*m had an increased risk of death vs *KRAS* wild-type; this effect was greater among non-smokers (HR 2.66 [1.33−5.35]); p=0.006).

Conclusions: In pts with mNSCLC receiving 1L IO tx at primarily community US practices, *STK11*m was associated with worse OS and rwPFS. Smoking history modified the effect of *KRAS*m on OS. These hard-to-treat populations may require novel combination tx approaches to overcome resistance.

1453P Trends in treatment regimens and survival in the use of immune checkpoint inhibitors for lung cancer treatment in the Netherlands from 2016-2020

E. Suazo Zepeda[1], M.A. Heuvelmans[1], M.J. Aarts[2], W.J. Maas[1], P.C. Vinke[1], J.T.J.N. Hiltermann[3], G.H. de Bock[1]

[1]Epidemiology, UMCG - University Medical Center Groningen, Groningen, Netherlands; [2]Department of Research and Development, IKNL - Netherlands Comprehensive Cancer Organisation, Utrecht, Netherlands; [3]Pulmonary Medicine, Aa11, UMCG - University Medical Center Groningen, Groningen, Netherlands

Background: Immune checkpoint inhibitors (ICIs) have revolutionized lung cancer (LC) treatment. This study aims to describe the trends of ICI in LC treatment.

Methods: We evaluated treatment regimens and clinical outcomes in the use of ICIs for LC in the Netherlands from 2016-2020 using data from the Netherlands Cancer Registry (NCR) on first-line treatments, and performed a secondary analysis using a local cohort within the University Medical Center Groningen (UMCG) containing all-line treatments. Between 2016-2018, the NCR contained mostly data from patients treated in randomized controlled trials (RCTs) as clinical guidelines advised ICIs only in later treatment lines, whilst NCR data from 2018-2020 and from the UMCG from 2016-2020 were mainly collected outside RCTs. Descriptive statistics and annual percentage change (APC) were used to evaluate changes over time. Also, a survival analysis was performed.

Results: The proportion of first-line ICIs in LC treatment increased from 1.1% in 2016 to 54.9% in 2020 in the Netherlands (6816 patients in total, APC=14.5%, p=0.002). In the UMCG, increases were observed in the proportion of any-line ICI-chemotherapy combination (APC=12.4%, p=0.049), patients surviving ≥1 year (APC=5.8%, $p<0.001$), and partial response as best overall treatment response (APC=9%, p=0.049), whilst NCR data showed no significant changes over the years. NCR median overall survival (OS) was higher in the period 2016-2018 compared to 2019-2020 (83.4 vs 72.7 weeks, $p=<0.001$), whilst in the UMCG, 2016-2018 showed a lower median OS compared to 2019-2020 (39.3 [95%CI 32.9-48.6] vs 72.4 weeks [95%CI 52.7-87.4]).

Conclusions: The use of ICIs for LC treatment in the Netherlands increased over the years. Survival data showed better response in the use of ICI as any-line treatment in the UMCG from 2019-2020, contrary to data from patients in the NCR. An explanation for this is the inclusion of mainly RCT patients in the NCR data during the early years of ICI use and the recent shift from second to first-line treatment. As new ICI based drugs emerge, updated analyses will be needed using real-world data to evaluate the real benefits of these newly developed treatments.

1454P Radiomic analysis predicts response to immunotherapy in metastastic non-small cell lung cancer (mNSCLC): Preliminary results

S. Grisanti[1], M. Ravanelli[2], E. Fassi[1], P. Ciolli[2], A. Monti[2], P. Scolari[1], M. Mandruzzato[1], S. Bianchi[1], G. Carola[1], A. Baggi[1], A. Esposito[1], M. Vezzoli[3], S. Calza[3], D. Farina[2], A. Berruti[1]

[1]Medical Oncology Dept., University of Brescia, Brescia, Italy; [2]Radiology, University of Brescia, Brescia, Italy; [3]Molecular and Translational Medicine, University of Brescia, Brescia, Italy

Background: Immunotherapy (IT) with single-agent immune-checkpoint inhibitors (ICI) is standard treatment in all comers mNSCLC patients (pts) with PD-L1 expression >50%. However, inter- and intratumoral heterogeneity of PD-L1 expression limits its predictive value. Radiomics has the potential to integrate imaging and biological data thus recapitulating tumor tissue heterogeneity. We used a machine learning approach to test computed tomography (CT) tumor radiomic features in terms of predictive value of immunotherapy response.

Methods: We retrospectively analyzed radiological and clinical data of 190 pts who received first-line immunotherapy with Pembrolizumab (P) for non-oncogene addicted mNSCLC with PDL1>50% treated at our Institution from 2017 to 2022. Baseline contrast-enhanced CT (CECT) imaging of the primary tumor was contoured to isolate a polygonal region of interest (ROI) enclosing the whole tumor volume and the peripheral tumor area (3mm thickness). After thresholding and filtration of images, radiomic analysis was conducted to isolate 107 radiomic features of mean grey level (GL) values within the ROIs. Median progression-free survival (PFS) was calculated from start of IT to first evidence of progression or death. A machine learning approach with cross-validation (Orange Data Mining Software) was applied to select the best radiomic features in terms of PFS predictive value.

Results: After pre-processing of CECT imaging, 78 eligible pts were finally included in the radiomic analysis. Median PFS was 5 months. In the whole series, 33% and 22% of pts were classified as hyper-responders (PFS>24 months) and hyper-progressive (PFS<1 month), respectively. PDL1 expression level (50-75% vs >75%) was not predictive of PFS at univariate analysis (3 vs 5 months, p 0.147). After machine learning selection with 10-fold cross validation, 30 out of total 107 radiomic features were extracted to best predict PFS (9 vs 2 months, $p<0.005$).

Conclusions: Preliminary results of this exploratory analysis indicate that as predictive PFS factors, radiomic features outperform common clinico-pathological factors including PD-L1 expression even at thresholds >75% and >90%. Validation of these results is warranted.

1455P Nivolumab (nivo) resumption in patients with advanced or metastatic non-small cell lung cancer (aNSCLC): Survival outcomes based on France and Germany real-world data (RWD)

M. Pérol[1], M. Sebastian[2], F. Barlesi[3], C. Schumann[4], D. Reynaud[5], D. Waldenberger[6], A. Lee[7], N. Varol[7], J.R. Penrod[8], F. Brellier[9]

Background: Nivo as monotherapy for the treatment of aNSCLC after prior chemotherapy (chemo) was approved by EMA in 2015 and has been used in clinical practice since. In this study, we describe RW survival outcomes of patients with aNSCLC who resumed nivo after interrupting an initial nivo treatment received as 2+ line-of-therapy (LOT).

Methods: This study leverages RWD collected in 2 prospective, non-interventional studies: EVIDENS (NCT03382496; France) and ENLARGE (NCT02910999; Germany) on patients with aNSCLC treated with nivo. Data were pooled and two cohorts were defined: 1) nivo resumption cohort (patients who re-started nivo after an interruption of $\geq$6 weeks) and 2) chemo cohort (patients who received chemo or other systemic anti-cancer therapy after nivo). Demographics and clinical characteristics were described, and overall survival (OS) was estimated using Kaplan-Meier methods from the start of the "index treatment" (LOT following the initial nivo treatment).

Results: Among 2,266 patients (1,397 from France and 869 from Germany), 210 (9.3%) resumed nivo after an initial interruption of $\geq$6 weeks. 697 (30.8%) started a chemo treatment after nivo, among which 171 - from the ENLARGE study - had data required for this analysis and constituted the chemo cohort. Median age was 67 (range: 41-89) in the nivo resumption cohort and 64 (21-83) in the chemo cohort. In both cohorts, majority of patients were male and received their index treatment as third LOT. Median OS was 19.6 months (mo) [95% CI: 16.2-25.2] for the nivo resumption cohort and 9.1 mo [7.1-10.0] for the chemo cohort. Nivo-resuming patients who had received an initial nivo treatment of $\geq$3 mo had a median OS of 22.8 mo, compared to 10.7 mo in patients with $<$3 mo initial nivo treatment. In the chemo cohort, patients with a duration of initial nivo therapy of $\geq$3 mo had a median OS of 9.9 mo in subsequent treatment, compared with 7.1 mo in patients with $<$3 mo of initial nivo treatment.

Conclusions: OS data show that patients with aNSCLC who interrupted their initial nivo treatment may benefit from resuming nivo, primarily when initial exposure to nivo lasted for more than three months.

1456P Exploring biological and molecular factors as outcome predictors for pembrolizumab (Pem) or pembrolizumab-chemotherapy (Pem-CT) in advanced non-small cell lung cancer (NSCLC)

L. Zullo[1], M. Aldea[1], F. Paoloni[2], A. Rosa[3], V. Fontana[3], E. Cella[4], D. Soldato[1], M. Gualtieri[2], M.P. Spotti[5], G. Barletta[4], C. Dellepiane[4], G. Rossi[4], E. Bennicelli[4], M-L. Meyer[1], C. Parisi[6], L. Del Mastro[7], D. Planchard[1], R. Berardi[2], B. Besse[1], C. Genova[8]

[1]Department of Medical Oncology, Institut Gustave Roussy, Villejuif, France; [2]Clinical Oncology, Università Politecnica delle Marche, Azienda Ospedaliero-Universitaria "Ospedali Riuniti di Ancona", Ancona, Italy; [3]Clinical Epidemiology Unit, IRCCS Ospedale Policlinico San Martino, Genoa, Italy; [4]Oncologia Medica 2, IRCCS Ospedale Policlinico San Martino, Genoa, Italy; [5]DIOPP Department, Institut Gustave Roussy, Villejuif, France; [6]Drug Development Department, Institut Gustave Roussy, Villejuif, France; [7]Clinica di Oncologia Medica, IRCCS Ospedale Policlinico San Martino, Genoa, Italy

Background: Pem and Pem-CT are first-line treatments for non-oncogene addicted NSCLC, but no validated predictors of benefit beyond PD-L1 are available. We explored the impact of biological or molecular factors on outcomes with Pem or Pem-CT.

Methods: We retrospectively collected data from patients (pts) treated with Pem or Pem-CT in three European centers. We categorized NLR and LDH into good, intermediate, and poor groups based on none, one, or both NLR$\geq$3 and LDH$>$upper limit of normal. Molecular profiles at baseline were obtained from tissue or blood samples, with varying techniques and panels among and within centers. We used multivariable Cox regression models to explore prognostic impact of NLR-LDH categories, differential efficacy of the treatments in the categories and in *KRAS*-mutant (mut) tumors. We adjusted for center and known prognostic factors (age, gender, PS ECOG, number of metastatic sites, brain and liver metastases), included if associated with progression free survival (PFS) and/or overall survival (OS) with a $p<0.05$ in univariate Cox models.

Results: We included 440 pts, 224 treated with Pem and 216 with Pem-CT. Pem population was older ($p<0.0001$), but the groups were balanced for other prognostic factors. At a median (m) follow up of 16.3 and 12.9 months for Pem and Pem-CT group, mPFS and mOS were 7.6 and 15.9 months; 7.2 and 22.8 months, respectively. The combination of baseline NLR-LDH was prognostic for both Pem and Pem-CT (Table). No statistically significant difference between the treatments was seen in the subgroups. 159 (36%) tumors were *KRAS*-mut. In *KRAS*-mut tumors no difference was seen between the two treatments neither in PFS ($p=0.55$) nor OS ($p=0.79$).

Table: 1456P

	OS			PFS		
	HR	95%CI	*p*	HR	95%CI	*p*
NLR-LDH			<0.001			<0.001
Good	1,00	Ref		1,00	Ref	
Intermediate	1,63	1.04-2.57		1,93	1.33-2.80	
Poor	2,79	1.75-4.44		2,42	1.63-3.60	

Conclusions: Combining baseline NLR and LDH provides a prognostic stratification, regardless of the addition of CT to Pem as first-line treatment. No difference between the two strategies was seen in the *KRAS*-mut tumors.

Background: Oligometastatic (OMD) non-small cell lung cancer (NSCLC) is a distinct but heterogeneous entity. Current guidelines recommend locally ablative therapy if technically feasible. Still, evidence is lacking to guide the choice of optimal multimodal treatment approaches and their impact on clinical endpoints.

Methods: Electronic medical records and clinical databases (years 2004 – 2022) from two major German comprehensive cancer centers were searched for cases with OMD NSCLC and treatment patterns. Prespecified OMD criteria included presence of $\leq$5 metastases in $\leq$2 organ systems, excluding primary tumor and mediastinal lymph nodes. Endpoints of this retrospective analysis were overall survival (OS), disease-free survival (DFS, first-line therapy until recurrence) and time-to-treatment failure (TTF).

Results: A total of 207 patients with OMD NSCLC were identified (46.9% female; median age 60.8; median follow-up 32 months; T1-2 vs. T3-4 51%/49%, N0-1 vs. N2-3 48%/52%, M1a 10.7%, metastases in one organ system 89.7% vs. multiple 10.3%). A dedicated OMD treatment strategy was explicitly specified in 164 patients (79.2%). Locally ablative therapy was applied to all tumor sites in 140 patients (67.6%), including radiotherapy (85%) and/or surgery (73.6%). Median OS of the full analysis cohort was 27.7 months, with 27.2% OS at 5 years. Median OS in patients receiving locally ablative therapy to all NSCLC sites amounted to 33.4 months (5y rate 35.7%) with a median DFS of 10.6 months (11.2% at 5y). First-line therapy included systemic therapy in 167 patients (80.7%), which was associated with doubling of DFS (median 12.2 vs. 6.0 months, $p<0.001$), and a trend towards improved OS. First-line chemoimmunotherapy was only approved in 2018/2019, thus limiting follow-up in this subgroup. Nevertheless, DFS (HR 0.5, $p=0.025$, 2y rate 46% vs. 15%) and TTF (HR 0.45, $p<0.001$) were greatly improved with first-line chemoimmunotherapy vs. chemotherapy.

Conclusions: Patients with OMD NSCLC benefit from multimodality approaches integrating systemic therapy and local ablation of all cancer sites. Although true freedom from recurrence is rare, extended OS can be achieved in a substantial fraction of patients.

1458P Pucotenlimab (HX008) - humanized anti-PD-1 monoclonal antibody plus pemetrexed and platinum as first-line treatment for advanced non-squamous non-small-cell lung cancer (nsqNSCLC): A single-arm multicenter phase II study

C. Zhou[1], L. Wang[2], Y. Yu[3], L. Cao[4], J. Fang[5], X. Li[6], Y. Ge[7], B. Cao[8], X. Chen[9], P. Pan[10], L. Wu[11]

[1]Department of Medical Oncology, Shanghai Pulmonary Hospital, Shanghai, China; [2]Department of Oncology, Shanghai Pulmonary Hospital, Shanghai, China; [3]Department of Medical Oncology, Harbin Medical University Cancer Hospital, Harbin, China; [4]Department of Respiratory Medicine, Anhui Provincial Hospital, Hefei, China; [5]Second Department of Thoracic Oncology, Beijing Cancer Hospital, Beijing, China; [6]Department of Thoracic Surgery, Liaoning Cancer Hospital & Institute, Shenyang, China; [7]Department of Oncology, Beijing Chao-Yang Hospital, Beijing, China; [8]Department of Oncology, Peking University Third Hospital, Beijing, China; [9]Department of Oncology, Hangzhou Cancer Hospital, Hangzhou, China; [10]Department of Respiratory Medicine, Xiangya Hospital of Central South University, Changsha, China; [11]Department of Thoracic Medical Oncology, Hunan Cancer Hospital, Changsha, China

Background: Pucotenlimab is a novel anti-PD-1 IgG4 monoclonal antibody. Several clinical trials conducted in China have demonstrated its efficacy and safety in various solid tumors including gastric cancer and breast cancer. Here we report a phase II study result of pucotenlimab for nsq-NSCLC without EGFR/ALK mutations.

Methods: In this open-label phase II study, patients naive to systemic treatment were enrolled with histologically diagnosed stage IIIB or IV nsq-NSCLC. Patients were received intravenous Pucotenlimab 200mg Q3w for up to 35 cycles, combined with platinum + pemetrexed Q3W for 4 cycles and followed by maintenance pemetrexed Q3W (all intravenous). The primary endpoint was overall response rate (ORR) and safety, and the secondary endpoints were progression-free survival (PFS), duration of response (DOR) and overall survival (OS).

Results: From September 25th, 2020 to April 15th, 2021, a total of 43 patients were enrolled and followed up with a median of 13.1 months by the cut-off date (August 3th, 2022). 22 patients achieved partial response and 20 remained stable disease, respectively, contributing an ORR of 48.8% (95%CI: 38.9%, 59.2%) and a DCR of 95.3% (95%CI: 88.7%, 98.4%). The median PFS, DOR were 11.1 months (95%CI: 6.8, 14.4) and 13.9 (95%CI: 6.6, NE) months, respectively. The median OS was not reached. The common treatment-related adverse events (TRAEs) of any grade included anemia (79.1%), neutrophil count decreased (72.1%), white blood cell count decreased (67.4%) and platelet count decrease (53.5%). Neutrophil count decreased (32.6%) was the most reported grade 3/4 TRAE.

Conclusions: Pucotenlimab combined with pemetrexed plus platinum demonstrated promising efficacy and safety for the 1st line nsq-NSCLC patients without EGFR/ALK mutations.

Clinical trial identification: NCT04750083.

1459P Preliminary efficacy and safety of KN046 (a bispecific anti-PD-L1/CTLA-4) in patients with metastatic non-small cell lung cancer who previously treated with immune checkpoint inhibitor(s)

C. Zhou[1], A. Xiong[1], X. Li[2], Y. Fan[3], W. Zhuang[4], Q. Yu[5], T. Xu[6], M. Xu[6], Q. Liu[6], N. Wang[6], X. Yan[6]

[1]Department of Medical Oncology, Shanghai Pulmonary Hospital, Shanghai, China; [2]Oncology Department, The First Affiliated Hospital of Zhengzhou University, Zhengzhou, Henan, China; [3]Oncology, Zhejiang Cancer Hospital - Cancer Research Institute, Hangzhou, China; [4]Respiratory Medicine, Fujian Provincial Cancer Hospital, Fuzhou, Fujian, China; [5]Oncology, Guangxi Medical University Affiliated Tumor Hospital, Nanning, China; [6]Medical Department, Jiangsu Alphamab Biopharmaceuticals Co., Ltd., Suzhou, China

Background: KN046 is a novel bispecific antibody that inhibits both PD-L1/PD1 and CTLA-4/CD80/CD86 pathways. Previous phase I (KN046-CHN-001, NCT03733951) and phase II (KN046-201, NCT03838848) trials showed promising anti-tumor effects of KN046 in non-small cell lung cancer (NSCLC) patients who had failed prior immune checkpoint inhibitor(s) (ICIs) therapy. We present the efficacy and safety outcomes of KN046 in this population from KN046-CHN-001 and Cohort C of KN046-201.

Methods: KN046-CHN-001 and KN046-201 assessed the efficacy, safety and tolerability of KN046 in NSCLC. Eligible patients had NSCLC that progressed after ICI(s) and platinum-based chemotherapy. Patients with EGFR mutation and/or ALK translocation were excluded. All patients received KN046 (26 at 5 mg/kg Q2W, 2 at 5 mg/kg Q3W, 2 at 300mg Q3W and 1 at 3 mg/kg Q2W) by IV infusion. The primary endpoints were confirmed ORR by RECIST version 1.1 (KN046-201) and safety (KN046-CHN-001).

Results: Between April 19, 2019 and July 13, 2020, 31 pts with metastatic NSCLC who failed ICI(s) and platinum-based chemotherapy were enrolled. At the data cutoff of July 30, 2022 for KN046-201 and August 31, 2021 for KN046-CHN-001, the median follow-up was 25.0months (95% CI, 24.4, NE). Among all 31 pts, the ORR was 3.2% (1/31, 95% CI, 0.1, 16.7%), disease control rate (DCR) was 38.7% (12/31, 95% CI, 21.8, 57.8%), clinical benefit rate (CBR) was16.1% (5/31, 95% CI, 5.5, 33.7%). Median progression-free survival (mPFS) was 2.8 months (95% CI, 1.8, 3.7) and median overall survival (mOS) was 13.3 months (95% CI, 6.5, 17.5). 7(22.6%) out of the 31 subjects had experienced treatment-related adverse event (TRAE) at grade 3 or higher levels. Commonly reported TRAEs of grade 3 or higher were anemia (9.7%), febrile neutropenia (3.2%), fatigue (3.2%).

Conclusions: KN046 was well tolerated and demonstrated encouraging OS benefit in NSCLC patients who had failed prior ICI(s) therapy. Further study is warranted to confirm the clinical results.

Clinical trial identification: KN046-201, NCT 03838848; KN046-CHN-001, NCT03733951.

Background: Gal-3 expression in tumours is associated with resistance to checkpoint inhibitors (CPIs). In a preclinical study, Gal-3 inhibitor GB1211 restored CPI-binding to their targets in the presence of Gal-3 (Mabbitt et al. J Clin Oncol 2022), and enhanced CPI effects in NSCLC mouse models (Vuong et al. Cancer Res. 2019). The GALLANT-1 study (NCT05240131) will assess whether GB1211 + atz (a CPI) increases anti-tumour effects in pts with NSCLC.

Methods: GALLANT-1 is a phase IB/IIA study of first line GB1211 + atz in pts with advanced/metastatic NSCLC. Part A is an open-label dose confirmation study of GB1211 200 mg or 100 mg twice daily (BID) + atz 1200 mg every 3 weeks; Part B is a 12-week, randomized double-blind study of the safety and efficacy of the GB1211 dose from Part A + atz vs placebo + atz. Following Part B, pts will continue into an open-label extension study until disease progression or unacceptable toxicity occur. Here we report data from the ongoing Part A.

Results: In the 200 mg cohort (n = 7), all pts had an adverse event (AE); most were mild (Grade [Gr] 1−2) and no serious AEs were deemed related to GB1211 alone. After 2 weeks of therapy, 2 severe (Gr 3−4) autoimmune skin rashes were observed: pemphigus deemed related to atz, and perivascular lymphocytic infiltration deemed related to GB1211 + atz; both responded to steroids. As per protocol, it was recommended that the study continue but with a reduced dose (100 mg BID) in new pts (n = 2); 9 AEs (all Gr 1−2) were reported in these 2 pts. Two partial responses, as assessed by investigators, have been seen: 1 confirmed (100 mg cohort; Week 6; time on therapy: 14 weeks) and 1 awaiting confirmation (200 mg cohort; Week 18; time on therapy: 23 weeks). Steady-state plasma exposure at 200 mg was consistent with pharmacokinetic (PK) simulations, predicting a 2-fold increase compared with healthy volunteers at 100 mg. GB1211 PK did not seem altered in pts with NSCLC vs healthy volunteers.

Conclusions: This is the first clinical study to show that combining GB1211 with atz may enhance the CPI effect. As the AEs have been manageable, Part A will continue with the 100 mg GB1211 dose to confirm the selected dose for Part B.

1461P Predictive value of residual FDG-PET metabolic activity in metastatic non-small cell lung cancer (mNSCLC) patients (pts) with long-lasting response to immune checkpoint inhibitors (ICIs)

A-C. Toublanc[1], A. Crombe[2], R. Veillon[3], C. Domblides[4], M. Cabart[5], F. Chomy[6], M. Zysman[3], S. Cousin[1]

[1]Medical Oncology, Institut Bergonié, Bordeaux, France; [2]Radiology Department, Bordeaux University Hospital, Bordeaux, France; [3]Onco-Pneumology, Hopital de Haut Leveque, Pessac, France; [4]Medical Oncology Department, CHU Bordeaux - Hopital St. André, Bordeaux, France; [5]Oncologie Médicale, Institute Bergonié - Centre Régional de Lutte Contre le Cancer (CLCC), Bordeaux, France; [6]Gironde, Institute Bergonié - Centre Régional de Lutte Contre le Cancer (CLCC), Bordeaux, France

Background: The optimal duration of ICIs treatment in mNSCLC is debated, arbitrarily fixed to 2 years in the 1st line setting. Unfortunately, pts will mostly relapse months or years after the end of the treatment (EOT). Physicians tend to confirm the partial or complete obtained response before stopping it, by performing ^{18}F-FDG -PET (PET). However, the interpretation of residual fixative areas remains unclear.

Methods: This is a bi-center retrospective study of mNCSLC pts who completed 2 years of ICI, or stopped it due to adverse event without progression and underwent a PET at the EOT. Collected data were: age, smoking status, PDL1 and KRAS status, type and line of treatment, ICI duration.

Results: We enrolled 80 pts who began ICIs between Sept. 2016 and Nov. 2021. Median follow up was 35.9 months. Median age was 61 years (range: 56-69), sex ratio was 1:1, 93.5% were current/former smokers, 87.5% had adenocarcinoma, 54% had PDL1>50%. ICI was given as monotherapy and as first line in 41% and 67.5% of pts respectively. Molecular analysis revealed KRAS G12C mutation in 29% pts. Median ICIs duration was 23.4 months (range: 3-48), 55 pts completed 2 years of ICI, 22 discontinued due to toxicity, 3 for others reasons. The 2-year progression-free survival (PFS) probability was 96% (range:92-100). Median SUVmax was 1.9 (range: 0-17). 55% pts had PET residual fixation (RF): 36% on initial lung tumor, 15% on mediastinal lymph nodes and 5% on extrathoracic sites. 6 pts underwent an excision surgery or a biopsy of a RF: 4 were immune-mediated inflammatory reactions, 2 found the initial histology. 6 pts were locally treated for RF by radiotherapy or surgery. Of the 17 pts who relapsed: 12 had a RF on the PET after ICIs. Conversely, 5/36 pts (14%) without RF relapsed. The presence of a RF was not associated with the PFS in univariable analysis (HR=2.4, 95%CI: 0.8-6.9, P=.121) and after adjusting for duration and type of ICI treatment (HR=1.4, 95%CI: 0.5-4.3, P=.539).

Conclusions: Positive 18F-FDG-PET/CT is not associated with relapse after completion of ICI treatment but has good negative predictive value. Treatment of oligopersistence after partial response to ICI based on PET-scan remains controversial.

1463P IL-6 triggers chemoimmunotherapy resistance by creating immunosuppressive tumor microenvironment in non-small cell lung cancer

Y. Yang[1], C. Liu[2], L. Yang[3], G. Yang[4], X. Hao[5], S. Zhang[6]

[1]Chinese Academy of Medical Sciences and Peking Union Medical College - National Cancer Center, Cancer Hospital, Beijing, China; [2]Thoracic Surgery, Chinese Academy of Medical Sciences and Peking Union Medical College - National Cancer Center, Cancer Hospital, Beijing, China; [3]Department of Medical Oncology and Radiation Sickness, Peking University Third Hospital, Beijing, China; [4]Department of Respiratory Medicine, Shandong Cancer Hospital and Institute, Shandong First Medical University and Shandong Academy of Medical Sciences, Jinan, China; [5]Department of Medical Oncology, Chinese Academy of Medical Sciences and Peking Union Medical College - National Cancer Center, Cancer Hospital, Beijing, China; [6]Department of Medical Oncology, National Cancer Center/National Clinical Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Bejing, China

Background: Chemotherapy in combination with anti-PD-1/PD-L1 antibodies (chemoimmunotherapy) has become the standard treatment for advanced non-small cell lung cancer (NSCLC). Our previous studies highlighted that low baseline concentrations of IL-6 in plasma specimens or tumor tissues responded better to anti-PD-1/PD-L1 immunotherapy alone. However, the role of baseline IL-6 levels in predicting responses to chemoimmunotherapy and the development of resistance to chemoimmunotherapy has not been fully understood yet.

Methods: To confirm the predictive value of IL-6 in the baseline plasma, we conducted an enzyme-linked immunosorbent assay (ELISA) in a group of 123 advanced NSCLC patients who received chemoimmunotherapy. Next, we evaluated the role of IL-6 in chemoimmunotherapy resistance and the underlying mechanisms in mouse models of both lung adenocarcinoma and lung squamous cell carcinoma.

Results: Based on our cohort of 123 NSCLC patients, we found that patients with progressive disease had a higher baseline level of IL-6 in their plasma. Additionally, the potential predictive value of the baseline level of IL-6 in plasma samples for responses was confirmed with area under curve (AUC) up to 0.677. Patients with a low baseline concentration of IL-6 also had a longer progression-free survival and overall survival, with a cut-off value of 7.002 obtained from receiver operating characteristic curve (ROC). Meanwhile, univariate and multivariate Cox regression analyses revealed that baseline IL-6 level in plasma samples was an independent prognostic predictor. Further experiments in mouse models showed that overexpression of IL-6 weakened the anti-tumor effects of immunotherapy in combination with chemotherapy. Immunohistochemical studies also revealed that $CD8^+$ T cells decreased while M2 macrophages, regulating T cells, and myeloid-derived suppressor cells infiltration increased in the IL-6 overexpressing group.

Conclusions: Our study highlights the potential of baseline IL-6 levels as a useful predictive biomarker for chemoimmunotherapy in NSCLC. IL-6 promotes an immunosuppressive tumor microenvironment, suggesting that targeting IL-6 could be a promising approach for cancer treatment.

1464P Impact of age on the benefit of immunotherapy for metastatic squamous cell lung cancer: An NCDB database analysis

Z. Hao

Department of Medicine, UK - University of Kentucky - Markey Cancer Center, Lexington, KY, USA

Background: Immunotherapy represents an alternative to chemotherapy and clinical trial for squamous cell lung cancer. Due to the underrepresentation of elderly patients in clinical trials, it is not clear whether they derive similar benefit from immunotherapy as their younger patients.

Methods: A retrospective analysis using National Cancer Database (NCDB) was conducted in patients diagnosed with metastatic squamous cell lung carcinoma between 2016 and 2019. Kaplan Meier survival plots were used to examine survival outcome of different age groups: 19-49, 50-79 and 80 and older. Each age group was examined for benefit from chemotherapy (CR), chemotherapy + immunotherapy (CI), immunotherapy (IO), and no treatment (NR). Cox regression analysis was used to identify factors associated with overall survival.

Results: Of the 24,111 patients analyzed, 3,072 were 80 years or older. Patient who received immunotherapy had much better overall survival than those without. The one-year and two- years overall survival in these groups are CI: 52.98%, 18.10%; IO: 46.85%, 16.34%; CR: 40.11%, 10.73% and NR: 11.13%, 3.81% respectively. Although overall survival declined with age, age itself was not responsible for the poor outcome coming with it. No significant interaction effect was found between age and treatment. In multivariate analysis, HR was 1.01; 0.91-1.11; P=0.862 in age 19-49 and HR 1.02; 0.98-1.06, P=0.397 in age 50-79 compared to age 80 year or older (HR 1.0). Different age groups benefited similarly to all treatments. Compared to CR only (HR 1.0), treatment with CI conferred the best survival outcome HR 0.73; 95% CI 0.71-0.76; $P<0.001$; IO comes in next with HR 0.84 95% CI 0.80-0.88; $P<0.001$ and NR performed the worst (HR 2.90; 95% CI 2.80-3.0; $P<0.001$), suggesting that differences in survival is related to factors other than age.

Conclusions: Although immune senescence is of concern in senior patients receiving immunotherapy, older patients with squamous cell lung cancer benefit from treatment with immune therapy and chemotherapy combination, immunotherapy, chemotherapy as much as younger patients. Age itself is not associated with immunotherapy inefficacy.

Background: Pembrolizumab monotherapy and immune checkpoint inhibitor plus chemotherapy (ICI/Chemo) have been approved as first-line treatment for non-small cell lung cancer (NSCLC) with programmed death ligand 1 tumor proportion score (PD-L1 TPS) ≥50%. However, the clear distinction between the two therapeutic options remains unclear. It was reported that using proton pump inhibitors (PPI) and antibiotics correlated with poorer treatment outcomes of ICI monotherapy for NSCLC.

Methods: We retrospectively enrolled consecutive PD-L1 TPS ≥50% advanced NSCLC patients who received pembrolizumab monotherapy or ICI/Chemo as first-line treatment. We analyzed the association between treatment outcome and patient characteristics, including concomitant drug history in each group. Comparing the treatment outcome, propensity score matching was used to reduce bias.

Results: The study included 425 patients, with 271 receiving pembrolizumab monotherapy and 154 receiving ICI/Chemo. According to the multivariate analysis, a history of PPI usage was independently associated with shorter progression-free survival (PFS) in pembrolizumab monotherapy group(hazard ratio (HR): 1.38, 95.0% CI: 1.00—1.91; P = 0.048), but not in ICI/Chemo group (HR: 0.83, 95.0% CI: 0.48—1.45; P = 0.515). In patients with a history of PPI, both the median PFS (19.3 months vs. 5.7 months, P=0.002) and the median overall survival (OS) (not reached vs. 18.4 months, P=0.025) were significantly longer in ICI/Chemo group than in pembrolizumab monotherapy group. In patients without a history of PPI, the median PFS (18.8 months vs. 10.6 months, P=0.259) and the median OS (not reached vs. 29.9 months, P=0.211) was not significantly different between each group.

Conclusions: History of PPI usage was negatively associated with treatment outcome of pembrolizumab monotherapy, but not ICI/Chemo in NSCLC patients with PD-L1 expression ≥50%. Our observations in real-world settings suggest that the history of PPI usage may be a predictive clinical factor to be considered in treatment decision-making in this population.

1466P Gut microbiota mediates the protective effects of postbiotics attenuating the immune-related adverse events in non-small-cell lung cancer patients: A randomized, controlled trial in Chongqing, China

H. Yu[1], M. Chen[2]

[1]Department of Geriatric Oncology and Department of Palliative Care, Chongqing Cancer Hospital, Chongqing, China; [2]Clinical Nutrition, Chongqing Cancer Hospital, Chongqing, China

Background: To evaluate the effects of JK5G postbiotics on regulating the imbalanced gut microbiota and its impacts on the efficacy and incidence rate of immune-related adverse events (irAEs) in non-small-cell lung cancer (NSCLC) patients treated with immune checkpoint inhibitors (ICIs).

Methods: We conducted a randomized, controlled trial in China and included non-squamous or squamous NSCLC patients without EGFR, ROS1, and ALK alteration, stage IIIb-IV. Patients were randomly (1:1) divided into two groups to receive four cycles of programmed cell death-1 (PD-1) plus chemotherapy plus placebo (control group) or to receive PD-1 plus chemotherapy plus JK5G postbiotics (JK5G group). The primary endpoint were adverse effects, quality of life (QoL), 16S DNA sequencing of gut microbiota, blood inflammatory cytokines, and lymphocyte subsets. This study was registered at www.chictr.org.cn (ChiCTR2200064690).

Results: 60 patients were enrolled. The JK5G group had better QoL and nutritional levels, as well as lower depression symptoms than the control group (all $p < 0.05$). The JK5G group had a lower incidence of anemia (55.56% vs. 11.11%, $p = 0.012$), decreased lymphocyte count (33.33% vs. 0%, $p = 0.019$), decreased appetite (55.56% vs. 16.67%, $p = 0.035$), nausea (55.56% vs. 11.11%, $p = 0.012$), and asthenia (50.00% vs. 11.11%, $p = 0.034$) than the control group. Moreover, JK5G attenuated intestinal flora imbalance, accompanied by increased Faecalibacterium, Ruminococcaceae, and fecal butyrate concentration. Furthermore, JK5G administration significantly decreased the pro-inflammatory markers, including TNF-α, IL-2, and C-reactive protein (CRP) ($p < 0.05$). Significant increases in CD3+CD4+ T cells and CD4/CD8 ratio were observed in the peripheral blood of JK5G group patients ($p < 0.05$).

Conclusions: Our current findings indicated that JK5G postbiotics may attenuated irAEs, enhanced the QoL and nutrition levels in advanced NSCLC patients who received ICIs. JK5G postbiotics could improve the gut microbiota structures and accompanied with the ameliorate of tumor microenvironment and inflammation.

Background: The combination of anti—PD-1/PD-L1 antibody and chemotherapy with or without anti-angiogenic agent has shown antitumor activity in NSCLC. This study aims to assess the efficacy and safety of envafolimab (anti- PD-L1 antibody) in combination with suvemcitug (anti-VEGF antibody) and chemotherapy as second-line or later therapy in patients(pts) with advanced NSCLC.

Methods: This was an open-label, multi-cohort, multicenter, phase II trial conducted in China. In Cohort C, NSCLC pts with at least one prior line of treatment were enrolled, stratified by the history of prior immunotherapy (IO). Envafolimab plus suvemcitug and docetaxel were administrated until disease progression or unacceptable toxicity. The primary endpoint was objective response rate (ORR) assessed by investigator review using RECIST v1.1. Secondary endpoints included progression-free survival (PFS), duration of overall response (DoR), disease control rate (DCR) and safety.

Results: As of March 31, 2023, there were 40 pts were enrolled in NSCLC cohort, including 20 IO treated NSCLC and 20 IO naïve NSCLC. 72.5% (29/40) pts were treated with one prior therapy and 27.5% (11/40) pts with EGFR/ALK / ROS1 alterations. For IO treated NSCLC, with a median follow-up time of 6.5 (4.6, 7.9) months, 18 pts have at least one assessment, the ORR and DCR were 27.8% (5/18) and 83.3% (15/18) respectively. The PFS was not reached (NR) (3.02-NR). Grade 3/4 TRAEs occurred in 13 pts (65.0%), most commonly occurred were neutrophil count decreased ($n = 8$; 40.0%) and leucopenia ($n = 6$; 30.0%). For IO naïve NSCLC, the median follow-up time was 6.3 (4.8, 7.1) months,17 pts have at least one assessment, 3 patients achieved partial response and the DCR was 82.4% (14/17). The PFS was NR (2.99-NR). Grade 3/4 TRAEs occurred in 15 pts (75%), most commonly occurred were neutrophil count decreased ($n = 12$; 60%) and leucopenia ($n = 11$; 55%). There was no grade 5 TRAE in either cohort.

Conclusions: This phase II clinical trial demonstrated antitumor activity and manageable safety profile of immunotherapy plus anti-angiogenic agent and chemotherapy in pts with NSCLC, who had failed at least one line of therapy.

1468P Patients' perspective on tolerability of dostarlimab in NSCLC: Patient-reported outcomes from the phase II PERLA trial

M. Reck[1], A.L.O. Ortega Granados[2], F. de Marinis[3], Q. Shen[4], S.H. Boklage[4], C. Dabrowski[5], L. Cho[6], O. Meyers[7]

[1]Department of Thoracic Oncology, Lungen Clinic, Airway Research Center North, Center for Lung Research, Grosshansdorf, Germany; [2]Medical Oncology Department, Hospital Universitario de Jaén, Jaen, Spain; [3]Division of Thoracic Oncology, Istituto Europeo di Oncologia (IRCCS), Milan, Italy; [4]Oncology Value Evidence and Outcomes, GSK, Collegeville, PA, USA; [5]Global Clinical Safety, GSK, Collegeville, PA, USA; [6]Global Medical Affairs, GSK, Collegeville, PA, USA; [7]Patient Centered Outcomes; Value, Evidence, and Outcomes, GSK, Collegeville, PA, USA

Background: In the phase II double-blind PERLA trial (NCT04581824), dostarlimab + chemotherapy (DCT) showed similar efficacy to pembrolizumab + CT (PCT) as first-line treatment (tx) for patients (pts) with metastatic non-oncogene-driven, non-squamous, non-small cell lung cancer (NSCLC); the proportion of pts experiencing tx-related adverse events (TRAEs) or AEs leading to tx discontinuation was similar between groups [1]. Exploratory analyses of pt-reported measures of tolerability were conducted.

Methods: Eligible pts with ECOG 0—1 were randomized 1:1 to receive ≤35 cycles (C) of DCT or PCT every 3 weeks (Q3W) (CT: ≤35 C of 500 mg/m^2 pemetrexed + ≤4 C of cisplatin or carboplatin). Patient-reported outcome version of CTCAE (PRO-CTCAE) and the tolerability item of FACT-G (FACT-GP5) were collected at Day 1 C1, then Q3W to Week 12, Q9W to Week 48, Q12W to end of tx, at end of tx, and 30-day safety follow-up.

Results: Completion rates for PRO-CTCAE (DCT N=96/PCT N=88) and FACT-GP5 (DCT N=95/PCT N=87) were >80% up to C4, then decreased in both tx arms. At baseline (BL), only the urinate frequently item had >10% of pts reporting occurrence as "frequently" or greater per PRO-CTCAE (DCT: 11.5% [n=11/96]; PCT: 10.2% [n=9/88]); "severe" or greater severity and "quite a bit" or greater interference responses were reported in <10% of pts. At C13 (∼1 yr of tx) urinate frequently was similar between arms ("frequently" or greater in DCT: 12.5% [n=4/32]; PCT: 10% [n=2/20]). Relative to BL, at C13 muscle and joint ache frequency, severity and interference responses of "quite a bit" or greater were increased in both arms, but occurred in <16% of pts. Per FACT-GP5, at BL (i.e., before trial tx) 85.3/94.3% of DCT/PCT pts were "not at all" or "a little bit" bothered by tx side effects; at C13 this was 77.4/84.2% and no pts in either arm were "very much" bothered.

Conclusions: Most pts reported little or no bother from tx side effects and responses were similar across tx arms, suggesting interventions are tolerable from pt perspective. These results supplement previously reported PERLA data and support further investigation of dostarlimab combined with existing and novel therapies in metastatic NSCLC. 1. 1469P The role of the CXCL12/CXCR4 pathway in the immunotherapy of non-small cell lung cancer

J. Rogado[1], F. Pozo[2], K. Troule[2], M. Pacheco[3], M. Adrados[4], J.M. Sanchez Torres[1], F. Al-Shahrour[2], A. Alfranca[5], N. Romero Laorden[6], R. Colomer Bosch[3]

[1]Medical Oncology Department, Hospital Universitario Infanta Leonor, Madrid, Spain; [2]Bioinformatics Unit, CNIO - Centro Nacional de Investigaciones Oncologicas, Madrid, Spain; [3]Medical Oncology Department, Hospital Universitario de la Princesa, Madrid, Spain; [4]Pathology Department, Hospital Universitario de la Princesa, Madrid, Spain; [5]Immunology Department, Hospital Universitario de la Princesa, Madrid, Spain; [6]Oncology Dept., Hospital Universitario de La Princesa, Madrid, Spain

Background: Peripheral blood mononuclear cells (PBMCs) trafficking is regulated by chemokines, which may interfere with their migration towards tumors and even collaborate in the efficacy of immunotherapy. In our study, we investigated whether the CXCL12/CXCR4 pathway plays a role in the efficacy of immunotherapy in non-small cell lung cancer (NSCLC) by analyzing the immunophenotypic profile of PBMCs expressing CXCR4 in peripheral blood (PB) and the expression of its ligand CXCL12 in tumor.

Methods: We identified T, B and NK lymphocytes, monocytes, and dendritic cells expressing CXCR4 in PB using flow cytometry in a prospective cohort of NSCLC patients (experimental group) before starting monotherapy with anti-PD-1 immunotherapy. As a control, we studied patients with advanced cancer before starting any non-immunotherapy treatment. The relative frequency of immune subpopulations in PB was correlated with treatment outcomes. Patients were classified according to high ($\geq$ 55th percentile) or low ($\leq$ 45th percentile) expression in PB for each cellular subpopulation. Uni- and multivariate survival analyses were performed using Cox regression and logistic regression. The expression of CXCL12 in tumor tissue was studied and correlated with the expression of its receptor (CXCR4) in PBMCs.

Results: Experimental group included 39 patients and control group 40. Low expression in PB of CXCR4-expressing CD8+ T lymphocytes was correlated with a greater benefit from immunotherapy: median OS NR vs 22.0 months, HR 0.6, $p<0.01$, with significance in multivariate models; and median PFS 14.2 vs 5.0 months, HR 0.38, $p=0.05$, with significance in multivariate models. ORR: trend towards significance. These differences were specific to the experimental group and were not observed in the controls. Low expression in PB of these lymphocytes was correlated with a higher expression of CXCL12 in tumors (trend towards significance: $p=0.14$). No significant results were obtained in any of the other subpopulations studied.

Conclusions: Patients diagnosed with advanced NSCLC with low expression of cytotoxic T lymphocytes in PB expressing CXCR4 show greater benefit from immunotherapy, due to greater tumor infiltration of lymphocytes receiving homing signals from the expression of CXCL12 in the tumor.

1470P Statin use and overall mortality in patients with advanced non-small cell lung cancer receiving anti-PD(L)1 immunotherapy: A SEER Medicare database analysis

J. Reuss[1], M. Marrone[2], A. Crawford[3], B. Neelon[3], J. Liu[4], E. Platz[5], J.R. Brahmer[6]

[1]Oncology Department, Lombardi Cancer Center Georgetown University, Washington, DC, USA; [2]Public Health Sciences, Medical University of South Carolina, Charleston, SC, USA; [3]Biostatistics, Medical University of South Carolina, Charleston, SC, USA; [4]Pharmacology and Molecular Sciences, Johns Hopkins University, Baltimore, MD, USA; [5]Oncology, Johns Hopkins Sidney Kimmel Comprehensive Cancer Center, Baltimore, MD, USA; [6]Oncology, Johns Hopkins Hospital, Baltimore, MD, USA

Background: Statins, commonly used to lower cholesterol, are inhibitors of Yes-associated protein (YAP), a transcription co-activator mediating cell survival and anti-tumor immunity. Concurrent statin with anti-PD1 immune checkpoint blockade (ICB) has shown preclinical synergy, and studies suggest improved survival among ICB-treated patients (pts) with non-small cell lung cancer (NSCLC) who take statins. We used the United States Surveillance Epidemiology and End Results (SEER) Medicare-linked database to assess overall mortality in a real-world population of pts with NSCLC receiving anti-PD(L)1 ICB and concurrent statin.

Methods: Pts in SEER ($\geq$65 years old) diagnosed with NSCLC in 2007—2017 and treated with anti-PD(L)1 ICB were included. ICB and statin therapy status were ascertained from Medicare claims. Pts were followed from date of first ICB claim until date of death, 4 weeks from last ICB claim, or 12/31/2018 (database cutoff), whichever came first. Hazard ratios (HR) were estimated using Cox regression models adjusted for propensity score, NCI comorbidity Index, and demographics to determine the association between time-updated statin use and overall mortality.

Results: 1401 pts were included, with 142 total deaths attained over 8710 person-months. 662 pts were statin-users and 739 were non-users. Statin users were more likely to be men compared to non-users (55% vs 43%). Median duration of anti-PD(L)1 ICB claim was similar for statin users and non-users (4.1 vs 4.2 months, respectively). Concurrent statin was associated with a 38% lower overall mortality (HR 0.62, 95% CI 0.41-0.94) compared to no statin. When extending follow-up beyond cessation of ICB claim, benefit was attenuated (HR 0.9, 95% CI 0.78-1.05). Subgroup data showed similar trends in overall mortality benefit when restricting to anti-PD-1 ICB (HR 0.63, 95% CI 0.42-0.93), as well as to simvastatin (HR 0.59, 95% CI 0.32-1.07) and atorvastatin (HR 0.67, 95% CI 0.42-1.07).

Conclusions: Concurrent statin use was associated with decreased overall mortality in a real-world population of pts with advanced NSCLC treated with anti-PD(L)1 ICB. Analyses from this dataset focused on lung-cancer specific mortality are ongoing.

1471P Immunotherapy prolongs long-term real-world survival compared to chemotherapy for metastatic non-small cell lung cancer: A propensity score-matched analysis

K. Kim[1], M. Sweeting[2], N. Wilking[3], L. Jönsson[1]

[1]Neurobiology, Care Sciences and Society, Karolinska Institute, Stockholm, Sweden; [2]Statistical Methodology and Data Sciences, AstraZeneca UK, Cambridge, UK; [3]Oncology and Pathology Department, Karolinska Institute, Stockholm, Sweden

Background: Survival benefit of immunotherapy (IO) has been demonstrated in clinical trials for patients with metastatic non-small cell lung cancer (mNSCLC) but no real-world study was found in literature to measure the long-term treatment effect compared to chemotherapy (CT). This retrospective and observational study aimed to evaluate whether IO has improved the long-term real-world overall survival (rwOS) and real-world time to receive next line of therapy (rwTTNT) in mNSCLC based on Flatiron Health oncology database.

Methods: Electronic health records of patients who received either IO (IO mono or IO+CT) or CT in first line (1L) and second line (2L) treatment from January 1, 2015 and onwards were extracted. Eligible patients were selected to match based on a developed propensity score to balance covariates that may confound the treatment effect. The effect of IO rwOS and rwTTNT was estimated using Cox regression. Subgroup analysis was performed to assess effect modification of known prognostic factors in mNSCLC.

Results: A total of 16,856 1L patients and 6,570 2L patients were included in the analysis. Patient characteristics between IO and CT arms were balanced after 1:1 propensity score matching with replacement. The maximum follow-up was 7.1 years for 1L and 7.3 years for 2L. Among 1L IO patients, median rwOS was 10.8 months (95% CI: 10.5 — 11.2) (vs. 1L CT: 9.0 [95% CI: 8.7 — 9.3]) with hazard ratio (HR) 0.84 (95% CI: 0.80 — 0.89). The HR for rwTTNT was 0.54 (95% CI: 0.51 — 0.57). Among 2L IO patients, median rwOS was 8.9 months (95% CI: 8.6 — 9.4) (vs. 2L CT: 8.3 [95% CI: 7.8 — 9.0]) with HR 0.91 (95% CI: 0.84 — 0.98). The HR for rwTTNT was 0.74 (95% CI: 0.69 — 0.79). Subgroup analyses among IO patients showed better survival outcomes for patients with younger age, low ECOG score, low comorbidity index, no history of smoking, PD-L1 positivity, and high PD-L1 expression level. The treatment effects increased over time and persisted until the end of the follow-up period.

Conclusions: IO was associated to prolong overall survival and delay receiving next line of therapies in mNSCLC patients. The significant survival benefits were found even after several years of follow-up.

1472P Radiotherapy affects immunotherapy efficacy based on tumor mutation status in patients with metastatic NSCLC

S. Li, Y. Zhao, R. Manochakian, Y. Lou

Hematology and Oncology, Mayo Clinic, Jacksonville, FL, USA

Background: Radiotherapy (RT) may enhance the antitumoral response of immunotherapy (IO) in metastatic non-small-cell lung cancer (mNSCLC). However, whether tumor mutation status can affect RT's effect on IO efficacy in mNSCLC is unknown.

Methods: We retrospectively studied all patients with mNSCLC who had tumor mutation profiles and were treated with IO at our institution from 2011 to 2022. Patients were excluded if they received targeted therapy, prior concurrent chemo-RT followed by durvalumab, or RT after IO discontinuation. We analyzed their demographic data, tumor mutation profiles, and compared progression-free survival (PFS) and overall survival (OS) between different subgroups. Kaplan-Meier method and log-rank test were used for survival analysis.

Results: A total of 171 patients were included. 66% received RT either prior to or during IO. Pembrolizumab was the most used IO agent (77%). IO was given mostly in the frontline setting (59%). Among 113 patients who received RT, ALK mutation (n=5) was associated with significantly shorter PFS of IO than those without ALK mutation (n= 108) (2m vs. 5.7m, p<0.0001). Similarly, MYC mutation (n=8) was associated with significantly shorter PFS than those without MYC mutation (n= 105) (3.3m vs. 6.2m, p=0.016). PFS of IO was not affected by the following genes: EGFR, KRAS, TP53, BRAF, ERBB2, BRAF, PIK3CA, TERT, and FGFR. For patients with tumors carrying STK11 mutation, those who received RT (n=21) had longer PFS of IO than those (n=8) without RT (6.5m vs. 2.8m, p=0.05). For patients with tumor carrying ARID1A mutation, those who received RT (n=11) had shorter PFS and OS of IO than those (n=7) without RT (PFS: 5m vs. 22.9m, p=0.08; OS: 16m vs. 28.1m, p=0.037, HR 0.28, 95% CI 0.08 − 0.9). No difference in the outcomes of IO between RT and no RT in the following mutations: EGFR, ERBB2, PIK3CA, KRAS, MET, and TP53.

Conclusions: In our real-world cohort, ALK and MYC mutations affect outcomes of IO in mNSCLC patients who received RT. RT is associated with better outcomes of IO in mNSCLC patients with STK11+, but poorer outcomes in those with ARID1A+. Our findings suggest certain gene mutations can affect radiotherapy's effect on immunotherapy efficacy in mNSCLC. Further prospective studies are needed to verify these results.

1473P Efficacy of anti-PD1/PDL1 antibody monotherapy in patients with advanced non-small cell lung cancer with increased hepcidin expression

M. Yamamoto[1], N. Hirama[1], S. Teranishi[1], K. Tashiro[1], S. Kubo[2], M. Kudo[1], T. Kaneko[2]

[1]Respiratory Disease Center, Yokohama City University Medical Center, Yokohama, Japan; [2]Department of Respirology, Yokohama City University, Yokohama, Japan

Background: T cell-promoted tumor ferroptosis, a form of iron-induced regulated cell death, is involved in the anti-tumor activities of immune checkpoint inhibitors (ICIs). The Efficacy of ICIs on advanced non-small cell lung cancer (aNSCLC) with iron metabolism disorders is unknown. Iron is an essential factor in metabolic pathways. However, iron facilitates the production of oxygen radicals, which may result in ferroptosis. This study explored the efficacy of anti-PD1/PDL1 monotherapy on survival in patients with aNSCLC with increased hepcidin expression.

Methods: A retrospective observational study was conducted in histologically confirmed aNSCLC patients with samples for hepcidin immunohistochemical staining. Eligible patients initiated nivolumab, pembrolizumab, or atezolizumab monotherapy as any line of treatment; the data cutoff was May 6, 2023. The hazard ratio for death was estimated with the use of the Kaplan−Meier method. Between-group comparisons were performed with the use of the log-rank test. Effects of hepcidin on ferroptosis induced by IFNg were examined using a lung cancer cell line.

Results: The 45 eligible patients included 39 (86.7%) men; the median age was 72 years (range, 36-83 years); 3 (6.7%) of 45 patients with driver gene mutations. The median patient follow-up was 15.3 months (26 days to 87.8 months). The median time to death was 69.6 (95% CI, not reached) and 15.3 months (95% CI, 0.94 − 29.7) for hepcidin High (TPS $\geq$ 50%) and None or Moderate (TPS $<$ 50 %), respectively. The hazard ratio and p-value for OS with hepcidin High versus None or Moderate were 0.55 (95% CI, 0.23 to 1.34) and p $=$ 0.19. The cytotoxicity of IFNg on A549 cells was enhanced by hepcidin with increasing levels of endogenous reactive oxygen species, a feature of ferroptosis.

Conclusions: In our cohort, aNSCLC patients with increased hepcidin expression and anti-PD1/PDL1 antibody monotherapy showed a longer survival time, but statistically insignificant probably due to a small sample size. Further study with a larger sample size is required to validate the effect of hepcidin on anti-PD1/PDL1 monotherapy. The potency of anti-PD1/PDL1 monotherapy enhancement by modulation of iron metabolism-related factors needs to be explored.

1474P Outcome of nivolumab and ipilimumab-based therapy for advanced non-small cell lung cancer with low or negative PD-L1 expression

T. Fukui[1], S. Hori[2], Y. Hatakeyama[3], T. Kiriu[4], K. Matsumura[5], N. Miwa[6], M. Katsurada[7], K. Okuno[8], S. Yoshimura[9], M. Tachihara[1]

[1]Division of Respiratory Medicine, Department of Internal Medicine, Kobe University Graduate School of Medicine, Kobe, Japan; [2]Division of Respiratory Medicine, Kakogawa Central City Hospital, Kakogawa, Japan; [3]Division of Respiratory Medicine, Akashi Medical Center, Akashi, Japan; [4]Division of Respiratory Medicine, Hyogo Prefectural Awaji Medical Center, Sumoto, Japan; [5]Division of Respiratory Medicine, Takatsuki General Hospital, Takatsuki, Osaka, Japan; [6]Division of Respiratory Medicine, Nishikobe Medical Center, Kobe, Japan; [7]Division of Oncology Respiratory Medicine, Kitaharima Medical Center, Ono, Japan; [8]Division of Respiratory Medicine, Hyogo Prefectural Tamba Medical Center, Tamba, Japan; [9]Division of Respiratory Medicine, Hyogo Prefectural Harima-Himeji General Medical Center, Himeji, Japan

Background: Immunotherapy is currently the standard care for advanced non-small cell lung cancer (NSCLC) in the first line. The combination therapy of nivolumab and ipilimumab addresses an unmet clinical need, as single immune checkpoint inhibitor (ICI) therapy has limited efficacy in PD-L1-negative NSCLC. This combination therapy may also benefit patients with NSCLC who have low PD-L1 expression.

Methods: A retrospective, multicenter observational study was conducted to evaluate the efficacy of nivolumab and ipilimumab-based therapy (dual group) and single ICI-based therapy (single group) for patients with low or negative PD-L1 expression.

Results: Between December 2018 and October 2022, a total of 240 patients with advanced/recurrent NSCLC and low/negative PD-L1 expression who received combination immunotherapy were enrolled. The median age of the patients was 72 years. PD-L1 Tumor Proportion Score (TPS) was negative in 109 patients (45.4%), 1-10% in 69 patients (28.7%), 11-20% in 19 (7.9%), 21-30% in 21 (8.8%), and 31-49% in 17 (7.1%). The median observation period was 11.5 months. The single group consisted of 201 patients (83.8%) and the dual group consisted of 39 patients (16.2%). In the overall population, there was no significant difference in overall survival (OS) and progression-free survival (PFS) between both groups after propensity score matching. However, in the patients with PD-L1 TPS negative and 1-20%, the dual group had a tendency for longer PFS and OS than the single group. In the dual group, patients with PD-L1 TPS 0-20% had significantly longer PFS (10.5 months (5.0-NA) vs. 4.1 months (0.23-NA), p=0.017) and OS (NA months (18.6-NA) vs. 9.0 months (0.23-NA), p=0.0014) than those with PD-L1 TPS 21-49%. In the single group, there was no association between PD-L1 expression and PFS/OS.

Conclusions: The results suggest that nivolumab and ipilimumab-based therapy may be a better treatment option, especially for patients with negative and lower PD-L1 TPS (<20%). Updated results with a larger patient population and an extended observation period will be presented at upcoming congresses.

Clinical trial identification: UMIN000050723.

1475P Torque teno virus DNA load as biomarker for tumor response to mono immune checkpoint inhibition in non-small cell lung cancer

B. Muntinghe[1], C. van Leer-Buter[2], P. Rozendal[3], E. Suazo Zepeda[4], H. Kievit[1], E.A.M. Verschuuren[1], H.J.M. Groen[1], A.J. Van Der Wekken[1], G.H. de Bock[4], E. Schuuring[3], J.T.J.N. Hiltermann[1]

[1]Pulmonary Diseases and Tuberculosis, UMCG - University Medical Center Groningen, Groningen, Netherlands; [2]Medical Microbiology, UMCG - University Medical Center Groningen, Groningen, Netherlands; [3]Department of Pathology, UMCG - University Medical Center Groningen, Groningen, Netherlands; [4]Epidemiology, UMCG - University Medical Center Groningen, Groningen, Netherlands

Background: The ubiquitous Torque Teno Virus (TTV) in serum may reflect immune status and is used clinically as a biomarker of immunosuppression in solid organ recipients. Its ability to reflect functional T-cell activity as a measure of immune suppression may be applicable in lung cancer patients as well, considering the role of tumor induced immunosuppression in these patients. We hypothesize that TTV DNA load, or its change early in treatment, may reflect response to mono immune checkpoint inhibition (ICI) with a PD-1 inhibitor.

Methods: This retrospective, exploratory study included patients with non-small cell lung cancer (NSCLC) who started treatment with pembrolizumab or nivolumab between 2014 and 2022. Patients were selected on durable response (≥6 months response or stable disease) and non-response (progressive disease as best response), and were divided into two equal groups. Subsequently, TTV DNA load was measured quantitively on prospectively collected plasma samples via the OncoLifeS biobank. TTV DNA load at baseline was compared, as well as change in TTV DNA load after 4-6 weeks to baseline.

Results: A total of 63 patients were included, 31 responders and 32 non-responders. Median progression free survival (mPFS) was 193 weeks [IQR 50 weeks — not reached] vs 6 weeks [IQR 5 —6 weeks]. Responders were slightly younger (median 64 vs 70 years, p=0.05) and had a better performance status (PS 0 in 58% vs 25%, p=0.03), all other baseline characteristics were comparable. TTV DNA load at baseline was above the threshold in 44 patients (70%). Median TTV DNA load was 2.77 log copy numbers/mL (cp/mL) [IQR 2.13 — 3.27] in responders and 3.25 cp/mL [IQR 2.26 — 2.80] in non-responders, p=0.173. Change in TTV DNA load after 4-6 weeks compared to baseline was -0.13 cp/mL [IQR-1.73 — 0.10] in responders vs -0.33 [IQR -1.61 — 0.20] in non-responders (p=0.833). Cox-regression analysis, adjusted for sex, age and PS, showed no correlation between change in TTV DNA load, and mPFS and overall survival.

Conclusions: Level of immune suppression in this cohort of NSCLC patients measured by TTV DNA load, either at baseline or change after 4-6 weeks after mono ICI, was not associated with tumor response or survival.

Background: Pembrolizumab stands as a first-line option for patients (p) with advanced NSCLC and high PD-L1 expression (≥50%). Several factors influenced outcomes such as antibiotic (AB) exposure, low body mass index (BMI), certain metastasic location (e.g. bone), or ECOG-PS of 2.

Methods: We performed a multicenter retrospective study in 8 Spanish hospitals to evaluate clinical outcomes according to several factors in patients with stage IV high PD-L1 expression NSCLC treated with first-line pembrolizumab in clinical practice. We included data from patients treated between May 2017 and July 2022.

Results: Among the 494 patients, median age was 67.2 years (29.4-89.43), 379p (76.7%) were male, 138p (27.9%) had an ECOG PS of 0, 269p (54.5%) had an ECOG PS of 1, 87p (17.6%) had an ECOG of ≥2 and 230p (46.6%) had a BMI of <24.9. 158p (32.0%) had bone metastases. 175p (35.5%) had antibiotic (AB) exposure during treatment with pembrolizumab or 4 weeks before initiation, and 210p (42.5%) underwent treatment with corticosteroids during treatment with pembrolizumab or 4 weeks before initiation [>10mg prednisone equivalent (>10mg PDNe)]. 308p (62.3%) had proton pump inhibitors (PPi) exposure. With a median follow-up of 12.6 months (m), the median overall survival (OS) and the progression-free-survival (PFS) were 16.9m (95% CI 12.9-19.2) and 9.9m (95% CI 7.7-12.1), respectively, and the overall response rate (ORR) was 43.3%. Multiple variables were associated with survival after univariate analysis (Table). After multivariate analysis, corticosteroid treatment (HR 1.41) and ECOG (HR 2.40) maintained a prognostic impact: poor PS (ECOG ≥2) and having been exposed to corticosteroids were predictive of poor outcome.

Table: 1476P

	Median OS - months (95% CI)	p-value (univariate analysis)
ECOG PS		
0 (N=138)	36.7 (20.3-53.2)	
1 (N=269)	14.8 (11.7-17.9)	
2 (N=81)	2.7 (1.8-3.7)	
3 (N=6)	0.3 (0.03-0.2)	< 0.001
Corticosteroid exposure		
No (N=284)	22.3 (17.9-26.7)	
Yes (N=210)	11.4 (8.0-14.7)	< 0.001
Reason for treatment with corticosteroids		
irAEs (N=57)	NR	
Baseline conditions/symptom management (N=153)	4.8 (1.4-8.3)	< 0.001
PPi exposure		
No (N=186)	23.0 (18.1-28.0)	
Yes (N=308)	12.6 (9.5-15.7)	0.002
Bone metastases		
No (N=336)	20.2 (16.6-23.8)	
Yes (N=158)	9.3m (4.9-13.7)	0.001
Best response to IO		
CR (N=30)	NR	
PR (N=184)	NR	
SD (N=113)	15.7 (13.8-17.8)	
PD (N=117)	4.0 (3.1-5.0)	
Not evaluated (N=50)	0.8 (0.6-1.0)	<0.001

Conclusions: First-line pembrolizumab in advanced NSCLC patients with high PD-L1 expression should only be used in patients with good PS. Patients with PS 2 are in urgent need of new treatment approaches.

1477P STK11 mutations predict poor prognosis for advanced NSCLC treated with first-line immunotherapy or chemo-immunotherapy according to KRAS, TP53, KEAP1, and SMARCA4 status

A. De Giglio[1], D. de Biase[2], A. Di Federico[1], T. Maloberti[2], C. Casadio[1], E. Gruppioni[2], A. Altimari[2], B. Melotti[3], F. Sperandi[3], F. Gelsomino[3], A. Ardizzoni[1]

[1]Department of Medical and Surgical Sciences, University of Bologna - Alma Mater Studiorum, Bologna, Italy; [2]Solid Tumor Molecular Pathology Laboratory, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, Italy; [3]Medical Oncology, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, Italy

Background: The upfront treatment of non-oncogene addicted NSCLC relies on immunotherapy single-agent (IO) or in combination with chemotherapy (CT-IO). Genomic aberrations such as *KRAS*, *TP53*, *KEAP1*, *SMARCA4*, or *STK11* may impact the survival outcomes. The prognostic role of *STK11* mutations under upfront IO or CT-IO is still unclear.

Methods: We performed an observational study of 145 patients (pts) treated with first-line IO or CT-IO for advanced non-squamous (nsq) NSCLC at our institution tested with an extensive lab-developed NGS panel. The primary objective was to assess the clinical outcomes of *STK11* mutated (mut) pts. Then, we performed an external validation through the public OAK/POPLAR dataset, including nsq NSCLC pts treated with single-agent IO or CT.

Results: Most pts were male (59.7%), former smokers (61.1%), with ECOG PS 0-1 (84%), and received first-line CT-IO (58.6%). 44.8% had a mutation in *KRAS*, 21.4% in *KEAP1*, 50.3% in *TP53*, 13.1% in *SMARCA4*, and 14.4% in the *STK11* gene. In 14/21 pts *STK11* and *KRAS* mutations co-occur (p=0.053). The median overall survival (OS) was 13.2 months (mo.) (95% CI, 8.6-19.6), while the median progression-free survival (PFS) was 6.5 mo. (95% CI, 4.8-8.9). The mOS was 8 mo. (95% CI, 5-16.7) for *STK11* mut pts and 17.3 mo. for *STK11* WT pts (95% CI, 8.9-24.4) (p=0.038). *TP53* (8.3 vs 17.3), *KRAS* (9.2 vs 15.9), and *KEAP1* (8.9 vs 15.9) mut pts evidenced a trend for dismal mOS. *SMARCA4* status had no impact on mOS. *STK11* mutations were detrimental to OS in the univariate (HR 1.74, p=0.041) and multivariate model (HR 1.97, p=0.025) after adjusting for sex, age, ECOG PS, treatment (IO vs CT-IO), *KRAS*, *KEAP1*, *TP53*, *SMARCA4* status. Genomic alterations did not impact the mPFS in our cohort. Within the OAK/POPLAR dataset, STK11 mutations (60/818 pts) were significantly associated with increased death risk in the univariate (HR 2.01, p<0.001) and multivariate model (HR 1.66, p=0.001) after adjusting for age, sex, treatment (IO vs CT), *KRAS*, *KEAP1*, *TP53*, *SMARCA4* status.

Conclusions: *STK11* aberrations hampered the mOS of nsq NSCLC pts treated with first-line IO or CT-IO. The negative prognostic impact seems to be unrelated to IO administration.

1478P Circulating pre-treatment T-Cell receptor repertoire as a predictive biomarker in non-small cell lung cancer patients treated with pembrolizumab

E.S. Gray[1], A. Abed[1], A. Beasley[2], A. Reid[2], N.C. Law[3], C. Leslie[2], M. Millward[4], J. Lo[5]

[1]Centre for Precision Health, Edith Cowan University, Joondalup, WA, Australia; [2]Centre for Precision Health, Edith Cowan University, Perth, WA, Australia; [3]Medical Oncology, Fiona Stanley Hospital, Perth, Australia; [4]School of Medicine, University of Western Australia, Perth, WA, Australia; [5]School of Science, Edith Cowan University, Perth, WA, Australia

Background: The circulating T-cell receptor (TCR) repertoire is a dynamic representation of overall immune responses in an individual.

Methods: We prospectively collected baseline blood from patients treated with first-line pembrolizumab monotherapy (N=48) or in combination with chemotherapy (N=65), and sequenced the Complementarity Determining Region 3 (CDR3) of the TCR beta chain from whole blood-derived DNA. TCR repertoire metrics were correlated with clinical benefit (objective response or stable disease $\geq$ 6 months), progression-free survival (PFS), overall survival (OS) and immune-related adverse events (irAEs). We built a logistic regression model combining all four TCR-β repertoire metrics to predict clinical benefit. Receiver operating characteristic (ROC) analysis of the resulting logistic regression model probabilities was used to identify the best cut-off values to maximise sensitivity and predict clinical benefit.

Results: We observed an association between a reduced number of unique TCR clones and clinical benefit among patients treated with pembrolizumab monotherapy (RR=2.86, 95%CI 1.04-8.73, P=0.039). For patients treated with pembrolizumab plus chemotherapy, increased number of unique clones (HR=2.96, 95%CI 1.28-6.88, P=0.012) and Shannon Diversity (HR=2.73, 95%CI 1.08-6.87, P=0.033), and reduced evenness (HR=0.43, 95%CI 0.21-0.90, P= 0.025) and convergence (HR= 0.41, 95%CI 0.19-0.90, P=0.027) were associated with improved PFS, while only increased number of unique clones (HR= 4.62, 95%CI 1.52-14.02, P=0.007) was associated with improved OS. Logistic regression models combining the TCR repertoire metrics improved the prediction of clinical benefit and was strongly associated with OS (HR=0.20, 95%CI 0.05-0.76, P<0.0001). Reduced TCR conversion was associated with increased irAEs needing systemic steroid treatment (P=0.04).

Conclusions: Pre-treatment circulating TCR repertoire might serve as a predictive biomarker for clinical outcomes among patients with advanced NSCLC treated with pembrolizumab alone or combined with chemotherapy.

1479P Association between high baseline low density neutrophils and resistance to immunotherapy in untreated non-small cell lung cancer: Molecular characterization of low-density neutrophils

H. Arasanz[1], N. Castro Unanua[2], L. Teijeira Sanchez[3], I. Morilla Ruiz[3], M. Martínez Aguillo[3], I. Labiano[1], A.E. Huerta-Hernández[2], P. Piedra Roset[3], M. Alsina Maqueda[1], R. Vera[3]

[1]Oncobiona, Hospital Universitario de Navarra (HUN)-Navarrabiomed-IdisNA, Pamplona-Iruna, Spain; [2]Oncobiona, Navarrabiomed-IdisNA, Pamplona-Iruna, Spain; [3]Medical Oncology, Hospital Universitario de Navarra (HUN)-Navarrabiomed-IdisNA, Pamplona-Iruna, Spain

Background: Circulating LDNs have been previously associated with resistance to ICI in NSCLC. We have compared the efficacy of ICI and CT + ICI in untreated patients with high LDNs. We studied the association of LDNs with clinical variables. We have compared LDNs and high-density neutrophils (HDNs) regarding activity and maturity. We have compared HDNs of NSCLC patients and healthy donors.

Methods: PBMCs from 35 patients treated with ICI and 41 treated with CT + IT were purified from fresh peripheral blood by Ficoll gradient. HDNs were purified using Mono-Poly™ buffer. Baseline LDNs were quantified by flow cytometry. Efficacy of ICI and CT + ICI was compared among those with high LDNs. Activity and maturity of LDNs and HDN were studied with PD-L1, HLA-DR, LOX1, CD119, CXCR2, CXCR4, CD10, CD95, CD62L, CD101.

Results: High levels of LDNs were found in 55.3%. Non-sq NSCLC presented higher mean levels, 22.4% vs 11.3% ($p = 0.047$). ORR was higher with CT + IT compared with ICI, 59.1% vs 0% ($p = 0.001$). mPFS and mOS were longer with CT + IT, 8.9 mo vs 1.3 mo ($p < 0.001$) and 24.6 mo vs 1.41 mo ($p = 0.008$). No differences were detected in > 70 years old. A depletion of LDNs was observed in responders to CT + IT. In patients with high LDNs, fast progressive disease (PD) was more frequent with ICI (75% vs 36.4%, $p = 0.031$). In patients treated with ICI, fast-PD was more frequent when LDNs were high (75% vs 16.7%, $p = 0.002$). LDN were more aged (CXCR4+ CXCR2-, 29.9% vs 1.95%), less immature (CXCR4+ CXCR2+, 49.2% vs 82.6%) and expressed higher LOX1 and PD-L1 (57.5% vs 41.8% and PD-L1, 2.7% vs 0.97%) than HDNs. HDNs from patients and healthy donors were equivalent.

Conclusions: LDNs are a distinct circulating myeloid subpopulation, with lower prevalence of immature neutrophils, that can be enriched in patients with NSCLC. High baseline LDNs are associated with resistance to ICI monotherapy. CT + IT can overcome this resistance.

1480P Integrating the on-treatment mGPS improves prognostic accuracy of imaging-based staging in patients with non-small-cell lung cancer (NSCLC) treated with immune-checkpoint inhibitors

J. Saal[1], T. Bald[2], M. Eckstein[3], D.J. Ralser[4], P. Brossart[1], J. Ellinger[5], M. Hölzel[2], N. Klümper[5]

[1]Medical Oncology, UKB - Universitätsklinikum Bonn, Bonn, Germany; [2]Institute of Experimental Immunology, UKB University of Bonn, Bonn, Germany; [3]Institute of Pathology, Universitätsklinik Erlangen, Erlangen, Germany; [4]Department of Gynaecology and Gynaecological Oncology, UKB - Universitätsklinikum Bonn, Bonn, Germany; [5]Urology, University Hospital Bonn, Bonn, Germany

Background: The clinical standard for response evaluation and treatment monitoring in advanced non-small cell lung cancer (NSCLC) is repeated, imaging-based staging. However, on immune checkpoint inhibition (ICI), many patients achieve stable disease (SD) as the best overall response. Clinical outcomes in this group vary widely, and whether measuring tumor size adequately captures the complex, dynamic processes following immune checkpoint inhibition is controversial. Hence, complementary biomarkers that improve outcome prediction are needed. A promising candidate is the modified Glasgow prognostic score (mGPS), a well-established prognostic score based on the serum markers C-reactive protein (CRP) and albumin that has demonstrated to predict clinical outcomes in a variety of oncological settings.

Methods: We re-evaluated the mGPS at the time of first staging (6 weeks after the start of therapy) in patients with NSCLC treated with atezolizumab (anti-PD-L1 antibody) in the phase 3 OAK trial.

Results: In patients treated with anti PD-L1 ($n = 412$), the on-treatment mGPS yields prognostic information similar to radiological staging (c-index 0.65 (95 % confidence interval 0.61 − 0.68) vs 0.61 (0.57 - 0.64). Notably, the mGPS low-risk subgroup is larger (54.4 %) compared to the partial response (PR) subgroup (7,5%). In the clinically heterogenous SD subgroup, on-treatment mGPS strongly correlated with survival (intermediate risk HR 2.4, $p < 0.001$, high-risk HR 3.5, $p < 0.001$, compared to low risk). On-treatment mGPS was also prognostic in patients with progressive disease (PD, intermediate risk HR 1.7, $p = 0.033$, high-risk HR 2.9, $p < 0.001$, compared to low risk). Remarkably, patients with PD and low-risk mGPS at first staging had a higher 12-month survival probability compared to patients with SD with intermediate or high-risk mGPS (67.0% vs 64.0%/47.7%).

Conclusions: Integrating on-treatment biomarkers into imaging-based staging can improve outcome prediction. A multi-modal approach to response assessment more akin to current practice in many hematologic malignancies should be further investigated in solid oncology, particularly in the context of immunotherapy.

1481P Singular immune-related adverse events and efficacy outcomes of immune checkpoint inhibitors in advanced non-small cell lung cancer

J.M. Jurado García[1], M. Cobo Dols[1], A. Cantero[1], V. Gutierrez Calderon[1], P. Jiménez Gallego[2], E. Perez Ruiz[1], M.A. Berciano Guerrero[1], A. Montesa Pino[1], I. Ramos Garcia[1], A. Rueda Dominguez[1]

[1]Medical Oncology, UGCI Oncol., Regional and Virgen de la Victoria University Hospitals, IBIMA, Malaga, Spain; [2]Medical Oncology, Hospital Universitario Regional de Málaga, Malaga, Spain

Background: ICIs have transformed the treatment of advanced NSCLC patients, no real-world data are available about the immune-related adverse events (irAEs). This retrospective study aimed to assess the safety and effectiveness of PD-1/PD-L1 inhibitors in patients with non-small cell lung cancer (NSCLC) and to analyze the association between singular irAEs and effectiveness.

Methods: This was a retrospective study of the clinical data of patients with NSCLC treated with PD-1/PD-L1 inhibitors as 1ª or 2ª lines from Marzo 2015 to Marzo 2022 at Hospital Universitario Regional de Málaga. We evaluated association of irAE with efficacy, response and overall survival. Kaplan-Meier and Cox proportional hazard analyses were performed.

Results: A total of 510 patients were included in this analysis. Any grade IrAEs were seen in 307 (60%) patients. Of these (Table), 135 (43,9%) patients had grade 1 toxicities, most commonly cutaneous (96), colitis (54), rheumatologic (46) and hepatitis (42). 112 (36,4%) patients had grade 2 toxicities pneumonitis (47), cutaneous (29), colitis (28). 53 (17,2%) patients had grade 3 toxicities: hepatitis (15), pneumonitis (13), cutaneous (10). 8 (2,6 %) patients had grade 4 toxicities hepatitis (5), pneumonitis (2), DRESS syndrome (1). For patients assessed for efficacy, objective response rate (ORR) to ICI was higher in patients with irAEs [46% vs 14%] p=0,001. In fact, the presence of any irAEs had a significantly improved median OS compared to those without irAEs (19,3 months vs 6,5 $p = 0.0001$) (Median OS in G1-2 20 months and G 3-4 16,2 months had significally higher OS vs non irAEs 6,1 months; p=0,0001). Singular toxicities that predict greater OS >30 months were (Hepatitis G4, endocrine G1 and cutaneous G2); point out toxicities with deleterious effects (colitis G3 and pneumonitis G4). Multivariable analysis demonstrated that the development of any irAEs was related to a significantly improved OS (HR 0.47, 95% 0.26-0.68, $p = 0.0001$).

Table: 1481P Summary of singular toxicities and OS (overall survival) in months

IrAEs N 307	Cutaneous 135 OS	Pneumo 92 OS	Colitis 89 OS	Hepatitis 79 OS	Rheuma 76 OS	Endocrine 61 OS	Renal 40 OS
G1 135	96 28.2	29 18.3	54 21.4	42 18.7	46 28.8	40 37.8	19 21.4
G2 112	29 31.1	47 13.8	28 21.4	17 19	28 20.1	18 28.8	14 28.2
G3 53	10 13.4	13 15.3	7 7.2	15 20.6	2 3.8	3 -	7 7.2
G4 8	-	3 1.9	-	5 40.6	-	-	-
Non N Ir 203	375 9.0 p=0.0001	418 11.4 p=0.54	421 11.2 p=0.018	431 11.6 p=0.146	434 11.1 p=0.001	449 11.1 p=0.001	470 12.6 p=0.05

Conclusions: This study confirms the feasibility and the safety of ICIs in a large, real-world cohort of patients with NSCLC. The development of irAEs in NSCLC patients treated with immunotherapy may predict better treatment efficacy and overall survival.

Background: Pembrolizumab (Pemb) is a key drug for the treatment of advanced or recurrent non-small cell lung cancer (NSCLC). However, there are limited data on Pemb use in older adults aged >75 years with NSCLC, especially in terms of pharmacokinetics (PK).

Methods: This open-label multicenter observational study aimed to evaluate real-world data on the safety, efficacy, and blood concentrations of Pemb (both monotherapy and combination therapies) in older adults with NSCLC. Blood samples for PK analysis were collected immediately before Pemb administration. Quantitative Pemb concentrations were measured by liquid chromatography-mass spectrometry.

Results: We enrolled 100 patients from July 2019 to September 2020; one patient was excluded due to stage migration. Patient characteristics were as follows: median age, 78 (75—87) years; male/female ratio, 70/29; performance status (PS) 0—1/2—3, 85/14; adenocarcinoma/squamous cell carcinoma/others, 62/25/12; stage I—III/IV/postoperative recurrence (TNM 7th edition), 9/60/30; PD-L1 TPS <1%/1%—49%/≥50%, 12/31/48; and monotherapy/combination therapy, 65/34. The best overall efficacy was CR/PR/SD/PD (7/40/32/20), and the response rate was 47.5%. The median progression-free survival (PFS) and overall survival (OS) were 8.0 and 19.0 months, respectively. The adverse event profile was generally similar to that reported in previous studies. In total, 77 blood samples were collected immediately before the second cycle (C1 trough). Although no clear association between Pemb concentrations and patient background was found, PFS and OS were significantly shortened in the population with low C1 trough, a population characterized by lower PS, high number of metastatic organs at the beginning of treatment, and low blood albumin level.

Conclusions: In older adults aged >75 years with NSCLC and low albumin levels and PS and a high number of metastatic organs, C1 trough of Pemb is reduced and not expected to prolong PFS and OS.

1483P Challenge of systemic first-line treatment of elderly lung cancer patients

K. Ferentinos[1], J. Volmerig[2], G. Nilius[3], B. Jaeger[4], A. Koziorowski[5], I. Stoever[5], D.C.C. Christoph[6]

[1]Medical Onkology, KEM | Evang. Kliniken Essen-Mitte gGmbH, Essen, Germany; [2]Thoracic Surgery, KEM | Evang. Kliniken Essen-Mitte gGmbH, Essen, Germany; [3]Pneumology, KEM | Evang. Kliniken Essen-Mitte gGmbH, Essen, Germany; [4]Radiotherapy, Alfried Krupp Krankenhaus, Essen, Germany; [5]Radiotherapy, Strahlentherapie Ruhr, Essen, Germany; [6]Medical Oncology / Hematology Department, KEM | Evang. Kliniken Essen-Mitte gGmbH, Essen, Germany

Background: At the time of diagnosis the majority of the lung cancer (LC) patients (pts) are old and have comorbidities. These elderly pts are underrepresented in clinical trials and their therapy options are limited. For pts whose tumor expresses PD-L1 at a lower level (TPS <50% or ICS <10%) combined platinum-based chemo-/immunotherapy is the recommended first line therapy, but elderly pts are usually unfit to receive these therapies at the regular dosage. A single-agent immunotherapy might be effective in some cases, but is only approved for pts with high PD-L1 expressing tumors (TPS ≥50% or ICS ≥10%). Data about the efficacy and safety of therapy for elderly LC pts are very limited.

Methods: In our retrospective data analysis all pts older than 75 years with LC regardless of stage treated at a German certified LC center and primary LC diagnosis from 2017 until 2022 were included. Progression-free and overall survival, objective response rate, and adverse events (AEs) resulting in therapy discontinuation were assessed for pts with systemic therapy. Data of geriatric assessment and its influence on therapy were analysed.

Results: 365 out of all 1.837 newly diagnosed LC pts from 2017 to 2022 were older than 75 years. Of these pts, 115 pts (31.5%) underwent primary surgery and 15 pts (4.1%) primary radiotherapy; 143 pts (39.2%) received only systemic treatment and 92 pts (25.2%) had best supportive care. 43 pts (11.8%) sufferered from small cell LC and 322 pts (88.2%) non-small cell LC. 99 pts with systemic therapy (69.2%) received combined chemo-/immunotherapy, 31 pts (21.7%) immunomonotherapy and 13 pts (9.1%) a small molecule inhibitor. 22 pts with systemic therapy (15.4%) had an ECOG performance status (PS) of 0, 80 pts (56 %) a PS of 1, 36 pts (25.1%) PS of 2 and 5 pts (3.5%) a PS of 3. All elderly pts with high PD-L1 expressing tumors received immunomonotherapy. 89 pts (90%) of 99 pts with chemo-/immunotherapy received platinum-based chemotherapy. Of these, 30 pts (30%) had to stop therapy prematurely due to AEs.

Conclusions: Many elderly pts received combined platinum-based chemo-/immunotherapy, but therapy was often prematurely stopped due to AEs. A quarter of the pts with systemic therapy had a PS of 2. Only few pts with a poor PS (2/3) were treated with monochemotherapy.

1484P Impact of concomitant KRAS/STK11 or KRAS/KEAP1 mutations on response to immune checkpoint inhibition in NSCLC: A real-world data analysis

L.C. Hempel[1], J. Veloso de Oliveira[1], S. Robert[2], D. Hempel[3]

[1]Medical Department, Sigmund Freud University Vienna, Vienna, Austria; [2]Fakultät GSW, Technical University of Applied Science, Rosenheim, Germany; [3]Oncology and Haematology, Center of Oncology, Donauwörth, Germany

Background: *STK11* and *KEAP1* mutations are among the most common gene alterations in lung adenocarcinoma and are associated with poor response to immunotherapy in patients with *KRAS* mutations. There is limited data on the clinical relevance of these alterations in a real-world setting.

Methods: Clinicopathologic and genomic data from patients with advanced lung cancer who underwent tissue-based panel next-generation sequencing (NGS) analysis, using the FoundationOne CDX assay, between January 2021 and February 2023 were retrospectively analyzed. Clinical outcomes were evaluated based on the molecular alterations and co-alterations that occurred.

Results: Of 100 patients (median age = 68 y [range: 40-92]), 51 women (51%), 39 smokers (39%), *KRAS* mutations were detected in 25 cases (25%), *STK11* in 12 (12%) and *KEAP1* mutations were found in 7 (7%) patients (pts.), respectively. Further alterations were *EGFR* exon 18-21 in 12 patients (12%), *BRAF p.V600E* in 3 pts. (3%), *ERBB2* ampl. 3 pts. (3%), *ALK* fusion in 2 pts. (2%), *ROS* fusion 1 (1%), *MET* exon 14 skipping mutation in 2 pts. (2%), *ERBB2* mutation in 1 pts. (1%), *EGFR* exon 20 insertion in 1 pts. (1%). In 5 patients (5%) concomitant *KRAS/STK11* mutations were detected. One patient showed KRASwt with concominant *STK11* mutation. Concomitant *KRAS/KEAP1* mutations were detected in 2 patients (2%). None of the patients with *STK11* or *KEAP1* mutations had concurrent *EGFR* mutations in exon 18-21, *ALK* fusions, or *ROS* fusions.

Conclusions: Therapeutically relevant gene variants were detected in the analyzed real world population. The data indicate that *STK11* or *KEAP1* mutations should be interpreted in the context of *KRAS* mutations and could serve as a clinical biomarker for poor response to immunotherapy in patients with lung adenocarcinomas. In addition, the data highlight the benefit of panel sequencing that includes the *STK11* and *KEAP1*.

1485P Systemic inflammatory index dynamics at 6 weeks as an early surrogate for clinical benefit in patients with NSCLC and PD-L1≥50% expression treated with pembrolizumab: Data from the real-life practice

M. Knetki-Wroblewska[1], A. Piórek[1], S. Tabor[1], K. Winiarczyk[1], P. Sobczuk[2], Z. Lewandowska[1], A. Pluzanski[1], D.M. Kowalski[1], M.J. Krzakowski[1]

[1]Lung Cancer and Chest Tumors Department, Maria Sklodowska-Curie National Research Institute of Oncology, Warsaw, Poland; [2]Department of Soft Tissue/Bone Sarcoma and Melanoma, Maria Skłodowska-Curie National Research Institute of Oncology, Warsaw, Poland

Background: Pembrolizumab is the standard first-line treatment for patients with metastatic Non-Small Cell Lung Cancer (NSCLC) with programmed death ligand 1 (PD-L1) expression of ≥50%. However, early loss of clinical benefit is observed in many cases. There is a need to identify predictors of this phenomenon in the real-world population.

Methods: This study is a retrospective analysis of patients (pts) with stage IV NSCLC treated with pembrolizumab in routine practice, who received treatment for at least 6 weeks. Inclusion criteria included good performance status (ECOG 0-1), no active brain metastases, and no *EGFR* or *ALK* alterations. The median progression-free survival (PFS) and overall survival (OS) were estimated using the Kaplan-Meier method. The log-rank test and Cox regression model were used for uni- and multivariate analysis.

Results: A group of 216 pts were included. The objective response rate was 35.6%, 25.5% of pts had PD, while 11.2% of pts died before the first CT-scan. Median PFS and OS were 9.88 months (95% CI 4.85-14.92; 127 events) and 14.88 months (95% CI 9.84-19.91; 122 events), respectively. The median Systemic Inflammatory Index (SII) was 1260 in the overall population. In univariate analysis, SII >1260 had a negative impact on PFS ($p=0.047$) and OS ($p<0.022$). Tumour burden ≥111.5 mm ($p<0.045$) was a negative prognostic factor for OS. Other factors assessed were not relevant. An increase in the SII of more than 25% after 6 weeks of treatment correlated with a higher likelihood of early progression ($p<0.001$) and shorter OS ($p<0.001$). The differences were more pronounced in the subgroup of patients with an initial SII >1260. On multivariate analysis, higher tumour burden (HR 1.52, $p=0.028$, 95%CI 1.043-2.018) and an increase in SII at 6 weeks of more than 25% (HR 2.62, $p<0.001$;95%CI 1.625-4.234) were found to be negative prognostic factors for OS.

Conclusions: Pembrolizumab is effective in pts treated in daily practice. Taking into account additional factors, such as inflammatory index, may help to identify the optimal patient population. The dynamics of SII after 6 weeks of treatment may be a surrogate for clinical benefit.

1486P Treatment patterns and real-world clinical outcomes of metastatic non-small cell lung cancer patients in the immunotherapy era

S. Sharman Moser[1], L. Apter[1], A. Arunachalam[2], S. Gazit[3], G. Chodick[3], N. Siegelmann-Danieli[4]

[1]Maccabi Institute for Research and Innovation (Maccabitech), Maccabi Health Services, Tel-Aviv, Israel; [2]CORE, Merck Research Laboratories - Merck & Co., Inc., Rahway, NJ, USA; [3]KSM Research and Innovation Center, Maccabi Healthcare Services, Tel Aviv, Israel; [4]Oncology Department, Maccabi Health Services, Tel-Aviv, Israel

Background: We describe PDL1 testing, treatment utilization and clinical outcomes in a real-world cohort of metastatic non-small cell lung cancer (mNSCLC) patients in a 2.5-million-member state-mandated health services database in Israel.

Methods: Newly diagnosed mNSCLC patients initiating systemic anti-cancer treatment between 01-Jan-2017-31-Dec-2020 were identified from the National Cancer Registry and Maccabi Healthcare Services database. Overall survival (OS) was estimated using Kaplan Meier analysis. The data cut-off date was 30-June-2021.

Results: Among 843 patients, 85% and 15% had adenocarcinoma (NSQ) and squamous cell carcinoma (SQ) histologies: of these 43% and 26% were female, median age was 67 and 69 years, 73% and 92% ever-smokers, 55% and 48% with 0-1 performance status (PS) respectively. Most patients with NSQ and SQ were tested for PD-L1(83.4% and 89.9% respectively), mostly within 30 days of diagnosis and prior to first-line (1L) treatment initiation. PD-1/PD-L1 inhibitor monotherapy (PDM) or combination (PDC) was the most common 1L therapy for NSQ and SQ histology (49% and 69%). For NSQ patients with no known EGFR/ALK/ROS1 and receiving PDM, PDC and platinum doublet therapy (PDT), the median OS from initiation of 1L was 12.5 (9.9-17.9), 14.8 (10.5-19.4) and 7.5 (6.4-12.2) months respectively, and for a subgroup of patients with PS 0-1, the median OS was 25.1 [4.9-NR], 17.6 [14.3-NR] and 12.7 [9.6-15.1] months respectively.

Conclusions: Our real-world data supports the benefit of PD-1/PD-L1 inhibitors in patients with mNSCLC.

Background: Immune checkpoint inhibitors (ICIs) regimens are the cornerstone of first-line treatment of advanced non-small cell lung cancer (NSCLC).Anlotinib is a multi-targeted tyrosine kinase inhibitor selective for VEGFR, FGFR, PDGFR, and c-kit. The ALTER 0303 trial showed that anlotinib improved both PFS and OS in later-line treatment for advanced NSCLC. Anti-angiogenesis agents has synergistic effect with ICIs. Anlotinib combined with PD-1/PD-L1 inhibitors as first-line or second-line treatment in advanced NSCLC showed encouraging efficacy and good tolerability. This is an update of the real-world study.

Methods: This is a prospective, multicenter real-world study. The NSCLC cancer patients who received anlotinib in combination with PD-1/PD-L1 inhibitors in first-line or second-line were enrolled. The primary endpoint was PFS, and secondary endpoints were ORR, DCR and OS. The response to treatment was evaluated according to RECIST version 1.1. In addition, adverse events were evaluated by CTCAE v5.0.

Results: From Aug 2021 to May 2023, 147 patients were enrolled in fifteen centers and 104 of them have received at least one tumor assessment. Median age was 66.3 (range:40-84); 82.7% male, 6.7% brain metastasis, 67.3% ECOG PS 1. 60 (57.7%) and 44 (42.3%) patients received anlotinib combined with PD-1 inhibitors as first-line and second-line therapy, respectively. Among all patients, 29 patients were partial response (PR), 72 patients were stable disease (SD), illustrating ORR of 27.9% and DCR of 97.1%. In the first-line, ORR was 30.0%, DCR was 96.6%. In the second-line, ORR was 25.0%, DCR was 97.7%.The median follow-up time was 9.4 months (95%CI:8.1-10.7). Median PFS and median OS were not reached. The most common Grade 3-4 AEs were decreased lymphocyte count (3.8%), decreased platelet count (2.8%), decreased white blood cells (1.9%), neutropenia (1.9%), hand-foot syndrome (1.0%) and there were no Grade 5 toxicities.

Conclusions: The combination of anlotinib and PD-1/PD-L1 inhibitors may represent a new treatment option as first-line or second-line treatment in advanced NSCLC. The further exploration is ongoing.

Background: Platinum-based chemotherapy (CT) with PDL-1 blockade is the standard of care in ES-SCLC. Relevant randomized controlled trials were restricted to patients(pts) with ECOG PS 0-1 at initiation of therapy. These trials also prohibited use of consolidation radiotherapy (RT) or salvage RT to treat of oligo-progression. We aimed to evaluate outcomes in pts with poor ECOG PS and those receiving non-palliative RT, as well as the prevalence and outcomes of durvalumab (DRV) beyond progression.

Methods: A retrospective data collection including pts from 11 centers in four countries. Primary endpoints were overall survival (OS) and duration of treatment (DOT) in the overall population and in the subgroup of pts with ECOG ≥2. Secondary endpoints included safety, OS and DOT in pts treated with non-palliative RT as well as the use of ICI beyond progression.

Results: A total of 100 pts received durvalumab with CT for ES-SCLC. 68% were male, median age was 65 years (range 39-83) and 23% had an ECOG ≥2. Overall, 29% of patients received RT during durvalumab treatment, 22% as salvage/consolidation. Fifteen pts (15%) were treated with DRV beyond progression for a median of 4 cycles (range 1-14). Median OS in the entire cohort was 11.5mo, 13.3mo in pts with ECOG 0-1 and 10.3mo in pts with ECOG ≥2 (p=0.028). Median DOT in the entire cohort was 4.5mo and 4.2 in pts with ECOG ≥2 (p=0.006). Pts receiving non-palliative RT showed a trend toward improved OS and DOT (Table). Eight pts (8%) discontinued DRV due to immune-related adverse events.

Table: 1488P mDOT and mOS in pts receiving non-palliative RT

	All patients	Pts with consolidation/salvage RT	P-VALUE
mDOT with durvalumab (months)	4.5	5.9	0.056
mOS (months)	11.5	14.7	0.190

Conclusions: Treatment with CT and DRV is safe and effective in pts with ES-SCLC with ECOG PS ≥2 as well as in pts receiving concomitant radiotherapy. Treatment discontinuation rate due to toxicity was comparable to that reported in the CASPIAN study.

1489P To investigate the differences in efficacy between immunotherapy and combined immunotherapy in elderly patients with non-small cell lung cancer

Y.Y. Mao[1], A. Wang[1], J. Zhai[1], S. Sheng[1], D. Lu[2], X. Ge[1], W. Yang[3], J. Cai[1], J. Wang[3]

[1]Oncology Department, The Fifth Medical Center of Chinese PLA General Hospital, Beijing, China; [2]The Fifth Medical Center of PLA General Hospital, Chinese PLA General Hospital (301 Military Hospital), Beijing, China; [3]Oncology Department, Chinese PLA General Hospital (301 Military Hospital), Beijing, China

Background: Lung cancer is the leading cause of cancer death worldwide. In recent years, the therapeutic landscape for advanced non-small cell lung cancer (NSCLC) has changed with the rise of targeted therapies and immunotherapy. Elderly patients represent approximately half of the patient population, but studies on the treatment of elderly patients are limited.

Methods: A retrospective collection of 244 patients with pathologically confirmed NSCLC at APL General Hospital's First Medical Center and Fifth Medical Center, including 69 patients treated with immune monotherapy and 175 patients treated with combined immunotherapy. Cox regression analyses were used to assess whether there were differences in efficacy between immune monotherapy and combined immunotherapy.

Results: A total of 244 elderly patients were included in the study, and the analysis found that combined immunotherapy has a longer median OS. Patients with distant lung cancer metastases (HR 1.633, 95% CI 1.133-2.354), using immunotherapy as a second-line treatment (HR 1.717, 95% CI 1.238-2.380), and with pleural effusion (HR 1.772, 95% CI 1.246-2.522) had a shorter OS, whereas the patients treated with the combined immune therapy had a longer OS (HR 0.538, 95% CI 0.387-0.748). For patients aged 60-65 years with pleural effusion and second-line use of immunotherapy shortened OS. OS was shorter in patients aged 65-75 years with brain metastases and longer in patients receiving the combined immunotherapy. Multivariate analysis showed that BMI >24.8 and the use of combined immunotherapy were protective factors for OS and that the presence of pleural effusion was a risk factor. For patients aged 60 to 65 and 65 to 75, the presence of pleural effusion was a risk factor. Among patients >75 years, we only found a longer OS in patients with BMI >24.8(P=0.023).

Conclusions: For older patients with advanced NSCLC, the survival benefit of using combined immunotherapy is higher than that of immune monotherapy. However, that there was no difference in the efficacy of immune monotherapy or combined immunotherapy in this group (P =0.762), but patients with a BMI >24.8 had a longer OS.

1490P Removal of TNF-Rs frees TNF-α's anticancer activity alone or in combination chemo- or immunotherapy in advanced NSCLC

M. Bozkurt[1], D. Gökhan[1], M. Teomete[2], C. Turam[1], L. Florin[3], A. Ostrowski[3], R. Segal[3], V. Manax[3]

[1]Medical Oncology, Acibadem Atakent Hastanesi, Istanbul, Turkey; [2]Medical Oncology, Acibadem Altunizade Hasta, Üsküdar/Istanbul, Turkey; [3]Clinical Development, Immunicom, Inc., San Diego, CA, USA

Background: Tumor necrosis factor (TNF-α) has anticancer activity. Tumors neutralize TNF-α by shedding excess soluble TNF receptors (sTNF-Rs) in the tumor microenvironment preventing TNF-α from binding to tumor membrane bound sTNF-Rs, triggering cell death pathways. Removal of sTNF-Rs via apheresis liberates the anticancer effects of TNF-α alone or with anticancer agents.

Methods: Protocol CP7-008 [NCT04690686] evaluated LW-02 Column Immunopheresis® ('LW-02 CI') in advanced (Stages IIIB/IV) squamous or adenocarcinoma NSCLC patients (pts), who progressed 1or 2 line(s) of treatment (1st-line with a platinum salt). Sixteen (16) pts were assigned to 1 of 3 arms to receive LW-02 CI 3x/week: with atezolizumab (Arm 1, n=7), with paclitaxel (Arm 2, n=3) or as monotherapy (Arm 3, n=6; pts progressed 2 lines, or 1 but not suitable for Arm 1) for 16 weeks. Clinically stable and/or objectively improved pts could receive extended therapy.

Results: Safety and tumor burden changes were evaluated in two groups—pts that had at least 1 LW-02 CI treatment ('ITT') and pts treated ≥4 weeks (≥4 wks). Pts' tumor burden was assessed via RECIST 1.1 (or iRECIST if appropriate). After 644 LW-02 CI procedures, 373 AEs (including 22 SAEs) were reported; 18 AEs (14.8%), including 3 SAEs (13.6%), had a causal relationship to treatment with the LW-02 Column. All were Grades 1 or 2, except for 2 Grade 3 SAEs. All resolved, and none required treatment discontinuation. For tumor burden, the best overall response was stable disease (11 pts), durable for ≥8 wks. Other endpoints were duration of treatment (DoT), overall survival (OS), disease control rate (DCR) and progression free survival (PFS). The results are summarized for both groups below.

Table: 1490P Median DoT, OS, DCR and PFS

Endpoint *(mos)*	Overall		Arm 1		Arm 2		Arm 3	
	ITT	≥4 wks	ITT	≥4 wks	ITT	≥4 wks	ITT	≥4 wks
DoT	**4.1**	**4.7**	**4.3**	**4.7**	**5.4**	**5.4**	**3.0**	**3.5**
OS	**9.9**	**11.1**	**16.5**	**17.0**	**9.5**	**9.5**	**7.7**	**10.2**
PFS	**4.1**	**5.2**	**4.0**	**4.0**	**7.7**	**7.7**	**5.5**	**5.8**
DCR *%*	**68.8**	**84.6**	**57.1**	**80.0**	**100.0**	**100.0**	**66.7**	**80.0**

Conclusions: LW-02 CI alone or combined with chemo- or immunotherapy appears safe with clear anticancer efficacy signals in treating advanced NSCLC. These results, when compared with data from existing therapies, warrant further investigation.

Clinical trial identification: NCT04690686.

1491P PD-L1 TPS ≥50% predicts durable response after discontinuing immune checkpoint inhibitors in metastatic non-small cell lung cancer patients

J. Seo, B. Keam, J. Youk, M. Kim, T.M. Kim, D-W. Kim

Department of Internal Medicine, Seoul National University Hospital, Seoul, Republic of Korea

Background: The optimal duration of immune checkpoint inhibitors (ICI) in metastatic non-small cell lung cancer (NSCLC) remains uncertain. Some physicians administer ICI for 2 years then discontinue it according to the designs of clinical trials, while other physicians continue ICI until progression. This study aims to explore the clinical course after discontinuation of ICI and identify factors related with durable responses after ICI cessation.

Methods: We retrospectively analyzed 45 patients with metastatic NSCLC who received ICI for ≥1.5 years and then discontinued treatment. All patients showed complete response or partial response or stable disease. Patients who initiated ICI between Jan 2014 and Dec 2020 were enrolled. Clinical factors including PD-L1 status were analyzed.

Results: The median duration of ICI treatment was 23.4 months, and the median follow-up duration from ICI discontinuation was 14.1 months. Thirty-five patients (77.7%) showed durable response after ICI cessation which lasted for median 17.0 months without any treatment, while 10 patients showed disease progression. Durable response was significantly associated with PD-L1 TPS ≥50% (28/31, OR 0.12, 95% CI 0.01-0.80, p=0.013). PD-L1 TPS ≥50% was significantly associated with longer PFS (median not reached *vs*. 41.9 months, HR 0.16, 95% CI 0.04-0.68, p=0.005). In multivariate analysis, only PD-L1 TPS ≥50% was an independent predictor of longer PFS after ICI discontinuation (HR 0.17, 95% CI 0.04-0.71, p=0.015).

Table: 1491P Baseline characteristics

	Durable response (n=35)	Disease progression (n=10)	P value
Male	32 (91.4%)	9 (90.0%)	1.000
Age	67 (37-79)	65 (59-78)	0.714
PD-L1 TPS	90% (0-100)	15% (0-100)	0.005*
≥1%	30 (90.9%)	6 (75.0%)	0.528
≥50%	28 (84.8%)	3 (37.5%)	0.019*
ICI agent			1.000
Pembrolizumab	21 (60.0%)	3 (30.0%)	
Nivolumab	10 (28.6%)	6 (60.0%)	
Others	4 (11.4%)	1 (10.0%)	
ICI line			0.124
1	15 (42.9%)	1 (10.0%)	
≥2	20 (57.1%)	9 (90.0%)	

Conclusions: PD-L1 TPS ≥50% predicts durable response without any treatment after ICI discontinuation in metastatic NSCLC patients treated with ≥1.5 years of ICI. Further biomarker research is required to identify which patients should continue receiving ICI and which can be tried with ICI cessation.

1492P Retrospective study of the real-world safety profile of extended dosing 6-weekly pembrolizumab in comparison to traditional 3-weekly dosing schedule for treatment of lung cancer and melanoma in a Queensland hospital

P. Sekar[1], A. Ashok Kumar[2], R. Mason[1], I. Hughes[1], M. Dzienis[1]

[1]Medical Oncology, Gold Coast University Hospital (GCUH), Southport, QLD, Australia; [2]Medical Oncology, Gold Coast Health, Gold Coast, QLD, Australia

Background: Due to the widespread uptake of 6-weekly Pembrolizumab (6wklyP) in the COVID-19 era, this audit attempts to clarify differences in clinically relevant immune therapy related adverse events (irAEs) between 6wklyP and traditional 3-weekly Pembrolizumab (3wklyP).

Methods: Oncology patients at the Gold Coast University Hospital with Advanced Melanoma or Metastatic Non-small cell lung cancer (NSCLC) who received single agent 3wklyP 200mg, 6wklyP 400mg or those who sequentially received 3wklyP followed by 6wklyP between 2017-2022 were analysed for frequency of clinically significant (Grade3-4) irAEs. Total time of immunosuppression for treatment of irAEs was recorded. Data was extracted from the electronic medical record and analysed using Cox-proportion hazard analysis.

Results: In total, 69 and 112 patients received 6wklyP and 3wklyP respectively. There were 52 patients with Melanoma and 129 patients with NSCLC. 30 patients received sequential treatment. Average observation time for toxicity was 327 days for 6wklyP and 352 days for 3wklyP. 17/69 (24.6%) patients who received 6wklyP developed Grade 3-4 irAEs compared with 9/112 (8%) 3wklyP patients (HR of 3.03; CI 1.34-6.83, p= 0.007). Grade 1-4 irAEs were 32/69 (46.4%) with 6wklyP and 31/112 (27.7%) with 3wklyP. 6/30 (20%) patients who received 6wklyP after initially receiving 3wklyP had Grade 3-4 irAEs (HR 0.56, CI 0.24-1.37; p= 0.187). Mean immunosuppression time for treatment of Grade 3-4 irAEs for 6wklyP and 3wklyP was 91 days and 55 days respectively (p =0.76). 6/17 (35.3%) 6wklyP patients required Steroid sparing agents to treat their Grade3-4 irAEs compared to 1/9 (11.1%) 3wklyP patients.

Conclusions: 6wklyP was associated with significantly higher immune therapy related adverse events than 3wklyP. Sequential delivery of 6wklyP after 3wklyP did not significantly alter clinically significant adverse effects. Immunosuppressive management of irAEs were not statistically different between arms however there was a higher rate of steroid sparing immunomodulation requirement with 6wklyP.

1493P A phase II, multi-center, open-label, dose-optimization study evaluating telomere targeting agent THIO sequenced with cemiplimab in patients with advanced NSCLC: Preliminary results

T. Jankowski[1], S. Sótér[2], R. Raumlau[3], N. Chilingirova[4], M.D. Cholakova[5], B. Seidl[6], M. Moore[7], R. Joshi[8], V. Vitoc[9], V. Zaporojan[10], S. Gryaznov[11], P. Watkins[11], M. Obrocea[9]

[1]Department of Pneumology, Oncology and Allergology, Medical University of Lublin, Lublin, Poland; [2]Oncology, OKTPI-Korányi National Institute for Tuberculosis and Pulmonology, Budapest, Hungary; [3]Department of Oncology, Poznan University of Medical Sciences, Poznan, Poland; [4]Oncology, MHAT Heart and Brain, Pleven, Bulgaria; [5]Medical Oncology Dept, MC Synexus, Sofia, Bulgaria; [6]Medical Oncology, Sunshine Coast Haematology and Oncology Clinic, Buderim, QLD, Australia; [7]Oncology, St Vincent's Cancer Centre, Fitzroy, VIC, Australia; [8]Medical Oncology, CRSA - Cancer Research SA, Adelaide, SA, Australia; [9]Clinical Development, MAIA Biotechnology, Inc., Chicago, IL, USA; [10]Safety, MAIA Biotechnology, Inc., Chicago, IL, USA; [11]Clinical Operations, MAIA Biotechnology, Inc., Chicago, IL, USA

Background: THIO (6-thio-2'-deoxyguanosine) is a small molecule, first-in class direct cancer telomere targeting agent which selectively targets telomerase positive (TERT+) cancer cells. It is incorporated de novo in synthesized telomeres leading to chromatin uncapping, DNA damage signals generation and rapid apoptosis. Preclinical data in NSCLC indicates that low doses of THIO induce sensitivity to immune check point inhibitors (ICIs) when administered prior to an ICI.

Methods: This is a phase 2, dose-optimization clinical study in adults with advanced NSCLC who either progressed or relapsed after 1L treatment with ICI alone or in combination with chemotherapy. Using a modified 3+3 design, the safety lead-in (Part A) enrolled 10 patients who received THIO, 360 mg IV [120 mg QD, D1—3], followed by 350 mg cemiplimab on D5, Q3W. The primary endpoints are safety, ORR, DCR. Once the safety of the 360 mg is characterized, additional patients are randomized in the dose-finding portion of the study (Part B). Using a Simon 2-stage design, a total of 123 patients (41 patients/arm) will be assigned to one of the THIO doses: 360, 180, or 60 mg followed by cemiplimab Q3W for up to 1 year. Disease status is assessed at 6-week intervals through cycle 5 and every 9 -12 weeks thereafter.

Results: As of April 2023, 13 patients received at least one dose of THIO followed by cemiplimab (10 in Part A and 3 in Part B). All patients had 1-3 prior treatments and had documented disease progression. In Part A, no DLTs were reported (n = 10 subjects, 9 evaluable and 1 replaced due to delayed toxicities from a previous treatment). Most AEs were G1; G3 anemia in 1 patient (8%); G3 nausea, G3 AST/ALT elevations reported in 2 patients (15%) and one death not treatment related; 29 cycles were administered, and 4 patients had at least one radiographic evaluation after 2 cycles. The first 2 patients enrolled were discontinued after 5 and 4 cycles respectively due to withdrawal of consent and delayed recovery of toxicities; they are alive and progression-free with no new treatment at 10- and 9-months follow-up.

Conclusions: The study continues patient enrollment at all 3 dose-levels.

Clinical trial identification: NCT05208944; Release date: 15 January 2023.

1494P Fruquintinib combined with sintilimab and chemotherapy as the first-line treatment in advanced naive EGFR- and ALK-negative non-squamous non-small cell lung cancer(nsq-NSCLC): Updated results of a phase II trial

Y. Shu, P. Ma, H. Shen, W. Gao, X. Chen, J. Sun, L. Xu

Department of Oncology, Jiangsu Province Hospital/The First Affiliated Hospital of Nanjing Medical University, Nanjing, China

Background: Furoquitinib(F) is an orally highly selective tyrosine kinase inhibitor targeting VEGFR1,2,3. We previously reported some results of NCT04956146, which demonstrated that F plus PD-1 inhibitor sintilimab(S) and platinum-based chemotherapy(chemo) had encouraging efficacy and manageable toxicity as the first-line treatment for advanced naive EGFR- and ALK-negative nsq-NSCLC. Herein, we present updated results.

Methods: This single-arm, open-label, phase II study consists of a safety lead-in phase (Part 1) and dose expansion phase (Part 2). In Part 1 the F taken orally at 5 mg (2 weeks on/ 1 weeks off, Q3W) plus S (200mg, iv, d1,Q3W) and chemo(Q3W). After 4～6 cycles followed by maintenance therapy with F(RP2D) plus S and pemetrexed or not. DLT was observed for 1 cycle. The primary objective of Part 1 is to assess the safety and confirm the RP2D of F. The primary objective of Part 2 is to estimate the PFS and the secondary endpoints including ORR, DCR, OS, and safety.

Results: From February 2022 to May 2023, 26 pts were enrolled. The median age was 62 years, with males 92.3%, ECOG PS 0 73.1%, and the median sum of longest diameters (SLD) is 100.805mm. Pts with PD-L1 TPS ≥1%, < 1%, and unknown were 14,

8, and 4 respectively. Of 20 evaluable pts, ORR and DCR were 80% and 100%. According to PD-L1 level, ORR was 91.7% and 57.1% for pts with PD-L1 TPS ≥1% and < 1%. ORR was 60% for baseline SLD < median SLD and 100% for median SLD > median SLD. Median PFS was not reached yet. All pts experienced≥1 treatment-emergent adverse events (TEAEs). The most common Gr≥3 TEAEs (≥10% pts) were Neutrophil count decreased (42.3%), Anaemia(15.4%), Gamma-glutamyltransferase increased(11.5%) and hypertriglyceridaemia (11.5%).

Conclusions: This finding showed promising efficacy for fruquintinib combined with sintilimab and chemo in pts with advanced NSCLC as a first-line treatment with a manageable safety profile. This study might represent a potential treatment option for pts with unresectable or metastatic advanced naive EGFR- and ALK-negative nsq-NSCLC.

Background: In EMPOWER-Lung 3 (NCT03409614; Part 2), a randomised, double-blind, placebo-controlled phase 3 trial, cemiplimab + chemotherapy (chemo) versus chemo alone showed improved overall survival (OS), progression-free survival (PFS), objective response rate (ORR), and patient-reported outcomes (PRO) and an acceptable safety profile in patients with advanced squamous and non-squamous non-small cell lung cancer (NSCLC) with all levels of programmed cell death-ligand 1 (PD-L1) expression and without *EGFR*, *ALK* or *ROS1* aberrations. Cemiplimab + chemo received FDA approval in 2022 as first-line treatment for advanced NSCLC irrespective of PD-L1 levels. In 2023, it received European Commission approval for PD-L1—positive patients. Here we describe outcomes for patients with PD-L1 expression ≥1% from EMPOWER-Lung 3 Part 2. PRO and subgroup results will be further described in the presentation.

Methods: A total of 466 patients were randomised 2:1 to receive 4 cycles of platinum-doublet chemo in combination with cemiplimab 350 mg (n=312) or with placebo (n=154) every 3 weeks up to 108 weeks. The primary endpoint was OS. Secondary endpoints included PFS and ORR. This post hoc analysis included patients with PD-L1 ≥1% with ∼2-year follow-up data (cutoff 14 June 2022).

Table: 1495P

EMPOWER-Lung 3 Part 2	Patients with PD-L1 ≥1% (N=327)	
	Cemiplimab + chemo (n=217)	Chemo alone (n=110)
OS, median, months	23.5	12.1
HR (95% CI)	0.52 (0.39, 0.70); *P*<0.0001	
PFS, median, months	8.3	5.5
HR (95% CI)	0.47 (0.36, 0.61); *P*<0.0001	
ORR, %	47.9	22.7
Odds ratio (95% CI)	3.09 (1.83-5.21); *P*<0.0001	
Complete response, n (%)	11 (5.1)	0
Partial response, n (%)	93 (42.9)	25 (22.7)
Duration of response, median (95% CI), months	17.5 (13.1, 21.5)	6.5 (4.2, 10.3)
Grade ≥3 TEAEs, n/N (%)	105/217 (48.4%)	30/109 (27.5%)

Results: In 327 patients with PD-L1 ≥1%, median OS was longer with cemiplimab + chemo than chemo alone (23.5 vs 12.1 months; HR: 0.52, *P*<0.0001). Median PFS was 8.3 months with cemiplimab + chemo versus 5.5 months with chemo alone (HR: 0.47, *P*<0.0001). ORRs were 47.9% vs 22.7%, with a response duration of 17.5 and 6.5 months. Grade ≥3 treatment-emergent adverse events (TEAEs) occurred in 48.4% of patients with cemiplimab + chemo versus 27.5% with chemo alone. The safety profile for cemiplimab + chemo in patients with PD-L1 ≥1% was generally consistent with that in overall patients.

Conclusions: Cemiplimab + chemo showed improved efficacy compared with chemo alone in PD-L1—positive patients with advanced NSCLC.

Clinical trial identification: NCT03409614; Part 2.

1496P Higher levels of CSF-1 support resistance to immune checkpoint inhibitors in advanced non-small cell lung cancer

P. Takam Kamga[1], M. Mayenga[1], L. Sebane[2], A.E. Costantini[2], C.G. Kotokpo Youkou[1], C. Julie[1], C. Capron[3], F. Parent[4], C. Guettier[5], A. Seferian[4], J-F. Emile[1], E. Giroux-Leprieur[2]

[1]EA4340 BECCOH, Université Paris-Saclay, UVSQ, Boulogne-Billancourt, France; [2]Department of Respiratory Diseases and Thoracic Oncology, University Paris-Saclay, UVSQ, APHP — Ambroise Paré Hospital, Boulogne-Billancourt, France; [3]Hematology Immunology., Hopital Ambroise Pare AP-HP, Boulogne-Billancourt, France; [4]Pulmonology, Hôpital Bicêtre AP-HP, Le Kremlin-Bicetre, France; [5]Pathology, CentraleSupélec - Paris-Saclay Campus, Gif Sur Yvette, France

Background: Since the recruitment and polarization of TAMs are regulated by CSF-1R/CSF-1, the expression levels of these factors may be indicative of TAM physiology and correlated with antitumoral immunity and response to therapy. This study aimed to investigate the influence of CSF-1R/CSF-1 activation levels on tumor response in patients with advanced non-small cell lung cancer (NSCLC) receiving first-line immune checkpoint inhibitor (ICI) therapy.

Methods: This bicentric study included a prospective cohort of 88 patients with advanced NSCLC treated with ICIs as first-line therapy. Plasma levels of CSF-1 were assessed by ELISA. Peripheral blood mononuclear cells were used both for immunomodulatory assays and to produce macrophages through CSF-1 treatment. To assess the mechanism of CSF-1-mediated suppression of immunotherapy, Isolated PBMC, activated with phytohemagglutinin (PHA) with or without pembrolizumab (20 nM), were cultured alone, or in the presence of macrophages or on an established NSCLC monolayer. INFγ levels and CD8+ proliferation/activation were assessed through ELISA assay and flow cytometry respectively.

Results: Plasma levels of CSF-1 were found to be higher in patients resistant to ICI therapy (8898 vs. 14031 pg/mL, $p < 0.001$). Higher levels of CSF-1 were associated with poor therapy response (RR = 7,944; $p = 0.013$), disease progression (RR = 8.556; $p < 0.001$), and shorter survivals (PFS, 50 days vs. 305 days; $p < 0.001$; OS, 248 days vs. 1369 days, $p < 0.01$). In vitro, recombinant CSF-1 inhibited CD8+ activation and interferon gamma (INFγ) production that was induced by PHA and Pembrolizumab. The use of Pexidartinib (PLX-3397), a CSF-1R inhibitor, reversed the effects of CSF-1 by restoring lymphocyte activation. However, these effects were dependent on the presence of monocytes/macrophages, suggesting that the immune suppression mediated by CSF-1 was an indirect effect resulting from the stimulation of monocytes that promote their differentiation into macrophages.

Conclusions: Our study suggests that plasma levels of CSF-1 could serve as a useful predictive biomarker for resistance to ICIs, while targeting the CSF-1/CSF-1R signaling pathway could potentially overcome resistance to ICIs in patients with NSCLC.

1497P Gut microbiome is associated with the clinical response to anti-PD-1 based immunotherapy in untreated advanced non-small-cell lung cancer

Y. Bin[1], F. Tong[1], Y. Zhang[2], R. Zhang[1], H. Zhou[1], P. Liu[1], S. Zhang[1], Y. Wang[1], N. Yang[2], X. Dong[1]

[1]Thoracic Oncology Department, Cancer Center, Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, China; [2]Lung Cancer and Gastrointestinal Unit, Hunan Provincial Cancer Hospital, Changsha, China

Background: Lung cancer is a malignancy with extremely high morbidity and mortality, of which non-small cell lung cancer (NSCLC) accounts for about 85%. With the advent of immunotherapy has brought survival benefit to NSCLC patients, some patients still be hard to achieving satisfactory outcomes. The link between gut microbes and immunotherapy is strong, but the role they play in NSCLC immunotherapy is unclear. The aim of this study was to investigate the relationship between gut microbial composition and the efficacy of immunotherapy in NSCLC.

Methods: Patients with advanced NSCLC receiving first-line immunotherapy were enrolled, and fresh stool samples were collected before and after 2 cycles of anti-PD-1 monoclonal antibody treatment for metagenomics sequencing and annotation using the KEGG and MetaCyc databases for subsequent differential flora analysis and functional analysis, and correlated the results with outcomes at 41 months.

Results: A total of 51 patients with advanced NSCLC treated with first-line immunotherapy were included in this study, and the relative abundance of *Streptomyces*, *Corynebacterium*, *Kineosphaera*, and *Schaalia* genus under the *Actinomyces* phylum was increased in the R group, and the PFS (progression-free survival time) of patients with high relative abundance of *Schaalia* and *Corynebacterium* genus was significantly longer than in those with low relative abundance. Functional analysis revealed reduced levels of glycolysis in the R group and may be due to the enrichment of *Schaalia* genus. The BMI and fasting glucose values of the patients may be influential factors in the relative abundance of *Schaalia* genus. In addition, the type of irAE occurrence was also correlated with the composition of gut microbes.

Conclusions: We have newly discovered that *Schaalia* genus under the *Actinobacteria* phylum may influence the efficacy of immunotherapy in NSCLC patients by inhibiting the level of glycolysis through affecting the level of PFP. Therefore, *Schaalia* flora may be a potential marker for predicting the efficacy of immunotherapy in NSCLC patients, and interfering with the levels of *Schaalia* or PFP is expected to be a new target to enhance the efficacy of immunotherapy in NSCLC patients.

1498P HGF/MET pathway is associated with poor efficacy of Immune checkpoint inhibitors (ICIs) in advanced-stage NSCLC

A. Akli[1], P. Takam Kamga[1], A.E. Costantini[2], C.G. Kotokpo Youkou[1], C. Julie[1], C. Capron[3], C. Dumenil[2], J. Dumoulin[2], V. Giraud[2], M. Glorion[4], E. Longchampt[5], J-F. Emile[1], E. Giroux-Leprieur[2]

[1]EA4340 BECCOH, Université Paris-Saclay, UVSQ, Boulogne-Billancourt, France; [2]Department of Respiratory Diseases and Thoracic Oncology, University Paris-Saclay, UVSQ, APHP − Ambroise Paré Hospital, Boulogne-Billancourt, France; [3]Hematology Immunology, Hopital Ambroise Pare AP-HP, Boulogne-Billancourt, France; [4]Service de Chirurgie Thoracique, Hopital Foch, Suresnes, France; [5]Service d'Anatomopathologie, Hopital Foch, Suresnes, France

Background: A pilot study has revealed a significant correlation between high levels of circulating HGF and poor response to ICIs therapy in late-stage NSCLC patients treated with ICIs. This study aimed to evaluate the prognostic value and role of the HGF/MET pathway in first-line immunotherapy treatment in advanced NSCLC patients.

Methods: We included 82 consecutive patients, 49 treated with immunotherapy and 33 treated with chemotherapy alone as a group control. We analysed the plasma levels of HGF by ELISA. Immunohistochemistry was used to assess the expression levels of PD-L1, MET, and CD8+ T-Cell infiltration. The contribution of HGF/MET to NSCLC response to ICIs was further investigated by culturing peripheral blood mononuclear cells (PBMC)stimulated with 10 μg/mL phytohemagglutinin (PHA) and/or pembrolizumab (20 nM). The cells were cultured with recombinant HGF or co-cultured with NSCLC patients-derived explants.in the presence of cMET inhibitors Crizotinib or SGX. The immune response was quantified through CD8+ activation and INFγ production.

Results: Correlation tests demonstrated that lower HGF levels were associated with a good response to ICIs (RR=2.143; p=0.004) and low progression (RR=0; p=0.01). Patients with low HGF levels (< Q1) at treatment initiation had longer progression-free survival (PFS) (841 vs 136.5 days; HR = 0.26 95% CI 0.1292-0.5411; p=0.0003) and longer overall survival (OS) (median not reached vs. 489 days; HR 0.36; 95% CI 0.1505-0.8408; p=0.02). Furthermore, when activated PBMCs were cultured in the presence of recombinant HGF or on NSCLC monolayer, the activation/proliferation of CD3+CD8+ lymphocytes, was inhibited, even in the presence of pembrolizumab. The addition of HGF/MET inhibitors (Crizotinib and SGX) suppressed the immunosuppressive properties of recombinant HGF or NSCLC, stimulating INFγ production.

Conclusions: Our study found that high levels of HGF in the peripheral blood are associated with poor response to ICIs, disease progression, and shorter survival in patients with advanced NSCLC. Furthermore, we showed through in vitro experiments that inhibiting the HGF/MET signaling pathway could be a promising therapeutic approach to enhance the efficacy of ICIs in this patient population.

1499P Wnt5-ROR2 signalling mediated resistance to immune checkpoint inhibitors in advanced non-small cell lung cancer

E. Giroux-Leprieur[1], P. Takam Kamga[2], M. Mayenga[2], A.E. Costantini[1], C.G. Kotokpo Youkou[2], C. Julie[2], C. Capron[3], M. Glorion[4], J-F. Emile[2]

[1]Department of Respiratory Diseases and Thoracic Oncology, University Paris-Saclay, UVSQ, APHP − Ambroise Paré Hospital, Boulogne-Billancourt, France; [2]EA4340 BECCOH, Université Paris-Saclay, UVSQ, Boulogne-Billancourt, France; [3]Hematology Immunology, Hopital Ambroise Pare AP-HP, Boulogne-Billancourt, France; [4]Service de Chirurgie Thoracique, Hopital Foch, Suresnes, France

Background: Emerging evidence suggests that Beta-catenin-independent Wnt signaling is upregulated in lung carcinogenesis, but few studies have investigated its prognostic value or its impact on the immune response in NSCLC patients undergoing checkpoint inhibitors (ICIs therapy. **The goal** of this study is to examine the prognostic significance of non-canonical Wnt signaling molecules, and their potential value as drug targets to enhance the efficacy of ICIs in NSCLC patients.

Methods: This study enrolled a prospective cohort of 52 patients with advanced NSCLC receiving immune checkpoint inhibitors (ICIs) therapy. Samples (plasma and lung biopsies) were collected at various stages of treatment and analysed for Wnt expression using RT-qPCR, flow cytometry, ELISA assays, and immunohistochemistry. To investigate the mechanism of Wnt-mediated drug response, including response to ICIs and/or chemotherapy, stimulated PBMCs (anti-CD3/CD28 + rh-IL2) were treated with or without pembrolizumab and cultured/co-cultured with recombinant Wnt5a,Wnt inhibitors and NSCLC explants.

Results: We found higher levels of Wnt5a and Wnt5b in patient's samples. Wnt5a was upregulated in patients' plasma compared to healthy donors (1262 vs 372.0 ± pg/mL, $p < 0.001$). Samples collected at first evaluation had low levels of Wnt5a compared to the baseline (1262 vs 771.9 pg/mL, $p < 0.01$). Wnt5a expression was related with poor therapy response (RR =2.4; p = 0,05) and shorter survivals (PFS non reached vs 259 days, HR =0.141, $p < 0.01$). ELISA analysis of supernatants from NSCLC cell culture showed that supporting the fact that Wnt5a and Wnt5b are produced by tumor cells. In vito experiments demonstrated that recombinant Wnt5a as well as NSCLC monolayer, suppressed lymphocytes activation and the production of INF γ. These effects were reverted by Wnt inhibitors, including porcupine inhibitors.

Conclusions: The preclinical results of our study provide comprehensive validation for the modulation of Wnt as a drug candidate to improve the effectiveness of immunotherapy in treating NSCLC. Our findings offer compelling evidence that Wnt5 signalling can serve as predictive biomarkers and drug targets to prevent disease relapse in advanced NSCLC patients receiving ICIs.

Background: Standard regimens for anti-PD1 agents nivo and pembro may result in overtreatment. These agents have high target affinity, saturate PD1 at low concentrations, occupy PD1 long after discontinuation and have a flat dose-response relationship across a wide range tested. Lower doses or longer administration frequency may retain efficacy. New approaches to optimise treatment regimens are required to enhance cost-effectiveness, pt quality of life and toxicity. However, conventional 2-arm non-inferiority designs are inefficient for this. We present a new multi-arm trial design to tackle the problem, implemented in the UK multicentre phase III REFINE-Lung study that aims to determine the optimal treatment frequency of pembro in NSCLC. Pts progression free after 6 months of standard therapy are randomised to 5 pembro frequency reduced arms (q6w, q9w, q12w, q15w and q18w). By evaluating the frequency-response relationship, the longest frequency that is equivalent to standard of care within a pre-defined margin will be determined.

Trial design: The REFINE-Lung trial (NCT05085028) is a multicentre, randomised open-label, phase III trial in advanced NSCLC, utilising a novel Multi-Arm Multi-Stage Response Over Continuous Interventions (MAMS-ROCI) design. 1750 pts aged $\geq$18 and progression free at six months of 1st line pembro and planning to continue, will be enrolled from up to UK 35 hospital groups. Pts will be randomised equally to 5 dose frequency arms, starting with q6w (control) vs. q12w arms for an interim analysis of safety. If q12w PFS is not significantly reduced, remaining q9w, q15w and q18w arms will be opened. Pts who progress may re-escalate to q6w therapy. Primary objective is to determine the optimal dose frequency of pembro, defined as the longest dose interval non-inferior to standard therapy using 2-year survival as the primary outcome. Secondary endpoints include OS, PFS, toxicity, quality of life and cost effectiveness. An exploratory sub-study will explore fundamental aspects of cancer immunotherapy and develop novel biomarkers of response, resistance and toxicity. The trial is currently open at 26 centres.

1501TiP A phase III global study of telisotuzumab vedotin versus docetaxel in previously treated patients with c-Met overexpressing, EGFR wildtype, locally advanced/metastatic nonsquamous NSCLC (TeliMET NSCLC-01)

A. Lugini[1], J.W. Goldman[2], J. Tanizaki[3], H. Akamatsu[4], S. Xia[5], C. Ratajczak[5], M. Li[5], E. Bolotin[5], J. Seraj[5], S. Lu[6]

[1]AO San Giovanni Addolorata, UOC Oncologia Medica, Rome, Italy; [2]David Geffen School of Medicine, University of California Los Angeles, Los Angeles, CA, USA; [3]Department of Medical Oncology, Kindai University - Faculty of Medicine, Osaka-Sayama, Japan; [4]Third Department of Internal Medicine, Wakayama Medical University, Wakayama, Japan; [5]Clinical Development, R&D, AbbVie, Chicago, IL, USA; [6]Shanghai Lung Center, Shanghai Jiao Tong University, Shanghai, China

Background: Non-small cell lung cancer (NSCLC) encompasses over two-thirds of lung cancer diagnoses, most presenting as advanced disease. c-Met (MET protein) is overexpressed in NSCLC. In this study, we investigate telisotuzumab vedotin (Teliso-V), a first-in-class antibody-drug conjugate composed of a c-Met—targeting antibody (telisotuzumab) and a microtubule polymerization inhibitor (cytotoxin monomethyl auristatin E). Interim efficacy analysis of the phase 2 LUMINOSITY study (NCT03539536) of Teliso-V monotherapy showed an objective response rate (ORR) of 37% (95% CI: 24—51) in previously treated patients (pts) with c-Met overexpressing epidermal growth factor receptor (*EGFR*) wildtype (WT) nonsquamous NSCLC and 52% (95% CI: 31—73) in the high c-Met overexpressing group.

Trial design: This randomized, open-label, global phase 3 study (NCT04928846) evaluates the efficacy, safety, pharmacokinetics, and pharmacodynamics of Teliso-V monotherapy compared with docetaxel in pts with locally advanced/metastatic c-Met overexpressing *EGFR* WT nonsquamous NSCLC who have progressed on prior therapy. Enrollment began in May 2022. To be eligible across global sites, pts must be $\geq$18 years old with c-Met overexpressing (ie, $\geq$25% tumor cells at 3+ intensity by IHC assay [anti-MET clone SP44; Roche Tissue Diagnostics]) locally advanced/metastatic *EGFR* WT NSCLC, with ECOG score $\leq$1. Pts must have progressed on at least one prior line of therapy, which can include no more than one line of prior chemotherapy, and must be naïve to c-Met—targeted antibodies and docetaxel. Target enrollment is 698 pts. Pts will be randomized 1:1 to Teliso-V (1.9 mg/kg every 2 weeks) and docetaxel (control, 75 mg/m^2 every 3 weeks). Treatment continues until disease progression or discontinuation criteria are met. Co-primary endpoints are progression-free survival by independent central review and overall survival. Secondary endpoints include ORR, duration of response, and patient-reported outcomes. Safety, adverse events (AEs), drug discontinuation or dosing modification due to AEs, and tolerability will be assessed.

Clinical trial identification: NCT04928846.

Background: While immunotherapy is a critical modality for the treatment of many cancers, many patients (pts) do not respond to checkpoint blockade. Vaccination against tumour antigens has potential to enhance this, and despite the historically limited success of vaccines in monotherapy, effective immune induction is observed. Prime-boost viral vaccination is a highly potent platform, priming immunity with the CHAdOx1 adenoviral vector, followed by MVA vaccinia vector boosting, against MAGE-A3 and NYESO-1. Nonclinical data to support the rationale for enhanced CHAdOx1-MVA efficacy, in combination with chemo- and immunotherapy, has been generated in an *in vivo* surrogate model (McAuliffe J et al, 2021). The MAGE-A3 antigen is expressed on tumours of a high percentage of cancer patients including non-small cell lung cancer (NSCLC). NYESO-1, expressed on a subset of MAGE-A3$^+$ tumours, has the additional advantage of being highly immunogenic in cancer patients, either spontaneously or in response to peptide vaccination. The safety, tolerability, efficacy and immunogenicity of ChAdOx delivery of MAGE-A3/NYESO-1 antigens, boosted by MVA-MAGE-A3 (MAGE-A3$^+$ pts) or MVA-MAGE-A3 and MVA-NYESO-1 (MAGE-A3$^+$NYESO-1$^+$ pts) are explored in this trial.

Trial design: This is a multi-centre, first-in-human, phase I/IIa, randomised, open label trial, run in the UK, for patients scheduled to receive first-line chemo-immunotherapy containing pembrolizumab as standard of care (SoC) treatment, for Stage III/IV NSCLC (and potentially additional indications) expressing MAGE-A3 +/- NYESO-1 (NCT04908111). Patients receive trial vaccination from Cycle 3 of their SoC treatment. In the initial Safety Run-In Stage, opened in October 2021, all patients receive ChAdOx1-MAGE-A3-NYESO prime vaccination and either MVA-MAGE-A3 single boost (3 evaluable pts) or MVA-MAGE-A3 and MVA-NYESO double boost (3 evaluable pts) vaccinations with SoC. The currently expanding Rolling Recruitment Stage includes a NSCLC Randomised Cohort of approximately 80 pts, randomised 1:1 to addition of vaccination. The primary objective is safety and tolerability, with key secondary objectives of immunogenicity and clinical efficacy. Tertiary objectives include correlative translational analyses.

1503TiP A phase II study of cemiplimab plus BNT116 versus cemiplimab alone in first-line treatment of patients with advanced non-small cell lung cancer with PD-L1 expression ≥50%

M.M. Awad[1], Y. Hao[2], S. Li[2], M. Kaul[3], F. Seebach[4], P. Goncalves[5], P. Brück[6], P. Rietschel[5]

[1]Department of Medical Oncology, Lowe Center for Thoracic Oncology, Dana-Farber Cancer Institute, Harvard Medical School, Boston, MA, USA; [2]Biostatistics, Regeneron Pharmaceuticals, Inc., Tarrytown, NY, USA; [3]Global Patient Safety, Regeneron Pharmaceuticals, Inc., Tarrytown, NY, USA; [4]Regulatory Affairs, Regeneron Pharmaceuticals, Inc., Tarrytown, NY, USA; [5]Clinical Sciences, Oncology, Regeneron Pharmaceuticals, Inc., Tarrytown, NY, USA; [6]Clinical Development, BioNTech SE, Mainz, Germany

Background: Cemiplimab is an anti—programmed cell death-1 (PD-1) antibody approved as first-line monotherapy for patients with locally advanced or metastatic non-small cell lung cancer (NSCLC) with ≥50% PD-ligand 1 (PD-L1) tumour cell expression. A high unmet medical need remains for patients with no or limited response to anti—PD-1/PD-L1 therapy. As prognosis is poor for these patients, there is growing interest in combining anti—PD-1 compounds with therapeutic cancer vaccines. BNT116 is an investigational mRNA-based therapeutic cancer vaccine consisting of a fixed set of 6 liposomally formulated RNAs, each encoding a different tumour-associated antigen frequently expressed in NSCLC.

Trial design: This is a randomised, multicentre, open-label phase 2 study of cemiplimab plus BNT116 versus cemiplimab alone in treatment-naive patients with stage IIIB, IIIC, or IV squamous or non-squamous NSCLC, who are ineligible for surgical resection or definitive chemoradiation. Patients must have PD-L1 expression on ≥50% of tumour cells (determined by analysis of resected tumour samples) and no actionable *EGFR, ALK*, or *ROS1* aberrations. Patients in arm A will receive cemiplimab beginning Cycle 1 Day 1 (C1D1). Patients in arm B will receive cemiplimab beginning C1D1 and BNT116. The primary endpoint is objective response rate per blinded independent review committee of cemiplimab plus BNT116 versus cemiplimab alone. Secondary endpoints will assess other antitumour activities of cemiplimab plus BNT116 versus cemiplimab alone, as measured by objective response rate per investigator assessment, duration of response, progression-free survival, and overall survival, as well as safety and tolerability. Enrollment of up to 100 patients is planned. Enrolment is ongoing.

Background: For patients (pts) with *EGFR*-mutant NSCLC, upfront treatment with tyrosine kinase inhibitors is standard. Drug resistance remains a challenge and an effective therapy after progression is needed. Ivonescimab (SMT112/AK112) is a novel bispecific antibody that provides dual blockade of PD-1 and VEGF activity. And coengagement of these 2 targets increases affinity to PD-1 by more than 10 fold. Given the correlation between VEGF-A and PD-1 expression in the tumor microenvironment, simultaneous blockade of these 2 targets by ivonescimab may produce enhanced antitumor activity, with an improved safety profile, compared to co-administration of individual anti-PD-(L)1 and an anti-VEGF agents. Phase 2 trial data reported that in 19 pts with *EGFR* mutated NSCLC who progressed following TKI therapy, the response rate to ivonescimab plus pemetrexed and carboplatin was of 68.4% (13/19) and a tolerable safety profile in the total population (N=83) treated with ivonescimab plus chemotherapy.

Trial design: HARMONi is a randomized, double-blind, multiregional phase 3 trial of ivonescimab or placebo in combination with pemetrexed and carboplatin in pts with locally advanced or metastatic *EGFR*-mutant NSCLC. 470 pts will be randomized 1:1 and to receive ivonescimab/placebo plus pemetrexed and carboplatin (Q3W, 4 cycles, 21 days per cycle) followed by ivonescimab/placebo plus pemetrexed for maintenance therapy for up to 2 yrs until progression or unacceptable toxicity. The co-primary endpoints are overall survival and progression-free survival assessed by IRC per RECIST v1.1. Secondary endpoints include overall response rate, incidence/severity of adverse events and immunogenicity of ivonescimab. Key eligibility criteria include advanced or metastatic NSq- NSCLC with an activating EGFR mutation, Eastern Cooperative Oncology Group Performance Status 0 or 1 and progression on/following third generation EGFR-TKI. The study will be a multi-national study including United States, Cana, Euroadpe and China.

Background: Immunotherapy has improved survival in patients (pts) with adv/met NSCLC. However, outcomes remain poor in pts with PD-L1 expression <50%, and more efficacious treatments are needed. Dato-DXd is an antibody-drug conjugate composed of a TROP2 directed monoclonal antibody covalently linked to a highly potent cytotoxic payload via a stable, tumor-selective, tetrapeptide-based cleavable linker. In the phase 1b TROPION-Lung02 trial, Dato-DXd + pembro ± Pt-CT had tolerable safety and promising antitumor activity in pts with adv/met NSCLC, notably as 1L therapy and irrespective of PD-L1 levels. Here, we describe the TROPION-Lung07 trial of Dato-DXd + pembro ± Pt-CT in pts with adv/met NSCLC without actionable genomic alterations (AGA) and PD-L1 expression <50%.

Trial design: TROPION-Lung07 (NCT05555732) is a global, randomized, open-label, phase 3 trial of 1L Dato-DXd + pembro ± Pt-CT in pts with nonsquamous adv/met NSCLC without AGA with PD-L1 expression <50%. Dato-DXd + pembro ± Pt-CT will be compared with pemetrexed + pembro + Pt-CT. Approximately 975 pts will be randomized 1:1:1 to Dato-DXd 6 mg/kg + pembro 200 mg (max, 35 cycles) ± Pt-CT (cisplatin 75 mg/m^2 or carboplatin area under the curve 5; max, 4 cycles) every 3 weeks (Q3W) or pemetrexed 500 mg/m^2 + pembro 200 mg + Pt-CT Q3W. Pts will be stratified by PD-L1 levels, Eastern Cooperative Oncology Group performance status, geographic region, and investigator choice of Pt-CT. Pts must have stage IIIB/C NSCLC ineligible for resection or definitive chemoradiation or stage IV disease and must not have received prior systemic therapy for adv/met NSCLC. The primary endpoints are progression-free survival by blinded independent central review and overall survival. Secondary endpoints include objective response rate (ORR), duration of response, time to response, disease control rate, and safety. Pt-reported outcomes, pharmacokinetics, and biomarkers will be explored. Enrollment is currently ongoing in the United States, Australia, China, Japan, Republic of Korea, Taiwan, and Thailand.

Clinical trial identification: NCT05555732.

Background: Osimertinib (osi) is the current first-line standard treatment for patients with NSCLCs with EGFR 19/21. Data suggest that combining EGFR tyrosine kinase inhibitor (TKI) with chemotherapy may be superior to a sequential approach of first-line TKI followed by salvage therapy. AMI is an EGFR/MET bi-specific antibody currently approved for NSCLCs with EGFR exon 20 insertions, but which is also being evaluated for NSCLCs with EGFR 19/21 in combination with chemotherapy (MARIPOSA-2 study) after osi progression. We designed AMIGO-1 to test the primary hypothesis that, in the first-line setting, the triplet regimen of AMI, combined with the 3rd generation irreversible TKI L, and P will improve progression-free survival (PFS) compared to historical controls, with an acceptable safety profile.

Trial design: AMIGO 1 is a single-arm, phase 2, multicenter trial, conducted through LACOG. Eligibility criteria include treatment-naïve, PS 0−1 patients with advanced NSCLCs with EGFR 19/21. Patients receive L 240mg PO daily, plus 21-day cycles of P 500mg/m^2 IV on Day 1, plus A: 1400mg IV (1750mg if body weight >=80Kg) once weekly in cycle 1; 1400mg IV (1750mg if body weight >=80Kg) on Day 1 in cycle 2; 1750mg IV (2100mg if body weight >=80Kg) at Day 1 from cycle 3 onwards. The primary endpoint is 18-month PFS (18m-PFS), estimated by the Kaplan-Meier method. A one group chi-square test with a type I error of 0.1 (one-sided) will have 80% power to detect the difference between the null hypothesis (18m-PFS of 50%, achieved with osi alone) and the alternative hypothesis (18m-PFS of 65%) with a sample size of 49. AMIGO-1 trial was opened to recruitment in May 2023 in research centers in Brazil. Clinical trial information: NCT05299125. This trial in progress is the first to assess the triplet regimen of lazertinib, amivantamab, and pemetrexed as first-line treatment for (NSCLCs) with EGFR mutations and will provide benchmark results to be contrasted with the present standard of care and future treatment combinations that are currently undergoing evaluation in phase 3 trials (eg. FLAURA2, MARIPOSA).

Clinical trial identification: NCT05299125.

Legal entity responsible for the study: Latin American Cooperative Oncology Group (LACOG).

Background: T-DXd is a HER2-directed antibody-drug conjugate available for the treatment of pts with metastatic NSCLC with activating *HER2* mutations, HER2+ breast or gastric cancer, or HER2-low breast cancer. DESTINY-Lung01 showed efficacy of T-DXd monotherapy in heavily pretreated pts with unresectable/metastatic, HER2-OE, nonsquamous NSCLC. In preclinical studies, the combination of T-DXd and immunotherapy was more effective than either therapy alone, and the addition of chemotherapy may improve efficacy. This trial is evaluating T-DXd alone or in combination with durvalumab (durva) or MEDI5752 (a PD-1/CTLA-4 bispecific antibody) with or without chemotherapy in pts with unresectable/metastatic, HER2-OE, nonsquamous NSCLC.

Trial design: DESTINY-Lung03 (NCT04686305) is a phase 1b, open-label, multicenter, dose-escalation and -expansion study in pts with HER2-OE unresectable, locally advanced or metastatic, nonsquamous NSCLC. In part 1 (enrollment completed), pts with disease progression after 1 or 2 lines of systemic therapy in the recurrent/metastatic setting receive T-DXd monotherapy or T-DXd + durva in combination with cisplatin, carboplatin, or pemetrexed. Part 2 of the trial was not initiated. In part 3, pts who have not received prior treatment for advanced or metastatic disease will receive T-DXd in combination with MEDI5752, with or without carboplatin; pts in this phase must not have a history of prior immunotherapy for early disease and must lack activating *EGFR* mutations, an *EML4-ALK* fusion, or other targetable alterations. The primary endpoint is the frequency of adverse events (AEs) and serious AEs (SAEs) with T-DXd + durva + chemotherapy (part 1) or T-DXd + MEDI5752 ± chemotherapy (part 3). Secondary endpoints include confirmed objective response rate, duration of response, disease control rate, progression-free and overall survival, pharmacokinetics, and immunogenicity in all arms as well as the frequency of AEs and SAEs with T-DXd monotherapy (part 1).

Clinical trial identification: NCT04686305.

Background: Lung cancer is the leading cause of cancer death worldwide. Radon is a radioactive gas tending to accumulate inside homes and it is considered one of the leading causes of lung cancer in non-smokers. The 2013/59 EURATOM directive regulates indoor radon in Europe, however regulating measures vary between countries. Radon emits alpha-ionizing radiation linked to a wide variety of cytotoxic/genotoxic effects; but the radon-associated molecular profile has never been described. Driver oncogenic alterations have been identified in non-small lung cancer (NSCLC), such as mutations (EGFR, ERBB2, BRAF, MET, etc.) or chromosomal fusions (ALK, ROS1, etc.), mainly in non-smokers, with no clear risk factor identified. Preliminary data suggest an association between radon and driver alterations in NSCLC. BIORADON's primary objective is to study the correlation of molecular profiles of NSCLC in patients with indoor radon concentration with special focus on drivers.

Trial design: This is a prospective observational study of 975 patients with all-stages NSCLC. Patients with current/previous history of NSCLC (survivors up to 5 years) will be enrolled in 30 centers from 5 European countries (Spain, France, Portugal, Belgium, Italy). Participants must have been living in the current home for $\geq$2 years before the diagnosis and molecular profile must have been previously performed in routine care to classify patients in 3 cohorts (each cohort n=325): A: driver-mutation group; B: driver-fusion group and C: control group. Patients will receive two alpha-track detectors to measure radon at their home for $\geq$ 3 months and complete a questionnaire, including demographics, home characteristics, smoking/environmental/occupational exposure. After measurement, the detectors will be sent to a central laboratory for analysis. A blood sample is collected and archived FFPE specimen is optional for additional research. All clinical data are electronically collected. Secondary objectives are the correlation of clinical/pathological profiles with radon +/- other risk factors. The duration of the study is 3 years (since 04/22) and enrolment period is estimated to be 18 months. This study is part of the RADONORM Consortium.

Background: Optimal therapeutic sequence has not yet been established in patients with *ALK* positive advanced non-small cell lung cancer (aNSCLC) developing *ALK* resistant mutations after treatment with 1st/2nd generation(gen.) ALK inhibitors (ALKi). Treatment selection based on *ALK* resistance mutations may be a strategic approach for the decision-making process as each ALKi has a different spectrum of coverage of *ALK* mutations. Liquid biopsy (ctDNA) can provide a non-invasive option to identify resistant mechanisms. Lorlatinib is a 3rd gen. ALKi that overcome *ALK* dependent resistance and being active against multiple *ALK* mutations that confer resistance to other inhibitors. ALKALINE aims to assess the activity of lorlatinib based on the presence of ALK mutations identified on ctDNA in patients progressing on 2nd gen. ALKi. A preselection sub-study will assess the time of emergence of resistance mutations in blood in patients under treatment with 2nd gen. ALKis.

Trial design: ALKALINE is a phase II, open-label, multicenter, single-arm study in 84 pts with *ALK+* aNSCLC progressing on 2nd gen. ALK TKI. ctDNA is performed before lorlatinib to stratify pts in 3 cohorts: A: if $\geq$ 1 ctDNA *ALK* mutations, B: non-*ALK* mutations and C: no ctDNA detected. Eligible patients receive lorlatinib until disease progression (PD), unacceptable toxicity or occurrence of any withdrawal criterion. Lorlatinib beyond PD is allowed if clinical benefit. Imaging, including brain MRI and ctDNA are performed every 2 months until week 40 and then 3 monthly. A prospective sub-study will assess the time to emergence of resistance mutations and its impact on outcomes in patient on treatment with 2nd gen. ALKi. ctDNA is collected 3 monthly until PD to 2nd gen. ALK inh. (RECIST v.1.1). Pts in the sub-study will enter the main study during PD based on RECIST v1.1. Primary endpoint is progression-free survival rate at 12 months in cohort A as assessed by Blinded Independent Central Review based on RECIST v1.1. Secondary objectives will evaluate activity in cohorts B and C, toxicity and patient reported outcomes. The estimated duration of the ALKALINE is 72 months, with an enrolment period of 42 months.

Clinical trial identification: EudraCT: 2019-003862-41; EU: 2022-502449-82-00; NCT04127110.

Background: Osimertinib (Osi) is the standard first-line therapy for patients (pts) with advanced NSCLC harbouring common Epidermal Growth Factor Receptor (EGFR) mutations. Not all pts achieve durable benefit during treatment developing early resistance. Increasing evidence suggest a potential implication of Tumor Protein 53 (TP53) in the biological mechanisms underlying resistance to Tyrosine Kinase Inhibitors (TKIs). Our previous study on EGFR+ advanced NSCLC pts receiving first-line gefitinib showed that additional coexisting mutations (ACM) significantly decrease the efficacy of TKIs and, among them, TP53 mutations were exclusively documented in poor/intermediate responders than in good, supporting the potential role of this gene in influencing the response to anti-EGFR agents. These data highlight the need of applying more informative and comprehensive techniques for molecular analysis and treatment monitoring to implement the prediction of the awaited TKIs efficacy, identify pts who will not benefit from TKIs and ideally build for them a rational polytherapy strategy.

Trial design: TEMPLE-2 (NCT05785208) is a prospective, biomarker-driven, multicenter, open-label, clinical trial to evaluate the efficacy of Osi in treatment-naïve patients affected by EGFR+ NSCLC according to TP53 mutational status. Inclusion criteria are: age >18 years, histologically confirmed diagnosis of EGFR+ NSCLC, available tumor tissue sample. The study consists of a screening phase to assess eligibility; a treatment phase in which pts will receive Osi at standard dose of 80 mg daily and a follow-up phase to monitor survival status and subsequent therapies. A population of 122 enrolled pts is expected, 61 TP51-wilde type and 61 TP-53 mutant. Primary endpoint is Progression Free Survival (PFS) according to TP53 mutational status; key secondary endpoints are Overall Survival (OS), Overall Response Rate (ORR), Disease Control Rate (DCR), Time to Central Nervous System (CNS) Progression, CNS ORR and Safety. Concomitant genomic alterations will be evaluated in tissue and blood at baseline and progression; ctDNA will be monitored during treatment. Enrollment is ongoing.

Clinical trial identification: NCT05785208.

Inc., Rahway, NJ, USA; [18]Clinical Research, Merck & Co., Inc., Rahway, NJ, USA

Background: In a previous analysis of the phase III KEYNOTE-811 study, pembrolizumab (pembro)/trastuzumab and chemotherapy (chemo) vs placebo (pbo)/trastuzumab and chemo provided an ORR of 74% vs 52% in the first 264 pts. These data led to FDA approval of first-line pembro/trastuzumab and chemo for HER2+ mG/GEJ adenocarcinoma. We present results of a prespecified interim analysis of PFS.

Methods: Eligible patients (pts) aged ≥18 years with treatment-naive unresectable, HER2+ mG/GEJ adenocarcinoma irrespective of PD-L1 status were randomized 1:1 to pembro 200 mg IV Q3W or pbo IV Q3W plus chemo (5-FU and cisplatin [FP] or capecitabine and oxaliplatin [CAPOX] and trastuzumab [SOC]). Randomization was stratified by region, PD-L1 status, and chemo choice. Treatment continued for ≤2 years or until disease progression or intolerable toxicity. Dual primary end points were PFS (RECIST v1.1, BICR) or OS. Data cut-off for this interim analysis was May 25, 2022. Per the DSMC, OS assessment is ongoing.

Results: At data cut-off, 698 pts were randomized (350 to pembro + SOC; 348 to pbo + SOC). Median follow-up was 28.4 mo. In all pts, pembro + SOC vs pbo + SOC significantly improved PFS (median 10.0 vs 8.1 mo; HR 0.72; 95% CI 0.60-0.87; p=0.0002). In pts with PD-L1 CPS ≥1, median PFS was 10.8 vs 7.2 mo (HR 0.70; 95% CI, 0.58-0.85). 24-mo PFS rates were 27% vs 13%. At data cut-off, 75% of required OS events had occurred. OS follow-up is ongoing. ORR was 72.6% vs 59.8% with pembro + SOC vs pbo + SOC (73.2% vs 58.4% [PD-L1 CPS ≥1]); median (range) DOR was 11.2 mo (1.1+ to 40.1+) vs 9.0 mo (1.4+ to 38.3+). Approximately 31% vs 19% of responders had a response duration ≥24 mo. Grade ≥3 drug-related AE rates were 58% vs 51%. Grade 5 drug-related AEs occurred in 4 (1.1%) vs 3 (0.9%) pts, respectively.

Conclusions: First-line pembro plus trastuzumab and chemo provided superior PFS, and improved ORR with durable responses vs pbo plus trastuzumab and chemo in pts with unresectable, HER2+ mG/GEJ adenocarcinoma, notably in pts with PD-L1 CPS ≥1. These efficacy and safety data continue to support use of this regimen in the first-line setting.

Background: The efficacy of standard perioperative chemotherapy for patients (pts) with localized resectable G/GEJ cancer still needs to be further improved. This ongoing multicentred, randomized, open-label, phase III study compared efficacy and safety of perioperative C plus R and chemo (SOXRC) versus chemo alone (SOX) in localized resectable G/GEJ adenocarcinoma.

Methods: Pts with T3-4aN$^+$M0 were randomized 1:1 to SOXRC (C 200 mg IV D1 + R 250 mg PO QD D1-21 + oxaliplatin 130 mg/m^2 IV D1 + S-1 PO BID D1-14, Q3W) or SOX for 3 cycles pre/post D2 surgery, then R plus C (SOXRC) or S-1 (SOX) up to 17 cycles per investigator's choice. Stratification was by tumour location (GEJ vs G) and bulky N (yes vs no). Blinded independent review committee (BIRC) assessed pathological complete response (pCR, ypT0) and investigators assessed EFS were primary endpoints. The secondary endpoints were major pathological response (MPR), total pCR (ypT0N0), R0 resection, DFS and OS. The planned sample size was 512 pts. The main analysis of pCR would be conducted after the first 360 randomized pts had the opportunity for D2 surgery.

Results: Of the first 360 randomized pts (SOXRC n=180; SOX n=180), 71.4% had gastric cancer and 28.6% had GEJ cancer; 66.7% had T4 and 100% had N$^+$ with balanced baseline between arms. 179 pts received neoadjuvant therapy, 164 completed all neoadjuvant therapy and 155 underwent surgery (SOXRC); 177, 169 and 156 did the same (SOX). In the ITT population, BIRC-assessed pCR was 18.3% (95% CI 13.0-24.8) for SOXRC and 5.0% (95% CI 2.3-9.3) for SOX, with a statistically significant improvement of 13.7% (95% CI 7.2-20.1, $p<0.0001$); MPR was 51.1% vs 37.8%; tpCR was 16.7% vs 4.4%. In the surgery set, R0 resection was 98.7% (SOXRC) vs 94.2% (SOX). Surgical complications occurred at rates of 27.7% (SOXRC) and 30.1% (SOX). Preoperative grade $\geq$3 treatment-emergent adverse events occurred at rates of 36.3% (SOXRC) and 16.3% (SOX).

Conclusions: The trial showed perioperative C combined with R and chemo significantly improved pCR compared to chemo alone with a tolerable safety profile for localized resectable G/GEJ adenocarcinoma.

Background: Microsatellite instability-high (MSI-H) is an established biomarker for response to immune checkpoint inhibitors. Herein, we report the efficacy and safety of nivolumab plus low-dose ipilimumab as first-line therapy in MSI-H advanced gastric or esophagogastric junction cancer (GC) patients from the phase II study.

Methods: Eligible patients were unresectable advanced, recurrent, or metastatic GC with a histologically confirmed diagnosis of adenocarcinoma; confirmed MSI-H status with the MSI-IVD Kit (FALCO); no prior systemic anticancer therapy given as primary therapy for advanced or metastatic disease. Nivolumab (240 mg) biweekly and ipilimumab (1 mg/kg) every six weeks were given until disease progression or unacceptable toxicity. The primary endpoint was the objective response rate (ORR) assessed by a blinded independent central review (BICR). Secondary endpoints included disease control rate (DCR), progression-free survival (PFS), duration of response (DOR), overall survival (OS), and safety.

Results: Between November 2020 and Aug 2022, 29 patients were enrolled from 935 screened cases. The median age was 75 (range 54-84), and 44.8% of patients were male. At the data cut-off (December 12, 2022), 3 and 15 patients achieved confirmed complete and partial responses with ORR of 62.1% (95% CI: 42.3-79.3). The DCR was 79.3% (95% CI, 60.3-92.0). With the median follow-up of 9.0 months (range, 4.0-18.0), the median PFS was 13.8 (95% CI, 13.7-NR) months, and median DOR and OS were not reached yet. 12-month PFS and OS rates yielded 73% (95% CI, 52-86) and 80% (95% CI, 57-91), respectively. The most common reason for treatment discontinuation was adverse events. The safety profile was consistent with the known profiles of nivolumab plus low dose ipilimumab, and there were no unexpected safety signals. Treatment-related death was not observed.

Conclusions: The chemo-free strategy with a combination of nivolumab and low-dose ipilimumab demonstrated high and robust efficacy with good tolerability in MSI-H GC patients.

Clinical trial identification: jRCT2080225304.

Ltd., Beijing, China; [18]Department of Medical Oncology, Mayo Clinic, Rochester, MN, USA

Background: At interim analysis (IA) of RATIONALE-306 (NCT03783442), 1L TIS + chemo demonstrated a statistically significant, clinically meaningful improvement in overall survival (OS) vs PBO + chemo, with a manageable safety profile, in patients (pts) with advanced/metastatic ESCC. Here, we report updated efficacy and safety data with minimum (min) 2 years' follow-up.

Methods: Adults with unresectable locally advanced recurrent/metastatic ESCC and no prior systemic treatment for advanced disease were enrolled and randomized (1:1; stratified by region, prior definitive therapy, and investigator [INV]-chosen chemo) to receive TIS 200 mg (Arm A) or PBO (Arm B) IV Q3W + chemo (platinum + fluoropyrimidine or platinum + paclitaxel), until disease progression, intolerable toxicity, or withdrawal. The primary endpoint was OS in the intent-to-treat population. Secondary endpoints included progression-free survival (PFS), objective response rate (ORR), duration of response (DoR) per INV, and safety.

Results: 649 pts were randomized (Arm A n=326, Arm B n=323). At data cutoff (Dec 31, 2022), min study follow-up was 25.2 months; improvements in OS, PFS, ORR, and DoR in Arm A vs B (Table) were maintained relative to the IA. Similar to the IA, incidences of any-grade (96.6% vs 96.3%) or ≥grade 3 (66.7% vs 64.5%) treatment-related adverse events (TRAEs) were comparable between Arms A and B, respectively; treatment-emergent adverse events leading to treatment discontinuation were higher in Arm A (31.8%) vs B (22.1%). In Arm A vs B, respectively, serious TRAEs occurred in 29.3% vs 19.6% of pts; TRAEs leading to death occurred in 1.9% and 1.2%.

Table: 1514P

	Arm A: TIS + chemo (n=326)	Arm B: PBO + chemo (n=323)
mOS, mo (95% CI) HR (95% CI)	17.2 (15.8, 20.1) 0.67 (0.56, 0.80)	10.6 (9.3, 12.1)

Continued

Table: 1514P Continued

	Arm A: TIS + chemo (n=326)	Arm B: PBO + chemo (n=323)
24-mo OS, % (95% CI)	37.9 (32.5, 43.2)	25.0 (20.2, 30.0)
mPFS, mo (95% CI)[a] HR (95% CI)	7.3 (6.9, 8.3) 0.61 (0.51, 0.73)	5.6 (4.9, 6.0)
24-mo PFS, % (95% CI)	18.1 (13.6, 23.1)	7.2 (4.4, 11.0)
ORR, % (95% CI)[a]	63.5 (58.0, 68.7)	42.4 (37.0, 48.0)
mDoR, mo (95% CI)[a]	7.1 (6.1, 8.1)	5.7 (4.4, 7.1)
24-mo DoR, % (95% CI)	19.6 (13.9, 25.9)	10.1 (5.0, 17.1)

[a]Per INV. CI, confidence interval; HR, hazard ratio; m, median; mo, months.

Conclusions: After min 2 years' follow-up, 1L TIS + chemo continued to demonstrate clinically meaningful improvements in OS and PFS and durable tumour response benefit vs PBO + chemo in pts with advanced/metastatic ESCC, with no new safety signals.

Clinical trial identification: NCT03783442.

[1]GI/Lymphoma Unit, The Royal Marsden Hospital (Sutton), Sutton, UK; [2]Oncology Department, Royal Derby Hospital - University Hospitals of Derby and Burton NHS Foundation Trust, Derby, UK; [3]Oncology, University Hospital Coventry - University Hospitals Coventry and Warwickshire NHS Trust, Coventry, UK; [4]Oncology Department, Sussex Cancer Centre - Royal Sussex County Hospital, Brighton, UK; [5]Oncology Department, Weston Park Hospital - Sheffield Teaching Hospitals NHS Foundation Trust, Sheffield, UK; [6]Medical Oncology, The Christie NHS Foundation Trust, Manchester, UK; [7]Clinical Oncology, Newcastle Upon Tyne Hospitals NHS Foundation Trust, Newcastle Upon Tyne, UK; [8]GI/Lymphoma Unit, The Royal Marsden Hospital (Sutton), Sutton, UK

Background: PLATFORM is a prospective, open-label, multi-centre, adaptive phase II trial assessing maintenance therapy in patients (pts) with OG adenocarcinoma after platinum-based first-line induction chemotherapy. HER2 -negative pts were randomised 1:1 to surveillance or rucaparib.

Methods: After 18 weeks of platinum-based chemotherapy, pts with response or stable disease were randomised, stratified by performance status, region, and disease extent. Pts in the control arm had 4- weekly surveillance visits vs. receiving rucaparib 600mg twice daily every 28 days to progression, death, or toxicity. Interim analysis target accrual of 61 pts was met, the futility endpoint was 12-week progression free rate (PFR). We also report progression-free survival (PFS) from randomisation to progression or death (pre-specified p-value of 0.025) and toxicity.

Results: 125 pts were randomised to the control arm and rucaparib. At data cut-off (28 April 2023) median follow up was 41 months (mo). 59 control and 62 rucaparib pts were evaluable for 12-week PFR; 36% in the control arm and 55% in the rucaparib arm had stable disease (Odds Ratio 2.2, 97.5% CI 1.0-5.1, p = 0.035). 39% of all pts had measurable disease at baseline and no responses were seen in either arm.

Median PFS was 2.8 mo in the control arm vs. 4.2 mo in the rucaparib arm (HR 0.70, 97.5% CI 0.46 − 1.08, p = 0.063). The 6 mo PFS rate was 20.4% (97.5% CI 9.9 - 33.5) in the control arm vs. 29.5% (97.5% CI 17.4 − 42.8) in the rucaparib arm but there was no difference in median survival (HR 1.15, 97.5% CI 0.73 − 1.82, p = 0.495). Grade ≥3 treatment related adverse events was 19% in the rucaparib arm and no new safety signals identified.

Conclusions: Interim results showed prolonged disease control in pts receiving maintenance rucaparib after first-line platinum-based chemotherapy. Translational biomarker analysis including homologous recombination deficiency testing may identify a subgroup of pts that could derive additional benefit from maintenance rucaparib.

Clinical trial identification: NCT02678182.

Inc., Rahway, NJ, USA; [17]Center for Observational and Real-world Evidence, Merck & Co. Inc., Rahway, NJ, USA; [18]Merck Research Laboratories, Oncology, Merck & Co., Inc., Rahway, NJ, USA; [19]Medical Oncology, Yonsei Cancer Center, Yonsei University Health System, Seoul, Republic of Korea

Background: In the phase III KEYNOTE-859 study (NCT03675737), 1L pembro + chemo significantly improved OS, PFS, and ORR vs placebo (pbo) + chemo regardless of PD-L1 expression and had a manageable AE profile in patients (pts) with locally advanced/metastatic HER2-negative G/GEJ adenocarcinoma. Prespecified exploratory HRQoL outcomes are reported.

Methods: HRQoL was assessed in treated pts who completed ≥1 HRQoL assessment using the EORTC QLQ-C30, EORTC QLQ-STO22, and EQ-5D-5L questionnaires. Least squares mean (LSM) changes from baseline (BL) to wk 18 in QLQ-C30 GHS/QoL; physical functioning (PF) and role functioning (RF) subscales; nausea/vomiting and appetite loss symptoms scales; QLQ-STO22 pain symptom scale; and EQ-5D-5L VAS were compared using a constrained longitudinal data analysis model (covariates: Tx by study visit interaction and stratification factors). Time to deterioration (TTD; ≥10-point decline from BL in a given scale/subscale) was estimated using the Kaplan-Meier method; between-arm difference (HR) was determined using a stratified Cox proportional hazards model.

Results: The latest timepoint at which the predefined rates of completion (≥60%) and compliance (≥80%) were met was wk 18. From BL to wk 18, LSM changes in QLQ-C30 GHS/QoL, PF, RF, nausea/vomiting, and appetite loss and EQ-5D-5L VAS were similar between arms; the QLQ-STO22 pain scale favored pembro + chemo (Table). TTD (HR; 95% CI) in QLQ-C30 GHS/QoL (0.87; 0.72-1.04), PF (0.91; 0.76-1.08), RF (0.90; 0.76-1.06), appetite loss (1.00; 0.82-1.22), and nausea/vomiting (0.95; 0.79-1.14) were similar between arms; the QLQ-STO22 pain scale favored pembro + chemo (0.76; 0.58-0.98).

Table: 1516P

	Change from BL to wk 18, LSM (95% CI)		Difference in LSM change from BL to wk 18 (95% CI)
	Pembro + chemo	Pbo + chemo	
EORTC QLQ-C30	**n = 771**	**n = 771**	N/A
GHS/QoL	0.40 (-1.37 to 2.18)	-0.85 (-2.62 to 0.93)	1.25 (-1.07 to 3.58)
PF	-5.87 (-7.53 to -4.22)	-7.53 (-9.18 to -5.88)	1.65 (-0.64 to 3.94)
RF	-5.41 (-7.59 to -3.22)	-7.97 (-10.15 to -5.79)	2.57 (-0.38 to 5.52)
Nausea/ vomiting	1.06 (-0.75 to 2.87)	1.36 (-0.45 to 3.16)	-0.30 (-2.67 to 2.07)
Appetite loss	-3.43 (-6.10 to -0.76)	-4.85 (-7.51 to -2.19)	1.42 (-1.93 to 4.77)
EORTC QLQ-STO22 pain	**n = 754** -8.21 (-9.91 to -6.51)	**n = 752** -5.64 (-7.34 to -3.94)	-2.57 (-4.72 to -0.41)
EQ-5D-5L VAS	**n = 771** -0.69 (-2.12 to 0.73)	**n = 771** -1.91 (-3.33 to -0.49)	1.22 (-0.65 to 3.08)

Conclusions: HRQoL data from KEYNOTE-859, combined with efficacy and safety results, support a favorable benefit-to-risk profile for pembro + chemo as a new 1L Tx option for advanced HER2-negative G/GEJ adenocarcinoma.

Clinical trial identification: NCT03675737.

Background: Beyond the report of an improvement in quality of life with EPC in pts with lung cancers, Temel et al. (NEJM 2010) also claimed for a survival benefit observed as a secondary endpoint. This prompted us to address the overall survival (OS) benefit of EPC within the EPIC trial dedicated to mUGIC pts.

Methods: EPIC is a randomised (1:1), open-label, phase III trial aimed to estimate OS of EPC compared to SOC for ECOG-PS $\leq$ 2 pts with mUGIC. Other objectives were PROs (quality of life [QoL, EORTC QLQ-C30], time until definitive deterioration [TUDD] of QoL, depression and anxiety scores [HADS], number of pts receiving chemotherapy in their last 30 days of life, and the presence or absence of advanced directives in pt files. With the following hypotheses: 1- year OS (40% vs. 50.3%, HR=0.75), 2-sided alpha=5%, beta=20%, 381 deaths were required, leading to include 480 pts. Pts were stratified according to centre, ECOG-PS (0-1 vs. 2) and tumor location.

Results: Modified Intent To Treat population was 470 pts, from the 473 pts randomized from 10/2016 to 12/2021 in 19 French centers. Main pts characteristics were: median age= 67.5; 273/470 males; tumour site: oesophagus 39, HER2-negative esogastric 48, pancreas 297, biliary tree 86; ECOG-PS 0/1/2: 104/278/88. The mean number of PC visits was 4.7 and 0.6 in the EPC and SOC group, respectively. Median follow-up was 46m. OS data has already been reported at ASCO-2023. Overall, all dimensions of QoL remained stable along the study course, without any difference between arms. TUDD analysis did not show any difference between treatment arms for any of the QoL dimensions. Anxiety and depressions scores varied over time similarly in both arms. Respectively in EPC and SOC arms, 33% and 28% pts received chemotherapy in their last month of life; 17% and 11% had advanced directive written.

Conclusions: EPC did not improve QoL, anxiety and depression scores versus SOC in mUGIC pts. Whether these unexpected findings are related to our study population, to our study design (including content or number of EPC we provided), or to real facts remains to be determined.

Clinical trial identification: NCT02853474.

Background: Zani, an anti-HER2 bispecific antibody, targets two distinct extracellular domains of HER2 and has shown preliminary antitumor activity and tolerability, with chemo, in pts with HER2+ GC/GEJC. These are updated results from the phase Ib/II study (NCT04276493) for zani plus chemo and TIS, an anti-PD-1 monoclonal antibody. Duration of response is reported for the first time.

Methods: Cohort 2 of this open-label study included pts with untreated, unresectable, locally advanced/metastatic HER2+ GC/GEJC. Cohort 2a received zani 30 mg/kg intravenously (IV), Cohort 2b received zani 1800 mg IV (weight <70 kg) or 2400 mg IV (weight $\geq$70 kg), each with TIS 200 mg IV every 3 weeks. Both cohorts also received standard capecitabine-oxaliplatin (CAPOX). Primary endpoints were safety and investigator (INV)-assessed objective response rate (ORR) per RECIST v1.1. Secondary endpoints included INV-assessed progression-free survival (PFS), duration of response, and disease control rate.

Results: As of 22 Nov 2022, 33 pts (median age 64 years [range: 29-80]) were assigned to Cohort 2a (n=19) or 2b (n=14). Overall, 13 (39.4%) pts remained on treatment. Confirmed ORR was 75.8% (95% CI: 57.7, 88.9); median PFS was 16.7 months (95% CI: 8.2, NE). Efficacy data are presented in the table. All pts had $\geq$1 treatment-related adverse event (TRAE), and 22 (66.7%) had grade $\geq$3 TRAEs. Serious TRAEs occurred in 11 (33.3%) pts; TRAEs leading to treatment discontinuation occurred in two (6.1%) pts; and TRAEs leading to death occurred in two (6.1%) pts.

Table: 1518P

	Cohort 2a (n=19)	Cohort 2b (n=14)	Overall (N=33)
Median follow-up, months	19.1	18.0	18.2
Best overall response[a], n (%)			
Complete response	1 (5.3)	0 (0.0)	1 (3.0)
Partial response	14 (73.7)	10 (71.4)	24 (72.7)
Stable disease	4 (21.1)	4 (28.6)	8 (24.2)
ORR[a], n (%) (95% CI)	15 (78.9) (54.4, 93.9)	10 (71.4) (41.9, 91.6)	25 (75.8) (57.7, 88.9)
DCR[a], n (%) (95% CI)	19 (100.0) (82.4, 100.0)	14 (100.0) (76.8, 100.0)	33 (100.0) (89.4, 100.0)
Median DoR, months (95% CI)	15.4 (4.9, NE)	NE (7.4, NE)	22.8 (7.4, NE)
Median PFS, months (95% CI)	8.3 (5.6, NE)	NE (8.8, NE)	16.7 (8.2, NE)

[a]Confirmed. DCR, disease control rate; DoR, duration of response; NE, not estimable; ORR, objective response rate; PFS, progression-free survival.

Conclusions: Zani plus TIS and CAPOX produced durable, promising antitumor activity with encouraging PFS as 1L therapy for pts with HER2+ GC/GEJC. Safety was

consistent with previous findings. A phase III trial (NCT05152147) evaluating this regimen is ongoing.

Clinical trial identification: NCT04276493.

1519P Fruquintinib plus sintilimab in patients (pts) with either treatment-naïve or previously treated advanced gastric or gastroesophageal junction (GEJ) adenocarcinoma: Results from a multicenter, single-arm phase II study

X. Wei[1], J. Li[2], H. Yuan[1], W. Zhang[3], W. He[3], P. Lu[4], H. Shi[4], P. Tan[4], S. Fan[4], M. Shi[4], W. Su[4], Y. Bai[1]

[1]Gastroenterology Department, Harbin Medical University Cancer Hospital, Harbin, China; [2]Department of Medical Oncology, Shanghai East Hospital, School of Medicine, Tongji University, Shanghai, China; [3]Department of Medical Oncology, The First Affiliated Hospital of Zhengzhou University, Zhengzhou, China; [4]C&R, HUTCHMED Limited, Shanghai, China

Background: Fruquintinib (F, a highly selective VEGFR inhibitor) plus sintilimab (S, an anti-PD-1 monoclonal antibody) showed promising antitumor activity in both preclinical and clinical studies. Here, we reported the results of F plus S from a gastric cancer (GC) cohort in an open-label, multicenter, single-arm phase II study in China.

Methods: Advanced gastric or GEJ adenocarcinoma pts with PD-L1 status of CPS $\geq$1, who had no prior systemic therapy or had failed at least first-line treatment were enrolled. Eligible pts received F (5 mg, 2 weeks on/1 week off, orally, once daily) plus S (200 mg, IV, every 3 weeks) in 21-day cycles, until disease progression or unacceptable toxicity. Treatment of S was allowed for up to 24 months (mo). The primary endpoint was ORR per RECIST v1.1.

Results: As of February 28, 2023, 27 pts were enrolled and received F plus S, including 20 treatment-naive pts (i.e.: 1st -line pts), and 7 pts with prior treatment (i.e.: $\geq$ 2nd-line pts). Median (range) age was 63.71 (35.8, 74.6) years. There were 8 (29.6%), 9 (33.3%), and 8 (29.6%) pts with PD-L1 status of 1$\leq$ CPS $<$5, 5$\leq$ CPS$<$10, and 10$\leq$ CPS, which was tested by the central lab, respectively. Median duration of treatment of F and S were 6.90 and 7.13 months. Among tumor evaluable pts (N=18 for 1st -line pts, N=6 for $\geq$ 2nd-line pts), confirmed ORRs were 72.2% and 33.3% in 1st -line pts and $\geq$ 2nd-line pts, respectively; clinical responses correlated with level of PD-L1 status. DCRs were 100% and 83.3% in 1st -line pts and $\geq$ 2nd-line pts; median TTR reached 2.7 mo and 2 mo in 1st -line pts and $\geq$ 2nd-line pts. 9-month PFS rates were 63.8% and 50.0% in 1st -line pts and $\geq$ 2nd-line pts. Median PFS and OS were not mature. Common ($\geq$20%) treatment-related treatment-emergent adverse events included proteinuria (48.1%), hypothyroidism (40.7%), aspartate aminotransferase increased (25.9%), alanine aminotransferase increased (22.2%), hypertension (22.2%), and weight decreased (22.2%).

Conclusions: F plus S provided favourable efficacy and manageable toxicity profile in pts with advanced gastric or GEJ adenocarcinoma, especially for pts who cannot tolerate chemotherapy.

Clinical trial identification: NCT03903705.

Background: Perioperative chemotherapy with FLOT is a standard of care for patients (pts) with resectable gastric or gastroesophageal junction (GEJ) adenocarcinoma, despite a still poor prognosis. This trial evaluates the anti—PD-1 antibody spartalizumab combined to FLOT as perioperative treatment (tt) for resectable pts.

Methods: GASPAR trial is a multicenter, single arm, phase II trial. Pts with untreated localized gastric or GEJ adenocarcinoma considered resectable ($\geq$ cT2 or cN+) were enrolled. Pts received 4 pre- and post-operative cycles of FLOT (Docetaxel 50 mg/m^2, oxaliplatine 85 mg/m^2, leucovorin 200 mg/m^2 and fluorouracile 2600 mg/m^2 24h infusion, q2w) and 2 pre- and post-operative cycles of spartalizumab (fixed dose of 400 mg, q4w). The main endpoint was the rate of pathological complete regression (pCR) assessed using Becker criteria.

Results: In total, 68 pts were included: men (78%), median age 63 yrs [range 31-79], cT3/T4 51%, GEJ 60%, cN+ 18/48 pts. Among 67 pts who started the tt, 64 (96%) received 2 pre-operative cycles of spartalizumab, the 3 others received 1 cycle due to toxicity. Similarly, 64 (96%) pts completed the 4 pre-cycles of FLOT, 1 discontinued after 2 cycles (toxicity), the 2 others received 3 cycles (pt decision). FLOT administration was delayed for 13 pts (19%) due to toxicity, and 26 pts (39%) observed dose reduction. Surgery, performed in 65 pts (97%) within 38 days from the end of preoperative tt in median [range 23-67], was R0 for 62 pts (95%). Among 64 pts assessable for efficacy, pCR was observed for 20 pts (31%), and sub-total regression ($<$10% residual tumor) for 12 pts (19%), meaning a major response rate of 50%. After a median follow-up of 6.9 months, 8 pts are still under adjuvant tt. No toxic death, nor spartalizumab-related grade (G) 4 adverse events (AEs) were observed. 5 pts developed G3 immune-mediated AEs: pancreatitis (2), hepatitis, enterocolitis and encephalitis. 15 pts (23%) experienced post-surgery G3/4 complications.

Conclusions: Spartalizumab combined with FLOT shows high efficacy as perioperative tt in pts with resectable gastric or GEJ adenocarcinoma with a high rate of pathological complete regression and an acceptable safety profile.

Clinical trial identification: NCT04736485.

1521P Addition of durvalumab to CROSS in oesophageal adenocarcinoma is feasible and safe

H. Schloesser[1], A. Lohneis[2], M.A. Garcia-Marquez[3], M. Thelen[3], P. Schiller[4], M. von Bergwelt[5], A. Hillmer[6], W. Schroeder[7], M.J. Hallek[2], A. Quaas[6], C. Bruns[7], T. Zander[2]

[1]Center for Molecular Medicine Cologne and Department of General, Viceral, Cancer and Transplantation Surgery, University of Cologne, Cologne, Germany; [2]Internal Medicine I, University Hospital of Cologne, Cologne, Germany; [3]Center for Molecular Medicine Cologne, University Hospital Cologne, Cologne, Germany; [4]Institute of Medical Statistics and Computational Biology, University Hospital Cologne, Cologne, Germany; [5]Department of Internal Medicine III, Hospital Munich Grosshadern - Ludwig-Maximilians-University (LMU), Munich, Germany; [6]Institute of Pathology, Universitätsklinikum Cologne (AöR), Cologne, Germany; [7]Department of General, Viceral, Cancer and Transplantation Surgery, University Hospital Cologne, Cologne, Germany

Background: Anti-PD-(L)1 is effective in esophago-gastric adenocarcinoma (EGA) and appears synergistic with chemoradiotherapy (CRT). The RICE trial aims to evaluate safety, feasibility and efficacy of addition of neoadjuvant durvalumab and adjuvant durvalumab ± tremelimumab to standard CRT.

Methods: In this open-label, randomized phase-2 trial, pts with locally advanced (≥uT3/Nx or uT2/N+) non-metastatic EGA (including EGJ-I and EGJ-II) receive two doses of neoadjuvant durvalumab (1500mg) in addition to CRT according to the CROSS protocol. After a safety-run in of 6 pts, adjuvant therapy was randomized 1:1 to 12 doses of durvalumab monotherapy or 12 doses of durvalumab (1500mg/4w) plus a single dose of adjuvant tremelimumab (300mg d1 of adjuvant treatment). Here we report the results from the neoadjuvant part of the trial including the primary endpoints for safety and efficacy and extensive translational immune monitoring.

Results: In the modified intention to treat analyses 95% (53/56) of pts completed neoadjuvant therapy and 93% (52/56) underwent resection (3 excluded due to peritoneal carcinomatosis, 1 to intraoperatively identified cirrhosis; R0 in all pts), which was not lower than 90.4% as predefined benchmark for feasibility. Regarding the primary endpoints for safety, the rate of anastomotic leakage was 6% (3/52) and significantly lower than the predefined threshold of 22% ($p<0.05$), while the rate of grade 3/4 toxicity exceeded the predefined threshold of 13% (25%, 13/56 G3, 1/56 G4). Clinicopathological evaluation of response revealed 5% (3/56) peritoneal carcinomatosis, 39% (22/56) minor response (>10% vital tumor), 30% (17/56) major response (<10%), 23% (13/56) complete response and 2% not evaluable (1/56, cirrhosis).The primary endpoint for efficacy (35% CR) was not reached, but at least <10% residual tumour was achieved in 53%, which was higher than in patients treated with CROSS during the same period at the same center (38.6%; 56/145; $p<0.05$). Patterns of response and resistance from translational analyses will be presented as well.

Conclusions: The first analyses of the RICE trial demonstrate safety and feasibility of addition of neoadjuvant immunotherapy with durvalumab to CROSS.

Clinical trial identification: NCT04159974.

1522P Camrelizumab plus chemotherapy versus concurrent chemoradiotherapy as neoadjuvant therapy for resectable thoracic oesophageal squamous cell cancer (REVO): A multicenter, randomized, open-label, phase II trial

W.P. Yuan[1], Y. Chen[1], J. Liu[2], W. Zhang[3], X. Chen[1], H. He[1], P. Chen[1], J-P. Lin[1], D. Zhang[1], H. Lin[1], W. Wei[1], W. Chen[1], H. Zhou[1], P. Gao[1], S. Liu[1], F. Wang[1]

[1]Department of Thoracic Oncology Surgery, Clinical Oncology School of Fujian Medical University, Fujian Cancer Hospital, Fuzhou, China; [2]Department of Thoracic surgery, Zhangzhou Second Hospital, Zhangzhou, China; [3]Department of Cardiothoracic surgery, Zhangzhou Affiliated Hospital of Fujian Medical University, Zhangzhou, China

Background: Preoperative chemoradiotherapy (CRT) is the current standard treatment for locally advanced oesophageal cancer in the world. In previous single-arm clinical trials, neoadjuvant camrelizumab (anti-PD-1 antibody) plus chemotherapy showed durable antitumor activity with a manageable safety profile in patients with locally advanced oesophageal squamous cell carcinoma (ESCC). In this multicenter, randomized, open-label, phase II REVO trial, we compared immunochemotherapy (ICT) with concurrent CRT as neoadjuvant therapy in patients with resectable thoracic ESCC using a non-inferiority design.

Methods: Patients were randomly assigned to two to four 21-day cycles of intravenous camrelizumab (200 mg, day 1) plus albumin-bound paclitaxel (125 mg/m^2, days 1 and 8) and cisplatin (75 mg/m^2, day 1), or two 21-day cycles of albumin-bound paclitaxel and cisplatin combined with concurrent radiotherapy (36-40Gy in 20 fractions, 5 days per week), followed by surgery. The primary endpoint was pathological complete response (pCR) rate.

Results: Between September 2021 and March 2023, 85 patients had been enrolled, and the enrolment is still ongoing. As of April 6, 2023, 32 of 41 and 28 of 44 patients underwent surgery in the ICT and CRT groups, respectively. All patients achieved R0 resection. The pCR (ypT0N0) and major pathological response (MPR) rates were 40.6% (13/32) and 62.5% (20/32) in the ICT group and 35.7% (10/28) and 71.4% (20/28) in the CRT group, respectively. The incidence of grade ≥3 treatment-related adverse events (TRAEs) was 22.0% in the ICT group and 31.8% in the CRT group. The most common grade ≥3 TRAE was decreased lymphocyte count (14.6%) in the ICT group, and decreased lymphocyte count (18.2%) and decreased platelet count (6.8%) in the CRT group. One patient in the CRT group died due to pneumonia after surgery.

Conclusions: The current results suggest that neoadjuvant camrelizumab plus chemotherapy is non-inferior to concurrent CRT for patients with locally advanced ESCC, with better safety. The final results and long-term survival will be reported in the future.

Background: Approximately 12%-23% of pts with GEC have HER2+ tumours. Ramucirumab (R) + paclitaxel (P) is commonly used in the 2L setting for GEC; however, overall response and survival rates remain low. Tucatinib (TUC) is a highly selective, HER2-directed TKI. Here, we report safety and efficacy results from the dose optimization phase of MOUNTAINEER-02 (NCT04499924), a trial evaluating TUC in combination with trastuzumab (T), P, and R.

Methods: MOUNTAINEER-02 is a global trial evaluating TUC 300 mg BID + T (6 then 4 mg/kg D1,15) + P (D1, 8, 15) + R (8 mg/kg D1, 15) every 28 days in pts with previously treated, locally advanced unresectable or metastatic HER2+ GEC. In the open-label phase II dose optimization stage, two P doses were explored (60 mg/m^2 and 80 mg/m^2). HER2+ status was confirmed by ctDNA or IHC/ISH assay. The primary endpoint is safety/tolerability of TUC+T+P+R. Secondary endpoints are ORR, confirmed ORR (cORR), DOR, DCR, PFS (all investigator-assessed), and PK.

Results: As of Jan 20, 2023, 17 pts (median age 59 yrs) received study tx (n=8 in 60 mg/m^2 vs n=9 in 80 mg/m^2). Ten pts (58.8%) remain on study after a median of 8 TUC cycles. All pts treated with 80 mg/m^2 P were DLT-evaluable; 2 experienced a DLT event (1 pt with G3 mucositis and 1 pt with G2 fatigue and diarrhea leading to dose holds). No DLTs were observed in 7 DLT-evaluable pts treated with 60 mg/m^2 P. TEAEs stratified by two P doses are summarized in the table. ORR was 76.5% (95% CI, 50.1-93.2), with cORR of 70.6% (44-89.7) and DCR of 94.1% (71.3-99.9). Median DOR was 10.6 months (95% CI, 6.7-inestimable), and median PFS was 11.9 months (4.1-inestimable) after 7 PFS events. Plasma concentrations of P were not affected by TUC administration.

Table: 1523P Most Common TEAEs (≥30%)

	60 mg/m²		80 mg/m²		Total	
	Any G	G ≥3	Any G	G ≥3	Any G	G ≥3
Any Event	8 (100)	6 (75.0)	9 (100)	8 (88.9)	17 (100)	14 (82.4)
Diarrhea	4 (50.0)	2 (25.0)	7 (77.8)	1 (11.1)	11 (64.7)	3 (17.6)
Nausea	2 (25.0)	0	7 (77.8)	0	9 (52.9)	0
Epistaxis	2 (25.0)	0	6 (66.7)	0	8 (47.1)	0
Fatigue	2 (25.0)	0	6 (66.7)	2 (22.2)	8 (47.1)	2 (11.8)
Peripheral sensory neuropathy	1 (12.5)	0	7 (77.8)	2 (22.2)	8 (47.1)	2 (11.8)
Stomatitis	2 (25.0)	0	6 (66.7)	1 (11.1)	8 (47.1)	1 (5.9)
Constipation	3 (37.5)	0	3 (33.3)	0	6 (35.3)	0
Neutropenia	1 (12.5)	1 (12.5)	5 (55.6)	4 (44.4)	6 (35.3)	5 (29.4)
Pyrexia	3 (37.5)	0	3 (33.3)	0	6 (35.3)	0
Weight decreased	2 (25.0)	1 (12.5)	4 (44.4)	1 (11.1)	6 (35.3)	2 (11.8)

Conclusions: Coadministration with TUC did not impact the PK of P. Based on the preliminary data from MOUNTAINEER-02, the combination of TUC+T+P+R was tolerable with encouraging antitumor activity in pts with previously treated HER2+ GEC.

Clinical trial identification: NCT04499924.

1524P First-line TST001 plus capecitabine and oxaliplatin (CAPOX) for advanced G/GEJ cancer with CLDN18.2 positive overall survival data from study transtar102-Cohort C

L. Shen[1], D. Liu[1], N. Li[2], W. Guo[3], T. Liu[4], L. Zhang[5], X. Zhu[5], C. Qi[6], L. Xu[5], X. Qian[6], C. Germa[7]

[1]GI Oncology Department, Peking University Cancer Hospital and Institute, Beijing, China; [2]Medical Oncology, Henan Cancer Hospital/Affiliated Cancer Hospital of Zhengzhou University, Zhengzhou, China; [3]Oncology Department, Fudan University Shanghai Cancer Center, Shanghai, China; [4]Oncology Dept., Zhongshan Hospital Affiliated to Fudan University, Shanghai, China; [5]GRD, Suzhou Transcenta Therapeutics Co., Ltd, Suzhou, China; [6]GRD, Transcenta Holding Ltd., Suzhou, China; [7]GRD, Transcenta Holding Ltd., Princeton, NJ, USA

Background: Phase III studies (SPOTLIGHT and GLOW) showed that combining anti-Claudin18.2 (CLDN18.2) antibody with chemotherapy significantly improved outcomes for first-line treatment for G/GEJ cancer with high CLDN18.2 expression. TST001 is a potential best-in-class antibody with improved CLDN18.2 affinity and enhanced ADCC effect, leading to anti-tumor activity in low to medium CLDN18.2 expression gastric cancer animal models.

Methods: Cohort C from Transtar102 study was designed to explore the safety and efficacy of TST001 plus CAPOX as 1st- line treatment in advanced G/GEJ cancer (NCT04495296—study Transtar102). Positive CLDN18.2 (membranous staining intensity ≥1+ in ≥10% of tumor cells) assessed centrally using the IHC 14G11 LDT assay was required in the expansion phase only.

Results: As of 21 April 2023, 64 patients have been dosed with TST001 plus CAPOX, including 15 patients who received TST001 at doses ranging from 1 to 8 mg/kg Q3W

in the dose escalation phase and 49 patients at 6 mg/kg in the dose expansion phase. The median follow-up is 197.5 days. The most common treatment related adverse events are nausea (70.3%), vomiting (53.1%) and hypoalbuminemia (75%) with grade 3 being 1.6% each. 42 out of the 49 patients in the 6 mg/kg expansion cohort have measurable lesions and had at least one post-treatment tumor assessment, with 28 (66.7%) achieving partial response (confirmed and unconfirmed). Across all doses, the objective response rate (confirmed and unconfirmed) is 65.4%, the estimated median progression-free survival is 9.5 months, and the estimated median duration of response is 9.9 months. 38 of 49 patients are CLDN18.2 positive with no notable difference in efficacy per CLDN18.2 level. Overall survival is immature and will be updated at the time of the conference.

Conclusions: TST001 plus CAPOX as first-line treatment for patients with G/GEJ cancer demonstrated good safety and tolerability. Encouraging anti-tumor activities have been observed regardless of the CLDN18.2 expression levels, including expression as low as ≥10% tumor cells staining ≥1+, <40% tumor cells staining <2+ or 3+. Overall survival data will be presented.

Clinical trial identification: NCT04495296.

Background: In the phase (ph) 2 FIGHT trial, BEMA+mFOLFOX6 had promising efficacy in patients with FGFR2b-selected G/GEJC. FORTITUDE-102 comprises part 1 (open-label ph1b) evaluated the safety and tolerability of BEMA+mFOLFOX6+NIVO and part 2 (randomized ph3) the safety and efficacy compared with placebo. Here, we present the results of part 1.

Methods: Up to 20 patients (pts) with/without FGFR2b overexpression could be enrolled. The initial dose of BEMA was 15 mg/kg IV Q2W with one 7.5 mg/kg dose on cycle 1 day 8. The dose-limiting toxicity (DLT) period was 28 days. At least 6 pts were treated at a dose level with less than 33% incidence of DLTs to determine the recommended ph3 dose (RP3D). An ad hoc review was performed 6mo after the DLT period.

Results: Eight pts (50-71 y) were enrolled and evaluated for DLTs: 6 pts were men, 4 pts were Asian, and 4 pts were White. No DLTs were reported; no new safety signals were identified. Mean exposures for the first 3 cycles and estimated terminal elimination half-life (7-11 days) were consistent with historical data. No meaningful BEMA exposure changes were observed with the addition of NIVO, indicating no drug interactions. The RP3D was 15 mg/kg Q2W with one 7.5mg/kg dose on cycle 1 day 8. Six mo post-DLT period, the median treatment duration was ∼34 weeks (8-40). Four pts had 6 serious AEs (n=1 AE [hyponatremia] considered BEMA-related); 7 pts had 13 grade ≥3 AEs (n=4 [neutropenia, mucositis, hyponatremia, and delirium] in 2pts considered BEMA-related). Five pts reported 8 ocular AEs of grades ≤2, with a median time to onset of ∼17 weeks. No AEs led to BEMA discontinuation. Treatment was interrupted in 4 pts due to BEMA-related AEs (1 was ocular related). PR was seen in 3 pts, SD in 4 pts, and PD in 1 pt. BEMA was stopped for consent withdrawal in 1pt and PD in 2pts. Updated data will be presented at the congress.

Conclusions: This is the first time a combination of BEMA, mFOLFOX6, and NIVO is assessed. In part 1, consistent safety and PK profiles suggest no negative interaction, with no new safety signals after 6 mo.

Clinical trial identification: NCT05111626.

1527P Efficacy and safety of infigratinib in locally advanced or metastatic gastric cancer or gastroesophageal junction adenocarcinoma patients with FGFR2 gene amplification

J. Yuan[1], L. Shen[1], T. Liu[2], H. Xu[3], J. Yang[4], J. Wei[5], H. Jiang[6], Y. Deng[7], Y. Wang[8], X. Zhang[1], J. Gong[1], C. Lyu[9], Y. Li[9], L. Song[9]

[1]GI Oncology Department, Peking University Cancer Hospital and Institute, Beijing, China; [2]Medical Oncology Department, Zhongshan Hospital Affiliated to Fudan University, Shanghai, Changning, China; [3]Oncology Department, Hubei Cancer Hospital, Wuhan, China; [4]Clinical Oncology, Fujian Provincial Cancer Hospital, Fuzhou, Fujian, China; [5]Oncology Department, The Affiliated Drum Tower Hospital of Nanjing University Medical School, Nanjing, Jiangsu Province, China; [6]Medicine Department, The First Affiliated Hospital of Medical School of Zhejiang University, Hangzhou, China; [7]Clinical Oncology, The Sixth Affiliated Hospital, Sun Yat-sen University, Guangzhou, Guangdong, China; [8]Gastroenterology Ward One Department, Shanxi Cancer Hospital, Taiyuan, China; [9]COTD, LianBio Development Co., Ltd. Shanghai, Shanghai, China

Background: The FGFR/FGF cascade is a complex intracellular pathway that controls cellular proliferation, tumor growth, angiogenesis, and dissemination. It is implicated in various human cancers including gastric cancer (GC). The FGFR2-amplification in a proportion ranging from 9% to 1.2% worldwide in GC patients. However, previous studies have demonstrated FGFR2-amplification may have poor PFS and OS survival in GC patients. Infigratinib (BGJ398) is a selective ATP-competitive, FGFR1−3 selective oral TKI. We present the data generated from the LB1001-201 trial **(NCT05019794) Cohort 1** to evaluate the efficacy and safety of infigratinib monotherapy in previously systemic second-line treated patients harbouring FGFR2 gene amplification.

Methods: Population and eligibility criteria - Failed on prior 2nd -lines treatment or above, locally advanced or metastatic GC/EGJ. FGFR2 gene amplification positive was confirmed via central FISH testing. Adequate organ function and laboratory values. MAPK-MEK or selective FGFR inhibitor treatment-naive. Procedures and treatment - Tumor biopsy or FFPE samples will be tested at the central lab for FGFR2 gene amplification orally infigratinib (125mg, QD) for 3 weeks on, 1 week off in each 28-day cycle; Dose adjustment will be based on drug-related AEs and severity per protocol demanded. Outcomes and assessments - ORR and DCR: Descriptive statistics were used, and an accurate 95% CI was provided. Time-to-event endpoints were summarized using K-M analyses. Safety endpoints were analyzed using frequency and percentage distribution in patients who received at least one dose of infigratinib.

Results: cORR 25.0% (95%CI 8.7, 49.1), DCR 80.0% (95%CI 56.3, 94.3), mDoR 3.8 months (mos) (3.6, NE). mPFS 3.3 mos (95%CI 2.3, 4.5), mOS 8.0 mos (95%CI 4.1, NE). 15/19 patients with tumor shrinkage, the maximum from baseline was -78.5%. ≥ Grade 3 TRAE was 42.9%, most were recoverable. No drug-induced death was reported.

Conclusions: Infigratinib in GC/GEJ patients with FGFR2 gene amplification has shown an inspiring clinical improvement, with acceptable tolerance, which is a potential first TKI regimen that precisely targeting in this population.

1528P A phase I/II trial investigating safety and efficacy of autologous TAC01-HER2 in relapsed or refractory solid tumors

D. Olson[1], E.E. Dumbrava[2], M. George[3], S. Saibil[4], A. Giordano[5], M. Gavrilliuc[6], B. Pieke[7], E. Lichtenstein[8], M. Apostolopoulou[9], K. Moss[9], D. Kirkwood[10], S. Dang[10], D. Adib[9], B.L. Schlechter[5]

[1]Medicine, The University of Chicago, Chicago, IL, USA; [2]Investigational Cancer Therapeutics Department, The University of Texas MD Anderson Cancer Center, Houston, TX, USA; [3]Health, Rutgers Cancer Institute of New Jersey, New Brunswick, NJ, USA; [4]Immunology, UHN - University Health Network - Princess Margaret Cancer Center, Toronto, ON, Canada; [5]Medical Oncology, Dana Farber Cancer Institute, Boston, MA, USA; [6]Investifational Cancer Therapeutics, MD Anderson Cancer Center, Houston, TX, USA; [7]Hematology/Oncology, University of Chicago Department of Medicine - Section of Hematology/Oncology, Chicago, IL, USA; [8]Human Research Services, Rutgers Cancer Institute of New Jersey, New Brunswick, NJ, USA; [9]Clinical Development, Triumvira, Austin, TX, USA; [10]Product and Process Development, Triumvira, Austin, TX, USA

Background: Despite therapeutic developments for patients with advanced HER2+ solid tumors, significant unmet medical needs still exist. The T-cell antigen coupler (TAC) technology is an approach to modifying T-cells *ex vivo*, which allows recognition and cytotoxicity of tumor cells by co-opting the natural T-cell receptor. TAC T-cells demonstrate a safer profile than chimeric antigen receptor T cells. TAC01-HER2 is an autologous T-cell product comprising T-cells expressing HER2 TAC.

Methods: The ongoing clinical trial (NCT04727151) is evaluating the safety and preliminary anti-tumor activity of TAC01-HER2 treatment of HER2+ solid tumors. Subjects undergo leukapheresis followed by lymphodepletion chemotherapy (LDC) prior to TAC01-HER2 infusion. In phase I dose escalation, TAC01-HER2 is administered at increasing doses (Cohorts 1-4) in adult subjects after $\geq$2 lines of therapy. Dose limiting toxicities (DLT) are assessed up to 28 days from TAC01-HER2 infusion. In phase II, dose expansion groups will further evaluate the safety, efficacy, and pharmacokinetics of the optimal TAC01-HER2 dose in gastric/GEJ tumors.

Results: As of 23 April 2023, 19 patients with solid tumors have been treated in Cohorts 1-4. Three were HER2 1+ or 2+/FISH-. One DLT event of grade (G) 3 pneumonitis has been reported in 1 subject in Cohort 4. No neurotoxicity has been reported. Most subjects treated at Cohorts 3-4 experienced CRS which resolved with supportive therapy. Thirteen subjects have reported a total of 26 serious adverse events, with 1 G3 pneumonitis, 1 G1, 3 G2 and 1 G3 CRS related to TAC01-HER2. A 67% disease control rate (DCR) was observed in Cohorts 2-4 at 4 weeks restaging after TAC01-HER2 infusion. For gastric/GEJ subjects of the same Cohorts, DCR was 83%. Two patients had an unconfirmed partial response (uPR). At Cohort 4, a uPR was observed in a subject with GEJ (HER2 2+, FISH+) with 100% reduction of target lesion. This patient had progressed on 4 prior lines of therapy including trastzumab and trastuzumab deruxtecan.

Conclusions: Treatment with TAC01-HER2 showed manageable safety and promising clinical activity in a heavily pre-treated cancer population. Dose escalation is complete.

Clinical trial identification: NCT04727151.

1529P Tislelizumab plus chemotherapy sequential neo-chemoradiotherapy therapy as total neoadjuvant therapy in locally advanced esophageal squamous cell carcinoma (ETNT)

W. He[1], C. Wang[1], L. Wu[2], G. Wan[2], Y. Han[1], X. Leng[1], Q. Wang[3], L. Peng[4]

[1]Thoracic Surgery, Sichuan Cancer Hospital and Institute/The Affiliated Cancer Hospital School of Medicine, UESTC, Chengdu, China; [2]Radiotherapy, Sichuan Cancer Hospital and Institute/The Affiliated Cancer Hospital School of Medicine, UESTC, Chengdu, China; [3]Radiaition Oncology, Sichuan Cancer Hospital, Chengdu, China; [4]Thoracic Surgery, Sichuan Cancer Hospital, Chengdu, China

Background: High recurrence and metastasis rates remain the main factors leading to the failure of the current standard treatment of neoadjuvant chemoradiotherapy plus surgery for resectable locally advanced ESCC. Improving the pathological complete response (pCR) rate may significantly benefit the survival of patients with resectable locally advanced ESCC after neoadjuvant therapy.

Methods: Patients aged 18-75 years with untreated, resectable, stage III-IVA ESCC, adequate organ and bone marrow function were eligible for inclusion. patients received neoadjuvant chemoradiotherapy (paclitaxel 135 mg/m2 d1 + carboplatin AUC = 3−5 d1, q3w × 2 cycles + 65 simultaneous radiotherapy (40 Gy/4 W/20F)) treatment, after the end of chemoradiotherapy, Tislelizumab (200 mg intravenously every 3 weeks for 2 cycles, and all patients undergo surgery after 4−6 weeks. The primary outcomes of the pCR rate and the incidence of adverse events will be analyzed completely within months, the secondary endpoints will include major pathological response rate, objective response rate, R0 resection rate, event-free survival, and overall survival. All enrolled patients were included in the activity and safety analyses.

Results: Thirty-two patients were enrolled in the study, among 8 patients are waiting for a surgery, with 24 patients undergoing surgical resection at a 100% R0 resection rate. All patients had stage III-IVA disease. Patients who received tislelizumab plus chemotherapy sequential nCRT achieved 13(54.2%) patients had a pathologic complete response, 16 (66.7%) patients achieved major pathologic response, and 21(87.5%) objective remission rate. Within 30 days after surgery, anastomotic fistula was found in 4 (16.7%) patients, but no deaths occurred, the most common grade 2 or 3 adverse event was leukopenia, hypothyroidism and lymphopenia. The analysis of survival was immature, and patients are still being followed up.

Conclusions: This study explored the safety and efficacy of tislelizumab plus chemotherapy sequential neo-chemoradiotherapy therapy for ESCC patients and provided a total neoadjuvant therapy model that can benefit patients with locally advanced ESCC.

Clinical trial identification: NCT05189730.

Background: In the randomized, double-blind, global SPOTLIGHT (NCT03504397) and GLOW (NCT03653507) trials, first-line zolbetuximab + chemo (mFOLFOX6 [SPOTLIGHT]; CAPOX [GLOW]) showed improved PFS (SPOTLIGHT, HR 0.75 [95% CI 0.60, 0.94], $P = 0.0066$; GLOW, HR 0.69 [95% CI 0.54, 0.87], $P = 0.0007$) and OS (SPOTLIGHT, HR 0.75 [95% CI 0.60, 0.94], $P = 0.0053$; GLOW, HR 0.77 [95% CI 0.62, 0.97], $P = 0.0118$) compared with placebo + chemo in patients with CLDN18.2+, HER2−, LA

unresectable or mG/GEJ adenocarcinoma at data cutoff. We present key patient-reported outcome (PRO) findings from these trials.

Methods: Patients completed the EORTC QLQ-C30 and QLQ-OG25 at screening, every 3 weeks on treatment, at discontinuation, and 30 and 90 days thereafter. Changes in scores from baseline, time to confirmed deterioration (TTCD), and time to definitive deterioration (TTDD) in PROs based on literature thresholds were evaluated. Least square mean (LSM) changes from baseline were summarized descriptively. TTCD and TTDD were assessed by Kaplan-Meier estimates and Cox hazard models.

Results: Table describes the LSM changes from baseline for SPOTLIGHT (N = 565) and GLOW (N = 507). No clinically meaningful deteriorations in global health status and quality of life (GHS/QoL), physical functioning (PF), abdominal pain and discomfort, or nausea/vomiting (N/V) were observed. Overall TTCD and TTDD results were similar between arms in both studies.

Table: 1530P

	Zolbetuximab + chemo LSM (standard error [SE])	Placebo + chemo LSM (SE)	Zolbetuximab vs placebo arms LSM (95% CI)	*P* value
SPOTLIGHT Cycle 9 Day 1	(N = 283)	(N = 282)		
GHS/QoL	1.65 (1.60)	4.20 (1.77)	-2.54 (-7.02, 1.93)	0.263
PF	-5.68 (1.77)	0.34 (1.88)	-6.02 (-10.85, -1.19)	0.015
Pain	-6.85 (1.86)	-9.12 (2.08)	2.27 (-2.97, 7.51)	0.394
N/V	-3.38 (1.64)	-2.31 (1.80)	-1.07 (-5.61, 3.47)	0.642
GLOW Cycle 17 Day1	(N = 254)	(N = 253)		
GHS/QoL	-0.04 (2.43)	-5.55 (2.89)	5.51 (-1.82, 12.84)	0.139
PF	-2.05 (1.88)	-2.93 (2.19)	0.88 (-4.67, 6.43)	0.753
Pain	-5.39 (2.32)	-7.27 (2.88)	1.88 (-5.30, 9.07)	0.604
N/V	-0.95 (1.89)	2.85 (2.31)	-3.79 (-9.57, 1.98)	0.192

Conclusions: There were not overall clinical HRQoL differences between patients in the zolbetuximab and placebo arms. Zolbetuximab + chemo improved clinical outcomes without negatively affecting HRQoL in key PROs in both SPOTLIGHT and GLOW.

Clinical trial identification: NCT03653507.

1531P Update results of anlotinib combined with TQB2450 (PD-L1 blockade) as first-line treatment for advanced esophageal squamous cell carcinoma (ESCC): A single-arm, multicenter, open-label phase II clinical trial

Y-G. Hong[1], X. Meng[2], X. Yang[3], Z-Y. Zhang[4], J. Xia[1], Y-F. Chen[5], T. Wu[1], Z. Shan[2], Q. Fan[2], F. Wang[2]

[1]Department of Internal Oncology, Anyang Tumour Hospital, Anyang, China; [2]Department of Internal Oncology, The First Affiliated Hospital of Zhengzhou University, Zhengzhou, China; [3]Department of Internal Oncology, First Affiliated Hospital of Nanyang Medical College, Nanyang, China; [4]Oncology, The First Affiliated Hospital of Henan University of Science and Technology, Luoyang, China; [5]Department of Internal Oncology, Zhumadian Central Hospital, Zhumadian, China

Background: Recent studies have demonstrated encouraging efficacy in patients with ESCC when combining PD-1 blockades with chemotherapy in the first-line setting. However, the safety profile of conventional chemotherapy remains unsatisfactory, suggesting the chemotherapy-free regimen a promising strategy. Anlotinib, a novel multitarget TKI primarily targeting VEGFR1-3, has shown therapeutic activity as first-line combination therapy or second-line monotherapy for ESCC patients in China. TQB2450 is a novel PD-L1 blockade developed by Chia Tai Tianqing Pharmaceutical Group Co., Ltd. (Nanjing, China). This study aims to investigate the efficacy and safety of anlotinib plus TQB2450 as first-line therapy for patients with advanced ESCC.

Methods: Patients with previously untreated metastatic or locally advanced ESCC, whose age was between 18 and 75 years, with ECOG PS of 0 or 1 score and life expectancy of >3 months were inclusion criteria. Eligible patients were administered with anlotinib (12mg, po, d1∼14, q3w) plus TQB2450 (1200mg, iv, d1, q3w) until disease progression or unacceptable toxicity. The predefined sample size was 46. The primary endpoint was ORR, secondary endpoints included safety, PFS, DCR, DoR and OS.

Results: From Mar 2022 to Sep 2022, a total of 46 patients were enrolled. At the data cut-off date (Mar 2023), the preliminary ORR was 69.6% (95%CI: 54.2%∼82.3%), DCR was 93.5% (95%CI: 82.1%∼98.6%). At the data cut-off date, 9 pts discontinued treatment due to PD, the preliminary prognostic result exhibited that the median PFS of the 46 pts was 9.92 months (95%CI: 8.26∼11.58). Additionally, safety profile exhibited that the regimen was tolerable. The common grade ≥3 treatment-related adverse events in 46 patients were hypertension (7%), hyponatremia (4%), low white blood cell count (2%), neutrophil count decreased (2%), platelet count decreased (2%), intestinal obstruction (2%), haemoptysis (2%) and toothache (2%).

Conclusions: The preliminary results highlighted that anlotinib plus TQB2450 as a first-line therapy for advanced ESCC showed encouraging efficacy and manageable safety profile.

Background: Combination therapy using FGFR inhibitors and Immune checkpoint inhibitors (ICIs) are being explored as a novel strategy for cancer patients (pts). Previously, we reported the preliminary antitumor activity of irreversible FGFR inhibitor futibatinib plus pembrolizumab in pts with advanced (adv) or metastatic

esophageal carcinoma (EC). Here, updated results and tolerability in combination with chemotherapy are presented.

Methods: Pts who are ICI naïve (Cohort A) or ICI refractory (Cohort B) for adv or metastatic EC who have received at least one prior therapy with a fluorouracil and platinum-based drug were administrated with futibatinib plus pembrolizumab. In addition, pts who have not received prior treatment with any systemic chemotherapy received futibatinib 20 mg once daily (QD) plus pembrolizumab 200 mg, fluorouracil 800mg/m^2 on days 1-5 and cisplatin 80mg/m^2 every 3weeks in Cohort D. Primary endpoint was overall response rate (ORR) in Cohort A and B, and dose-limiting toxicity (DLT) in Cohort D.

Results: As of March 15, 2023, 31 pts (Cohort A), 50 pts (Cohort B) and 11 pts (Cohort D) were enrolled. As results of the analysis for the cut-off data, confirmed partial responses (PRs) were observed in 11 pts in Cohort A; ORR was 39% with DCR of 75%. In Cohort B, confirmed PRs were observed in 3 pts; ORR was 6% with DCR of 57%. DLT was observed in one pt (Grade 3, Stomatitis) in Cohort D and the RD of futibatinib in combination with pembrolizumab and chemotherapy was determined as 20 mg QD. In Cohort D, most common TRAEs (N=11; all grade, grade ≥3) were hyperphosphatemia (82%, 0%) and stomatitis (82%, 9.1%). Of the 8 pts evaluated for efficacy in Cohort D, confirmed PRs and unconfirmed PRs were observed in 2 pts and 5 pts (5 pts are ongoing), respectively.

Conclusions: Futibatinib plus pembrolizumab showed encouraging antitumor activity in ICIs naïve adv or metastatic EC pts. Futibatinib plus pembrolizumab and chemotherapy showed no new safety signals and manageable safety profile, with promising antitumor activity in pts with adv or metastatic EC who have not received prior treatment with systemic chemotherapy.

Clinical trial identification: jRCT2080224975.

Background: A T-cell immunoreceptor with immunoglobulin and immunoreceptor tyrosine-based inhibitory motif domains (TIGIT) inhibitor + an anti-PD-1 antibody is a promising combination which shows potent efficacy in solid tumors. AdvanTIG-105 (NCT04047862) is a phase I/1b open-label study designed to assess the safety and preliminary antitumor activity of anti-TIGIT mAb OCI + anti-PD-1 mAb TIS in pts with metastatic unresectable solid tumors. OCI + TIS was well tolerated in the dose-escalation part, preliminary efficacy was observed, and the recommended phase II dose (RP2D) of OCI 900 mg IV Q3W + TIS 200 mg IV Q3W was established. Here we report results from dose-expansion cohorts 6 (C6) and 7 (C7).

Methods: Treatment-naïve adult pts with histologically/cytologically confirmed metastatic ESCC (C6) or EAC (C7) were enrolled. Pts received the RP2D of OCI + TIS with cisplatin + 5-fluorouracil/paclitaxel until disease progression, intolerable toxicity, or consent withdrawal. Primary endpoint: investigator-assessed ORR per RECIST v1.1. Secondary endpoints: efficacy (PFS, DoR, DCR), safety and PD-L1 and TIGIT expression as predictive efficacy biomarkers.

Results: As of Feb 2, 2023, 27 pts (C6: n=21; C7: n=6) with a median age of 63.0 y (range C6: 51-72; C7: 58-69) were enrolled; 24 (C6: n=19; C7: n=5) were efficacy evaluable. Efficacy and safety data are summarized in the table. ORRs by biomarker subgroups: C6, 100% in pts with PD-L1 tumor area positivity (TAP) score ≥10% (n=4) vs 76.9% in pts with PD-L1 TAP <10% (n=13); 80.0% in pts with TIGIT IC score ≥5% (n=10) vs 87.5% in pts with TIGIT IC <5% (n=8). C7 had too few pts for biomarker subgroup analysis.

Table: 1533P Efficacy and Safety Summary

	Efficacy Evaluable Set	
	C6	C7
Parameter	**n=19 % (95% CI)**	**n=5**
ORR	84.2 (60.4-96.6)	80.0 (28.4-99.5)
DCR	94.7 (74.0-99.9)	100 (47.8-100)
	mo (95% CI)	
Median DoR	6.7 (4.7-NE)	3.4 (1.7-NE)
Median PFS	8.1 (6.5-NE)	6.2 (3.0-NE)
	Safety Set	
Parameter	**n=21**	**n=6**
Median study follow-up (range), wks	36.1 (1.7-77.0)	29.3 (8.6-57.1)
	n (%)	
Pts with ≥1 TEAE	21 (100)	6 (100)
Grade ≥3	14 (66.7)	6 (100)
Serious	9 (42.9)	4 (66.7)
imAE	11 (52.4)	2 (33.3)

DCR, disease control rate; DoR, duration of response; imAE, immune-mediate adverse event; mo, months; NE, not estimable; ORR, objective response rate; PFS, progression-free survival; TEAE, treatment-emergent adverse event.

Conclusions: These results demonstrate that OCI 900 mg + TIS 200 mg + CT had a safety profile consistent with previous reports and showed encouraging antitumor activity in pts with stage IV ESCC and EAC.

Clinical trial identification: NCT04047862.

Inc., Rahway, NJ, USA; [10]Oncology Clinical Research, Merck & Co., Inc., Rahway, NJ, USA; [11]Global Clinical Development, Merck & Co., Inc., Rahway, NJ, USA; [12]GI Oncology Department, Peking University Cancer Hospital and Institute, Beijing, China

Background: LEAP-014 (NCT04949256) is a randomized, two-part, open-label, phase III study evaluating the safety and efficacy of len + pembro + chemo vs pembro + chemo in patients (pts) with previously untreated mESCC. Results from part 1 (safety run-in cohort) are reported.

Methods: Eligible pts had confirmed previously untreated mESCC; measurable disease per RECIST v1.1 by investigator; and ECOG PS score $\leq$1. In part 1, pts received induction with IV pembro 400 mg Q6W$\times$2 cycles + oral len 8 mg QD + chemo (cisplatin + 5-FU [FP] Q3W$\times$4 cycles or paclitaxel + cisplatin [TP] Q3W$\times$4 cycles) and consolidation with IV pembro 400 mg Q6W for $\leq$16 doses + oral len 20 mg QD. Pts were treated until disease progression or unacceptable toxicity. Primary end points for part 1 were dose-limiting toxicities (DLTs), adverse events (AEs), and discontinuations due to AEs. DLTs were evaluated for 21 days after the first dose; if $\geq$3 DLTs occurred in the TP or FP cohort, then part 2 could be delayed to further examine safety data and consider study design changes.

Results: At data cut-off (February 2, 2023), 13 pts were treated (FP: 7; TP: 6). Median time from first dose to data cut-off was 16.6 mo (range, 15.9-17.3) and 5.6 mo (4.6-6.2) with len + pembro + FP and len + pembro + TP, respectively. Median (range) age was 64 y (43-77) and 66 y (53-71), respectively. One DLT of grade 3 acute kidney injury associated with increased creatinine level and 1 DLT of grade 3 hypokalemia occurred in the FP cohort; no DLTs were reported in the TP cohort. No pt discontinued because of a DLT. No treatment-related deaths occurred. ORR and DOR will be reported.

Conclusions: Part 1 (safety run-in) of LEAP-014 showed that len + pembro + chemo had acceptable safety and tolerability in pts with previously untreated mESCC, allowing initiation of part 2. Part 2 is ongoing and will evaluate the efficacy and safety of len + pembro + chemo vs pembro + chemo as first-line therapy for mESCC.

Clinical trial identification: NCT04949256.

Background: Ramucirumab (Ram) combined with docetaxel is an approved 2nd-line treatment in patients (pts) with squamous cell carcinoma (SCC) of the lung (REVEL study) and with paclitaxel for esophagogastric adenocarcinoma (RAINBOW study). In SCC of the oesophagus, nivolumab is currently the only evidence-based 2nd-line treatment option. This study evaluates the safety and efficacy of Ram plus paclitaxel.

Methods: This prospective, randomized, open-label, multicentre, phase II trial evaluated paclitaxel plus Ram (Ram 8 mg/kg d1, 15 and paclitaxel 80 mg/m^2 d1, 8, 15) Arm A vs. paclitaxel alone (80 mg/m^2 d1, 8, 15) Arm B, both q4w. Primary endpoint was overall survival rate at 6 months (mos) (OS@6), main secondary endpoints were OS, PFS, objective response rate (ORR) and safety.

Results: From 3/2019 to 4/2021, 21/186 planned pts were treated within the study protocol (Arm A 11 pts; Arm B 10 pts) in 9 German centres. Due to slow accrual, the study was terminated prematurely. Median age was 63y, 71% were male and 86% had relevant concomitant disease. Pts received a median of 9 and 10 cycles in Arms A and B, respectively. Median follow-up was 9 mos (0.7 — 32.4 mos). OS@6 in Arm A was 73% for Ram/paclitaxel and 50% for paclitaxel. However, the study design did not allow for statistical comparison of the arms. ORR (CR+PR 18% vs. 20%) and DCR (CR+PR+SD 55% vs. 60%) were in the same range, as well as median PFS (3.8 vs. 3.5 mos) and OS (12.1 vs. 9.2 mos) for Arms A and B, respectively. The most common treatment related adverse events (AEs) in Arm A were leucopoenia (55%), fatigue (27%) and peripheral sensory neuropathy (18%). Treatment related AEs $\geq$ grade 3 occurred in 27% in Arm A and 50% in Arm B. Serious AEs (SAEs) occurred in 36% and 50% in Arms A and B, respectively.

Conclusions: Ram and Paclitaxel shows an acceptable tolerability and numerically improved OS@6. Due to the small number of pts the current trial must be considered exploratory, and more data are needed in this indication.

Clinical trial identification: NCT03762564.

Background: HER-Vaxx is a B cell peptide-based anti-Her2 vaccine (IMU-131) comprising B cell epitopes located within trastuzumab's binding site. In the phase Ib HERIZON trial (NCT02795988), HER-Vaxx has been shown to be safe and to prolong progression-free survival in patients with Her2-overexpressing gastric/gastro-oesophageal junction cancer (GC). The present randomized phase II open-label, multicentre study, compared two different doses of HER-Vaxx plus chemotherapy vs chemotherapy alone and aimed to evaluate antibody and clinical responses in patients with advanced or metastatic Her2-overexpressing GC naïve to Her2 therapy.

Methods: Patients were randomized to chemotherapy alone (n=17) or HER-Vaxx (50µg dose, n=19; 100µg, n=7) plus chemotherapy. In both vaccination groups, the patients received the vaccine at days 0, 14, 35, and 77 followed by q. 63 days until disease progression. Chemotherapy consisted of oxaliplatin plus capecitabine and was started at day 0, repeated q. 21 days for a maximum of 6 cycles. Specific anti-Her2 IgG antibody levels in the patient's sera were evaluated by ELISA and clinical responses were assessed by RECIST 1.1 criteria.

Results: Evaluation of the vaccine's two doses showed no difference in the induced Her2-specific IgG and IgG1 antibody responses, which, compared to patients from the chemotherapy-only group, were both significantly elevated ($P<0.001$) at all time points after 3 or more vaccinations. No further reduction of tumour diameters was observed with the vaccine's higher dose, and the induced Her2-specific antibodies following vaccination with either dose significantly correlated with the anti-tumour effect (IgG, $P=0.001$; IgG1, $P=0.016$). Moreover, the vaccine-induced IgG antibodies had the capacity to inhibit intracellular phosphorylation of Her2 and exhibited binding to the gastric cancer cell line N87 overexpressing Her2.

Conclusions: Vaccination with HER-Vaxx in patients with Her2-overexpressing GC at doses of 50µg and 100µg led to an anti-tumour effect that correlated with anti-Her2 IgG antibody levels.

Clinical trial identification: NCT02795988.

1537P A phase I study of pevonedistat plus capeOX in patients with advanced gastric cancer refractory to platinum (NCCH-1811)

D. Takahari[1], H. Shoji[2], A. Ooki[1], H. Hirano[3], N.T. Okita[2], K. Nagashima[4], J. Adachi[5], K. Yamaguchi[1], K. Kato[2], N. Boku[6]

[1]Department of Gastrointestinal Medical Oncology, The Cancer Institute Hospital of JFCR, Koto-ku, Japan; [2]Department of Gastrointestinal Medical Oncology, National Cancer Center - Tsukiji Campus, Chuo-ku, Japan; [3]Department of Gastrointestinal Medical Oncology, National Cancer Center Hospital, Tokyo, Japan; [4]Biostatistics Unit, Clinical and Translational Research Center, Keio University, Fujisawa, Japan; [5]Center for Drug Design Research, National Institute of Biomedical Innovation, Ibaraki, Japan; [6]Department of Oncology and General Medicine, IMS Hospital, Institute of Medical Science, University of Tokyo, Minato-ku, Japan

Background: Pevonedistat (MLN4924/TAK924), which is an inhibitor of NEDD8 (neural precursor cell expressed developmentally down-regulated protein 8)-activating enzyme (NAE), shows synergistic effects with platinum, suggesting possibility of conquest over platinum-resistance, in preclinical studies. This phase I study was conducted to determine the recommended dose (RD) of pevonedistat in combination with capecitabine plus oxaliplatin (CapeOX) and explore its efficacy and safety as third- or later line treatment in patients (pts) with unresectable advanced gastric cancer (AGC).

Methods: This study consisted of two parts: the dose-finding part, and the expansion part at the RD. In both parts, treatment was started as monotherapy with pevonedistat for a week (Lead-in) and followed by 3-drug combination in a 3-week cycle: Capecitabine (1000 mg/m2/day, twice daily, for 14 days), oxaliplatin (130 mg/m2 on day 1) and pevonedistat (20 mg/m2 in level 1, 15 mg/m2 in level 0, on days 1, 3, and 5). Pharmacokinetics (PK) of pevonedistat was compared between its mono and combination therapy. Translational research for pharmacodynamics and genetic biomarkers were performed.

Results: Between April 2019 and September 2021, 12 pts having prior chemotherapy containing fluoropyrimidine plus platinum were enrolled. The initial 2 pts in the level 1 experienced DLTs (grade 3 elevation in ALT and AST, delay of starting cycle 2). After confirming that six pts in the level 0 showed no DLTs, 4 pts were added in the expansion part. Grade3 AEs included AST increased (25%), ALT increased (17%), and platelet count decreased (17%). No obvious difference in the PK of pevonedistat was observed when combined with CapeOX. Two (17%) and 8 (75%) pts achieved partial response and disease control. The median overall and progression-free survival were 9.3 and 4.4 months. Inhibition of NAE by pevonedistat was confirmed in all patients by positive Cdt1 expression in the post-treatment biopsy. No genetic alterations associated with efficacy were identified.

Conclusions: Pevonedistat plus CapeOX was well tolerated and showed promising efficacy in AGC pts previously treated with platinum containing chemotherapy.

1538P A phase II study to evaluate the efficacy and safety of tislelizumab combined with chemotherapy (cis-platinum plus albumin-paclitaxel/paclitaxel) in neoadjuvant treatment of locally advanced oesophageal squamous cell carcinoma

J. Wang, Y. Sun

Thoracic Surgery Department, Fudan University Shanghai Cancer Center, Shanghai, China

Background: Neoadjuvant chemoimmunotherapy might benefit pts with locally advanced oesophageal squamous cell carcinoma (ESCC). Herein, we aimed to evaluate the efficacy and safety of Tislelizumab (a humanized anti-PD-1 antibody) combined with cisplatin plus albumin-paclitaxel(nab-PTX)/paclitaxel (PTX).

Methods: A prospective, open, single-arm, two-cohort phase II trial was conducted. ESCC Pts with resectable locally advanced disease were enrolled and randomly allocated into group nab-PTX (group A) or group PTX (group B). Pts received intravenous Tislelizumab (200 mg, day 1) combined with cisplatin (25mg/m2, day 1-3) plus nab-PTX (130 mg/m2, day 1, 8) in group A or PTX (75 mg/m2, day 1, 8) in group B of each 21-day cycle for two cycles before surgery, respectively. The primary endpoint was major pathologic responses (MPR) rate. The Secondary endpoints were pathological complete response (pCR) rate, R0 resection rate, treatment related adverse events (TRAEs), DFS and OS.

Results: From Feb 14, 2022, to Mar 8, 2023, 39 pts were enrolled (n=20 in group A, n=19 in group B). 35 pts received the full two-cycle chemoimmunotherapy successfully and received surgery (n=19 in group A, n=16 in group B), 2 pts in group B didn't receive the second cycle due to intolerance and dropped out, and 2 patients gave up surgery after neoadjuvant therapy for personal reasons (n=1 in each group). Pts underwent surgery within 23-97 days (median 35 days) after neoadjuvant treatment, among others, 2 pts delayed surgery due to TRAEs. All patients achieved radical (R0) resection. No patient died during neoadjuvant therapy and perioperative period. In group A, the MPR rate and pCR rate were 78.9% (15/19) and 36.8% (7/19), respectively. In group B, the MPR rate and pCR rate were 18.8% (3/16) and 0% (0/16), respectively. The most common TRAEs were lymphopenia (45.7%), diarrhoea (34.3.0%) and fatigue (31.4%), and there was no significant difference between groups.

Conclusions: Neoadjuvant treatment with Tislelizumab combined with cisplatin plus nab-PTX demonstrated promising anti-tumor efficacy with acceptable toxicity in pts with locally advanced thoracic ESCC.

1539P Efficacy and safety of perioperative chemotherapy combined with tislelizumab and trastuzumab for HER2-positive resectable gastric/gastroesophageal junction cancer (GC/EGJC): Preliminary results of a phase II, single-arm trial

F. Wang[1], C. Zhao[2], J. Xia[3], Z. Liu[4], X. Meng[1], Z. Shan[1], J. Jiang[1], X. Liu[2], H. Li[2], J. Sun[2], C. Ding[2], H. Zhang[2], W. Liang[2]

[1]Medical Oncology, The First Affiliated Hospital of Zhengzhou University, Zhengzhou, China; [2]Gastrointestinal surgery, The First Affiliated Hospital of Zhengzhou University, Zhengzhou, China; [3]Medical Oncology, Anyang Tumour Hospital, Anyang, China; [4]General surgery, Anyang Tumour Hospital, Anyang, China

Background: Immunotherapy combined with trastuzumab, and chemotherapy have been recommended by the clinical guidelines of many countries as the first-line treatment for advanced HER2-positive G/GEJ adnocarcinoma. Combining chemotherapy with tislizumab and trastuzumab in the neoadjuvant/adjuvant setting may benefit patients with locally advanced, resectable HER2-positive GC/GEJC.

Methods: This study is a multicentre, single-arm, open-label phase II study. Patients with histologically confirmed cT2-4NxM0 or cTxN+M0, (TNM 8th edition), resectable GC/GEJC are eligible for this study. Neoadjuvant therapy will be administered for four cycles. The patients will receive tislelizumab and trastuzumab for 1 cycle (Q3W), followed by tislelizumab and trastuzumab combined with DOS (Docetaxel + Oxaliplatin + S-1) for 3 cycles (Q3W). Surgery is planned 4-6 weeks after preoperative treatment. Patients will receive adjuvant therapy starting within 4−6 weeks after surgery for 9 cycles. The primary endpoint was pathological complete response rate (pCR). Secondary endpoints included R0 resection rate, 1-year and 2-year event-free survival (EFS), overall survival (OS) and safety.

Results: From September 13, 2021, to May 05, 2023, 18 patients were enrolled, and the median follow up time was 9.2 months (0.1-20.0).11 patients completed surgery, and 5 patients were undergoing neoadjuvant therapy, 2 patients required organ preservation therapy. R0 resection rate was 100%, 6 patients (54.5%) achieved pCR, and 7 patients (63.6%) achieved MPR. Postoperative pathology showed that T stage decreased in 9 cases after neoadjuvant therapy, with a decrease rate of 81.8%. Median OS and EFS have not been reached. The most common AEs (grade ≥3) were anaemia in 1 (5.6%) and neutropenia in 1 case (5.6%). The immune-related adverse events were all grade 1. No treatment related deaths were reported.

Conclusions: According to the preliminary results, tislelizumab combined with trastuzumab and standard chemotherapy in the perioperative period of HER2-positive GC / EGJ have a good clinical benefit trend and controllable security.

Clinical trial identification: NCT04819971.

1540P Tislelizumab combined with neoadjuvant chemoradiotherapy for resectable locally advanced oesophageal squamous cell carcinoma: A prospective, phase II clinical study

Y. Zhang[1], Y. Yuan[2], Y. Xu[1], R. Tian[3], J. Liao[4], X. Zeng[5], Y. Wang[1], Y. Liu[1], X. Zhou[1], F. Peng[6], L. Zhou[1], H. Wang[3], W. Hou[3], M. Yu[1], W. Xiu[1], M. Huang[1], X. Zhang[1], Y. Gong[1], Y. Lu[1], B. Zou[1]

[1]Division of Thoracic Oncology, Department of Radiation Oncology, West China School of Medicine/West China Hospital of Sichuan University, Chengdu, China; [2]Department of Thoracic Surgery, West China School of Medicine/West China Hospital of Sichuan University, Chengdu, China; [3]Department of Nuclear Medicine, West China School of Medicine/West China Hospital of Sichuan University, Chengdu, China; [4]Department of Gastroenterology, West China Forth Hospital, Chengdu, China; [5]Department of Radiation Oncology, West China School of Medicine/West China Hospital of Sichuan University, Chengdu, China

Background: Neoadjuvant chemoradiotherapy (nCRT) is a standard treatment for resectable locally advanced oesophageal squamous cell carcinoma (ESCC); however, its effectiveness is curtailed by recurrence and distant metastasis. Developing novel therapies, such as combined checkpoint inhibitors, is crucial for improving patient survival. Tislelizumab, an anti-PD-1 monoclonal antibody, has shown promise in various malignancies. This is the first phase II study to assess the efficacy and safety of Tislelizumab combined with nCRT for resectable locally advanced ESCC.

Methods: All subjects underwent nCRT with a 40 Gy total radiation dose given daily for 5 days/week. Paclitaxel albumin (taxanes) with cisplatin/carboplatin were given on days 1 and 22, while Tislelizumab was administered twice on days 8 and 29 concurrently with radiation therapy. Finally, surgery was performed at 6-8 weeks post-treatment.

Results: By April 2023, 26 patients were enrolled in the study, with 21 undergoing surgical resection at a 100% R0 resection rate. Patients who received Tislelizumab combined with nCRT achieved a 100% objective remission rate, with 9 (42.8%) patients had complete response rate and 14 (66.6%) patients achieved major pathologic response, no surgical delay, among 6 patients continue to receive postoperative adjuvant therapy. Common side-effects included leukopenia, thrombocytopenia, neutropenia, anemia, anastomotic leakage, and rash. Most adverse events were grades 1/2, and grades 3/4 adverse events include four cases of grade 3 leukopenia, and one case of grade 3 neutropenia. Regrettably, 2 patients have passed away due to the novel coronavirus. The analysis of survival was immature, and patients are still being followed up.

Conclusions: Tislelizumab in combination with nCRT is a safe and effective treatment strategy for resectable locally advanced ESCC. The high complete response rate and favorable safety profile observed in this study warrant further investigation in larger, randomized controlled trials to confirm the benefit of Tislelizumab in improving treatment outcomes for patients with locally advanced ESCC.

1541P Neoadjuvant therapy of camrelizumab combined with chemotherapy in patients (pts) with resectable esophageal squamous cell cancer (ESCC)

Y. Dong[1], J. Luo[2], S. Liu[2], H. Han[3], Y. Lin[3]

[1]Thoracic Surgery, Shandong Cancer Hospital and Institute Affiliated Shandong First Medical University and Shandong Academy of Medical Sciences, Jinan, China; [2]Oncology, Shandong Cancer Hospital Affiliated to Shandong University, Jinan, China; [3]Department of Medicine, Jiangsu Hengrui Pharmaceutical Co., Ltd., Shanghai, China

Background: The study aimed to evaluate the efficacy and safety of neoadjuvant therapy of camrelizumab, combined with chemotherapy in resectable ESCC pts.

Methods: In this single-center, single-arm, exploratory clinical trial (ChiCTR2100050057), treatment naïve pts with histologically identified resectable ESCC were included. Eligible pts was treated with camrelizumab (200 mg, d1) combined with nab-paclitaxel (100 mg/m^2, d1 and d8) and nedaplatin (75 mg/m^2, d1) for 2 cycles (21 days per cycle). Radical surgery was conducted in the following 4-6 weeks. Primary endpoints were pathological complete response (pCR) rate, and major pathologic response (MPR).

Results: From Aug 13, 2021, to Jul 9, 2022, a total of 70 pts were enrolled in this study. Sixty-eight pts completed the two-cycle neoadjuvant therapy, with two pts discontinued the 2nd cycle therapy for intolerable toxicity. As of March 15, 2023, 61 pts were available for efficacy evaluation, with 6 complete responses (CR), 35 partial responses (PR), and 20 stable diseases (SD) based on RECIST 1.1 criteria, resulting in an objective response rate (ORR) of 67.2%. Then 59 pts underwent surgery, as 11 pts refused. Overall, surgery-related complications occurred in 53 (89.8%) pts after resection. Pulmonary complications occurred in forty-nine pts (83.1%) and cardiac complications were observed in four pts (6.8%). The rate of anastomotic leakage was 20.3%. Vocal cord paralysis and wound infection occurred in 2 pts, respectively. The pCR and MPR rate were 27.1% and 59.3%, respectively. According to tumor regression grade, 19/59 (32.2%) pts had TRG0, 16/59 (27.1%) TRG1, 14/59 (23.7%) TRG2, and 10/59 (16.9%) TRG3. We analyzed the correlation between PD-L1 expression and pathological tumor regression and found no significant correlation between PD-L1 status and pathological reactions in ESCC. The most common AEs were anemia (70.0%) lymphocyte count decreased (67.1%) white blood cell count decreased (52.9%) and neutrophil count decreased (50%). Most AEs were grade 1-2. No grade 4/5 AEs occurred.

Conclusions: Neoadjuvant therapy of camrelizumab combined with chemotherapy has promising efficacy and good safety in ESCC pts.

Legal entity responsible for the study: Affiliated Cancer Hospital of Shandong First Medical University.

1542P Updated results of a phase II clinical trial: Paclitaxel and carboplatin plus PD-1 blockades combined with anlotinib as first-line treatment for advanced oesophageal cancer

M. Xu, Y. Pu, Y. Jiang, H. Liu, Y. Feng, C. Qian, N. Dai, M. Li

Cancer Center of Daping Hospital, Army Medical University, Chongqing, China

Background: The combination of PD-1 blockades with chemotherapy is the standard first-line therapy for advanced esophageal cancer. Recent studies exhibited that anti-angiogenic drug combined with PD-1 blockades or chemotherapy demonstrated potential synergistic action and bright prospect in the combined application of anti-tumor therapy. We present updated data from the study of paclitaxel and carboplatin combined with anlotinib and PD-1 blockades in the treatment of advanced oesophageal cancer.

Methods: This study was a parallel, open-label, phase II clinical trial. A total of 90 patients (pts) with previously untreated, advanced or metastatic ESCC, with an age ranging from 18-75 years old were planned to be enrolled into three arms with an allocation ratio of 1:1:1. Arm A received TC (paclitaxel + carboplatin) + camrelizumab (200mg, q3w) + anlotinib (8mg, q3w); Arm B received TC with camrelizumab; Arm C received TC only. After 4-6 cycles of induction therapy, arm A and arm B would receive maintenance therapy until disease progression or intolerable adverse events. The primary endpoint was ORR. Secondary endpoints included PFS, OS and safety.

Results: At data cut-off date (Apr. 30, 2023), a total of 90 pts was enrolled. 25 of 30 pts achieved partial response (PR) and 2 pts achieved complete response in arm A, 13 of 30 pts achieved PR in arm B, and 7 of 30 pts achieved PR in arm C. The ORR were 90.0% in arm A, 43.3% in arm B, and 26.7% in arm C. The median PFS (95% CI) were 13.4 months (10.1-16.8) in arm A, 7.2 months (3.6-10.9) in arm B, and 4.8 months (4.0-5.6) in arm C. The median OS was not reached. The rate of treatment related adverse events (TRAEs) of any grade was 100% in all three groups, and grade 3 TRAEs were 30.0%, 23.3% and 13.3%, respectively. The most common grade 3 TRAEs were thrombocytopenia (8.9%), decreased white blood cell count (6.7%), neutropenia (5.6%). No grade 4 or 5 TRAEs were observed.

Conclusions: Addition of anlotinib to immunotherapy plus chemotherapy as first-line therapy showed amazing clinical outcomes in ESCC pts with a manageable safety profile. The study was still ongoing, and the data would be updated to confirm this conclusion subsequently.

Clinical trial identification: NCT04471480.

1543P Clinical study of camrelizumab combined with docetaxel and carboplatin in neoadjuvant treatment of locally advanced oesophageal squamous cell carcinoma

R. Wang, G. Zhang, Q. Zhu, T. Ma, C. Weng, D. Zhang, H. Zeng, T. Wang, F. Gao, L. Mi

Department of Thoracic Surgery, The Fourth Hospital of Hebei Medical University - North Gate, Shijiazhuang, China

Background: Immunotherapy is effective in treating unresectable oesophageal squamous cell carcinoma (ESCC). This study aims to evaluate the clinical efficacy and safety of neoadjuvant camrelizumab combined with docetaxel and carboplatin in locally advanced ESCC.

Methods: All patients underwent surgery within 4-8 weeks after receiving 2 cycles of neoadjuvant therapy, which was camrelizumab (200mg IV Q3W) combined with docetaxel (75 mg/m^2 IV Q3W) and carboplatin (AUC= 5-6 IV Q3W). The pathological complete response (pCR) rate was the primary endpoint, and the secondary endpoints included R0 resection rate, objective response rate (ORR), disease-free survival (DFS), overall survival (OS) and safety.

Results: A total of 40 patients were included, of which 37 patients were evaluated, including 9 cases of complete response (CR), 18 cases of partial response (PR), 10 cases of stable disease (SD), and the ORR was 73% (27/37). The main adverse events were ALT/AST increase 52.5% (21/40), leukopenia 50% (20/40), nausea and vomiting 47.5% (19/40), bilirubin increase 40% (16/40), all of which were grade 1-2. One patient had Guillain-Barre Syndrome. Among these patients, 31 underwent surgical treatment, pCR rate was 22.6% (7/31), R0 resection rate was 100% (31/31), tumour regression grade (TRG) 0, 1, 2 and 3 were 22.6% (7/31), 16.1% (5/31), 22.6% (7/31) and 38.7% (12/31), respectively. The average operation time (310.0±57.6 minutes). The average intraoperative blood loss (136.1±41.4 ml) and the average hospitalization time after operation (10.9±2.7 days). The average number of resected lymph nodes (24.4±8.2). Surgery-related complications: anastomotic leakage 6.5% (2/31), pleural effusion 6.5% (2/31), cardiac arrhythmia 9.7% (3/31), pneumonia 3.2% (1/31), gastric emptying disorder 3.2% (1/31). The median follow-up time was 12 months (range 1—32 months). One patient had liver metastasis 21 months after surgery. No treatment-related death occurred.

Conclusions: Camrelizumab combined with docetaxel and carboplatin is effective and safe in the neoadjuvant treatment of locally advanced ESCC.

Clinical trial identification: ChiCTR2000033252.

1544P Camrelizumab plus albumin-bound paclitaxel and S-1 as first-line treatment of advanced gastric/gastroesophageal junction cancer: A phase II clinical trial

X.F. Hou[1], S. Li[2], C. Wu[2], J. Liu[2]

[1]Medical Department, Henan Cancer Hospital, Zhengzhou, China; [2]Medical Department, Henan Cancer Hospital/Affiliated Cancer Hospital of Zhengzhou University, Zhengzhou, China

Background: Patients (pts) with advanced gastric/gastroesophageal junction cancer that progresses on chemotherapy have poor outcomes. We investigated the safety and efficacy of camrelizumab combined with albumin-bound paclitaxel and S-1 in first-line treatment of HER-2-negative advanced gastric/gastroesophageal junction cancer.

Methods: This study was a single-arm, open-label, phase II clinical study. Eligible pts were adults with histologically confirmed HER-2 -negative advanced gastric/ gastroesophageal junction cancer. Pts participating in this study were required to detect PD-L1 expression, MSI/MMR status, and EBV virus content. Pts received camrelizumab (200 mg, day 1), S-1 (60mg/m^2 bid, days 1-14), and albumin-bound paclitaxel (125mg/

m^2, days 1, 8) every 3 weeks. The maintenance therapy of camrelizumab (200 mg, day 1, every 3 weeks) was given to pts who did not progress after 4-6 cycles of chemotherapy until disease progression or unacceptable toxicity. Response was assessed every 6 weeks in accordance with RECIST1.1. The primary endpoint was overall response rate (ORR), and secondary endpoints included safety profile, progression free survival (PFS), overall survival (OS), and disease control rate (DCR).

Results: Between December 2020 and March 2023, a total of 28 pts were enrolled in this study. Median age was 57.5 (range: 35-71) years, and most pts were male (75.0%). Among 21 pts who were evaluated, the ORR was 71.4% (15/21) and the DCR was 95.2% (20/21). The median PFS was 9.3 months (95% CI: 7.0-11.6), the Median follow-up time was 14.3 months (95% CI: 9.9-18.7), and the one-year survival rate was 85.7%. The most common treatment-related adverse events of grade 3 or 4 included neutropenia (22.2%), leukopenia (22.2%), erythra (3.7%). There were no treatment-related deaths.

Conclusions: Camrelizumab plus albumin-bound paclitaxel and S-1 demonstrated promising activity and manageable safety in first-line treatment of HER-2- negative advanced gastric/gastroesophageal junction cancer.

Clinical trial identification: NCT04675866.

1545P Phase II trial of endostar in combination with concurrent chemoradiotherapy in patients with locally advanced squamous cell carcinoma of esophagus

Y. Qi, S. Wei, L. Shao

Radiation Oncology, The Tumor Hospital of Gansu Province, Lanzhou, China

Background: To evaluate the efficacy and safety of Endostar combined with concurrent chemoradiotherapy (CCRT) in patients with locally advanced esophageal squamous cell carcinoma (ESCC).

Methods: From May 2017 to February 2021, 92 patients with unresectable thoracic ESCC, clinical staged as IB to IVB disease based on the 8th edition of the American Joint Committee on Cancer (stage IVB: Only metastasis to supraclavicular/celiac lymph nodes) and local recurrence, were enrolled and randomly allocated in Endostar plus concurrent chemoradiotherapy (CCRT)(intervention group; n=46) and concurrent chemoradiotherapy (CCRT) (control group; n=48). Five or six cycles of Endostar (7.5mg/m2/24h ×120h, 7 days/cycle) were delivered in intervention group. The primary endpoint was overall survival (OS). The secondary endpoints were progression-free survival (PFS), 1-year and 2-year overall survival rate and adverse events (AE).

Results: The median age was 63(interquartile range, 50-77) years in intervention group and 65(interquartile range, 52-79) years in control group. A total of 68 patients (74%) had stage III and IV disease. The intervention group had a significant higher complete response rate (ORR) than the control group (80% vs. 63.8%; $P<0.05$). The 1- and 2-year overall survival rates were 88.1% and 75.2% in intervention group, 87.4% and 62.3% in control group, respectively ($P>0.05$). The were no significant differences in the incidence of grade 3 or higher toxic effects between the intervention group and control group ($P>0.05$).

Conclusions: The median age was 63(interquartile range, 50-77) years in intervention group and 65(interquartile range, 52-79) years in control group. A total of 68 patients (74%) had stage III and IV disease. The intervention group had a significant higher complete response rate (ORR) than the control group (80% vs. 63.8%; $P<0.05$). The 1- and 2-year overall survival rates were 88.1% and 75.2% in intervention group, 87.4% and 62.3% in control group, respectively ($P>0.05$). The were no significant differences in the incidence of grade 3 or higher toxic effects between the intervention group and control group ($P>0.05$).

Background: Prostaglandin E_2 (PGE_2) and its receptor EP4 showed immunosuppressive activity in cancers. In the ONO-4578-01 phase I study parts A/B, ONO-4578 (4578), which is an antagonist of EP4, alone and in combination with nivolumab (NIV) demonstrated a manageable safety profile in patients (pts) with advanced or metastatic solid tumors (Cancer Sci. 2023;114:211-220). Part C evaluated the safety, preliminary efficacy, and biomarkers of 4578 + NIV in pts with gastric or gastroesophageal (G/GEJ) cancer.

Methods: Part C was conducted at 22 sites in Japan, and it included pts with unresectable advanced or recurrent G/GEJ cancer who previously received at least two regimens. We categorized pts into three groups: IO-treated, pts who received immune-oncology (IO) treatment with anti-PD-(L)1 antibody as the most recent treatment; IO-naïve, pts without IO treatment; UGT1A1p, pts with *UGT1A1* polymorphism. Pts received oral 4578 (40 mg) daily and NIV (480 mg) every 4 weeks. The primary endpoint was safety. We assessed biomarkers with multiple methods including immunostaining and RNA-seq using pts' tumor tissues, and urine PGE_2 metabolite (PGEM) analysis.

Results: The IO-treated, IO-naïve, and UGT1A1p groups included 30, 30, and 6 pts, respectively, with a median age of 65.0 years. Treatment-related adverse events (TRAEs) occurred in 46 (70%) pts, wherein grade ≥3 TRAEs occurred in 17 (26%). No pts died due to TRAEs. Tolerability was confirmed in UGT1A1p. The investigator-assessed objective response and disease control rates were 10% and 73% in IO-treated and 17% and 40% in IO-naïve, respectively. Of note, >50% of the IO-treated pts achieved tumor shrinkage. In biomarker analyses, we observed signs of activated immune status in the tumor microenvironment after treatment, such as increases in T cell signature score and number, and relative increase of the ratio of M1 macrophage signature score to that of M2. Baseline urine PGEM, the potential surrogate marker of tumor PGE_2, was higher in pts with PR or SD than in pts with PD, suggesting the contribution of 4578 to the antitumor activity.

Conclusions: 4578 + NIV demonstrated a manageable safety profile and antitumor activity in pts with G/GEJ cancer.

Clinical trial identification: NCT03155061.

Background: Nivolumab (Nivo) monotherapy showed a survival benefit for patients (pts) with advanced gastric cancer (AGC), while its efficacy is limited, raising an urgent need to discover biomarkers. Here, we performed SNP discovery based on gene ontology (GO) terms analysis from transcriptome sequencing of whole blood RNA to find predictive biomarkers of Nivo in AGC.

Methods: We analyzed differential gene expression and SNPs data in pts with available pre-treatment blood samples from the DELIVER trial (JACCRO GC-08), an observational/translational study (UMIN000030850) that enrolled 501 AGC pts treated with Nivo alone. The GO-terms analysis was performed to identify genes associated with outcomes (CR/PR vs. SD/PD, non-PD vs. PD, non-hyper progressive disease [HPD] vs. HPD) in the exploratory cohort (the first 200 pts), and then the results were confirmed in the validation cohort (the last 301 pts). For the validated genes, SNP analysis was carried out to further assess genetic relatedness.

Results: When comparing pts with non-PD and PD, 205 genes in metabolic-related GO-Terms were upregulated in pts with non-PD; 12 SNPs in 12 genes (BICD1, PKD2, GOPC, TXK, SYPL1, PAQR8, ZC3H3, RNF138, ZFP90, ZC3H3, DDX60, FAM175B) were correlated to non-PD. In tumor response, 107 genes in nucleic acid-related GO-Terms were upregulated in pts with CR/PR; 5 SNPs in 4 genes (PDE3B, ZNF333, ACACB, ZNF780A) were correlated to CR/PR. In comparison between pts with non-HPD and pts with HPD, 306 genes in immune-related GO-Terms were enriched in pts with non-HPD and the median expression value of this genes set was significantly higher in pts with non-HPD; 16 SNPs in 12 genes (COX10-AS1, PASK, DOCK10, CDS2, PASK, CSGALNACT1, ARHGAP26, HLA-DQA1, DIAPH2, NFATC1, ARHGAP6, LCP2, RASA3) were correlated to non-HPD.

Conclusions: Our translational study demonstrated for the first time that gene expression of whole blood and SNPs as host-related markers can potentially predict response to Nivo in AGC.

1548P PD-L1 assessment in oesophageal and gastro-oesophageal adenocarcinoma with PD-L1 IHC 22C3 pharmDx and PD-L1 IHC 28-8 pharmDx assays on Autostainer Link 48: The University Hospitals Birmingham experience over a period of 18 months

B. O'Sullivan[1], P. Taniere[2], K. Charles[1], J. Pritchard[1], S. Gawthorpe[1], J. Thompson[1], J. Dowds[1], S. Diaz-Cano[1]

[1]Molecular Pathology Diagnostic Service, Queen Elizabeth Hospital - University Hospitals Birmingham NHS Foundation Trust, Birmingham, UK; [2]Cellular Pathology Department, Queen Elizabeth Hospital - University Hospitals Birmingham NHS Foundation Trust, Birmingham, UK

Background: In England, the National Institute for Health and Care Excellence (NICE) recommends Nivolumab and Pembrolizumab with platinum- and fluoropyrimidine-based chemotherapy, as an option for untreated HER2-negative, advanced or metastatic oesophageal and gastro-oesophageal junction adenocarcinoma in adults whose tumors express PD-L1 with a combined positive score (CPS) of 5 or more (Nivolumab) or of 10 or more (Pembrolizumab).

Methods: Our Department uses both PD-L1 IHC 22C3 pharmDx (Agilent) and PD-L1 IHC 28-8 pharmDx (Agilent) assays on Autostainer Link 48. We report on our experience of testing over a period of 18 months. Both tests are ISO accredited; reporting was performed by 2 expert pathologists and 1 expert scientists, all trained for PD-L1 reporting.

Results: 3892 tumours were tested with the PD-L1 IHC 22C3 pharmDx (Agilent) assay: 31.5% showed CPS more than 10 1209 tumours were tested with the PD-L1 IHC 28-8 pharmDx (Agilent) assay: 25% showed CPS more than 5. 700 tumours were tested with both assays: 95% were eligible for none or both Nivolumab or Pembrolizumab according to the respective guidelines; 13% of tumours showed CPS >5 and <10 with the PD-L1 IHC 28-8 pharmDx (Agilent) and CPS >10 with the PD-L1 IHC 22C3 pharmDx (Agilent) assay.

Conclusions: The rate of positivity of PD-L1 expression with both assays is lower than initially shown in trials (was up to 45%); we do not have a clear explanation for this; we however have ruled out technical artefacts since we used companion diagnostics, validated in our Laboratory and have negative and positive controls in each slide; the interpretation is performed by trained experienced pathologists or scientists. Our audit provides data on the equivalence between both assays; this could help Laboratories to adopt a strategy regarding PD-L1 testing, especially to decide on the need or not to test tumours with both assays.

Background: The genomic profile of gastric or GEJ cancer is unclear in cases that have recurred after primary adjuvant chemotherapy. We investigated genomic alterations (GA) detected in ctDNA using a liquid biopsy test and compared the results to the those of the primary tumor.

Methods: This prospective observational study was conducted at 17 institutes from Jan 2021 to Dec 2022. Eligible patients (pts) had previously resected stage II or III gastric/GEJ cancer with recurrence after or during adjuvant chemotherapy. Whole blood was collected before chemotherapy for recurrent disease; ctDNA was analyzed

using a next-generation sequencing gene panel (Guardant360). The primary endpoint was the detection rate of actionable GA with at least level 3 evidence by OncoKB for any cancer type. Secondary endpoints included a comparison of ctDNA and primary tumor GA profiles, and biomarkers relevant to clinical outcomes. A binomial test was used to determine with 90% probability that actionable GA were found in ctDNA in more than 5% of cases.

Results: Among 51 enrolled pts, 50 were available for analysis, 14% stage II and 86% stage III. The most common primary site was gastric body (56%) followed by gastric antrum (26%), and GEJ (12%). The number of metastatic sites was 1 for 76%, 2 for 18%, and 3 for 6% pts. Liquid biopsy analysis detected actionable GA in 64% [90%CI: 49.2-77.1] and actionable GA for targeted therapy in 36% pts [90%CI: 22.9-50.8, *P*=0.0075]:*PIK3CA* in 20%, *ARID1A* in 10%, *ERBB2* in 8% (6% amplification and 2% mutation), *ATM* in 6%, and *BRCA2*, *EGFR*, *IDH2*, *RAF1*, and *ROS1* in 2% pts each. MSI-high was detected in one patient. Comparison of primary tumor DNA and ctDNA at recurrence is ongoing.

Conclusions: Using ctDNA analysis, our study demonstrated that potentially actionable GA occur in nearly one-third of pts with recurrence after curative-intent treatment of stage II-III gastric/GEJ cancer. Genomic profiling should be strongly considered in this setting. We will compare these data with genomic analysis of primary tumor tissues.

1550P Evaluating the novel combination of pressurized intraperitoneal aerosol chemotherapy-oxaliplatin (PIPAC-OX) as an immunomodulator in combination with systemic nivolumab for gastric cancer peritoneal metastases

R. Sundar[1], D. Chia[2], W. Ceelen[3], C. Chia[4], G. Kim[5], A. Shabbir[5], W. Willaert[3], J. Ong[4], J. Wong[4], C.J. Seo[4], H.L. Tan[1], E. Callebout[6], K. Geboes[6], M.C.H. Ng[7], J. Lum[8], W.Q. Leow[9], S. Selvarajan[9], A. Hoorens[10], W.P. Yong[1], J.B.Y. So[11]

[1]Haematology-Oncology, NUHS - National University Health System, Singapore; [2]Surgery, NUH - National University Hospital (S) Pte. Ltd., Singapore; [3]Gastrointestinal surgery, UZ Gent - University Hospital Ghent, Ghent Belgium; [4]Sarcoma, Peritoneal and Rare Tumors, National Cancer Centre, Singapore; [5]Surgery, NUHS - National University Health System, Singapore; [6]Department of Gastroenterology, UZ Gent - Universitair Ziekenhuis Gent, Ghent Belgium; [7]Medical Oncology Department, NCCS - National Cancer Centre Singapore, Singapore; [8]Pathology, NUHS - National University Health System, Singapore; [9]Anatomical Pathology, SGH - Singapore General Hospital, Singapore; [10]Pathology, Ghent University - Campus Ufo, Ghent Belgium; [11]Surgery, NCIS - National University Cancer Institute Singapore, Singapore

Background: Combination therapies with immunomodulators and systemic immune checkpoint inhibitors (ICIs) may overcome cancer resistance to immunotherapy. In gastric cancer patients with peritoneal metastases (GCPM), PIPAC-OX has been shown to induce direct DNA-damage and immunogenic cell death but has not been evaluated in combination with ICIs. We conducted a phase I study, evaluating the safety and efficacy of PIPAC-OX in combination with systemic nivolumab.

Methods: Patients with predominant GCPM who had progressed on at least 1st -line systemic chemotherapy were recruited across 3 centers in Singapore and Belgium. After initial staging laparoscopy, patients received PIPAC oxaliplatin at 90mg/m2 every 6 weeks with intravenous nivolumab at 240mg every 2 weeks, up to disease progression or death. Response was evaluated clinically by Peritoneal Carcinomatosis Index (PCI) and Response Evaluation Criteria in Solid Tumors (RECIST), while histological response was determined with the Peritoneal Regression Grading Score (PRGS).

Results: In total, 18 patients with GCPM were prospectively recruited and underwent a combined total of 32 cycles of PIPAC with a median follow-up of 7.1 months. The first cycle of PIPAC was successfully administered in all patients while 50% (9/18), and 28% (5/18) received 2 & 3 cycles respectively. Common adverse events included abdominal pain and diarrhea while three (9.4%) PIPAC-related severe adverse events including diarrhea and transaminitis were reported. Objective response was seen in 7.1% while disease control was achieved in 57.1% of patients. The median PCI decreased by 5 and 7 points, while PRGS grade 1-2 response was seen in 67% and 100% at 2nd & 3rd PIPAC respectively. Those that received 3 PIPACs had a median OS of 19.8m (vs 2.9m for 1 PIPAC, p = 0.01).

Conclusions: PIPAC-OX in combination with systemic nivolumab was safe and tolerable, with some responses seen. Ongoing biomarker and translational analyses may yield further insights into the unexpected long-term responders and define the subgroup most likely to benefit from combination locoregional and systemic therapy for GCPM.

1551P Clinicopathologic characteristics and genomic profiling of HER2-low advanced gastric cancer

C-K. Lee[1], S. Park[2], J. Che[2], W.S. Kwon[2], S.Y. Rha[3]

[1]Division Of Medical Oncology, Yonsei Cancer Center, Yonsei University College of Medicine, Seoul, Republic of Korea; [2]Sondang Institute for Cancer Research, Yonsei University College of Medicine, Seoul, Republic of Korea; [3]Medical Oncology Department, Yonsei University, Seoul, Republic of Korea

Background: Recent advances in HER2-targeting agents, including HER2 antibody-drug conjugates have shown promising results in targeting HER2-low expressing cancers. We performed retrospective study to characterize clinicopathologic features and genomic profiling of HER2-low advanced gastric cancer (AGC) compared to HER2-high or HER2-none expressing tumors.

Methods: We retrospectively analyzed patients with stage IV AGC with known HER2 status who were systemically treated in Yonsei Cancer Center, Korea. HER2-low tumors were defined as HER2 IHC 2+/ISH- or HER2 IHC 1+. Patients whose pre-treatment tumors were molecularly profiled with in-house next-generation sequencing (NGS) were further evaluated. Clinicopathologic characteristics including biomarker distribution and survivals, and genomic profiling including oncogenic signalling pathways were analyzed according to HER2 status.

Results: Among total 953 patients diagnosed as recurrent/metastatic AGC from August 2008 to February 2022, HER2-high, HER2-low, and HER2-none (HER2 IHC 0) patients were 122 (12.8%), 244 (25.6%), and 587 (61.6%), respectively. For HER2-low tumors compared to HER2-high and HER2-none, there was no statistical difference in distribution of pathology, EBV, MSI, or PD-L1 expression status. HER2-low patients showed similar survival as HER2-none, but shorter survival compared to HER2-high, in terms of progression-free survival of palliative first-line chemotherapy (6.3 vs 6.0 vs 8.5 months, *P*=0.0002) and overall survival (14.8 vs 14.4 vs 20.7 months, *P*=0.0001). There was no difference in survival between HER2 IHC 2+/ISH- and IHC 1+. HER2-low tumors had enhanced survival with the first-line chemotherapy when combined with immunotherapy. Among patients who have undergone in-house NGS excluding EBV-positive or MSI-H tumors (n=183), HER2-low tumors showed similar TMB compared to HER2-high and HER2-none tumors, but highest genetic alteration rates in PI3K pathway (62 vs 54 vs 54%), TGF-ß pathway (32 vs 22 vs 29%), and JAK/STAT pathway (15 vs 9 vs 8%).

Conclusions: We observed that HER2-low AGC patients showed similar but distinct clinicopathologic and genomic profile compared to HER2-none patients. Further strategies to target HER2-low AGC patients are warranted.

Background: Gastric cancer is heterogenous with poor prognosis. The LEGACy project aimed to deepen GC molecular understanding through multi-omics analysis of tumours from EU and LatAm. We present partial results including histopathology, immunohistochemistry (IHC) + in-situ hybridization (ISH) markers, immune cell infiltration pattern, broad multi-gene sequencing panel and targeted transcriptomics of stage IV GC paraffin-embedded tissues.

Methods: After the central pathological confirmation of GC, standard IHC/ISH was performed, nucleic acids were extracted for DNA sequencing of 435 genes (covering mutations, copy number, fusions, MSI + TMB), and mRNA was profiled with custom Nanostring gene expression assay. The primary aim was to explore a clinically feasible diagnostic classification of GC: a. MSI; b. EBV+; c. HER2+; d. other intestinal-type (IT); and e. other poorly cohesive-type (PCT) f. and mixed. Only significant associations (P values <0.05) in non-parametric tests adjusted for multiple testing are reported.

Results: Out of 334 GC patients were enrolled in the project, 148 were eligible for molecular analysis Prevalence of GC subtypes: MSI 11%, EBV+ 4%; HER2+ 9%, IT 41%, PCT 31% and mixed 4%. We found higher HER2+ and IT tumors in EU vs. LatAm (14% vs. 6% and 46% vs. 30%, respectively). MSI tumors had highest TMB (median 38 mut/Mb) enriched for KMT2D, KRAS, PIK3CA and RNF43 mut, but no differences in immune cell infiltration/activation. EBV+ tumors had intermediate TMB (median 14 mut/Mb), highest PIK3CA mut, highest CD3/CD8 infiltration, cytotoxic and apoptotic signatures. HER2+ tumors were enriched for TP53 mut. While both IT and PCT samples had low TMB (median $<$ 7 mut/Mb) and higher dendritic cell/mast cell infiltration, IT tumors had high cell cycle activation + TP53 mut, and PCT tumors had low Ki67, highest Hedgehog + Notch + Wnt activation scores. Interestingly, PCT tumors from LatAm had higher median TMB (7 mut/Mb) when compared to EU (4 mut/Mb). Overall, PDL1 expression was similar across the groups.

Conclusions: Our pathological-molecular classification of GC is comparable with TCGA and others, with potential differences in prevalence and mutational signatures for EU and LatAm populations that will be further explored.

Clinical trial identification: NCT04015466.

Background: Production of IL6 by the tumor stroma of esophageal adenocarcinoma (EAC) causes epithelial-to-mesenchymal transition of tumor cells and resistance to chemoradiation (Ebbing *et al.* 2019). Serum ADAM12 protein levels measure stroma activity (Veenstra *et al.* 2018) whilst IL6 and IL6R monitor IL6 inhibition (Nishimoto *et al.* 2008). Here, we aim to demonstrate that targeting stroma with tocilizumab in EAC patients increases efficacy of chemoradiation.

Methods: This was a multicenter, randomized, open label, phase II proof-of-concept trial in 48 patients with resectable EAC. Patients were stratified for serum ADAM12 (cutoff of 203 pg/mL) and randomized for standard of care chemoradiation according to the CROSS regimen or addition of tocilizumab to standard of care, followed by surgery. Tocilizumab 8 mg/kg with a maximum of 800 mg was given intravenously for three cycles. Serum ADAM12, IL6 and IL6R was measured at baseline, during treatment, at resection and three months thereafter. Primary endpoint was histopathological response to chemoradiation according to the Mandard score.

Results: After inclusion of 36 patients, the trial was discontinued due to safety concerns. Perforation of the esophageal wall was observed in 3/20 (15%) of patients in the intervention arm compared to 0/16 (0%) in the control arm. There was no significant difference in Mandard score between treatment arms ($p = 1.000$). Patients treated with tocilizumab had significantly higher serum levels of IL6 and IL6R during treatment ($p < 0.0001$). Baseline ADAM12 was not associated with histopathological response to tocilizumab ($p = 0.672$). There was no difference in serum ADAM12 levels over time between treatment arms.

Conclusions: Addition of tocilizumab to neoadjuvant chemoradiation in patients with EAC is unsafe and should not be considered for clinical practice. Potentially, concurrent inhibition of IL6 impairs wound healing whilst chemoradiation obliviates the tumor in the esophageal wall, increasing the risk for perforation. We plan to investigate this hypothesis with RNA sequencing, immunohistochemistry, cytokine profiling, and flow cytometry of peripheral blood mononuclear cells and tumor biopsies.

Background: We conducted a clinical trial evaluating safety and efficacy of T-mab plus N-mab with S-1/Capecitabine plus oxaliplatin (UMIN000034222). The aim of this study was to investigate the clinical significance of *ERBB2* amplification (amp.) and TMB-H for this new combination therapy.

Methods: Patients were treated with S-1 80 mg/m2/day or Capecitabine 2000 mg/m2/day on days 1-14 with oxaliplatin 130 mg/m2, N-mab 360mg, and T-mab 8mg/kg for initial treatment, and subsequently with 6 mg/kg on day, repeated every 3 weeks. Pretreatment primary tumor samples were collected for whole exome sequencing (WES) and immunohistochemistry (IHC).

Results: Among 42 patients enrolled in this clinical trial, WES was performed on 23 patients. ERBB2 amp. ($\geq$ 6 copies) was observed in 15 patients (65%). Fourteen (93.3%) of these 15 patients with ERBB2 amp. and 2 (25%) of 8 patients without ERBB2 amp. were IHC3+, respectively ($p = 0.002$). There was a weak positive correlation between ERBB2 copy number and PFS ($r = 0.449$, $p = 0.032$). Patients with ERBB2 amp. showed longer PFS than those without ERBB2 amp. (mPFS: 16.3 vs 5.8 months, HR = 0.70 [95%CI 0.24-2.09], $p = 0.522$). In particular, 7 patients with high ERBB2 copy number ($\geq$ 50) showed remarkably longer PFS and a higher response rate than 16 patients with $<$ 50 (mPFS: 20.8 vs 6.7 months, HR = 0.40 [95%CI 0.12-1.30], $p = 0.117$, response rate: 100% vs 63%, $p = 0.124$). TMB-H ($\geq$ 10 muts/Mb) was observed in 6 patients (26%), and these patients also showed substantially longer PFS than those with TMB-L (mPFS: 16.3 vs 9.2 months, HR = 0.43 [95%CI 0.12-1.51], $p = 0.172$) with a comparable response rate (83% vs 73%). Eleven patients with ERBB2 copy number $\geq$ 50 or TMB-H showed significantly longer PFS (mPFS: 20.8 vs 5.8 months, HR = 0.28 [95%CI 0.09-0.88], $p = 0.021$) and OS (mOS: not reached vs 15.0 months, HR = 0.10 [95%CI 0.01-0.78], $p = 0.007$) and a higher response rate (91% vs 58%, $p = 0.155$) than the remaining 12 patients.

Conclusions: High ERBB2 copy number and TMB-H may be a candidate biomarker for this new combination therapy including T-mab and N-mab in patients with HER2-positive advanced gastric cancer.

Clinical trial identification: UMIN000034222.

Background: Cell-free DNA (*cfDNA*) analysis has shown promising results for the management of patients with cancer, but few data exist in patients with metastatic gastro-esophageal adenocarcinomas (mGEA). In this study, we analyzed *cfDNA* extracted from blood of patients included in the REGIRI - PRODIGE 58 trial (Regorafenib + irinotecan as 2nd line in patients with mGEA).

Methods: 239 samples from 34 patients with mGEA included in the Regiri arm were available for analysis. Plasma samples were taken before treatment's initiation, then at days 1, 2, 8 and 15 of Cycle 1 and days 1, 8 and 15 of Cycle 2. *cfDNA* was extracted from plasma, concentrations and fragments sizes determined by fragment analysis. First and last time points were selected to estimate concentration's evolution for each patient.

Results: A cfDNA threshold concentration (tc) of 0.55 ng/µL was settled as the best threshold at baseline to separate patients into 2 groups "low" and "high" corresponding to concentrations lower or greater than tc respectively. Among the 34 patients analyzed, 1 patient was excluded because of genomic DNA contamination in plasma at baseline. 16 patients (48.48%) were in the "low" group and 17 (51.52%) in the "high" group. For *cfDNA* concentration at baseline and PFS, a trend non-statistically significant difference (HR=0.53; CI95[0.2595;1.085]; p=0.0564) was found: Low cfDNA concentration at baseline was associated with a better PFS (2.6 vs 1.7 months). 4 distinct subgroups emerged: Patients with low concentration at baseline that remains low (low-low), low at baseline with an increase during follow-up (low-high), high at baseline with a decrease during follow-up (high-low) and high at baseline that remains high (high-high). A statistically significant difference was found for PFS (4.55 vs 2.11 months) between the low-low and high-high subgroups respectively (HR=0.4139; CI95[0.1652;1.037]; p=0.022).

Conclusions: Our findings suggest that cfDNA concentration at baseline and cfDNA clearance might have an interest to predict PFS in patients with mGEA. Further investigations are ongoing to decipher if genomic signatures can be predictive of PFS in patients with mGEA.

Clinical trial identification: NCT03722108.

1556P Pharmacokinetics, pharmacodynamics and exposure response analyses of osemitamab in patients with locally advanced or metastatic solid tumors

L. Shen[1], J. Yao[2], D. Chen[3], M. Yu[2], X-A. Lin[3], C. Qi[3], Z. Xia[3], L. Zhang[3], S. Yu[3], C. Germa[2]

[1]Department of Gastrointestinal Oncology, Peking University Cancer Hospital, Beijing, China; [2]Global R&D, Transcenta Holding Ltd., Princeton, NJ, USA; [3]Global R&D, Transcenta Holding Ltd., Suzhou, China

Background: Osemitamab, a humanized Claudin18.2 monoclonal antibody with enhanced antibody-dependent cellular cytotoxicity (ADCC) via improved binding affinity and reduced fucosylation, is being developed to treat metastatic gastric/gastroesophageal junction (G/GEJ) adenocarcinoma. Pharmacokinetics (PK), pharmacodynamics (PD) and exposure-response (ER) relationship of Osemitamab were evaluated in two phase I/IIa studies.

Methods: Osemitamab was administrated as monotherapy or in combination with standard of care (SOC) in patients. PK profiles of osemitamab were determined using non-compartmental analysis and population PK. The ADCC capacity of circulating osemitamab was tested in a subset of patients who received 3-10mg/kg Q3W. Relationships between PK and objective response rate (ORR) and safety were explored.

Results: A total of 2401 PK data were obtained from 248 patients from two clinical trials. Similar PK was observed between the US and Chinese patients. PK is dose proportional between 0.3 to 15 mg/kg. A two-compartment model with first-order elimination described the PK profile of osemitamab. Clearance (CL) was affected by body weight and gastrectomy history. Model simulated steady state trough concentration will achieve in vitro ADCC assay EC95 and in vivo MKN45-CLDN18.2 tumor growth inhibition model EC50 in most subjects following 6mg/kg Q3W and 4mg/kg Q2W. ADA incidence is less than 10%. Serum ADCC response remained at $\sim$ 50% of the maximum lysis up to 21 days following osemitamab 6 mg/kg Q3W. Anti-tumor activity data from 58 patients with 1L G/GEJ adenocarcinoma treated with osemitamab and capecitabine and oxaliplatin (CAPOX) showed patients with average concentration in 56 days above 24 µg/mL tended to have a better ORR. Grade 2+ nausea/vomiting are found to be associated with osemitamab exposure; however, simulations demonstrated the proportion of patients that developed Grade 2+ nausea or vomiting by 6 months were just slightly higher ($<$ 10% in difference) following 6 mg/kg Q3W than 3 mg/kg Q3W.

Conclusions: Osemitamab at 6mg/kg Q3W or 4mg/kg Q2W are predicted to have favorable PK/PD/safety profiles and might be associated with better ORR in combination with SOC compared to the lower doses.

Clinical trial identification: NCT04396821, NCT04495296.

1557P Single-cell RNA-seq dissecting the initiating liver metastasis cells and liver metastatic microenvironment in gastric cancer

S-Y. Zheng, X. Guan

Clinical Oncology Dept., HKU - The University of Hong Kong, Hong Kong

Background: Liver metastasis (LM) frequently occurs in patients with advanced gastric cancer; yet our understanding of the underlying salient biology is preliminary. Here, we performed single-cell RNA-seq in two patients with LM of gastric cancer to explore the initiating liver metastasis cells and liver metastatic microenvironment in gastric cancer.

Methods: Single cell RNA sequencing was performed on tissues from LM of gastric cancer. Also, we downloaded the single-cell RNA-seq of hepatocellular carcinoma (HCC) and primary gastric cancer from GEO database. Seurat were applied to sort single-cell RNA-seq of LM in gastric cancer and primary gastric cancer into different clusters via feature dimension reduction and then we investigated their expression profiling, stemness initiating and enrichment pathways. Furthermore, CellChat and monocle2 were used to explore the cellular communication and regulatory network of liver metastatic microenvironment.

Results: The transcriptomes of 13305, 26373, 20207 single cells among LM of gastric cancer, HCC, and primary gastric cancer were extracted respectively. There were 14 clusters divided into epithelial cells of liver metastasis single cells. Differential gene analyses and ratio analyses in LM and corresponding primary cancers groups showed that C10 and C12 might be the LM initiating cells clusters. And they were both enriched in the positive regulation of cell migration. $SOX6^+$ $MMP7^+$ epithelial cells might be the LM initiating cells in gastric cancer. Cell communication and inverse temporal analysis showed that $SEPP1^+$ macrophage and $CXCL2^+$ cancer associated fibroblasts (CAFs) might regulate metastatic microenvironment, of which promoted cancer stem cells migration.

Conclusions: The initiating liver metastasis cells and liver metastatic microenvironment in gastric cancer have been investigated in this study, which provided a further understanding of the potential biological mechanisms of LM in gastric cancer.

1558P Preoperative pembrolizumab plus chemotherapy for resectable esophageal squamous cell carcinoma (ESCC): The phase II Keystone-001 trial

H. Jiang[1], X. Shang[2], Y. Xie[3], G. Zhao[4], C. Zhang[5], W. Zhang[6], L. Liu[7], R. Li[6], J. Yue[5], C. Chen[5], X. Duan[5], Z. Ma[5], Y. Sun[4], J. Yu[6], X. Ren[8]

[1]Esophageal Invasive Surgery Department, Tianjin Medical University Cancer Institute & Hospital, Tianjin, China; [2]Department of Minimally Invasive Esophageal Surgery, Tianjin Medical University Cancer Institute & Hospital, Tianjin, China; [3]Department of Pancreatic Cancer, TMUCIH - Tianjin Medical University Cancer Institute and Hospital, Tianjin, China; [4]Department of Pathology, Tianjin Medical University Cancer Institute and Hospital, Tianjin, China; [5]Department of Minimally Invasive Esophageal Surgery, Tianjin Medical University Cancer Institute and Hospital, Tianjin, China; [6]Department of Immune oncology, Tianjin Medical University Cancer Institute and Hospital, Tianjin, China; [7]Department of Immune oncology, TMUCIH - Tianjin Medical University Cancer Institute and Hospital, Tianjin, China; [8]Department of Immune oncology, Tianjin Cancer Hospital, Tianjin, He Xi District, China

Background: The Keystone-001 study was designed to prospectively evaluate the efficacy and safety of preoperative treatment with pembrolizumab plus paclitaxel and cisplatin followed by Da Vinci robotic radical surgery in patients with locally advanced (stage III) ESCC. The study also explored the potential mechanism of this treatment strategy (NCT 04389177, 5/15/2020).

Methods: The full study methods for this prospective, single-arm, single-center, open-label, phase-II study have been published previously. For further investigating the immune cell subpopulations that determine the efficacy, we performed single-cell sequencing on peripheral blood and tumor tissues after neoadjuvant therapy, and validated using flow cytometry.

Results: Of the 49 patients enrolled between July 8, 2020, and February 10, 2022, 47 received neoadjuvant therapy and were included in the ITT analysis. Among all patients who received neoadjuvant therapy, no grade $\geq$3 AEs were reported. Improvements from baseline nutritional status were observed with increases in patients' median body weight and NRI. QoL evaluations showed improvements from baseline to post-adjuvant therapy in all functional scales and symptom scales of EORTC QLQ-C30 and in all items of the EORTC QLQ-OES18 questionnaire. Among all 45 patients in the efficacy analysis, the MPR rate was 73.3%, the pCR rate was 42.2%, the ORR was 95.6%, and the DCR was 100%. After a median follow-up of 23.3 months (95% CI 20.6, 24.9; maximum follow-up 34 months), the 1- and 2-year OS and DFS rates were 95.6 and 90.5% and 95.6 and 86.3%, respectively. The single-cell sequencing results showed that the main cell populations that affect the response of this treatment strategy were NKT and NK cell subpopulations in peripheral blood. Further analysis

results showed that the TRGC2+NKT and FGFBP2+NK cell subpopulation in peripheral blood were more significantly increased in peripheral blood from patients with a good response.

Conclusions: The preliminary findings of this trial were safe and effective, and further phase III studies (Keystone-002) have begun to recruit participants.

Clinical trial identification: NCT 04389177.

1559P PD-L1 expression as a negative predictive biomarker in advanced esophageal squamous cell cancer treated with chemotherapy alone: A KMSubtraction derived analysis

M. Sachdeva[1], J.J. Zhao[2], K.X. Zhu[3], D. Ting Wei Yap[4], N. Zhun Hong Wong[4], N.K. Barr[5], R. Sundar[6]

[1]Medical Oncology, NCIS - National University Cancer Institute Singapore, Singapore; [2]Internal Medicine, NUS - National University of Singapore, Singapore; [3]Department of Biomedical Informatics, National University of Singapore (NUS) - Faculty of Science, Singapore; [4]Yong Loo Lin School of Medicine, NUS-National University of Singapore - (YLLSoM), Singapore; [5]NUHS, NUS - National University of Singapore, Singapore; [6]Haematology-Oncology, NUHS - National University Health System, Singapore

Background: Prognosis for aESCC (advanced esophageal squamous cell carcinoma) remains poor. Programmed death-ligand 1 (PD-L1) expression is a well-established positive predictive biomarker for response to immunotherapy in aESCC. However, the association between PD-L1 and response to chemotherapy alone remains unclear. This study aims to determine the prognostic significance of PD-L1 expression in patients treated with first-line chemotherapy alone in aESCC.

Methods: First-line phase III randomized trials that included PD-L1 expression as a biomarker in aESCC were extracted after a systematic search of Embase and PubMed from inception until September 24, 2022. Only trials that reported PD-L1 stratified Kaplan-Meier (KM) curves of chemotherapy arms were included. A graphical reconstructive algorithm was used to estimate time-to-event outcomes from reported KM plots in all overall and reported subgroup cohorts. Where unavailable, KMSubtraction was utilized to derive KM plots of unreported PD-L1 subgroups. Thereafter, individual patient data meta-analysis was conducted. Survival analyses for overall and progression-free survival (OS, PFS) were conducted with Cox proportional hazards models with a shared-frailty term incorporated to account for inter-study differences.

Results: Chemotherapy arms from 5 randomized phase III trials - CheckMate-648, ESCORT-first, KEYNOTE-590, RATIONALE306 and ORIENT-15 — comprising 1,517 patients were included in the OS analysis. Compared to PD-L1 low expressing tumors, patients with PD-L1 high expressing tumors were at a significantly higher risk of mortality (PD-L1 high [n=769] vs PD-L1 low [n=748], HR=1.152, 95%-CI: 1.018 — 1.305, p=0.025). Three trials — CheckMate-648, ESCORT-first and ORIENT-15 — comprising 949 patients treated with chemotherapy alone were included in the PFS analysis. Likewise, patients with PD-L1 high expressing tumors were at a higher risk of tumor progression, although this was not significant (PD-L1-high [n=513] vs PD-L1-low [n=436], HR=1.076, 95%-CI: 0.923 - 1.253, p=0.35).

Conclusions: Our study found PD-L1 expression is a negative predictor of overall survival in aESCC treated with first-line chemotherapy.

1560P Osemitamab (TST001): An ADCC enhanced humanized anti-CLDN18.2 mab, demonstrated improved efficacy in combination with anti-PD-L1/PD-1 mab and oxaliplatin/5-FU in preclinical tumor models

X. Qian, F. Teng, H. Guo, X. Yao, L. Shi, Y. Wu, D. Zhao, Y. Gu

Suzhou Transcenta Therapeutics, Suzhou, China

Background: Osemitamab (TST001) is a best-in-class humanized antibody with improved CLDN18.2 binding affinity and ADCC activity. Here, we evaluated the dynamics of on-treatment PD-L1 expression on the tumor cells in both *in vivo* tumor models and *in vitro* tumor cells and studied preclinical efficacy of the combination of Osemitamab and anti-PD-L1/PD-1 mAb +/- oxaliplatin/5-FU (Oxa/5-FU) in both CLDN18.2+/PD-L1+ and CLDN18.2+/PD-L1- tumor models.

Methods: For *in vitro* cell assay, we co-cultured the CLDN18.2-expressing GC cells w/wo human PBMC and 30 μg/ml Osemitamab for 72hr, and then transferred the supernatant to the matched tumor cells for another 72hr incubation. PD-L1 expression on the tumor cells was detected by using FACS analysis. The mouse with CLDN18.2-expressing tumors were injected intraperitoneally with Osemitamab or in combination with anti-PD-L1/PD-1 mAbs twice a week and injected intravenously with oxa/5-FU weekly in *in vivo* efficacy studies. CLDN18.2 and PD-L1 expression on the tumors was detected by using IHC analysis.

Results: We found that in the presence of human immune cells, PD-L1 expression on the CLDN18.2-expressing GC cells *in vitro* and tumors *in vivo* was upregulated after Osemitamab treatment. In two CLDN18.2+/PD-L1+ mouse syngeneic models, Osemitamab combined with Atezolizumab exhibited significantly higher tumor growth inhibition (TGI) than the single agents. Furthermore, in the same tumor model, the triplet [Osemitamab in combination with anti-mouse PD-1 (RMP1-14) + Oxa/5-FU] showed even better TGI than the doublet [Osemitamab + Oxa/5-FU or RMP1-14 + Oxa/5-FU]. Additionally, in a CLDN18.2+/PD-L1- GC PDX model with human PBMC reconstruction on B-NSG-hIL-15 mice, the Osemitamab in combination with Oxa/5-FU was also superior to either Oxa/5-FU or Oxa/5-FU + nivolumab.

Conclusions: PD-L1 upregulation after Osemitamab treatment provides a rationale for combination of Osemitamab and anti-PD-L1/PD-1 mAb. And the potential synergistic effect of Osemitamab and GC standard of care (SoC: anti-PD-1 mAb + Oxa/5-FU) in preclinical tumor models supports Osemitamab in combination with SoC chemotherapy +/- nivolumab in G/GEJ patients.

Background: Recently, we reported safety and efficacy of T-mab plus N-mab with S-1/Capecitabine plus oxaliplatin (UMIN000034222). The aim of this study was to explore a candidate biomarker for this new combination therapy.

Methods: Patients were treated with S-1 80 mg/m2/day or Capecitabine 2000 mg/m2/day on days 1-14 with oxaliplatin 130 mg/m2, N-mab 360mg, and T-mab 8mg/kg for initial treatment, and subsequently with 6 mg/kg on day 1, repeated every 3 weeks. Pre-treatment primary tumor samples were collected for whole exome sequencing (WES).

Results: 42 patients enrolled in this clinical trial, and WES was performed on 23 patients. In the copy number analysis, *ERBB2* amp. was observed most frequently in 15 patients (65%). Subsequently, *GATA6*, *MYC* and *CCNE1* amp. were observed in 8 (35%), 6 (26%), and 5 (22%) patients, respectively. In the mutation analysis, *TP53* was observed most frequently in 20 patients (87%). Subsequently, mutations in *APC*, *ERBB3*, and *PIK3CA* were observed in 6 (26%), 3 (13%), and 3 (13%) patients, respectively. Among them, *APC* mut., *MYC*, and *GATA6* amp. were associated with worse survival. Patients with *APC* mut. showed significantly shorter PFS (median 5.6 vs 20.8 months, HR 3.47, 95%CI 1.16-10.44, p = 0.018), but not for OS (median 21.0 vs 26.5 months, HR 1.19, 95%CI 0.31-4.60, p = 0.806). Patients with *MYC* amp. showed significantly shorter PFS (median 4.2 vs 18.0 months, HR 3.48, 95%CI 1.09-11.12, p = 0.024) and OS (median 13.9 months vs not reached, HR 3.97, 95%CI 0.95-16.54, p = 0.042), respectively. Patients with *GATA6* amp. showed significantly shorter PFS (median 5.8 vs 32.0 months, HR 3.53, 95%CI 1.25-9.99, p = 0.011) and OS (median 13.9 months vs not reached, HR 3.74, 95%CI 1.04-13.40, p = 0.030). As for objective response rates (ORRs), patients with *APC* mut. and *MYC* amp. showed lower

response rates (50% vs 82% for *APC* mut., 67% vs 77% for *MYC* amp.), whereas comparable ORR was shown for *GATA6* amp. (75% vs 73 %).

Conclusions: *APC* mut., *MYC,* and *GATA6* amp. may have negative clinical impacts on the effects of the new combination therapy including T-mab and N-mab.

1562P Claudin 18.2 expression in resected gastric cancer

M. Furuta[1], Y. Hiroshima[2], S. Sato[3], M. Oonishi[1], T. Hama[1], K. Furusawa[1], K. Hayashi[1], Y. Inokuchi[1], M. Tanabe[4], J. Morita[4], S. Nagasawa[4], K. Kanematsu[4], T. Yamada[4], T. Ogata[4], T. Oshima[4], Y. Miyagi[3], T. Yokose[5], N. Machida[1], J. Furuse[1]

[1]Department of Gastroentelogy, Kanagawa Cancer Center, Yokohama, Japan; [2]Center for Cancer Genome Medicine, Kanagawa Cancer Center, Yokohama, Japan; [3]Molecular Pathology & Genetics Division, Kanagawa Cancer Center, Yokohama, Japan; [4]Department of Gastrointestinal Surgery, Kanagawa Cancer Center, Yokohama, Japan; [5]Department of Pathology, Kanagawa Cancer Center, Yokohama, Japan

Background: Zolbetuximab showed efficacy for gastric cancer with Claudin (CLDN) 18.2 expression. CLDN18.2 is reported to be expressed in about 20-50% of gastric cancer, but the definitions varied in previous reports and the relationship with prognosis is controversial. The present study aimed to examine the expression of CLDN18.2 based on SPOTLIGHT/GLOW study and the relationship with prognosis and clinical/molecular characteristics in resected gastric cancer.

Methods: We used a tissue microarray set including gastric cancer samples resected in our institution between July 1989 and September 2009. VENTANA CLDN18 (43-14A) assay was used for immunohistochemistry (IHC) of CLDN18.2. CLDN18.2 expression was judged as positive when $\geq$75% of the tumor cell membrane was stained in moderate-to-strong intensity by IHC. The Combined Positive Score (CPS) was evaluated using Dako PD-L1 28-8 pharmDx assay.

Results: CLDN18.2 was evaluable in 366 samples and expressed in 139 samples (38%). Clinical data was available in 129 patients (pts) with CLDN18.2+ vs 191 CLDN18.2- pts. Patient characteristics in the CLDN18.2+ group vs the CLDN18.2- group were as follows; median age (range), 64 (27 - 85) vs 66 (35 - 83); gender male 94 (73%) vs 139 (73%); HER2 positive 11 (10%) vs 19 (10%); CPS $\geq$5, 64 (50%) vs 88 (46%); dMMR, 4 (3.1%) vs 5 (2.6%); Lauren classification diffuse, 71 (55%) vs 107 (56%); pTstage 1/2/3/4, 13/15/17/84 vs 17/34/28/112; pNstage 0/1/2/3, 27/31/32/39 vs 41/39/50/61; pStage I/II/III, 13/36/80 vs 14/68/109; and adjuvant S-1, 43 (33%) vs 54 (28%). Three-year RFS was 56.8% in the CLDN18.2+ group vs 60.3% in the CLDN18.2- group (HR = 1.07 [95% CI 0.77-1.49], p = 0.68). Three-year OS was 66.9% in the CLDN18.2+ group vs 68.7% in the CLDN18.2- group (HR = 1.13 [95% CI 0.80-1.59], p = 0.49).

Conclusions: CLDN18.2 expression was observed in 38% of resected gastric cancer samples, which was consistent with previous reports. CLDN18.2 expression was not related to prognosis and specific relationship was not observed in clinical/molecular characteristics of resected gastric cancer.

Background: Effective treatment of esophageal adenocarcinoma (EAC) is hampered by a high degree of mesenchymal plasticity that contributes to acquired therapy resistance and disease recurrence. Many trials are or have been investigating new treatments, such as additional epidermal growth factor signaling inhibition, to improve patient outcome. However, patient selection methods are limited. The existence of a tissue-level molecular subtype that could be used to stratify patients has remained elusive, in large part due to an abundance of non-tumor cells confounding bulk gene expression data.

Methods: We profiled gene expression from 186 esophageal cancer samples and applied non-negative matrix factorization to identify tumor-intrinsic features. Subgroups were discovered using consensus clustering of the tumor-intrinsic gene expression signatures and single-nucleus RNA sequencing analysis.

Results: Two subtypes were identified; intestinal-like (IL) and mesenchymal-like (ML). The latter enriched following neoadjuvant treatment and during disease progression. In a separate cohort of RNA-sequenced metastatic EAC, the ML subtype was found to predict poor response to treatment. Conversely, IL subtype cancer cells were highly dependent on epidermal growth factor signalling, and sensitive to receptor tyrosine kinase inhibition. Mechanisms behind the dependence on epidermal growth factor signalling are currently elucidated using comprehensive analyses.

Conclusions: Targeting of epidermal growth factor signaling is currently only available for HER2-positive patients, about 15% of all cases. Based on our tumor-intrinsic subtypes, a larger fraction of EAC patients seem to benefit from epidermal growth factor inhibition. Therefore, the ability to assign subtype labels in the clinic will be an important step forward to identify patients who may benefit from additional epidermal growth factor inhibition.

Clinical trial identification: NCT05188313.

1564P Gut microbiome and metabolome are associated with the response to chemoradiotherapy in patients with esophageal cancer

M. Lin, Q. Yao, J. Li

Radiation Oncology, Clinical Oncology School of Fujian Medical University, Fujian Cancer Hospital, Fuzhou, China

Background: To explore the dynamic change of gut microbiota and metabolites and its predictive role in progression-free survival (PFS) in esophageal cancer (EC) after concurrent chemoradiotherapy (CCRT).

Methods: In this prospective study, 94 newly diagnosed EC patients were recruited. A total of 282 fecal samples were collected at 3 time points (T0, before CCRT; T1, 2 weeks after the initiation of CCRT; and T2, the end of CCRT). Gut microbiota and its metabolites were analyzed by 16S rRNA sequencing and untargeted metabolomics, respectively. Microbe-metabolite correlation networks were compared between patients in the long-PFS group (PFS $\geq$18.0 months) and short-PFS group (PFS $<$18.0 months). A random forest classifier was constructed to identify microbial signature related to PFS. Clinical and microbial factors potentially predictive of PFS were assessed in the univariate and multivariate Cox regression analysis.

Results: At baseline, there was no significant difference in the distribution of microbial species or pathway abundance between the two groups. The abundance of Bacteroidota and Acidobacteria increased, while the abundance of Firmicutes decreased after CCRT. Shannon index (P = .016) and PD index (P = .007) were significantly higher in the long-PFS group than for those in the short-PFS group at T1. These distinct changes in gut microbiota were accompanied by functional alterations in tryptophan, fatty acid, and bile acid metabolism and nucleotide biosynthesis pathways during CCRT. Further metabolomic analyses revealed that the distributions of metabolites from these four essential metabolic pathways varied in the two groups at T1. The PFS-prediction microbial signature at T1 included members of the *Ruminococcus*, and various strains from within the *Blautia* and *Prevotella*. The machine learning classifier based on gut microbiota and metabolites yielded an area under the ROC curve of 0.93. Multivariate analysis indicated PD index (P = .027), the abundance of *Blautia* (P = .033) and deoxycholic acid (P = .025) at T1 were independent predictors of PFS.

Conclusions: Gut microbiota and metabolites composition at 2 weeks after the initiation of CCRT were associated with PFS in EC. Further research is needed to confirm these results.

1565P ERCC1 gene polymorphism influences overall survival in early oesophageal cancer: Results from the phase III MRC OEO2 randomised controlled trial

G.A. Keogh[1], D. Chai Kai Ann[2], D. Cunningham[3], R.E. Langley[4], W. Allum[5], M. Nankivell[6], P. Tan[7], R. Sundar[8], H.I. Grabsch[9]

[1]Gastrointestinal Medical Oncology, Royal Marsden Hospital, London, UK; [2]Gastrointestinal surgery, Cancer Science Institute (CSI) - National University of Singapore (NUS), Singapore; [3]Medicine Dept., The Institute of Cancer Research and Royal Marsden Hospital, Sutton, UK; [4]UCL, The Medical Research Council, London, UK; [5]Surgery, The Royal Marsden Hospital - NHS Foundation Trust, London, UK; [6]Statistics, MRC - Medical Research Council Clinical Trials Unit - University College London (UCL), London, UK; [7]Programme in Cancer & Stem Cell Biology, Duke-NUS Graduate Medical School, Singapore; [8]Haematology-Oncology, NUHS - National University Health System, Singapore; [9]Pathology, University of Leeds, Leeds, UK

Background: Germline polymorphisms may have an association with survival and response to chemotherapy. We examined the gene polymorphism data from the landmark OEO2 trial which compared chemotherapy plus surgery vs surgery alone in early oesophageal cancer. We reviewed common DNA repair genes polymorphisms and selected a subset that has been validated as predictors of survival or chemotherapy toxicity across different tumor types.

Methods: DNA formalin-fixed paraffin embedded normal tissue was available for 515/802 OEO2 patients and successfully extracted in 90% (464/515) of samples. Gene polymorphisms were investigated for *GSTP1, TS 3'UTR, TS 5'UTR, OPRT, DYPD, ERCC1, ERCC2, XRCC1* using Sequenom or multiplex PCR and gel electrophoresis. We investigated these polymorphisms and their relationship with clinicopathological variables including overall survival (OS) and progression free survival (PFS).

Results: All patients with the ERCC1_rs116115 CT genotype had superior OS and PFS when compared to those with a non CT genotype, OS HR 0.790 95% CI 0.642-0.972 (p=0.026), PFS HR 0.80 95% CI 0.656-0.979 (p=0.03). When stratified into chemotherapy + surgery (C+S) vs surgery alone (S), OS for those in the C+S arm was statistically significantly better in the CT genotype (OS 1.975 vs 1.547 years p=0.047) (HR 0.744 95% CI 0.55-0.998 p=0.048). In the S arm there was no significant difference in OS in the CT vs non CT genotype (1.339 vs 1.258 years p=0.275) (HR=0.849 95%CI 0.633-1.140 p=0.276). Test of interaction between treatment groups and ERCC1 polymorphisms was not significant for OS (p=0.58) and PFS (p=0.17). In patients who received preoperative chemotherapy, those with ERCC1 CT genotype were more likely to have any response to chemotherapy (Mandard TRG 1-4) than patients with non CT genotypes (CT vs non CT, 63% vs. 37%, p=0.031).

Conclusions: Patients with ERCC1 CT genotype had superior OS and PFS when compared to those with non CT genotype. Patients with ERCC1 CT genotype receiving preoperative chemotherapy had a better response compared to those with non CT genotype. ERCC1 polymorphisms have prognostic implications and may serve as biomarkers for preoperative chemotherapy response.

Background: Anti-PD-1 antibody in addition to HER2-targeted therapy and chemotherapy may enhance antibody-dependent cell-mediated cytotoxicity and add further chemotherapeutic efficacy for HER2 -positive advanced gastric cancer (AGC). On the other hand, it remains unclear molecular profiles related to efficacy and resistance to this dual targeted therapy. Real-time tracking of these changes of the alteration using ctDNA may contribute to the treatment optimization.

Methods: We enrolled tissue-confirmed HER2 -positive AGC who received chemotherapy with HER2 and anti-PD-1 dual targeted therapy from phase Ib clinical trial. Genomic profiling of 74 genes of their plasma by next-generation sequencing was carried out using ctDNA panel (Guardant 360®) to compare with their clinical parameters, clinical outcomes of dual targeted therapy and *HER2* gene amplifications in matched tissue samples.

Results: Twenty-one patients were eligible in this study. *HER2* gene amplification and single nucleotide variant (SNV) / Indels were detected in 12 (57.1%), 3 (14.3%) patients, respectively. Maximum mutant allele frequency (mMAF) in diffuse type histology were significantly lower than intestinal type histology (P = 0.01), and mMAF were associated with tumor diameter (r = 0.626, P = 0.0032). Tissue and ctDNA *HER2* copy numbers were significantly correlated (r = 0.662, P = 0.019). Patients without *HER2* SNV / Indels (n=17) had significantly longer PFS and OS than patients with *HER2* SNV / Indels (n=3) (median PFS: 20.8 vs 8.4 months; P = 0.04; HR, 0.24, median OS: NA vs 14.0 months; P = 0.037; HR, 0.18). Moreover, patients with focal *HER2* gene amplification (n = 9) had significantly longer PFS and OS than patients with *HER2* aneuploidy (n=3) (median PFS: 20.8 vs 8.4 months; P = 0.007; HR, 0.08, median OS: NA vs 14.8 months; P = 0.0046; HR, 0.077). In patients achieving CR or PR (n=16), mMAF 3 weeks after initiation of chemotherapy was significantly lower than those in patients achieving SD (n=4) (P = 0.0087).

Conclusions: Our data confirmed that *HER2* SNV / Indels and gene amplification status may be predictor of treatment efficacy in patients with HER2- positive AGC who received chemotherapy with HER2 and PD-1 dual targeted therapy.

1567P The effect of SGLT2i and DPP4i on new-onset gastric cancer and gastric diseases in type 2 diabetes mellitus: A population-based cohort study

H.I. Chou[1], V.K. Chauhan[2], L. Lu[2], C.T. Chung[3], T.T.L. Lee[4], S. Lee[4], H. Liu[5], T.K.R. Pang[6], A. Kaewdech[7], B. Cheung[8], G. Tse[9], J. Zhou[10]

[1]Department of Medicine, HKU - The University of Hong Kong, Hong Kong, China; [2]Department of Engendering Science, University of Oxford, Oxford, UK; [3]Cardiovascular Analytics Group, Cardiovascular Analytics Group, Hong Kong, China; [4]Laboratory of Cardiovascular Physiology, Cardiovascular Analytics Group, Hong Kong, China; [5]Research Centre for Intelligent Healthcare, Research Centre for Intelligent Healthcare, Coventry, UK; [6]School of Nursing and Health Studies, Hong Kong Metropolitan University, Hong Kong, China; [7]Division of Internal Medicine, PSU - Prince of Songkla University - Faculty of Medicine, Amphoe Hat Yai, Thailand; [8]Department of Medicine, University of Hong Kong, Hong Kong, China; [9]Department of Cardiology, The Second Hospital of Tianjin Medical University, Tianjin, China; [10]Nuffield Department of Medicine, University of Oxford, Oxford, UK

Background: The effects of sodium-glucose cotransporter 2 inhibitors (SGLT2I) and dipeptidyl peptidase-4 inhibitors (DPP4I) on the risk of gastric cancer remains unknown. This study aims to compare the effects of SGLT2I and DPP4I on gastric cancer and other gastric diseases.

Methods: This was a retrospective population-based cohort study of patients with type-2 diabetes mellitus (T2DM) on either SGLT2I or DPP4I between 1st January 2015 and 31st December 2020 in Hong Kong. The primary outcome was new-onset gastric cancer, peptic ulcer (PU), acute gastritis, non-acute gastritis, and gastroesophageal reflux disease (GERD). Propensity score matching (1:1 ratio) using the nearest neighbour search was performed. Univariable and multivariable Cox regression was applied to identify the associations.

Results: This cohort included 62858 T2DM patients (median age: 62.2 years old [SD: 12.8]; 55.93% males). 23442 patients used SGLT2I, and 39416 patients used DPP4I. After matching, the incidence of gastric cancer (incidence rate ratio, IRR: 0.26; 95% confidence interval, CI: 0.18-0.37) was significantly lower in SGLT2I users than in DPP4I. SGLT2I was associated with lower risks of gastric cancer (Hazard ratio, HR: 0.30; 95% CI: 0.19-0.48). SGLT2I was also associated with lower risks of PU (HR: 0.66; 95% CI: 0.47-0.91), acute gastritis (HR: 0.31; 95% CI: 0.20-0.48), non-acute gastritis (HR: 0.35; 95% CI: 0.25-0.49), and GERD (HR: 0.62; 95% CI: 0.50-0.76) compared to DPP4I after adjustments. In the subgroup analysis, the results remained consistent across different age groups and genders. SGLT2I was associated with lower risks of gastric cancer amongst patients without prior H. pylori infection (HR: 0.26; 95% CI: 0.18-0.37) but not those with prior infection (HR: 0.28; 95% CI: 0.08-1.01). The results were consistent in the competing risk models and the different matching approaches in the sensitivity analysis.

Conclusions: SGLT2I was associated with lower risks of new-onset gastric cancer than DPP4I. SGLT2I was also associated with lower risks of PU, acute gastritis, non-acute gastritis, and GERD after matching and adjustments compared to DPP4I.

1568P Establishment of a platform to predict radiation sensitivity in organoids derived from esophageal cancer patients

G.Y. Kim[1], E. Jeong[1], D.W. Lee[2], B. Ku[1], S.Y. Choi[3], M.K. Chung[4], D. Oh[5]

[1]Precision Medical Dept., MBD Co., Ltd, Suwon, Republic of Korea; [2]Biomedical Engineering, Gachon University - Global Campus, Seongnam, Republic of Korea; [3]Otorhinolaryngology-Head and Neck Surgery, Uijeongbu Eulji Medical Center, Uijeongbu, Republic of Korea; [4]Otorhinolaryngology-Head and Neck Surgery, Samsung Medical Center (SMC), Seoul, Republic of Korea; [5]Radiation Oncology, Samsung Medical Center (SMC), Seoul, Republic of Korea

Background: To increase the effectiveness of the treatment, radiotherapy (RT) is frequently combined with chemotherapy, immunotherapy, or radiosensitizer medications. Identifying a patient's radiosensitivity can be important for determining patient's therapy strategy. But there isn't a reliable and pertinent radiation sensitivity prediction model for assessing radiation sensitivity. Here, we propose the cancer organoid-based platform for predicting the individual RT response evaluation and recurrence.

Methods: Eighteen Esophageal cancer biopsy tissues were dissociated to single cells and then disposed with BME on pillar plate (MBD co., Korea) to make the cancer organoids. After forming the organoids, these were exposed to radiation doses of 2, 4 and 8Gy. We are staining live organoid with calcein AM after radiation and obtain organoid viability. From viability, AUC (area under curve) and growth rate were calculated to predict patient's radiation sensitivity. With these two variables, the patient's cancer stage score was also used to predict patient's radiation sensitivity. CODRP (cancer organoid-based diagnosis reactivity prediction), radiosensitivity predication index, were calculated by patient's AUC, growth rate, and cancer stage.

Results: Radiation sensitivity prediction model using each single-factor (patient's AUC, growth rate and cancer stage) showed about 62% specificity, 72% sensitivity and positive predictive value (PPV) was 69%. However, when applying multi-factor model (CODRP), the specificity was 81.8%, the sensitivity was 85.7%, and the PPV was 90%. In the CODRP model, the radiation sensitive group showed 11.1% recurrence rate, while the radiation resistive group showed 72.7% recurrence rate. Therefore, there was a significant difference in recurrence-free survival rate between the sensitive group and the non-responder group based on the CODRP model.

Conclusions: Our proposed CODRP models using patient derived cancer organoid successfully predict clinical response of patient's radiation treatment. Thus, this platform has promise as a novel prognostic indicator for people with esophageal cancer and can support precision treatment.

1569P The CODRP model for predicting drug sensitivity in patient-derived 3D gastric cancer cells

D.W. Lee[1], I.H. Kim[2], J. Lee[3], S.H. Yun[2], B. Ku[4], S. Lee[3], M. Yoo[3], D. Seol[3], T-K. Lee[3], E. Lee[3], D-Y. Hwang[3], S.H. Kang[3], Y.S. Park[3], J-W. Kim[5], J.W. Kim[5], S-H. Ahn[3], K-W. Lee[5], H-H. Kim[3], H. Oh[6], Y-S. Suh[3]

[1]Biomedical Engineering, Gachon University - Global Campus, Seongnam, Republic of Korea; [2]Precision Medicine Research, MBD Co., Ltd, Suwon, Republic of Korea; [3]Surgery, Seoul National University Bundang Hospital, Seongnam, Republic of Korea; [4]MBD Co., Ltd, Suwon, Republic of Korea; [5]Internal Medicine, Seoul National University Bundang Hospital, Seongnam, Republic of Korea; [6]Pathology, Seoul National University Bundang Hospital, Seongnam, Republic of Korea

Background: Recently, cancer organoid-based drug sensitivity tests have been studied to predict patient responses to anticancer drugs. This study proposes a multi-factor analysis method (cancer organoid-based diagnosis reactivity prediction, CODRP) that considers the cancer stage and cancer cell growth rate, which represent the severity of cancer patients, in the sensitivity test for gastric cancer patients.

Methods: Primary cells were isolated from surgical tissues from 143 gastric cancer (GC) patients and mixed with matrigel to make patient derived 3D cultured cells. Due to small number of patient's cells, we used 384 pillar plate (MBD, Korea) for high throughput screening. 1.5ul spots dispensed on pillar and, the cells were stabilized in a culture medium optimized for GC cells for 3days and the drug response was observed for 7days. 3D cell morphology was scanned after calcein staining and cell viability was quantified using ATP assay. The primary characteristics of GC 3D cultured

cells were confirmed by IHC. The drug responses were calculated by a sigmoidal dose response curve and compared to clinical case report form.

Results: Evaluation of drug response was established for various drugs in 143 patients and success rate was 71%. We analyzed drug response through CODRP analysis method using multi-factor (cell growth rate, TNM stage, AUC). In clinic, 56 patients were treated by oxaliplatin after surgery, the CODRP index about oxaliplatin compared with clinical response. Although the clinical recurrence rate was low due to the 1 year follow up, the early recurrence rate by CODRP analysis in the resistant group was 10% p higher than AUC analysis, while there was almost no difference in the sensitive group. When we analyze the 1-year recurrence-free survival rate in the CODRP model, the sensitive group showed 78% survival, while the resistant group showed 38.2% survival. Therefore, there was a significant difference in 1 year recurrence-free survival rate based on the CODRP model.

Conclusions: This study proposes a novel drug sensitivity prediction model using patient derived 3D cultured cells. In 56 gastric cancer patients, CODRP models based on the drug sensitivity AUC, growth rate, and cancer stage successfully predict clinical response of patient's drug treatment.

1570P Dynamic changes in imaging biomarkers on dynamic contrast-enhanced magnetic resonance imaging (DCE-MRI) are associated with survival outcomes in patients with concurrent chemoradiotherapy for esophageal cancer

Y. Li, Y. Liu, P. Qian

Department of Radiation Oncology, Nanjing Medical University Affiliated Cancer Hospital & Jiangsu Cancer Hospital & Jiangsu Institute of Cancer Research, Nanjing, China

Background: Patients with Esophageal Cancer (EC) have variable responses to (chemo)radiotherapy. A reliable early prediction of outcomes allows for enhancing treatment efficacy and follow-up monitoring. DCE-MRI can provide information regarding tumor perfusion and permeability and has shown prognostic value in certain tumor types. Our aim was to investigate the potential application of DCE-MRI parameters as predictors for progression-free (PFS) and overall survival (OS) in-patients with EC treated with concurrent chemoradiation (CRT).

Methods: This study involved fifty-two patients with esophageal cancer and treated with CRT. The patients underwent DCE-MRI before CRT (pre-CRT) in three weeks and three weeks after starting CRT (post-CRT). Patients were grouped into high and low risk groups according to the cut-off value of best OS and PFS respectively. The correlations between quantitative parameters of DCE-MRI (pre-K^{trans}, post-K^{trans} and the changes and ratios of parameters (ΔiK^{trans}, riK^{trans}), and OS/PFS were calculated and compared between two-time frames in two groups, respectively. The K-M method was used to calculate the survival curve, and the log-rank method was used to compare differences in the survival curves.

Results: The level of pre-CRT K^{trans} was positively associated with OS (cutoff value=70.53/min, p=0.113) and PFS (cutoff value=70.53/min, p=0.026). The level of post-CRT K^{trans} was impaired associated with OS (cutoff value=45.60/min, p=0.001) and PFS (cutoff value=45.60/min, p=0.003). Level of riK^{trans} was impaired associated with OS (cutoff value=0.374, p=0.024) and PFS (cutoff value=0.374, p=0.040). The level of ΔiK^{trans} was impaired associated with OS (cutoff value=4.5/min, p=0.048) and PFS (cutoff value=0.595/min, p=0.056).

Conclusions: This study suggests an important role for DCE-MRI parameter K^{trans} as a predictor of outcome in Esophageal Cancer patients treated with CRT.

1571P Exploration of immune and metabolism gene signature for prognosis of esophageal carcinoma and establishment of a combined prediction model

H. Wu, Y. Luo, G. Wu, C. Xiao, Z. Ouyang, Y. Qian

Thoracic surgery, Shenzhen Second People's Hospital, Shenzhen, China

Background: Esophageal carcinoma (EC) a high rank common and death cancer. The intricate tumor microenvironment of EC necessitates a better performance signature to distinguish different tumor prognoses, which may facilitate enable appropriate treatment selection for patients. This is the first study aimed to identify the immune and metabolism gene signature for prognosis prediction of EC and constructing a prediction model, from EC transcriptional data.

Methods: Using differential expression analysis to compare the transcriptomic data associated with immune and metabolism from TCGA dataset between 10 normal population and 162 EC patient samples. Screen the differentially expressed genes (DEGs) related to prognosis by univariate Cox regression, the subtype clusters were identified, and the characteristics were analyzed. Through multivariate Cox and LASSO regression, a prediction model of the EC prognostic risk score (RS) was established and validated.

Results: Compared with the normal population, there were 568 immune-related genes of differential expression in EC, with 369 up-regulated and 199 down-regulated; and 810 metabolism-related genes, including 428 up-regulated and 382 down-regulated. Based on these immune and metabolic DEGs, 12 prognosis-related genes identified that could be clustered patients into three subtypes. The prognosis of the three subtypes was significantly different (P= 0.0016). Furthermore, the prediction model of prognostic RS was constructed based on six genes included STC2, APLN, GPER1, FMO1, SNRPB, and FABP3 from above DEGs. The patients with low RS had significantly higher OS ($P < 0.001$) than those in the high RS group, and it had a certain predictive accuracy (AUC of 5 years OS = 0.818). Those were verified in the GSE53625 cohort.

Conclusions: Immune and metabolism gene were significantly correlated with the prognosis of EC patients, and the prognostic model by six DEGs had good prediction efficiency. These were expected to help clinical diagnosis and therapy, and provides a new perspective to explore the molecular mechanisms of EC.

1572P Impact of HER2 and PD-L1 co-expression in Claudin18.2 positive resectable gastroesophageal cancers

A. Cammarota[1], G. Devonshire[2], A. Miremadi[3], A. Ustaoglu[4], B. Filippi[5], J.L. Zhuang[4], S. Zamani[2], N. Masqué-Soler[2], L. Rimassa[6], R.C. Fitzgerald[4], E. Smyth[7]

[1]Department of Biomedical Sciences, Humanitas University, Milan, Italy; [2]Cancer Reasearch UK Cambridge Institute, University of Cambridge, Cambridge, UK; [3]Histopathology Department, Cambridge University Hospitals NHS Foundation Trust, Cambridge, UK; [4]Department of Oncology - Early Cancer Institute, University of Cambridge, Cambridge, UK; [5]Medical Oncology Department, Fondazione IRCCS Policlinico San Matteo, Pavia, Italy; [6]Humanitas Cancer Center, IRCCS Humanitas Research Hospital, Milan, Italy; [7]Department of Oncology, Oxford University Hospitals NHS Foundation Trust, Oxford, UK

Background: The identification of CLDN18.2, HER2, and PD-L1 as targetable biomarkers has contributed to defining different molecular subsets of gastroesophageal adenocarcinoma (GEA) and developing tailored treatments in the unresectable space. However, the prevalence and significance of their co-expression in the resectable stages remain unclear.

Methods: We evaluated CLDN18.2, HER2 and PD-L1 in a cohort of resectable GEA with paired clinical and WGS data. CLDN18.2 (ab222512, Abcam), HER2 (ab16662, Abcam) and PD-L1 (E1L3N, Cell Signaling) were assessed by immunohistochemistry (IHC) on adjacent slides from FFPE tumor samples. Positivity was defined as 2+/3+ staining in ≥40% of tumor cells for CLDN18.2, in ≥10% (surgical samples) or any percentage of tumor cells (biopsies) for HER2, and as a combined positive score (CPS)≥1 for PD-L1. Tumor mutational burden (TMB) was calculated as the number of non-synonymous somatic mutations per mega-base from WGS. Fisher's exact test or Mann-Whitney test was used to compare baseline characteristics and log-rank test to compare survival curves, with statistical significance set at p=0.05 (two-sided).

Results: Eighty-four patients with resected GEA (71% GEJC/20% GC; 77% after neo-adjuvant chemotherapy) were evaluated. CLDN18.2 was overexpressed in 18%, HER2 in 19%, and PD-L1 in 31% of the cases. Clinicopathological characteristics and OS were similar across subgroups (all p>0.05), except for significantly more stage III disease at diagnosis in HER2+ve (OR 6.07, p=0.02) and PD-L1+ve (OR 7.91, p<0.01) compared to their negative counterpart. Among CLDN18.2+ve cases, 4 patients (27%) co-expressed HER2 and 6 (40%) PD-L1. CLDN18.2+ve/HER2+ve cases were all MSS, mostly PD-L1-ve (n=3/4), and their TMB was significantly higher compared to CLDN18.2+ve only (10.46 vs 5.62, p=002). TMB was not significantly different by PD-L1 status in the CLDN18.2+ve subgroup nor between CLDN18.2+ve and HER2+ve subgroups, taking co-expressors out.

Conclusions: Biomarker co-expression may be frequent in the CDLN18.2+ve subset, and CLDN18.2+ve/HER2+ve may reveal a genomically more complex subgroup. Evaluation in larger datasets is required to understand its biological significance and potential therapeutic implications.

Background: Concurrent chemoradiation is standard treatment for locally advanced esophageal squamous cell carcinoma (ESCC), while the optimal regimen of radiotherapy, especially in terms of total dose and planned range of target field, remained unclear. We performed this phase III clinical trial (ChiCTR-IPR-15007172) to compare the survival benefits between different radiation dose and different target field.

Methods: This trial compared two radiation treatment aspects of total dose and field under two-by-two factorial design. The involved field irradiation (IFI) group and elective nodal irradiation (ENI) group adopted different radiation plans of clinical target volume. The high radiation dose group (HD) totally received 59.4Gy radiation and standard dose group (SD) received 50.4 Gy. The participants were assigned to one of the four groups (HD+ENI, HD+IFI, SD+ENI and SD+IFI) by simple randomization (1:1:1:1 ratio). The planned sample size was 147 in each arm (588 totally) and the primary endpoint was overall survival (OS). All statistical analysis was performed according to intention-to-treat principle.

Results: The median follow-up time reached 64.6 months up to April 2023. In comparison of target field, patients in IFI or ENI presented similar OS (HR=0.99, log rank test p =0.93) and PFS (HR=1.02). The HD treatment did not present significantly prolonged OS (HR=0.90, log rank test p value=0.318) compared with SD but suggested improved PFS (25.2 months to 18.0 months, HR=0.76). No significant synergistic effect was detected between dose and radiation field in interaction analysis (p=0.11). In subgroup analysis, the HD radiation suggested benefits in T4 tumors, and the ENI treatment was associated with better OS in N0 patients. No significant difference in occurrences of severe adverse events was detected in dose or field comparisons.

Conclusions: The IFI has similar treatment efficiency to ENI, which indicated a reasonable choice for locally advanced ESCC. HD radiation did not suggest significant benefits in OS, but associated with better PFS compared to SD.

Clinical trial identification: ChiCTR-IPR-15007172.

1574P Trastuzumab deruxtecan versus ramucirumab and paclitaxel as second-line therapy for patients with her2-positive gastric or gastro-esophageal junction adenocarcinoma: A propensity score matched comparison

R.H.A. Verhoeven[1], S. Kuijper[2], F. Lordick[3], M. Slingerland[4], A. Qin[5], H.W.M. van Laarhoven[2]

[1]Research and Development Department, IKNL - Netherlands Comprehensive Cancer Organisation, Utrecht, Netherlands; [2]Medical Oncology, Amsterdam University Medical Centers - location Academic Medical Center (AMC), Amsterdam, Netherlands; [3]Department of Medicine, University of Leipzig Medical Center, Comprehensive Cancer Center Central Germany, Leipzig, Germany; [4]Medical Oncology, Leiden University Medical Center (LUMC), Leiden, Netherlands; [5]Daiichi Sankyo, Inc., Basking Ridge, NJ, USA

Background: The single arm phase II DESTINY-Gastric02 (DG-02) study investigated the objective response rate, overall survival (OS) and safety of patients treated with Trastuzumab Deruxtecan (T-DXd) as second-line therapy in Western patients with HER2+ unresectable or metastatic gastric or gastro-esophageal junction (GEJ) adenocarcinoma who progressed during or after trastuzumab-based first-line therapy. As the DG-02 study had no control group, the aim of the current study was to compare patients in the DG-02 study to a real-world reference group treated with Ramucirumab and Paclitaxel (Ram+Pac) as second-line therapy.

Methods: DG-02 patients who received trastuzumab in a non-metastatic setting (N=8) were excluded, due to absence of similarly treated patients in the Netherlands Cancer Registry (NCR). All other DG-02 patients (N=71) were included. A comparable set of patients with HER2+ esophageal, gastric or GEJ adenocarcinoma who received trastuzumab in first-line and Ram+Pac in second-line settings were identified from the NCR (N=120). Propensity score trimming (exclusion of patients at the extremes of the propensity score) and propensity score matching based on sex, age, performance status, primary tumor location, BMI, renal function, number of metastatic sites, presence of liver metastases, and duration of first-line treatment were used to select a reference group for the DG-02.

Results: Propensity score trimming resulted in exclusion of 12 DG-02 and 33 NCR patients. Thereafter, propensity score matching resulted in a balanced group of patients from the NCR (N=78) and DG-02 (N=58). Median OS was significantly longer among patients treated with T-DXd (11.6 months, 95%CI: 9.0-20.5) compared to the Ram+Pac group (6.2 months, 95%CI: 4.5 − 10.0) (HR: 0.39, 95%CI: 0.26 −0.59, $p<0.0001$).

Conclusions: Compared to propensity score-matched patients with metastatic, trastuzumab-pretreated HER2+ gastric or GEJ adenocarcinomas who received Ram+Pac in the real-world as a second -line therapy, overall survival was better for patients who received T-DXd. Due to the nature of the comparison, the results should be interpreted with caution.

Background: Adjuvant nivolumab is approved and reimbursed for resected patients with esophageal or gastro-esophageal junction (GEJ) cancer with incomplete response to neoadjuvant chemoradiation (nCRT) in the Netherlands since January 2022. This study investigated factors associated with uptake of adjuvant nivolumab in a nationwide population.

Methods: Patients were selected from the Netherlands Cancer Registry based on the EMA indication (non-metastasized esophageal or GEJ cancer treated with nCRT plus surgery and residual pathological disease). Following the Checkmate-577 inclusion criteria, we also investigated a subpopulation using additional criteria: R0 resection and WHO performance status 0-1. Treatment with nivolumab is presented according to time of surgery. The association of not administering nivolumab with patient, disease and treatment characteristics was assessed with multivariable logistic regression.

Results: Of 275 eligible patients in the EMA-indicated population, 177 (64%) were treated with adjuvant nivolumab. Uptake increased from 51% in November-December 2021 to 72%, 68%, and 66% in Q1, Q2 and Q3 of 2022, respectively. According to the Checkmate-577 criteria, 215 patients were eligible, of whom 147 (68%) were treated with nivolumab, with a similar pattern over time (49%, 78%, 67% and 76%, respectively). In the EMA-indicated population, nivolumab was administered less often to patients with ypN0-1 nodal status, irradical resection, post-operative grade 3-4 complications and patients undergoing a gastrectomy (Table).

Table: 1575P Factors associated with nivolumab treatment

Variable	*N*	Univariable proportion treated with adjuvant nivolumab	Multivariable odds ratios on not starting with adjuvant nivolumab (95% confidence interval)	P-value
Age (continuous)	275	*Not applicable*	1.02 (0.99 − 1.05)	0.28
ypN				
- ypN0	130	56%	3.54 (1.57 − 7.98)	<0.01
- ypN1	92	66%	2.43 (1.04 − 5.69)	0.04
- ypN2-3	53	79%	Ref	
Type of surgery				
- Esophagectomy	267	65%	Ref	
- Total gastrectomy	8	12%	12.13 (1.41 − 105.6)	0.02
Surgical radicality				
- R0	222	67%	Ref	
- R1-2	49	49%	2.91 (1.45 − 5.87)	<0.01
- Unknown	4	75%	0.81 (0.08 − 8.83)	0.86
Post-operative grade 3-4 Clavien-Dindo complications				
- No grade 3-4 complication	217	68%	Ref	
- Grade 3-4 complication	58	50%	2.11 (1.13 − 3.96)	<0.01

Conclusions: Treatment with adjuvant nivolumab has been implemented in the Netherlands, reaching a quarterly maximum of 72-78% of theoretically eligible patients. Small differences in uptake were found between eligible populations based on EMA indicated and Checkmate-577 criteria. Specific disease and treatment characteristics were associated with administration of nivolumab.

1576P Comparison of efficacy and safety of first-line systemic therapy combined with or without radiotherapy for stage IVb esophageal squamous cell carcinoma: A propensity score matching analysis

B. Chen, W. Chen, C. Yang, Q. Cheng, X. Cheng, M. Xi, Q. Li, B. Chen

Radiation oncology Department, Sun Yat-sen University Cancer Center, Guangzhou, China

Background: The role of additional radiotherapy (RT) to systemic therapy including chemotherapy plus anti-PD-1 for metastatic esophageal squamous cell carcinoma (ESCC) is not clear. This analysis aims to compare the survival and safety profile of stage IVB ESCC treated by first-line systemic therapy combined with or without radiotherapy.

Methods: We retrospectively enrolled 155 patients with metastatic ESCC who were treated with first-line systemic therapy including chemotherapy plus anti-PD-1 combined with or without radiotherapy of primary tumor. Propensity score matching (PSM) was performed to minimize the effects of confounding factors. Kaplan-Meier analysis and the log-rank test were conducted to analyze the survival. Prognostic factors were identified by univariate and multivariate cox regression analyses.

Results: The median follow-up period was 22.1 (interquartile range [IQR]: 17.5-27.7) months in the whole cohort. OS and PFS were significantly longer in additional RT group ($P = 0.017$ for OS, $P = 0.04$ for PFS). One hundred and twenty-four patients were enrolled after PSM. Additional RT group has superior OS compared to no RT group ($P = 0.026$). Additional RT group has higher 1-year OS and PFS rates compared to no RT group (1-year OS: 74% vs 52.4%, $P = 0.027$; 1-year PFS: 61.4% vs 44%, $P = 0.046$). Multivariate analyses suggested that RT was an independent prognostic factor for OS (hazard ratio [HR]:0.52, 95 % confidence interval [CI]: 0.3-0.91, $P = 0.022$) and tumor length was an independent predictor for unfavorable PFS (HR: 1.9, 95% CI: 1.06-3.38, $P = 0.03$). Grade 3-4 lymphocytopenia (83.5% versus 11.1%, $P < 0.001$) and grade 3-4 esophagitis (21.5% versus 6.7%, $P = 0.031$) were more frequently observed in additional RT group. Regarding fistula, no significant difference was found between two groups (13.3% versus 8.9%, $P = 0.544$).

Conclusions: Radiotherapy combined with first-line systemic therapy including chemotherapy plus anti-PD1 has superior survival and tolerable toxicities compared to systemic therapy alone for stage IVB ESCC.

Background: Antibiotic therapy has been known to disrupt microbiota homeostasis and systemic immune responses, both of which are linked to response to immune checkpoint blockade. We aim to investigate whether prior antibiotics (pATB) administration influences outcomes following treatment with programmed cell death protein-1 (PD-1) inhibitors or chemotherapy in patients with advanced gastric cancer (AGC).

Methods: We analysed data of patients with AGC who were treated with PD-1 inhibitors (retrospective exploratory cohort; n=152) or irinotecan (chemotherapy cohort; n=101). Patients were classified into two groups based on whether they had received pATB within 28 days prior to the treatment. Another independent retrospective validation cohort (n=123) and prospective validation cohort (n=30) treated with PD-1 inhibitors were further analysed. Distinct features in gut microbiome and circulating immune cells were analysed (experimental cohort; n=24).

Results: In the retrospective exploratory cohort, pATB administration was associated with poor 17 progression-free survival (PFS; hazard ratio [HR]=2.897, 95% confidence interval [CI]=2.043−4.109) and overall survival (OS; HR=2.294, 95% CI=1.622−3.242) but did not affect outcomes among patients treated with irinotecan. In the validation cohorts, pATB administration was associated with poor treatment outcomes following PD-1 blockade. Multivariate analysis of the overall patients treated with PD-1 inhibitors confirmed that pATB was an independent predictor of poor PFS (HR=3.243, 95% CI=2.427−4.333) and OS (HR=3.046, 95% CI= 2.358−3.935). Administration of pATB was associated with diminished gut microbiome diversity, reduced abundance of *Lactobacillus gasseri*, and disproportional enrichment of circulating exhaustive $CD8^+$ T cells, all of which can hinder the efficacy of PD-1 blockade.

Conclusions: Considering the inferior treatment response and poor survival outcomes by pATB followed by PD-1 blockade, antibiotics should be prescribed with caution in patients with AGC planned to receive PD-1 inhibitors.

1578P Effect of immune checkpoint inhibitors in metastatic gastric cancer: A real-world evidence study

F. Puccetti[1], E. Mazza[2], G. Hernández-Ibarburu[3], F. Rusconi[3], N. Liscia[2], L.A. Barbieri[1], E. Treppiedi[1], A. Cossu[1], R. Rosati[1], U. Elmore[1]

[1]Gastrointestinal Surgery, IRCCS Ospedale San Raffaele, Milan, Italy; [2]Medical Oncology, IRCCS Ospedale San Raffaele, Milan, Italy; [3]TriNetX Europe NV, Sint-Martens-Latem, Belgium

Background: Despite the beneficial findings from different clinical trials, targeted immunotherapy is still debated in advanced gastric cancer care. Immune checkpoint inhibitors (ICIs) of programmed cell death protein 1 (PD-1) have emerged as a promising therapeutic option, demonstrating clinical activity in gastric cancer. This study aims to analyze the impact of PD-1 inhibition overall survival of a large-scale series of patients treated for metastatic gastric cancer.

Methods: A retrospective study was designed by using TriNetX Platform for a large-scale search of patients with metastatic gastric cancer, who underwent immunotherapy at large healthcare organizations collaborating through TriNetX-mediated network at both European (EMEA collaborative group) and international (GLOBAL) levels. Propensity score matching was used to balance these cohorts against the cohort of metastatic gastric cancer patients not treated with PD-1 inhibitors, to remove possible confounding effect of age and gender. Kaplan Meier analysis was used to compare the 2-year overall survival of these two cohorts, after propensity score matching was used.

Results: From a total of 15.318 patients affected by metastatic gastric cancer, a cohort of 1.425 patients treated with PD-1 inhibitors was identified, including 1.372 from TriNetX healthcare organization network at a global level (TNX-GLOBAL) and 53 from the EMEA group (TNX-EMEA). When compared to the propensity score matched control patient's cohort with no PD-1 treatment, anti-PD-1 treated patients had significantly better overall survival in both TNX-GLOBAL, 44.73% vs 41.26% ($p<0.01$), and in TNX-EMEA, 39.31% vs 21.47% ($p<0.01$).

Conclusions: The evidence from the present retrospective cohort study using real-world data from TNX-GLOBAL and TNX-EMEA collaborative networks created the unique opportunity to analyze a large-scale series of patients with metastatic gastric cancer. Positive effects of anti-PD-1-targeted therapy on survival of such a frail cohort demonstrated the clinical relevance of prevalence of PD-1 expression and supported the effectiveness of new therapies based on ICI's for metastatic disease. Given these results, further studies on the role of ICI's also in perioperative setting are awaited.

1579P Gender differences and worse metastatic survival outcomes in young adult patients with oesophagogastric cancer: 12-year data from a Czech comprehensive cancer center

T. Sokop[1], I. Selingerova[2], R. Obermannova[3]

[1]Department of Comprehensive Cancer Care, Masaryk Memorial Cancer Institute - Masaryk University, Brno, Czech Republic; [2]Research Center for Applied Molecular Oncology, Masaryk Memorial Cancer Institute - Masaryk University, Brno, Czech Republic; [3]Department of Comprehensive Cancer Care, Masaryk Memorial Cancer Institute - Masaryk University, Brno, South Moravian, Czech Republic

Background: The US Surveillance, Epidemiology, and End Result (SEER) data indicated an increasing incidence of early-onset GI tract cancers. According to published data, the treatment outcomes of young adults (YA) are comparable to the general population. We aimed to analyze the clinicopathological characteristics and overall survival (OS) of YA treated in a comprehensive cancer center.

Methods: Patients diagnosed with oesophagal (OC), oesophagogastric junction (OGJ), or gastric (GC) cancer between 2010 and 2022 were retrospectively identified from the Masaryk Memorial Cancer Institute database. Inclusion criteria were 1) age 18-50 years, 2) histology, and 3) treatment according to international recommendations.

Results: The consecutive patient cohort included 1725 patients, of which 162 met the inclusion criteria, representing approximately 10% of YA patients from the Czech Republic. In 63% of cases, the patients were men, significantly older than women (84% vs 65% in the age group 40-49 years, p=0.005). In women, tumors were more often located in the stomach (78% vs 53%, p=0.001) and primary metastatic (67% vs 50%, p=0.039). Six patients had localized disease (stage I), 36 (16 OC/OGJ, 20 GC) underwent radical resection, 31 (15 OC/OGJ, 16 GC) were unresectable, and 86 metastatic (25 OC/OGJ, 61 GC). With a median follow-up of 67 months, 131 (81%) deaths were recorded. Radically resected patients achieved a median OS of 54 mo with a 5-year OS of 42%, whereas the median OS for the unresectable and metastatic disease was 11 mo, and 8.6 mo, respectively.

Conclusions: In our YA cohort, men were older, while women were more likely to have metastatic gastric cancer. OS for the locally advanced disease was comparable to published studies observing the general population but noticeably shorter for metastatic disease.

1580P Early onset oesophageal adenocarcinoma: A separate biological entity?

D.V. Valand[1], E.E. Scanlon[1], A.C. Hamilton[2], G. Devonshire[3], B. Nutzinger[3], N. Grehan[3], H. Coleman[2], R.C. Fitzgerald[3], R.C. Turkington[1]

[1]Patrick G Johnston Centre for Cancer Research, Queen's University Belfast, Belfast, UK; [2]Centre for Public Health, Queen's University Belfast, Belfast, UK; [3]Early Cancer Institute, University of Cambridge, Cambridge, UK

Background: There is concern that the incidence of oesophageal adenocarcinoma (OAC) in patients under 50, described as early onset (EO) OAC, may be rising steadily. Epidemiological studies suggest that EO-OAC patients present with higher-stage disease compared to late-onset patients, receive more aggressive treatment but may have poorer survival outcomes. We utilised Whole Genome Sequencing (WGS) and

RNA-seq to investigate if EO-OAC represents a distinct biological entity compared to late-onset disease.

Methods: We obtained WGS and clinical data for stage and treatment matched OAC patients who received neoadjuvant chemotherapy prior to surgical resection (n=29 patients ≤50 years and n=144 patients ≥70 years) from the OCCAMS consortium. We performed statistical analysis between age groups using chi-squared testing with FDR correction for copy number aberrations (CNA), insertions and deletions (INDELS) and single nucleotide variants (SNV), assessing gene-level mutations and mutational burden considering coding genes only, prior to assessing 76 OAC driver genes as described by Frankell et al., 2019. Biological pathways between age groups were assessed for n=66 patients using available RNASeq data and Gene Set Enrichment Analysis (GSEA).

Results: Our results indicate that EO-OAC had a lower combined mutational burden (Wilcoxon p=0.0204) and lower indel counts (Wilcoxon p=0.0031) compared to late-onset patients. When considering gene-level mutations for SNV, CNA, INDELS and 76 OAC driver genes (Frankell et al., 2019), multiple analyses showed genes at a nominal p-value <0.05 between age groups yet none reached significance at FDR p-value <0.25. GSEA indicated 179 enriched pathways, several related to immune signalling for EO-OAC at nominal p-value <0.05 and a higher DNA Damage Immune Response (DDIR) assay score in EO-OAC (p=0.012).

Conclusions: Our comparison of early and late-onset OAC using WGS and RNA-seq data highlights the possibility of EO-OAC as a separate biological entity, with potentially enhanced immune signalling. Future work in larger sample cohorts and the investigation of clinically relevant gene and mutational signatures is required to further assess molecular differences between early and late onset OAC.

1581P Total neoadjuvant chemotherapy with FOLFIRINOX regimen in patients with resectable locally advanced gastric and gastroesophageal junction cancer

M.V. Sedova[1], M.A. Batov[1], A.A. Kolomeytseva[1], V.M. Khomyakov[2], N.N. Volchenko[3], A.A. Fedenko[4], A.D. Kaprin[5]

[1]The Department of Medical Oncology, P.A. Hertsen Moscow Oncology Research Institute, Moscow, Russian Federation; [2]The Department of Thoracoabdominal Oncosurgery, P.A. Hertsen Moscow Oncology Research Institute, Moscow, Russian Federation; [3]Oncomorphology Department, P.A. Herzen Moscow Research Oncological Institute, Moscow, Russian Federation; [4]Medical Oncology Devision, P.A.Herzen Moscow Cancer Research Center, Moscow, Russian Federation; [5]P.A. Herzen Moscow Research Oncological Institute, P.A. Herzen Moscow Research Oncological Institute, Moscow, Russian Federation

Background: Surgery with perioperative chemotherapy has been standard of care in patients with locally advanced gastric and gastroesophageal junction (GEJ) cancer since FLOT4-AIO trial. However, less than half of patients complete all adjuvant cycles. We studied total neoadjuvant chemotherapy with FOLFIRINOX regimen followed by surgery in this setting.

Methods: We conducted non-randomized, open-label, single-center phase II study in 119 patients with locally advanced resectable gastric and GEJ cancer. Sixty patients were enrolled to received 8 cycles of FOLFIRINOX preoperatively. This prospective cohort was compared to the retrospective cohort (n = 59), that received standard perioperative FLOT regimen (4 cycles before and 4 cycles after surgery). The primary endpoint was disease-free survival (DFS). Secondary endpoints were safety profile and pathological complete response rate (pCR).

Results: In the FOLFIRINOX and FLOT groups 78,6% and 77,8% of patients completed all planned cycles and underwent surgery, respectively. Dose reductions and drug withdrawal rates were higher in the FLOT group. More patients achieved pCR and near-pCR in the FLOT group by three different tumor regression grading systems (TRG 1a/b by Becker, 1/2 by Mandart, and 3/4 by Lavnikova): 47,7%, 40,5%, and 35,7% in the FLOT group and 25%, 27,3%, and 29,6% in the FOLFIRINOX group, respectively, though statistically insignificant. pCR or partial pathological response by any of TRG systems did not predict one-year DFS regardless of the treatment regimen. One-year DFS was numerically higher in the FOLFIRINOX group - 90,4% vs 67,5 % in the FLOT group (hazard ratio [HR] 0,65, 95% CI 0,29 — 1,45, p=0,29). The risk of recurrence in the FOLFIRINOX group was lower than in the FLOT group (odds ratio [OR] 0,40, 95% CI 0,16-0,97, p=0,047). Regional lymph node involvement (ypN2), lymphatic, vascular and perineural invasion negatively affected DFS (p=0,046; p=0,014; p=0,0021; p=0,04, respectively).

Conclusions: The total neoadjuvant chemotherapy with FOLFIRINOX regimen in patients with locally advanced gastric and GEJ cancer demonstrated comparable to the perioperative FLOT one-year DFS rate regardless of pCR and manageable safety profile.

1582P Gastroesophageal adenocarcinoma in young adults: Retrospective analysis of clinical and molecular features

D.A. Acosta Eyzaguirre[1], G. Castillo[2], S. Vega[3], S.A. Bueno Salazar[3], A. Carmona[1], A. Vázquez[1], S. Landolfi[4], S. Aguilar Izquierdo[5], A. Vivancos[6], M. Díez García[1], T. Macarulla[1]

[1]Gastrointestinal Cancer Unit, Vall d'Hebron University Hospital, Barcelona, Spain; [2]VHIO, Vall d'Hebron Institute of Oncology (VHIO), Barcelona, Spain; [3]Medical Oncology Department, Vall d'Hebron University Hospital, Barcelona, Spain; [4]Pathology Department, Vall d'Hebron University Hospital, Barcelona, Spain; [5]VHIOTECA & Pre-screening Program, Vall d'Hebron Institute of Oncology (VHIO), Barcelona, Spain; [6]Cancer Genomics Group, Vall d'Hebron Institute of Oncology (VHIO), Barcelona, Spain

Background: Gastroesophageal adenocarcinoma (GEA) in young patients presents poor prognosis due to heterogeneity of the disease and lack of dedicated treatment resulting in high socioeconomic impact. Objective was to explore clinical and molecular features.

Methods: Included patients had diagnosis of GEA at an age of ≤50 years evaluated at Vall d'Hebron University Hospital between 2015 and 2023. Clinical data was obtained retrospectively from the electronic medical history. ESMO Scale of Clinical Actionability for molecular Targets (ESCAT) was used to classify biomarkers. Survival was calculated by the Kaplan-Meier method.

Results: We identified 170 patients with GEA under 50 years. Clinical characteristics are outlined in the table. Median overall survival (OS) was 15.9 months (m) (95% CI 14.7 — 18.1) since diagnosis of advanced disease (n=159). Patients with esophagogastric junction (EGJ) tumors had better OS compared to esophageal (HR 0.29 (95% CI 0.15-0.58) 20.1 vs 13.3 m p= 0.0003) or gastric (HR 0.48 (95% CI 0.26-0.86) 20.1 vs 15.9 m p=0.01). Survival analysis didnt show statistically significant differences in OS regarding sex, *HER2* status, ascites or signet ring cells. We found ESCAT I, II and III alterations in 52, 5 and 10 cases respectively. Most tier I (38) were *HER2* overexpression/amplification, all received matched therapy with trastuzumab. Other were: MSI (10), TMB-H (3) and *FRFR2* amp (1). Among Tier II: *BCRA1* mut (1), *BRCA2* mut (1) and *EGFR* amplification (3) and Tier III: *PIK3CA* mut (5), *HER2* mut (3) and *ATM* mut (2).

Table: 1582P

	N = 170 (100%)
Sex	
Male:Female	91 (53,5): 79 (46,5)
Age	Median 42 (18-50)
Localization	
Esophageal	20 (11,8)
EGJ	44 (25,9)
Gastric	106 (62,4)
Histology	
Diffuse	33 (19,4)
Intestinal	17 (10)
Poorly cohesive	29 (17,1)
Undifferentiated	18 (10,6)
Others	73 (43)
Signet ring cells	
Yes	67 (39,4)
No	103 (60,6)
Stage	
I-III	53 (31,2)
IV	117 (68,8)
Metastatic site	
Peritoneal	85 (50)
Liver	35 (20,6)
Ascites at diagnosis	
Yes	38 (22,4)
No	118 (69,4)
Not applicable	14 (8,2)
NGS	
Yes	82 (48,2)
No	88 (51,8)

Conclusions: Our results indicate that young patients present poor prognosis features (localization, advanced stage, histology) but a significant number of them presented ESCAT I alterations, being candidates to receive a matched therapy as standard of care.

1583P Intraperitoneal chemotherapy for peritoneal metastases of gastric origin: A systematic review and meta-analysis

N.A.D. Guchelaar[1], K. Nasserinejad[2], B. Mostert[1], S.L. Koolen[1], P.C. van der Sluis[3], S.M. Lagarde[3], B.P.L. Wijnhoven[3], R.H. Mathijssen[1], B.J. Noordman[3]

[1]Department of Medical Oncology, Erasmus MC Cancer Institute, Rotterdam, Netherlands; [2]Department of Hematology, Hovon Data Center, Erasmus MC, Rotterdam, Netherlands; [3]Department of Surgery, Division of Surgical Oncology and Gastrointestinal Surgery, Erasmus MC Cancer Institute, Rotterdam, Netherlands

Background: Gastric cancer with peritoneal metastases is associated with a dismal prognosis. Catheter-based intraperitoneal (IP) chemotherapy and pressurized intraperitoneal aerosol chemotherapy (PIPAC) are methods to deliver chemotherapy intraperitoneally leading to higher intraperitoneal concentrations of cytotoxic drugs, compared to intravenous administration. We reviewed the effectiveness of palliative intraperitoneal chemotherapy for patients with peritoneal metastases of gastric origin.

Methods: Embase, MEDLINE, Web of Science, and Cochrane were searched for articles on chemotherapy with palliative intent in patients with peritoneal metastases of gastric origin published up to April 2023. The primary outcome was overall survival. Secondary outcomes included toxicity and clinicopathological outcomes in patients that underwent conversion surgery. A Bayesian random effect model was used to calculate the pooled median overall survival (mOS).

Results: 21 studies including 904 patients were retrieved, categorized in 3 treatment groups (IP docetaxel, IP paclitaxel and PIPAC). The pooled mOS for all intraperitoneal chemotherapy treatments was 14.2 months (95% CI: 10.8 — 17.7 months). The pooled hazard ratio of IP paclitaxel and docetaxel favored the combination of IP and systemic chemotherapy compared to systemic chemotherapy only (0.64, 95% CI: 0.47 — 0.86). mOS of IP paclitaxel, IP docetaxel and PIPAC with cisplatin and doxorubicin were respectively 18.3 months (95% CI: 14.0 — 22.7 months), 13.2 months (95% CI: 3.6 — 25.1 months) and 9.0 months (95% CI: 2.3 — 16.5 months). All treatment methods had a relatively safe toxicity profile. Conversion surgery was performed in 14% of the patients and a radical resection was achieved in 69%, with a mOS ranging from 24 to 33 months.

Conclusions: Patients with peritoneal metastases of gastric origin treated with intraperitoneal chemotherapy had a pooled median overall survival of 14.2 months and a pooled hazard ratio of 0.64 compared to systemic chemotherapy. Intraperitoneal chemotherapy, regardless of method of administration, is a safe treatment and conversion surgery is possible in a selected subset of patients.

1584P Conversion effect of PD-1 antibody camrelizumab (Cam) combined with modified FLOT (mFLOT) regimen in patients(pts) with initially unresectable locally advanced or limited metastatic gastric or gastroesophageal junction (GEJ) adenocarcinoma

Q. Geng[1], W. Feng[1], H. Huang[2], X. Zhao[1], H. Fu[2], Y. Zhou[2], W. Zhang[1], M. Huang[1], G. Zhao[2], D. Xu[2], W. Guo[1]

[1]Department of Gastrointestinal Medical Oncology, Fudan University Shanghai Cancer Center, Shanghai, China; [2]Department of Gastric Surgery, Fudan University Shanghai Cancer Center, Shanghai, China

Background: The AIO-FLOT3 Trial suggested that conversion therapy might improve outcome in pts with metastatic gastric cancer (GC). We conducted this prospective, single-arm, phase II trial to improve conversion efficacy of ICIs combined with mFLOT regimen (fluorouracil, oxaliplatin, and nab-PTX) in pts with initially unresectable locally advanced or limited metastatic GC or GEJ adenocarcinoma.

Methods: Eligible pts received Cam 200mg, oxaliplatin 85 mg/m^2, nab-PTX 125 mg/m^2 or with trastuzumab if Her2 positive, each was an IV followed by fluorouracil 2400 mg/m^2 as a 48-h continuous iv on day 1, every 2 weeks. Pts were assessed for tumor response and surgical feasibility every 3 cycles. The primary endpoint was R0 conversion rate.

Results: 35 pts were enrolled up to 04/2023. 30 pts were evaluable. The median age was 50y. Male was 76.7%. The metastatic sites included liver 50.0% (15), retroperitoneal lymph nodes (LNs) 33.0% (10), axillary and supraclavicular LNs 6.7% (2), Krukenberg 3.3% (1), adrenal gland 3.3% (1), and locally advanced unresectable 10% (3). 7(23.3%) pts had two or more unresectable lesions. 4 pts were dMMR/MSI-H and 4 were Her2 positive. ORR was 86.7% and DCR was 96.7%. 25(83.3%) pts were assessed as resectable after conversion therapy. One pt refused surgery and 2 were cCR under observation. 22 pts (73.3%) received operation with R0 resection and no perioperative mortality. With 2 cCR included, R0 conversion rate was 80.0% (24/30). 5 pts (22.7%) achieved pCR and 12(54.5%) achieved MPR. Grade 3 AEs included 2 cases of rash, 1 case of adrenal insufficiency, 1 case each of ALT, AST elevation and febrile neutropenia. 1 pt was Grade 4 Neutrophil count decreased. (Table)

Table: 1584P

Response and surgical conversion, n (%)		N = 30
ORR		26 (86.7)
	CR	2 (6.7)
	PR	24 (80.0)
DCR		29 (96.7)
	SD	3 (10.0)
	PD	1 (3.3)
R0 conversion rate		24 (80.0)
Pathological response	pCR	5/22 (22.7)
	MPR	12/22 (54.5)
cCR+pCR		7 (23.3)

Conclusions: Cam combined with mFLOT regimen safely induced a high conversion rate, with very high R0 resection, pCR and MPR. The findings warrant further prospective investigations.

Clinical trial identification: NCT04510064.

Background: The IVY study (UMIN000033376) investigated the impact of first-line platinum-induced PN on the incidence of PN during second-line PTX-based chemotherapy and its efficacy in patients with unresectable AGC.

Methods: The study utilized the Common Terminology Criteria for Adverse Events (CTCAE), the Patient Neurotoxicity Questionnaire (PNQ), and the Functional Assessment of Cancer Therapy/Gynecologic Oncology Group-Neurotoxicity (FACT/GOG-Ntx) to assess PN. The primary endpoint was to determine the incidence of grade 3 or greater PN during second-line treatment in patients with and without PN at the start of treatment. The secondary objective was to examine the relationship between PN and the efficacy.

Results: Of 162 patients enrolled in this study, 156 received second-line PTX-based chemotherapy and were divided into two groups based on their PN status at the start of the treatment. The characteristics of 156 patients are as follows: the median age was 69 years, 72% were male, 90% were ECOG PS: 0 or 1, 81% used oxaliplatin in their first-line chemotherapy regimen. Of the 156 patients, 90 patients (58%) were in the group with PN (CTCAE grade: 1 to 3), and 66 were in the group without PN (grade: 0). The group with PN had a higher incidence of grade 3 or greater PN than the group without PN (16.7% vs. 4.6%, p=0.02). The progression-free survival and the overall response rate were not significantly different between the two groups (4.0 months in the group with PN vs. 3.5 months without PN, p=0.20; and 23% vs. 19%, p=0.69). However, the median overall survival was significantly better in the group with PN (10.3 months vs. 8.1 months, p=0.04). The quality-of-life scores, as assessed by PNQ and FACT/GOG-Ntx, were lower in the group with PN than the scores of the group without PN during two months of treatment.

Conclusions: Starting second-line PTX-based chemotherapy with existing PN increased the severity of PN during treatment. However, this adverse effect did not impact the effectiveness of second-line PTX-based chemotherapy for patients with unresectable AGC.

1586P Characteristics, treatment (Tx) patterns and outcomes of patients with advanced/metastatic gastric cancer (GC) or gastro-esophageal junction (GEJ) adenocarcinoma previously treated with anti-HER2 therapy in an English national registry

N. Starling[1], L. Zhang[2], K. Dunton[2], A. Struebing[3], Y. Xiong[4], C. Livings[5], L. Brannman[6], M. Yakhchi Beykloo[7], H. Mohamed[7], N. Trankov[8], P. Egger[7]

[1]Gastrointestinal unit, The Royal Marsden Hospital - Chelsea, London, UK; [2]HEOR, Daiichi Sankyo Europe GmbH, Munich, Germany; [3]HEOR, Daiichi Sankyo Europe GmbH, Martinsried (Planegg), Germany; [4]Real-world Evidence, Daiichi Sankyo International, Basking Ridge, NJ, USA; [5]Health Economics and Payer Evidence, AstraZeneca, London, UK; [6]RWE Science, AstraZeneca, Gaithersburg, MD, USA; [7]EMEA RW Methods & Evidence Generation, IQVIA, London, UK; [8]RW Methods & Evidence Generation, IQVIA, Sofia, Bulgaria

Background: Understanding the natural history of patients with GC/GEJ adenocarcinoma treated previously with anti-HER2 regimens is useful for understanding the disease burden and selecting the optimal Tx for this population. This study reports Tx patterns and outcomes of patients with GC/GEJ adenocarcinoma treated previously with anti-HER2-based regimens.

Methods: Adults with advanced/metastatic GC/GEJ adenocarcinoma who received first-line (1L) trastuzumab-containing regimens were identified in the English Cancer Outcomes and Services Dataset (Jan 2010—Dec 2019). Tx pathways and outcomes were obtained from the Systemic Anti-Cancer Therapy Dataset, which captured nearly all treatments in England. A novel regimen-based algorithm for reporting Tx sequencing and outcomes was developed since line of therapy was not in the database. Descriptive statistics were reported. Overall survival (OS) and time to Tx discontinuation or death (TTD) underwent Kaplan—Meier analysis.

Results: A total of 948 patients were identified. At the start of their 1L trastuzumab-containing Tx, median age was 67 years (interquartile range [IQR] 57—73]); 82.1% were male; 90.4% were White; 85.4% had an ECOG status of 0—1; 26.0% had liver metastases; 1.0% had brain metastases; and 81.2% had a Charlson Comorbidity Index of 0—1. Three hundred and sixteen patients (33.3%) received 2L onward; 63 (6.6%) received 3L onward. The most common 2L regimens were paclitaxel (n=115 [36.4%]), docetaxel (n=98 [31.0%]), and 5-fluorouracil (5FU) + irinotecan (n=19 [6.0%]). Common 3L regimens included 5FU + irinotecan (n=12 [19.1%]), paclitaxel (n=11 [17.5%]) and capecitabine + irinotecan (n=10 [15.9%]). Median TTD was 2.8 months from the start of 2L. Median OS was 6.1 months (IQR, 3.4—11.2) from the start of 2L and 5.9 months (IQR, 3.2—9.5) from the start of 3L.

Conclusions: Survival of patients with GC/GEJ adenocarcinoma previously treated with 1L anti-HER2 regimens remains poor after 2L and 3L therapy, which is limited mainly to chemotherapy. These findings reflect an urgent need to improve 2L and 3L options.

1587P Analysis of survival outcomes according to start timing of adjuvant chemotherapy in patients with gastric cancer: A retrospective nationwide cohort study

T-H. Kim[1], E. Lee[2], H.W. Lee[1], M.S. Ahn[1], Y.W. Choi[1], M. Kwon[3], S.Y. Kang[1], J-H. Choi[1]

[1]Hematology-Oncology, Ajou University School of Medicine, Suwon, Republic of Korea; [2]Medical Research Collaborating Center, Ajou University Medical Center, Suwon, Republic of Korea; [3]Ajou University Hospital School of Medicine, Suwon, Republic of Korea

Background: Gastrectomy with D2 lymph node dissection followed by adjuvant chemotherapy (AC) has been the standard treatment for patients with stage II and III gastric cancer (GC). Especially, 1-year S-1 and 6-month capecitabine/oxaliplatin (CAPOX) are the standard chemotherapeutic regimens for AC. However, there is no established guideline for start timing of AC for GC. We aimed to investigate treatment outcomes according to start timing of AC using big-data analysis from Korean Health Insurance and Review Assessment (HIRA).

Methods: A total of 19,140 patients with GC who underwent AC with S-1 (n=10,442) or CAPOX (n=8,698) after gastrectomy were identified from January 2014 to December 2018 in the database of HIRA. Disease-free survival (DFS) and overall survival (OS) were analyzed according to the start timing of AC from surgery classified into within 6 weeks (group A, n=12,843), from 6 to 8 weeks (group B, n=5,386), and more than 8 to 16 weeks (group C, n=911).

Results: The median follow-up duration of all patients was 3.6 years. Five-year DFS and OS were significantly inferior in group B (57%, 66%) and group C (47%, 53%) compared with group A (63%, 72%) (all $p<0.0001$), which were consistently observed in either S-1 or CAPOX group (all $p<0.005$). In multivariate analysis, group B and C were independently associated with poor DFS and OS (all $p<0.0001$). Moreover, DFS and OS were inferior in group B (n=5386) compared with group A (n=5386) even after propensity score matching (both $p<0.0001$).

Conclusions: AC for GC with S-1 or CAPOX showed the best outcomes when initiated within 6 weeks following surgery. Therefore, AC for GC should be started within 6 weeks after gastrectomy if patients have fully recovered.

1588P Analysis of risk factors of anastomotic leakage after minimally invasive esophagectomy with circular cervical anastomosis

M. Lu[1], H. Tian[2], L. Li[1]

[1]Thoracic surgery Department, Qilu Hospital of Shandong University, Jinan, China; [2]Thoracic surgery Department, QiLu Hospital of Shandong University, Shandong, China

Background: Esophagectomy is a high-risk surgical procedure with significant postoperative morbidity and mortality. Anastomotic leakage is still one of the most serious complications after anterior resection for esophageal carcinoma. This study aimed to analyze the risk factors after minimally invasive cervical anastomosis of esophageal cancer and postoperative mortality.

Methods: This was a retrospective study of 312 minimally invasive cervical anastomosis of esophageal cancer in a single institute between 2013 and 2016. The anastomotic level and perioperative confounding factors were analyzed by univariate and multivariate logistic regression to identify potential risk factors for postoperative leakage.

Results: Total 312 patients were evaluated. Overall leak rate was 10.6%. In-hospital or 30-day mortality was 0%. Only 3 patients received intensive care unit due to postoperative complications and mean hospital stay was 14.22 ($\pm$7.70) days. Univariate analysis showed that the following variables were related to the incidence of anastomotic leakage: neoadjuvant chemotherapy before operation ($p=0.007$); body mass index (BMI) ($p=0.000$); diabetes ($p=0.001$); operation time ($p=0.006$). Multivariable analysis identified diabetes [$P = 0.032$, odds ratio (OR) 2.637, 95% confidence interval (CI): 1.087-6.393], BMI [$P = 0.003$, odds ratio (OR) 1.223, 95% confidence interval (CI): 1.070-1.399] and operation time [$P = 0.033$, odds ratio (OR) 1.012, 95% confidence interval (CI): 1.001-1.024] as the risk factors of anastomotic leakage.

Conclusions: Diabetes, operation time and BMI are independent prognostic factors for cervical anastomotic leakage of minimally invasive esophageal cancer. Cervical anastomotic leakage will not affect the short-term survival of the patients.

1589P Systemic treatment strategies and outcomes of patients with peritoneal metastases of gastric origin

N.A.D. Guchelaar[1], B.J. Noordman[2], M. Welten[3], M. van Santen[1], M.J. de Neijs[1], S.L. Koolen[1], R.H.A. Verhoeven[4], E. Oomen-de Hoop[1], H.W.M. van Laarhoven[5], I.H.J.T. de Hingh[6], G-J. Creemers[3], B. Mostert[1], B.P.L. Wijnhoven[2], R.H. Mathijssen[1]

[1]Department of Medical Oncology, Erasmus MC Cancer Institute, Rotterdam, Netherlands; [2]Department of Surgery, Division of Surgical Oncology and Gastrointestinal Surgery, Erasmus MC Cancer Institute, Rotterdam, Netherlands; [3]Department of Medical Oncology, Catharina Hospital Eindhoven, Eindhoven, Netherlands; [4]Research and Development Department, IKNL - Netherlands Comprehensive Cancer Organisation, Utrecht, Netherlands; [5]Department of Medical Oncology, Amsterdam UMC location University of Amsterdam, Amsterdam, Netherlands; [6]Department of Surgery, Catharina Hospital Eindhoven, Eindhoven, Netherlands

Background: Patients with peritoneal metastases of gastric origin are often underrepresented in clinical studies due to unmeasurable radiological disease. In theory, the efficacy of systemic treatment might be hampered by the peritoneal-plasma barrier. Here, we describe the outcomes of systemic treatment strategies in patients with peritoneal metastases in a real-world setting.

Methods: Patients with gastric adenocarcinoma and peritoneal metastases (with or without other metastases) treated with systemic therapy in the Netherlands between 2015 and 2020 were identified from the Netherlands Cancer Registry. Treatment regimens were classified into groups with one, two or three agents. Median overall survival (mOS) was determined, and multivariable Cox regression analyses were used to compare treatment groups, corrected for relevant tumor and patients' characteristics.

Results: In 909 patients, a total of 36 different treatment regimens were administered as first-line therapy. Local peritoneal therapies (i.e., HIPEC) was not observed. 5-FU or derivate combined with oxaliplatin (62%) was used most frequently, followed by epirubicin/oxaliplatin/capecitabine (9%) and capecitabine monotherapy (5%). mOS after first-line treatment was 8.1 months. Triplets containing docetaxel (mOS: 10.7 months, HR: 0.68, 95% CI 0.52-0.89) and trastuzumab-containing regimens (mOS: 11.4 months, HR: 0.65, 95% CI 0.50-0.85) had superior mOS compared to doublet therapy with 5-FU/capecitabine + oxaliplatin (mOS: 7.6 months) in multivariable analysis. Monotherapy was associated with a significantly lower mOS of 3.9 months (HR: 2.33, 95% CI 1.69-3.20). Best supportive care had a mOS of only 1.7 months.

Conclusions: In this real-world study, heterogeneity in the first-line treatment for patients with peritoneal metastases of gastric cancer was seen. Triplet therapy with docetaxel and trastuzumab-containing regimens were associated with longer survival. For docetaxel, this result is in contrast to previous meta-analyses in patients with metastases at any location. Whether this is caused by better exposure of peritoneal metastases to docetaxel or results from bias by indication should be the subject of further research.

Background: The LEGACy project aims to improve personalized medicine for gastric cancer in EU and LATAM populations. A hospital-based registry was implemented to compare these populations as a potential tool to plan prevention and treatment strategies providing real-world data.

Methods: A retrospective observational cohort design was used. Survival estimates were determined using actuarial Kaplan-Meier curves. Comparison was performed with the loge-rank test, and differences were considered statistically significant for P values .05.

Results: A total of 689 patients diagnosed with GC from 11/2018 to 04/2021 were included. Country and clinical characteristics are shown in the table. Both cohorts had the body as the most common site reported (34.4% for EU and 51% for LATAM). The most used method for staging was computed tomography for both cohorts, but 6.9% of the LATAM population had a PET/TC instead. The staging at diagnose for LATAM was lower than for the EU population (2.8% and 17.4% respectively). Intestinal histological subtype was the most common (41.9% and 46.3% reported by EU and LATAM), while diffuse subtype was 44.9% for LATAM and 21.3% for EU population. Among patients tested for HER2, 12.5% were positive in the EU cohort and 13.8% in the LATAM cohort. For both cohorts, the most common site of HER2 positive was the GOJ. Surgery was reported in 43.4% of EU population and 48.9% in the LATAM cohort. Systemic treatment with curative intention was indicated in 50.7% in the EU cohort and 46.4% of the LATAM cohort. The most frequent scheme indicated was platinum-based (42.6% and 84.8% for EU and LATAM). Considering both cohorts only 14.4% of the patients got a 2° line of treatment and 3% of the patients received a 3° line. After using cox regression analysis, no difference in overall survival was reported, with a median of 10.9 months.

Table: 1590P

Characteristic	EU Cohort (n: 407)	LATAM Cohort (n: 282)
Age - Median y [IQR]	70.50 [61.00, 78.00]	63.00 [53.00, 71.00]
Sex - n (%)		
Male	243 (59.9%)	166 (59.1%)
Country - n		
Argentine		67
Chile		112
Mexico		70
Netherlands	159	
Paraguay		31
Portugal	124	
Spain	121	
ECOG n (%)		
0	45 (21.1%)	61 (27.7%)
1	110 (51.6%)	116 (52.7%)
≥2	47 (22.1%)	43 (19.9%)

Conclusions: Although the limitations of hospital-based registry analysis, this study have provided valuable insights into clinical characteristics and treatment approaches of EU and LATAM populations.

1591P Gastric cancer in young patients under 40 years: 5-year analyses of Georgian cancer registry

T. Esakia[1], E. Smyth[2], M. Abuladze[1], E. Mariamidze[1], N. Sharikadze[3], M. Maglakelidze[1], K. Tsiklauri[1], T. Rukhadze[4]

[1]Oncology & Hematology Dept., Todua Clinic, Tbilisi, Georgia; [2]Gastrointestinal Oncology Department, Cambridge University Hospitals NHS Foundation Trust, Cambridge, UK; [3]Oncology Department, Mardaleishvili Medical Centre, Tbilisi, Georgia; [4]Faculty of Medicine, Ivane Javakhishvili Tbilisi State University (TSU), Tbilisi, Georgia

Background: Gastric cancer (GC) is 5th most common cancer and 4th most common cause of cancer death worldwide. The rate of GC in patients < 40 years in different countries is ∼ 5%. The incidence and characteristics of GC in <40 patients were not studied in Georgian population. We analyzed clinicopathologic features of early onset GC in Georgia.

Methods: In this study we analyzed data from national cancer registry of Georgia 2015-2021. The data included number of cases, age, sex, anatomic location, stage, pathology and treatment types of GC. Aim of the study was to investigate clinicopathologic characteristics, treatment approaches and survival rates of GC in patients <40 compared to entire cohort. Survival was summarized by Kaplan-Meier method.

Results: A total of 1775 patients with GC were included in the study during 2015-2021. Out of 1775 patients 52 (2,9%) were < 40 years. Median age 34 (17-39). In <40 patients 50% were female, while in entire cohort 62% were male. No differences were seen in anatomic location, tumor grade, stage. Stage III (25 % in <40 patients vs 29% in entire cohort) and IV (40% vs 43%) were most common. Differences were seen in pathologic types - not otherwise classified adenocarcinoma 31% in <40 patients vs 25% in entire cohort (P value 0.3367), not otherwise classified carcinoma 26 % vs 2% (P value <0.0001), signet ring carcinoma 17% vs 6% respectively (P value 0.0004). In entire cohort rate of undifferentiated carcinoma was 30% and tubular adenocarcinoma 16%, which were not seen in <40 patients. 23% of <40 patients vs 30% entire cohort had surgery (P value 0.2294) and 42% vs 30% chemotherapy (P value 0.0714). Median overal survival (OS) for patients <40 was 20 months (95% CI 9,0-30,0) and 13 months for entire cohort (95% CI 12,0-15,0) (p value — 0,1488).

Conclusions: This study showed, that in Georgian <40 patients GC is equally distributed between both sexes, while in the entire cohort it is slighlty more common in males. Pathologic types as not otherwise classified carcinoma and signet ring carcinoma were seen most frequently in <40 patients. <40 patients were slightly more likely to receive chemotherapy and surgery. However, median OS was <2 years for patients <40. Further studies are required to understand causes of early onset GC in Georgian patients and to improve survival.

Background: Early palliative care (PC) and regular use of patient self-reported symptoms at End-of-Life (EoL) have shown beneficial results on diverse quality of life (QoL) outcomes and survival. Effect on anticancer therapy (ACT) use is rarely investigated. The primary outcome in this cluster-randomized trial was use of ACT at EoL, i.e., last 3 months of life following a complex intervention in one arm (INT) versus conventional care in the other (CTR).

Methods: Hospitals were stratified on size prior to randomization. Patient eligibility was age $\geq$18, advanced stage solid tumours, starting last ACT line, estimated life expectancy $\leq$12 months. The intervention consisted of a physician educational program, compulsory PC referrals at inclusion, and patient symptom reporting (paper/digitally) prior to all consultations. Clinical data were recorded, and all patients completed postal QoL forms bimonthly. Follow-up was 1 year/till death, whichever came first.

Results: 616 (93%) patients were eligible (INT:309/CTR:307); 63% male, median age 69 (IQR 62-75), 71% with Karnofsky score (KPS) 80-100. 77% had gastrointestinal (GI) cancers. Median survival time from inclusion was 8 (IQR 3-14) and 7 months (IQR 3-12) (INT/CTR). Median number of days between ACT start and death was 188 (OQR 77-370). Median number of days between diagnosis, ACT start or stop, and death did not differ by group. 177 (28.7 %) patients received ACT in the last 3 months, 75 (12.1%) in the last month. Adjusted model for the time from ACT cessation to death was longer in INT (p=0.25; HR=0.81 95% CI 0.57-1.15) and in patients with high KPS at inclusion (p<0.001). No QoL differences across groups was found for those with complete measures at 2, 4 and 6 months (n=215). Physical function was significantly lower at 6 months, while insomnia improved (p <.05).

Conclusions: The intervention did not have the desired effect. This may be due to a relatively low national use of ACT at EoL in Norway. A lower proportion of GI cancers had been desirable. Additionally, the intervention was too general and maybe too focused on communication skills to exert a substantial influence on conventional clinical practice. We recommend close, continuous monitoring to secure adherence to study procedures.

Clinical trial identification: NCT01362816.

1593MO Combined early palliative care in patients with non small cell lung cancer: A randomised controlled trial in Chongqing, China

M. Chen[1], H. Yu[2]

[1]Clinical nutrition, Chongqing Cancer Hospital, Chongqing, China; [2]Department of Geriatric Oncology and Department of Palliative care, Chongqing Cancer Hospital, Chongqing, China

Background: Effective interventions to improve prognosis in non-small-cell lung cancer (NSCLC) are urgently needed. We assessed the effect of the early integration of interdisciplinary palliative care (based on Ewarm model) for patients with NSCLC on the quality of life (QoL), psychological state, cancer pain and nutritional status.

Methods: In this randomised controlled trial, 280 newly diagnosed NSCLC patients were enrolled and randomly assigned (1:1) to the combined early palliative care (CEPC) group integrated with standard oncologic care or standard oncological care (SC) group. QoL and psychological state were assessed at baseline and at 24 weeks by Functional Assessment of Cancer Therapy-Lung (FACT-L) scale, the Hospital Anxiety and Depression Scale (HADS) and Patient Health Questionnaire-9 (PHQ-9), respectively. Cancer nutritional and pain status were assessed with the use of the Patient-Generated Subjective Global Assessment (PG-SGA) and Numerical Rating Scale (NRS), respectively. The primary end point was overall survival (OS). The second end point was the change in the quality of life, psychological state, pain and nutritional status at 24 weeks. Analysis was by intention to treat.

Results: 280 patients were enrolled: 140 in CEPC group (102 completed) and 140 in the SC group (82 completed). CEPC group had a better QoL than SC group (all $P <$ 0.05). In addition, fewer patients in the CEPC group than in the SC group had depressive ($P <$ 0.05) symptoms. Furthermore, patients in CEPC group had a better nutritional status and pain than SC group (P =0.007 and P =0.003). Patients in the CEPC group had significantly longer survival than those in the SC group (median OS, 24.6 vs. 20.4 months; P=0.042) (HR, 0.19; 95% CI, 0.04 to 0.85; P=0.029).

Conclusions: Among patients with non-small-cell lung cancer, early palliative care led to significant improvements in longer survival, quality of life, psychological state, pain and nutritional status.

1594P End-of-life hospital cancer care in the COVID-19 era: A retrospective population-based study in the Netherlands

E. Slotman[1], H. Fransen[1], H.W.M. van Laarhoven[2], M.H. van den Beuken-van Everdingen[3], V. Tjan-Heijnen[4], A. Huijben[5], A. Jager[6], C. van Zuijlen[7], E. Kuip[8], Y. van der Linden[9], N. Raijmakers[1], S. Siesling[1]

[1]Research and Development, IKNL - Netherlands Comprehensive Cancer Organisation, Utrecht, Netherlands; [2]Medical Oncology Dept., Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands; [3]Centre of Expertise Palliative Care, Academisch Ziekenhuis Maastricht (AZM), Maastricht, Netherlands; [4]Medical Oncology Dept., Maastricht University Medical Center (MUMC), Maastricht, Netherlands; [5]Medical Oncology Dept., Maasstad Ziekenhuis, Rotterdam, Netherlands; [6]Medical oncology Department, Erasmus MC - Daniel den Hoed Cancer Center, Rotterdam, Netherlands; [7]Medical Oncology Dept, Amsterdam UMC - Vrije University Medical Centre (VUmc), Amsterdam, Netherlands; [8]Medical Oncology Department, Radboud University Medical Center, Nijmegen, Netherlands; [9]Department of Radiotherapy and Centre of Expertise in Palliative care, LUMC-Leiden University Medical Center, Leiden, Netherlands

Background: The COVID-19 pandemic impacted cancer diagnosis and treatment. However, little is known about end-of-life (EOL) cancer care during the pandemic. Therefore, the aim of this study was to investigate potentially inappropriate EOL hospital care in patients dying with cancer before and during the COVID-19 pandemic.

Methods: This population-based study used linked data from the Netherlands Cancer Registry and the Dutch National Hospital Care Registration. Patients deceased between January 2018 and May 2021, who were diagnosed with cancer or received hospital care for cancer in the year preceding death were included. Potentially inappropriate EOL care was compared between four periods during the COVID-19 pandemic and corresponding periods in 2018/2019. Six international indicators of potentially inappropriate care in the last month of life were used: chemotherapy

administration, >1 emergency room contact, >1 hospitalization, hospitalization >14 days, intensive care unit admission and hospital death.

Results: In total, 112,919 patients were included. Less patients received potentially inappropriate EOL hospital care during the COVID-19 pandemic compared to the preceding years, most pronounced during the first COVID-19 peak (22,4% vs 26,0%). Regression analysis showed lower odds of potentially inappropriate EOL care during all COVID-19 periods (ranging between OR 0.81; 95%CI:0.74-0.88 and OR 0.92; 95%CI 0.87-0.97) after adjusting for age, gender and cancer type. For the separate indicators, less patients experienced multiple or long hospitalizations, intensive care unit admission or a hospital death during the pandemic.

Conclusions: Cancer patients experienced less potentially inappropriate EOL hospital care during the COVID-19 pandemic. Because lack of capacity, patients avoiding hospital and increased awareness for triaging and advance care planning (ACP) may all have contributed, it is unclear whether this reflects better quality care. Nevertheless, retaining awareness for triaging and ACP is important because it may help provide appropriate EOL care to an increasing number of patients in the context of limited resources.

1595P Incidence and characterization of end-of-life (EoL) systemic anticancer therapy (SACT) in melanoma patients (pts): A monocentric experience

S. Buriolla[1], F. Pravisano[1], J. Costa[1], M. Alberti[1], G. Bortolus[1], G. Zapelloni[1], G. De Pieri[1], G. Targato[1], G. Pascoletti[2], F. Puglisi[1], G. Fasola[2], A.M.M. Minisini[2]

[1]Department of Medicine (DAME), University of Udine - Dipartimento di Area medica - DAME, Udine, Italy; [2]Department of Medical Oncology, ASU Friuli Centrale - Ospedale S. Maria della Misericordia, Udine, Italy

Background: The administration of SACT in the last month of life represents an indicator of poor quality of care and exposes subjects to unbalanced side effects with limited therapeutic benefit. As a result, the overuse of SACT at the EoL is associated with higher rates of downstream acute care, delayed hospice care and higher costs. A recent evaluation on a cohort of unselected cancer pts showed an increased use of target agents (TA) and immunotherapy (IT) at the EoL, while chemotherapy (CT) has declined since 2015. Overall, SACT use rate was 39% within 30 days of death. Few data are available in melanoma population.

Methods: We retrospectively retrieved data on date of death and last SACT in a cohort of stage IV melanoma pts treated between January 2013 and December 2022 at the Oncology Unit of the University Hospital of Udine. Type of last SACT, occurrence of acute event (AE) and incidence of Hospital admission in the last 30 days were recorded.

Results: Overall, 140 pts treated with SACT for stage IV melanoma were included, with prevalence of male (64%) and BRAF mutated pts (60%). Fifty-five pts (39%) started a new SACT in the last three months of life and 36% of pts (51/140) received the last dose of SACT during the last 30 days. As last therapy, mono-IT was administered in nearly one third of pts (35%), TA in 41% and CT in 14% of pts. Twenty-seven (53%) patients had brain metastasis and 63% presented with more than 2 metastatic sites at last SACT administration. With regards to hospitalization rate, 70% (36/51) of pts treated in the last month was hospitalized with only 3 pts (8%) referred to the Palliative care Unit. The majority of subjects was admitted due to an AE (77%). Overall, the median survival from the last dose of SACT was 1,7 months.

Conclusions: In our cohort of melanoma pts the rate of SACT within the last 30 days of life was consistent with the historical literature data across all cancer type. However, we found a higher rate of hospital admission in the population who received a dose of SACT in the last months of life, compared to untreated population in that period (70% vs 42%). In accordance with the current therapeutic scenario, chemotherapy has been playing a limited role in advanced stage melanoma pts, as well in the EoL setting.

1596P Exploring the economic impact of palliative care in oncology at the end of life

S.A. Gomes[1], F.S. Sorice[2], C.D. Bergerot[3], D.N.E. Silva[1], R.M. Peixoto[1], M. Costa e Silva[4], H.M. Oliveira[5], A.V. Nogueira[1], C.G.M. Ferreira[6], A. Andrade Dos Anjos Jacome[7], B.L. Ferrari[8]

[1]Palliative Care, Grupo Oncoclinicas - Oncocentro, Belo Horizonte, Brazil; [2]Palliative Care, Grupo Oncoclinicas, Sao Paulo, Brazil; [3]Multidisciplinary, Grupo Oncoclinicas, Sao Paulo, Brazil; [4]Big Data, Grupo Oncoclinicas, Sao Paulo, Brazil; [5]Palliative Care, Grupo Oncoclinicas - ONCOBIO, Nova Lima, Brazil; [6]Education and Research, Grupo Oncoclinicas Botafogo, Rio De Janeiro, Brazil; [7]Gastrointestinal Medical Oncology, Grupo Oncoclinicas, Sao Paulo, Brazil; [8]Clinical Oncology, Grupo Oncoclinicas - Oncocentro, Belo Horizonte, Brazil

Background: Palliative care has shown a positive economic impact in oncology. However, research on its financial viability in oncology, especially in developing countries, is lacking. This study estimates hospitalization costs for cancer patients in the southeast region of Brazil.

Methods: We used a retrospective analysis of electronic medical records for cancer patients treated at a Cancer Center in the southeast region of Brazil. Inclusion criteria were adult patients with any type of cancer who had died at a hospital setting between January 2022 and March 2023. Patients were divided into two groups: those who received outpatient palliative care (OPCT) and those who did not receive any OPCT. Based on the available clinical outcomes of the sample, data was collected on the hospital admission date, length of stay until death, and the type of accommodation until death [admission at intensive care unit (ICU) versus general ward]. To estimate the costs, we used real-world data from private hospitals in the southeast region, measuring the general amounts spent on daily hospitalization and ICU stays, and their respective lengths of stay, without reference to any specific patient or procedures. We performed univariate comparisons using Linear Regression.

Results: Out of the 72 patients with cancer, 29 were followed by the OPCT team, while 43 were not. The average cost of hospitalization for patients who did not receive the OPCT was found to be R$ 20,000.00 (€ 3,651.00; SD = 9.19) higher than those who received OPCT ($p = 0.03$). We observed that patients who were admitted to the ICU had hospitalization cost, on average, R$ 17,800.00 (€ 3,249.00; SD = 9.61) more than those who stayed in general ward ($p = 0.06$).

Conclusions: Our study highlights the economic benefits of providing OPCT in a developing country. Based on this analysis, OPCT can reduce healthcare costs by decreasing the length of hospital stay and preventing unnecessary ICU admissions. Our study suggest that policymakers and healthcare providers should prioritize the provision of OPCT in Brazil, and this type of support should be considered as an essential component of end-of-life care.

1597P Improving in-hospital end-of-life care (EOLC) for oncology patients in a tertiary cancer centre

C. Moloney[1], H.K. Carroll[1], E. Cunningham[2], M. Lyons[3], D. Nuzum[3], R. Bambury[1], D.C. Collins[1], R.M. Connolly[4], S. Iqbal[1], S.A. Noonan[1], D.G. Power[5], A. Lowney[2], M.J. O'Leary[2], S. O'Reilly[1]

[1]Department of Medical Oncology, CUH - Cork University Hospital, Cork, Ireland; [2]Palliative Care, Marymount University Hospital & Hospice, Cork, Ireland; [3]EOL Committee, CUH - Cork University Hospital, Cork, Ireland; [4]Cancer Research @UCC, University College Cork, Cork, MD, Ireland

Background: Cancer is the leading cause of death in Ireland, accounting for 28.5% of all deaths in 2021. Our aging population is predicted to drive a significant increase in new cancer cases in the coming decades. As such, high quality end-of-life care (EOLC) for patients dying in the acute hospital setting is an essential part of delivering holistic care to patients with cancer and their families. This is the second audit cycle to examine the quality of EOLC in one of the largest university teaching hospitals in Ireland. The first audit cycle, during the COVID-19 pandemic, identified several shortcomings in EOLC (ESMO 2022 : S1134).

Methods: A care of dying patients guidance document, EOLC quality checklist, and staff education huddles facilitated by the Hospital Palliative Care Team were introduced in July 2022. A second retrospective chart review of patients who died under the care of the medical oncology service between 11th July 2022 and 30th April 2023 was performed. Data on the quality of EOLC delivered was collected and assessed using the published Oxford Quality Indicators for mortality review. An overall score for EOLC between 1 (very poor) and 5 (excellent) was assigned to each patient. These were compared with the previously presented 2021 cohort.

Results: We identified 72 patients (41 female). The median age at death was 65 years [23-89]. The mean length of admission resulting in death was 15.2 days [0-118]. The mean quality score for EOLC was 4.0, compared to 3.5 pre-intervention. Exploration of patient wishes, and spiritual care were documented in 45.8% and 58.3% of cases

respectively, compared to 24.2% and 10.6% in the initial audit. 42 patients (58.3%) had care of the dying patient documents completed. The mean quality score for EOLC for these patients was 4.6, versus 3.2 for those without the document.

Conclusions: The quality of EOLC in our organisation has improved numerically in the second audit cycle. Areas of ongoing non-compliance to the Oxford Quality Indicators include exploration of patient wishes and spiritual care. The end-of-life committee, which now includes doctors in training, is committed to continuing to address deficits in the quality of EOLC in our institution, as an ESMO Designated Centre of Integrated Oncology and Palliative Care.

1598P Differences in referral patterns to the palliative care team among specialized physicians in patients with terminal cancer

H.J. Shim, I.J. Chung, S-H. Cho, W.K. Bae, J.E. Hwang, H.J. Bang, H-J. Kim, S.H. Lee

Hemato-Oncology, Chonnam National University Medical School & Chonnam National University Hwasun Hospital, Hwasun, Republic of Korea

Background: The importance of Hospice & Palliative care for patients with terminal cancer is well established. Although hospice use is increasing, the use of hospice services is still suboptimal. Previous studies reported that surgeons tend to underuse palliative care (PC) consultation. This study aimed to investigate potential variations in referral patterns to the PC team and differences in end-of-life care among specialized physicians in patients with terminal cancer.

Methods: A single-institution retrospective observational study of consecutive PC consultations within a National Cancer Institute-designated cancer center in 2020-2021 was conducted. We categorized specialized physicians into medical oncologists (MO) and non-medical oncologists (NMO), which include hematologists, gastroenterologists, surgical and radiation oncologists.

Results: We analyzed 1710 patients, 1130 were referred from MO and 580 from NMO. Patients in the NMO group had lower levels of prognostic awareness (PA) regarding their terminal cancer status compared to those in MO. 44.7 % of patients in the MO group and 16.2 % of patients in the NMO group had accurate PA ($p<0.01$). The median survival from a day of PC consultation was 40.7 days for all, 47.3 days for the MO group, and 28 days for NMO group ($p = 0.00$). The survival time after planning Advance Directives was 100 days for all, significantly longer in the MO group (131.2 vs. 54.9 days, $p=0.00$). The median time from notification of discontinuation of active cancer treatment to PC consultation was 40 days. The interval to PC consultation was significantly longer in patients referred from the NMO group (92.6 days in the NMO group vs. 13.5 days in the MO group, $p=0.00$). The rate of discharge to specialized inpatient hospice facilities or home hospice was higher in the MO group. However, the discharge rate to acute-stage hospital, ICU was higher in the NMO group.

Conclusions: There was significant variation in referral patterns to the PC team according to a division of physicians. NMO patients had a lower level of prognostic awareness (PA) compared to MO patients. Late referrals to the PC team were observed in the NMO group. This suggests a need for increased education and training in palliative care for the NMO.

1599P Clinical predictors of 30-day mortality in hospitalized patients with lung cancer: A retrospective single-center observational study

Leonetti[1], M. Peroni[2], V. Agnetti[2], F. Pratticò[2], M. Manini[1], A. Acunzo[2], F. Marverti[2], S. Sulas[2], E. Rapacchi[1], G. Mazzaschi[2], F. Perrone[1], P. Bordi[1], S. Buti[1,2], M. Tiseo[1,2]

[1]*Medical Oncology, University Hospital of Parma, Parma, Italy;* [2]*Department of Medicine and Surgery, University of Parma, Parma, Italy*

Background: Lung cancer patients experience high rates of hospitalization, mainly due to the high risk of complications that emerge during the natural history of disease. We designed a retrospective single-center observational study aimed at defining clinical predictors of 30-day mortality in hospitalized lung cancer patients.

Methods: Clinical records from the first admission of lung cancer patients to the Oncology ward of University Hospital of Parma from January 1st, 2017, to January 1st, 2022, were collected.

Results: 251 patients were consecutively enrolled. Median age was 66 years (Range, 29-85). 161 (64.1%) patients were men and 217 (86.5%) current/former smokers. ECOG PS was 0-1 in 182 (72.5%) cases. The most frequent histology was adenocarcinoma (n=120, 47.8%), followed by small-cell carcinoma (n=73, 29.0%), and the majority of patients had stage IV disease (n=209, 83.3%). Main reasons for hospital admission were anticancer treatment start (n=146, 58.2%) and cancer-related complications (n=75, 29.9%). The most frequently symptoms at admission were pain (n=131, 52.2%) and dyspnea (n=92, 36.7%). Median Blaylock Risk Assessment Screening Score (BRASS) was 7 (Range, 1-28). Clinical deterioration (n=102, 40.6%) was the main complication during the hospital stay. Baseline clinical predictors of 30-day mortality were poor ECOG PS ($\geq$ 2 vs 0-1: 27.5% vs 14.8%, $p=0.028$), high BRASS (High vs Intermediate-Low: 34.3% vs 11.9%, $p<0.001$), high number of metastatic sites ($\geq$ 3 vs $<$ 3: 26.5% vs 13.4%, $p=0.017$), presence of bone metastases (Yes vs No: 29.0% vs 10.8%, $p=0.001$) and presence of pain (Yes vs No: 24.4% vs 11.7%, $p=0.009$). At multivariate analysis, only high BRASS remained significantly associated with higher 30-day mortality (BRASS High vs Intermediate-Low Odds Ratio 2.87, 95% CI 1.21-6.78, $p=0.016$).

Conclusions: Baseline poor ECOG PS, high BRASS, high tumour burden, presence bone metastases and pain were associated with increased 30-day mortality in hospitalized lung cancer patients, with high BRASS being statistically significant at multivariate analysis. Our study draw attention on BRASS as a new feasible potential indicator of 30-day mortality in hospitalized lung cancer patients.

1600P Sarcopenia, depression, and poor health perception among cancer patients registered in an oncology center in Pakistan

S. Yaqub[1], M.A. Khokhar[1], G. Abid[2], M. Naveed Sheikh[1], M. Farrukh Dar[1], I. Asif[1], G. Naseem[1]

[1]*Medical Oncology & Radiotherapy Dept., King Edward Medical University, Lahore, Pakistan;* [2]*Biostatistics, Kinnaird College for Women, Lahore, Pakistan*

Background: Sarcopenia is a disorder that causes muscle mass and strength loss, which can result in diminished mobility and functional limits. Depression and a bad assessment of one's own health are common results among cancer patients. As a result, this study aimed to look at the association between sarcopenia, depression, and health perception.

Methods: Cancer patients were the subject of a retrospective study from January to April 2023. The study included 150 patients who had different forms of a verified cancer diagnosis. These individuals were admitted to Mayo Hospital's Palliative Care Cancer Department. The presence of depressive symptoms was assessed using the Patient Health Questionnaire (PHQ-9). SARC-F was used to measure all the five dimensions of sarcopenia. To examine self-perceived health, a self-report questionnaire was used. The relationships between sarcopenia, depression, and health perception were investigated using correlation analysis.

Results: We observed a significant and positive association between depression and the dimensions of sarcopenia. Specifically, we found a positive correlation between depression and SARC1=Strength ($r = 0.378$, $p<0.01$), SARC2=Assistance in walking ($r = 0.390$, $p<0.01$), SARC3=Rise from a chair ($r = 0.488$, $p<0.01$), and SARC4=Climb stairs ($r = 0.392$, $p<0.01$). However, we found a positive but insignificant relationship between depression and SARC5=Falls ($r = 0.150$, $p>0.05$). In addition, we discovered that patients' perception of poor health was correlated with depression ($r = -0.391$, $p<0.01$), SARC2=Assistance in walking ($r = -0.235$, $p<0.01$), SARC3=Rise from a chair ($r = -0.259$, $p<0.01$), and SARC4=Climb stairs ($r = -0.277$, $p<0.01$). However, we did not find a significant relationship between health perception and two dimensions of sarcopenia (i.e., SARC1=Strength and SARC5=Falls).

Conclusions: Sarcopenia adversely affects the physical and mental health of cancer patients. They feel depressed and perceive their health as bad which imparts a negative impact on the outcome of these patients.

1601P Relationship between CT and ultrasonography-based sarcopenia and hematologic toxicity in patients with cancer receiving chemotherapy

G. Guner[1], A. Erdemir[2], M.R. Onur[2], B.Y. Aktas[1], D.C. Guven[1], M. Kara[3], L. Özçakar[3], O. Dizdar[1]

[1]Department of Medical Oncology, Hacettepe University Cancer Institute, Ankara, Turkey; [2]Department of Radiology, Hacettepe University Faculty of Medicine, Ankara, Turkey; [3]Department of Physical and Rehabilitation Medicine, Hacettepe University Faculty of Medicine, Ankara, Turkey

Background: Sarcopenia is a common condition among cancer patients. The aim of this study is to investigate the potential relationship between sarcopenia and hematologic toxicity in cancer patients by evaluating skeletal muscles with computed tomography (CT) and ultrasound (US) before chemotherapy.

Methods: A prospective cohort study was conducted on cancer patients who received anthracycline-based chemotherapy between 2018 and 2020 and had baseline abdominal CT containing L3 level for measuring skeletal muscle index (L3 SMI) and/or muscle US were included. Sex-specific cut-offs for L3 SMI were used for diagnosis of sarcopenia. Sex- and body mass index—adjusted sonographic thigh adjustment ratio (STAR) values (cut-off values 1.0 for female patients and 1.4 for male patients) were used for US assessment of sarcopenia.

Results: A total of 65 patients (14 male, 51 female) were included; 40 (61.5%) with breast cancer, 17 (26.2%) with lymphoma, and 8 (12.3%) with sarcoma. Mean age was 46.3 $\pm$ 14 years. Sarcopenia was determined in 13 patients (20%) according to CT, and in 10 patients (15.4%) according to US assessment. Regarding acute toxicity, patients with sarcopenia according to CT L3-SMI value had a significantly higher incidence of grade $\geq$ 3 neutropenia (39% vs 12%, p = 0.045) but similar level of thrombocytopenia (%3 vs %0, p > 0.9) after the first cycle of chemotherapy compared to non-sarcopenic patients. Patients with sarcopenia based on STAR values also had a significantly higher incidence of grade $\geq$ 3 neutropenia (50% vs 16%, p = 0.03) and higher incidence of grade $\geq$ 3 thrombocytopenia (10% vs 0%, p = 0.15) after the first cycle of chemotherapy compared to non-sarcopenic patients.

Conclusions: We found a significant association between sarcopenia diagnosed by CT and US and hematologic toxicity. Routine CT scans performed for cancer staging may help clinicians identify high-risk patients and facilitate closer monitoring of side effects and earlier introduction of supportive measures. US based assessment of sarcopenia also has high diagnostic accuracy and may predict neutropenia risk. US may serve as an easy-to-use, point of care tool for assessing sarcopenia with the advantage of repeated sequential assessment.

1602P Simulation training for compassionate extubation in the pediatric intensive care unit

N. Fernandez

Pediatrics, Memorial Sloan Kettering Cancer Center, New York, NY, USA

Background: When a child has a life-limiting, irreversible condition such as advanced cancer, a healthcare team and family may decide to limit care lacking clear benefit. In such circumstances, a compassionate extubation, or discontinuation of life-sustaining ventilator support allowing natural death, may be pursued. Compassionate extubations are an infrequently performed procedure with complexities that include difficult conversations and dynamic symptom management which can lend to this being a challenging process to execute, particularly without opportunity for practice. Simulation can be a helpful tool to enhance knowledge, confidence, and preparedness with unfamiliar or uncommon scenarios in a safe environment. A compassionate extubation simulation training experience focusing on the conversational and technical skills was implemented within the Pediatric Intensive Care Unit at an academic medical center in New York City. The aim of the project was to determine whether participation in one simulation training improved healthcare providers' confidence with performing a compassionate extubation.

Methods: A one group pretest-posttest design project was implemented using The Confidence Scale to evaluate RN and APRN confidence with performing a compassionate extubation before and after the simulation. The sample was described using descriptive statistical analysis and the Wilcoxon signed-rank test was used to evaluate for differences between first and second observations.

Results: A Wilcoxon signed-rank test determined that the compassionate extubation simulation elicited a statistically significant median increase in C-Scale scores after participation in the simulation (*median* = 20) compared to C-Scale scores prior (*median* = 12), $W = 45$, $p = 0.007$.

Conclusions: Affording opportunity for healthcare providers to sculpt and refine their practice with certain challenging clinical scenarios has been shown to improve their confidence navigating these situations. All efforts to improve confidence related to sensitive situations such as with a compassionate extubation are made with the intention of improving the experience of children at the end of their lives as well as the experiences of the families and loved ones who walk this journey with them.

1603P The ability of the LACE index to predict 30-day readmissions in oncology patients

B. Ulas Kahya, O. Yazici, O. Sutcuoglu, N. Ozdemir, N. Günel, A. Uner, G. Savaş, D. Ercan Uzundal, A. Özet

Medical Oncology Department, Gazi University - Faculty of Medicine, Ankara, Turkey

Background: The LACE index predicts readmission within 30 days. We evaluated the success of this score in oncological patients for whom hospitalisation is a common condition.

Methods: Between February and July 2022, 188 patients hospitalised in the oncology service of a tertiary referral university hospital were retrospectively screened. Patients admitted for chemotherapy and day care procedures, patients who died during hospitalisation, and subsequent hospitalisation within a month were excluded. LACE scores of the patients were calculated using the length of stay, acuity of the admission, Charlson comorbidity index and emergency Department use six months before admission.

Results: A total of 60 patients were included in the study. Thirty-six (60%) of the patients were under 65 years of age. Most of the patients admitted had gastrointestinal system cancer (n=27, 45%) and lung cancer (n=14, 23.3%), respectively. Twenty-two (36.7%) patients were hospitalised due to infection, and 38 (63.3%) were for palliative care. The median hospital stay of the patients was ten days (min-max: 2-65). The median LACE score of the patients was 11.5 (min-max: 6-16). Fifty-two (% 86.7) patients had a high LACE score, eight were in the moderate group, and none were in the low-risk group. Thirty-three (63.5%) of 52 patients with high LACE scores were readmitted to the hospital within 30 days. This rate was statistically significantly higher (p = 0.040) than the moderate group (n=2, 25%). While 55.8% of the patient group with a high LACE score died within 90 days, this rate was (37.5%) in the moderate patient group (p = 0.33).

Conclusions: The LACE index predicted one-month readmission in oncology patients but was insufficient to predict one-month death.

1604P A comparative study of symptom prevalence between adults and elderly patients with advanced cancer diagnosis under palliative care: A single institution experience

H.M. Abdullah[1], A. Allam[2], S. Alkeldi[3], Z. Idris[3], A. Hassan[2]

[1]Nursing, Hamad Medical Corporation (HMC) - National Center for Cancer Care and Research (Al Amal Hospital), Doha, Qatar; [2]Palliative care, Hamad Medical Corporation (HMC), Doha, Qatar; [3]Nursing, Hamad Medical Corporation (HMC), Doha, Qatar

Background: Analysis of the most common prevalent symptoms among patients with advanced cancer diagnosis is needed in order to reach the most appropriate interventions leading to improved quality of life of these patients. The aim of this study is to report on the overall symptom prevalence among patients with advanced cancer diagnosis under palliative care and to analyze the difference of symptom prevalence between elderly ($\geq$ 65 years) and adult (<65 years) patients.

Methods: A retrospective cohort study of 400 patients with advanced cancer who were admitted under palliative care between 1st January 2017 to December 31st, 2021. Data were retrieved from electronic medical records.

Results: Anorexia (91%), fatigue (98%), drowsiness (84%) and pain (83%) were the highest 4 prevalent symptoms for the whole group, followed by depression (76%) and anxiety (72%). Adult patients had significant higher pain (80% versus 76%), depression (83% versus 68%) and anxiety (77% versus 65%), compared to elderly ($\geq$ 65 years) patients. On multivariate analysis, pain only was significantly higher in adult patients (p=0.021). The reported percentage of symptom prevalence for the whole group is higher than that in the literature, indicating late referral to palliative care.

Conclusions: There is a high percentage of symptom prevalence among our patients and a short median overall survival that indicates late referral to palliative care. Adult patients had significantly higher pain, depression, and anxiety compared to elderly

patients. An earlier integration of palliative care is recommended in the overall management of our patients.

1605P The impact of cancer pain on survival of lung cancer patients receiving immune checkpoint inhibitors

S. Wang[1], Z-H. Ye[1], J. Zhang[2], T.T.L. Lee[3], A.K.C. Wai[3], F. Kong[1]

[1]Clinical Oncology, The University of Hong Kong - Li Ka Shing Faculty of Medicine, Hong Kong, China; [2]State Key Laboratory of Ultrasound in Medicine and Engineering, Chongqing Medical University, Chongqing, China; [3]Emergency Medicine, The University of Hong Kong - Li Ka Shing Faculty of Medicine, Hong Kong, China

Background: Pain is one of the most common symptoms experienced by cancer patients. Previous studies have shown that unrelieved cancer pain can affect the quality of life dramatically and is associated with worse survival in patients with cancer, including lung cancer. Non-opioid analgesics are often used in the management of cancer pain. Yet whether the usage of non-opioid analgesics can affect the survival of lung cancer patients receiving immune checkpoint inhibitors (ICIs) remains undetermined.

Methods: We identified 910 patients with records of at least two cycles of ICI prescription with or without records of non-opioid analgesics prescription between 2018 and 2020 within the Clinical Data Analysis and Reporting System of Hong Kong. Kaplan-Meier curves and Cox proportional hazards regression analysis were used to compare the overall survival (OS) of patients who received ICI with non-opioid analgesics versus those without.

Results: In total, 765 (84.1%) and 145 (15.9%) patients with lung cancer received ICI with or without non-opioid analgesics, respectively. The median follow-up time was 35.9 months (95% CI: 34.7-37.3 months). Patients with records of non-opioid analgesics prescriptions had significantly shorter OS than those without (13.4 vs 40.5 months, $p < 0.0001$). In Cox regression analysis, ICI with a history of non-opioid analgesics usage was associated with a significantly worse prognosis. (HR = 2.42, 95% CI: 1.86-3.10, $p < 0.001$).

Conclusions: Lung cancer patients who received ICI with a history of non-opioid analgesics usage had shorter survival than those without. Patients with a history of non-opioid analgesics usage are likely to have cancer pain or suboptimal tumour control, which were associated with a worse prognosis.

1606P Sarcopenia, depression, and modes of feeding among cancer patients

M.A. Khokhar[1], S. Yaqub[1], G. Abid[2], I. Asif[1], M. Farrukh Dar[1], M. Naveed Sheikh[1], G. Naseem[1]

[1]Department of Medical Oncology and Radiotherapy, King Edward Medical University, Lahore, Pakistan; [2]Biostatistics, Kinnaird College for Women, Lahore, Pakistan

Background: Sarcopenia refers to the loss of muscle mass and strength that occurs with aging and due to some medical conditions like cancer. Depression and inability to eat without assistance are common effects documented in cancer patients with sarcopenia. As a result, the goal of this study was to look into the relationship between sarcopenia, depression, and modes of feeding.

Methods: During the period beginning in January 2023 and ending in April 2023, cancer patients participated in a retrospective study. There has been a total of 150 participants enrolled in the trial, all of whom have been diagnosed with cancer. These people were enrolled in Mayo Hospital's Palliative Care Cancer Department in order to receive treatment. The Patient Health Questionnaire (PHQ-9) was used to determine the presence of depressive symptoms. The SARC-F was utilized to assess sarcopenia across all five dimensions. A self-report measure was utilized to assess modes of feeding [options include: 1) unable to eat without assistance 2) (self-fed with some difficulty, and 3) self-fed without any problem]. Sarcopenia, major depressive disorder, and feeding modes were studied using correlation analysis.

Results: We have observed a significant and negative association between modes of feeding and depression ($r=-0.459$, $p<0.01$), SARC1=Strength ($r = -0.326$, $p<0.01$), SARC2=Assistance in walking ($r = -0.196$, $p<0.05$), and SARC3=Rise from a chair ($r = -0.238$, $p<0.01$). These findings show that cancer patients are unable to eat without assistance when they suffer from sarcopenia which ultimately leads to more depressive symptoms.

Conclusions: Sarcopenia has a negative impact on the quality of life of patients, leading to depression and dependence on daily activities like self-eating which further complicates management.

1607P Patient perceptions of the efficacy, safety, and quality of the evidence available on medicinal cannabis: A survey of Australian cancer patients - comparing users to non-users

J. Taylor[1], J. Lynam[1], B. Britton[2], J. Martin[2], M. Carlson[2], P. Bridge[2], G. Watts[2], S. Morris[2], E. Fradgley[2]

[1]Dept of Medical Oncology, Calvary Mater Hospital Newcastle, Newcastle, NSW, Australia; [2]School of Medicine and Public Health, The University of Newcastle, Callaghan, Australia

Background: Despite the increased demand [8], and accessibility [5], to medical cannabis (MC) there is a general consensus among physicians that evidence on its efficacy [10,12,13], and safety [4,11], is lacking. Although research has been undertaken to explore medical professionals' perceptions of the: benefits, risks, and evidence of MC in general [10], and specifically in a cancer setting [12,13]; there is minimal research exploring patients' perceptions, particularly in a cancer setting [14,15,16].

Methods: We conducted a prospective cross-sectional questionnaire of Australian cancer patients' attending adult oncology outpatient clinics between April 2019 to March 2020.

Results: 350 patients completed the survey; 19% being MC users. Demographics significantly associated with use were male gender ($P <.05$) and tobacco smoking ($P<.01$). The most common indication for use was pain (61%). Over 85% of all patients, regardless of using, had accessed some form of information on MC, but only a minority received such information from their healthcare team; relying instead on resources like: friends, TV, and social media. Interestingly, despite using MC, and generally scoring it as highly beneficial, most users "disagreed", that there was high quality evidence to support this.

Conclusions: To our knowledge, this is the first study exploring cancer patient's perceptions of: the evidence for MC, the sources of information used to shape their health beliefs, and which directly compares users to non-users. Surprisingly, our results showed that despite using MC, and believing it worked for them as individuals, the majority of users felt the evidence was not high quality. Concerningly, a high proportion of patients believe MC has anti-cancer activity; and are relying on information provided by resources other than traditional healthcare providers, which are considered unreliable [23, 24]. We hope that our results highlight the need for the treating team to combat potential misinformation that patients may be receiving on MC and link them to the palliative care team for treatments with greater evidence.

1608P Albumin-myosteatosis gauge as a prognostic factor in patients with advanced pancreatic cancer undergoing first-line chemotherapy

O. Dizdar[1], T.K. Sahin[2], Y. Ozbay[3], A.Y. Altunbulak[3], H.İ. Altunbulak[3], M.R. Onur[3], F. Ceylan[4], D.C. Guven[1], S. Yalcin[1]

[1]Department of Medical Oncology, Hacettepe University Cancer Institute, Ankara, Turkey; [2]Department of Internal Medicine, Hacettepe University Faculty of Medicine, Ankara, Turkey; [3]Department of Radiology, Hacettepe University Faculty of Medicine, Ankara, Turkey; [4]Department of Medical Oncology, Ankara City Hospital, Ankara, Turkey

Background: Sarcopenia and myosteatosis have been associated with a poor prognosis for certain cancers. The albumin-myosteatosis gauge (AMG) is a novel integrated measure proposed to assess myosteatosis along with serum albumin level as a surrogate of systemic inflammation. The aim of this study was to investigate the prognostic value of AMG in patients with advanced pancreatic cancer (APC).

Methods: Patients with APC treated with chemotherapy between 2013 and 2022 were evaluated. Skeletal muscle index (SMI) and skeletal muscle radiodensity (SMD) were calculated using computed tomography at the L3 level. The AMG was defined as SMD $\times$ albumin and expressed as an arbitrary unit (AU). Patients were categorized

into two groups by sex-specific cut-off value according to the AMG. Univariate and multivariate Cox analyses were performed for survival analysis.

Results: A total of 196 patients were included. The median age (interquartile range) was 62 (54-67), and 128 (65.3%) were male. ECOG PS was 0/1/2 in 48%/46%/6% of the patients, respectively. At presentation, 79% of patients had metastatic disease, and 21% had locally advanced disease. With regard to AMG, 142.86 and 114.15 AU were identified as cut-off values for males and females, respectively. The patients with low AMG had significantly poorer OS than those in high AMG group (median: 8.33 vs. 12.93 months, p=0.040). In multivariable analyses, lower AMG values (HR: 1.61, 95% CI: 1.17-2.21, p=0.003), higher ECOG performance score (>0 vs 0) (HR: 1.51, 95% CI: 1.10-2.06, p=0.009) and metastatic disease (vs. locally advanced) (HR: 1.88, 95% CI: 1.27-2.79, p=0.001) were associated with decreased OS (see table).

Table: 1608P

Variable	Multivariate analysis		
	HR	95%CI	p value
ECOG status (>0 vs. 0)	1.51	1.10-2.06	0.009
Stage at diagnosis (metastatic vs locally advanced)	1.88	1.27-2.79	0.001
Sarcopenia	1.33	0.96-1.83	0.081
Albumin-myosteatosis gauge (G1-G2 vs. G3-G4)	1.61	1.17-1.21	0.003

Conclusions: This study suggests strong prognostic value for AMG in patients with APC undergoing first-line chemotherapy. Further studies are warranted to validate these findings and assess potential predictive role in guiding treatment.

1609P A machine learning-based prognostic model to predict survival in patients with advanced cancer admitted to an acute palliative care unit

E.H. Jung[1], Y. Park[2], Y.J. Kim[1], S. Yi[2], K. Kim[2], J. Oh[2], S. Lee[3], B. Kang[4], K.J. Suh[1], J.Y. Lee[1], J-W. Kim[1], S.H. Kim[1], J.W. Kim[1], J-O. Lee[1], K-W. Lee[1], J.H. Kim[1], S-M. Bang[1], J-S. Lee[1]

[1]Internal Medicine Department, Seoul National University Bundang Hospital, Seongnam, Republic of Korea; [2]R&D Department, C51 Inc, Seoul, Republic of Korea; [3]Palliative Care Center, Yonsei Cancer Center Yonsei University, Seoul, Republic of Korea; [4]Medical oncology, CHA Bundang Medical Center, Seongnam, Republic of Korea

Background: Although accurate prognostication is very important to assist with patients with advanced cancer at the end-of-life (EOL), current prognostic models have several limitations. We aimed to develop a machine learning (ML)-based prognostic model to predict survival at 2 weeks, 1 month, and 2 months in patients with advanced cancer referred to palliative care specialists.

Methods: A total of 2,104 consecutive patients admitted to the acute palliate care unit (APCU) in a single tertiary cancer center between April 2015 and December 2019 were selected for analysis. Variables for developing the ML algorithm included age, gender, performance status, cancer type, body mass index, laboratory findings, and Edmonton Symptom Assessment System scores. Analysable patients (N=2,084) were divided into training set (N=1,667) and validation set (N=417), and the performance of the ML algorithm model was evaluated by accuracy, sensitivity, precision, specificity, area under the receiver-operating characteristic curve (AUROC), and area under the precision-recall curve (AUPRC).

Results: Among 2,084 patients, the median age was 67 years, 865 (41.5%) patients were female, and the most common cancer type was lung cancer (20.4%). As for the final performance of the ML algorithm, the ensemble model using gradient boosting, random forest, and logistic regression was the best in terms of AUROC and AUPRC. The AUROC and AUPRC for predicting 2-week, 1-month, and 2-month survival were 0.84, 0.79, 0.79, and 0.66, 0.77, 0.92, respectively. Because our data cannot reflect all characteristics of patients with imminent death, AUPRC was relatively low in 2-week mortality model. More precise results could be obtained by deep learning with multilayer perceptron using soft labelling (AUPRC 0.90).

Conclusions: Our study demonstrated ML-based prognostic models capable of predicting short-term survival of 2 weeks, 1 month, and 2 months in patients with advanced cancer admitted to an APCU. Integrating these models in the real-world may help patients nearing the EOL to make timely clinical and personal decisions.

1610P A new updated prognostic index for patients with brain metastases (BM) treated with palliative whole brain radiotherapy (WBRT) in the era of precision oncology: METASNCore project

P. Flores Paco[1], M.L-H. López[1], I. Lopera[2], A. Vargas Aliaga[1], G.M. Guevara[1], L. Rodríguez Ruiz[3], J.A. Camús[3], J.L. González[1], E.D. Inga Saavedra[1], M. Montero Gómez[1], A. Palacios[3], J. De la Haba Rodriguez[4], E. Aranda Aguilar[5]

[1]Medical Oncology, Hospital Universitario Reina Sofía, Córdoba, Spain; [2]Medical School, Universidad de Cordoba, Cordoba, Spain; [3]Radiaton Oncology, Hospital Universitario Reina Sofía, Cordoba, Spain; [4]New therapies in cancer, IMIBIC - Instituto Maimónides de Investigación Biomédica de Córdoba, Córdoba, Spain; [5]Medical Oncology, Hospital Universitario Reina Sofía, Córdoba, Spain Department of Medical Oncology IMIBIC, Universidad de Córdoba, CIBERONC, Instituto de Salud Carlos III, Córdoba, Spain

Background: Palliative WBRT is the main treatment for multiple brain metastases. Recent studies report no benefit in survival after WBRT compared to palliative supportive care in patients (pts) with poor prognosis. The purpose of this study is to develop and statistically validate a prognostic score in palliative pts with BM who undergo WBRT and compare it with previous scores.

Methods: 239 pts with BM who received palliative WBRT between 2013-2022 in our center were analyzed retrospectively. The score was designed according to the value of the β coefficient of each variable with statistical significance in the multivariate model. Once the score was established, a comparison was performed according to Kaplan-Meier and was analyzed by log-rank test. We also studied the concordance between MetaSNCore and the RPA scale (gold standard). Finally, METASNcore was validated in a different sample of 100 patients.

Results: 149 pts (62.3%) were male and median (m) age was 60 years. 139 (58,2%) were lung cancer and 35 (14,6%) breast cancer. All patients received 30Gys in 10 sessions. 37 pts (15,5%) had a specific target mutation and mOS was 3,74 months. Each point in the score is associated with a HR 1.243 (CI 95% 1.164 - 1.329) (p<0.001) (Table). 144 pts were in group "good prognosis" (up to 7 points) with mOS 4.9ms (CI 95% 3.94 - 5.8); 92 in group "bad prognosis" (above 7) with mOS 2.73ms (CI 95% 1.93 - 3.5) (p<0.001). After RPA concordance analysis, METASNcore had a specificity of 88.5% (CI 95% 82.9-94.2) and a sensitivity of 68.4% (CI 95% 59.9-77). We also found statistically significant differences in the validation sample (mOS 4.6ms (CI 95% 3 - 6.2) versus mOS 1.45ms (CI 95% 1.16 - 1.74)) (p<0,05).

Table: 1610P

VARIABLE	SCORE
ECOG >= 2	1
Gastrointestinal cancer	3
Urothelial cancer	2
Progression on known BM	2
No indication of systemic treatment after WBRT	3
Target mutation treatment received before WBRT	2
Protein C reactive (>20)	2

Conclusions: The variables in our cohort included in METASNCore are independently associated with OS and could be useful for selecting palliative patients who are candidates for WBRT. Further studies are needed to corroborate our findings.

1611P Family carers' experiences with brain metastases: A longitudinal qualitative study

T. Lundeby[1], N. Aass[1], S. Andersen[2], S.B. Hanssen[1], M.J. Hjermstad[1], S. Kaasa[1], G. Kitzmüller[3], T.E. Wester[1], B. Ervik[2]

[1]Department of Oncology, Oslo University Hospital, Oslo, Norway; [2]Department of Oncology, University Hospital of North Norway, Tromso, Norway; [3]Department of Health and Care Sciences, UiT, The Arctic University of Norway, Tromso, Norway

Background: Living with brain metastasis (BM) causes distress for patients and family carers. Patients report a wide range of physical, social and psychological problems that affect daily life for them and their families. Despite the high prevalence of BM, little is known about the experiences of family carers. This qualitative study explores how family carers of BM patients perceive the information and communication about diagnosis, the health care services provided, and how their lives are affected by the BM.

Methods: This was a prospective qualitative study with individual semi-structured interviews. Participants were interviewed three times; shortly after the BM diagnosis, and then after two and four months. A total of 40 interviews with 18 adult family carers (13 spouses, 2 adult children, 2 siblings) were conducted. Transcripts were analysed using a reflexive thematic analysis. A trajectory matrix was developed for the longitudinal design, searching for overarching themes over time as well as changes in the themes identified.

Results: For many family carers the BM diagnosis was experienced as particularly frightening, given that the metastases were located in the brain. Family carers felt that they lived in a rapidly changing, chaotic and unpredictable situation. They reported working nonstop to coordinate family life, the patient's health care follow-up, and to maintain a sort of normality in daily life. The situation affected their relationship with the patient, especially daily life activities and communication. The need for information was extensive among most family carers. They emphasized a need for more information about treatment and prognosis to be able to plan for the future. This information need remained high through all interviews.

Conclusions: Being a family carer of a patient with BM implies extensive practical, emotional and psychosocial challenges. The need for continuous information is particularly high, and health care providers should tailor their information to the individual recipient. Palliative care, with a person-centred approach and systematic follow up of the needs of family carers, should be introduced in an early stage.

1612P Demonstrating the complexity of need and the effectiveness of integrated palliative care: An analysis of routinely collected patient centred outcome measures

J. Hayes[1], J.M. Droney[2], J.E. Wood[2], A. Farley[1], E. Collard[1], A. Halley[2], L. Kamal[2]

[1]Symptom Control and Palliative Care Department, The Royal Marsden Hospital, Sutton, UK; [2]Symptom Control and Palliative Care Department, The Royal Marsden Hospital, London, UK

Background: Patient centred outcome measures (PCOMs) are increasingly used to structure proactive symptom assessment and help centre care around the specific needs of the patient. This study aimed to review the use of PCOMs as part of the routine care of inpatients reviewed by the integrated palliative care team in a specialist cancer centre.

Methods: Anonymised electronic palliative care PCOM data were retrieved for inpatients between 7/4/2021 to 31/01/2023, including Integrated Palliative Outcome Scale (IPOS), ECOG performance status, Australian Karnofsky Performance Status (AKPS) and Phase of Illness (POI). Descriptive statistics were used to define the complexity of palliative care needs based on IPOS, PS and POI. The effectiveness of the integrated palliative care service was evaluated by examining the difference between PCOM at initial and follow up assessment.

Results: Digital PCOM records for 1115 episodes of inpatient care were included, of which 391 had follow up data. On initial assessment 63% (703) patients had ECOG PS of 3 or 4 and 77% (864) had AKPS of less than 70. The most prevalent physical symptoms were weakness (84%, 1265), pain (80.7%, 1215), and poor mobility (72.3%, 1089). The most prevalent psychosocial symptom was family or friends feeling anxious or worried (85.8%, 1292). 83% (1250) had at least one palliative care need of severe or overwhelming intensity on initial assessment. 67.5% (753) were in an unstable POI on initial assessment, requiring urgent input. On follow up 92% (328) patients were in a stable, deteriorating or dying POI with no change to the care plan required. In patients with initial moderate to overwhelming symptoms, pain improved in 74%, nausea improved in 84%, vomiting improved in 93%, and constipation improved in 68% at follow up.

Conclusions: The high prevalence of physical and psychosocial symptoms demonstrates the complexity of needs and provides evidence of the requirement for integration of specialist palliative care services in cancer centres. The improvement in symptom scores between initial and follow up assessment demonstrates the effectiveness of integrated palliative care for cancer centre inpatients.

1613P The BreakThrough cancer malnutrition

S. De Santis[1], G. Nazzicone[2], F. Petricola[3], O. Bacciu[4], F. Scarcella[5], A. Amadei[1], G. Tonini[6], M. Roselli[7], C. Garufi[8]

[1]Palliative care Service, Azienda Ospedaliera San Camillo Forlanini, Rome, Italy; [2]UOC Oncologia, Ospedale San Pietro Fatebenefratelli, Rome, Italy; [3]UOCP/HOSPICE, Istituto Chirurgico Ortopedico Traumatologico (ICOT) Gruppo GIOMI, Latina, Italy; [4]Oncologia Medica, Azienda Ospedaliera San Giovanni Addolorata, Rome, Italy; [5]UOC Oncologia, Ospedale San Camillo De Lellis ASL Rieti, Rieti, Italy; [6]UOC Oncologia, Policlinico Universitario Campus Bio-Medico, Rome, Italy; [7]UOSD Oncologia, Policlinico Tor Vergata, Rome, Italy; [8]Oncology Department, Azienda Ospedaliera San Camillo Forlanini, Rome, Italy

Background: The BreakThrough Cancer Pain (BTCP) is a symptom that affects different aspects of the daily life of the patient. The aim of this research was to assess the impact of BTCP on the nutritional status of cancer patients initiating a palliative care program in home and hospital setting.

Methods: In this Italian observational, multicentre study "NO PAIN", cancer patients, affected by BTCP, were included. ECOG PS, MNA, BMI, EORTC QLQ-C15-PAL, PSQI, ESAS, PGIC, HADS, BRASS were assessed. Cancer Malnutrition is defined as patient who experienced weight loss >5% of their usual weight over 3 months, combined with BMI <20 kg/m2 if <70 years old, or < 22 kg/m2 if >70 years old (ESPEN guidelines).

Results: In total, 61 patients (57.6%) male, median age (range) 70 (42-92) were accrued. The majority [40 (65%)] of them had metastatic primaries of the lung and liver, PS of 2 [39 (64%)]. Patients reported 2.4 ± 0.9 BTCP episodes/day with a mean intensity of 6.96 ± 1 NRS; 45 patients (73.7%) had incident BTCP, and 44 patients (72.1%) reported rapid onset pain (<10 min).

We observed a short "time lag" (median 30 days) between the onset of pain and the diagnosis of BTCP and severe malnutrition. We proposed the term BreakThrough Cancer Malnutrition (BTCM) as the exacerbation of rapidly progressive malnutrition that occurs in cancer patients with uncontrolled BTCP. Weight loss was reported by 88% and BMI <21 by 62%. There was a decrease in food intake in 66% of patients. BTCP was statistically significant associated with anorexia, weight loss and MNA.

Conclusions: BTCP, if left untreated, can lead to weight loss and severe malnutrition. The BTCM is the new concept of cancer malnutrition defined as the exacerbation of rapidly progressive malnutrition that occurs in cancer patients with uncontrolled BTCP. The prospective study "NO PAIN" confirmed that BTCP has deleterious consequences for the nutritional status, this information may have important significance in early palliative care.

1614P Integrated palliative care for patients referred for Chimeric Antigen Receptor T-cell (CAR-T) therapy: A service evaluation

R. Williams[1], J.M. Droney[1], E. Nicholson[2], C. Arias[2], R. Ellard[2], N. Bradley[2], C. Maycock[2], A. Halley[1]

[1]Symptom Control and Palliative Care Department, The Royal Marsden Hospital - Chelsea, London, UK; [2]Haematology, The Royal Marsden Hospital (Sutton), Sutton, UK

Background: CAR-T therapy is potentially lifesaving for patients with certain types of refractory or relapsed lymphoma. However, patients face uncertainty about treatment outcomes and are at risk of severe toxicity. A novel integrated service was developed at our cancer centre offering patients with lymphoma being considered for CAR-T therapy a review by the Palliative Care team. The aims of this study were to describe the uptake of this service and the nature of the palliative care interventions.

Methods: Health record data was analysed for all patients with lymphoma referred for consideration of CAR-T therapy at a tertiary referral cancer centre between January 2020 and March 2022. Outcomes were recorded up to 1 year. This service evaluation was approved by the local Committee for Clinical Research.

Results: 37 patient records were included. 83.8% (n=31) proceeded with CAR-T therapy. All patients had 2 or more previous lines of systemic treatment. 97.3% had an ECOG performance status of 0-1 at time of referral and median age was 66 years. Post CAR-T therapy, 35.5% had disease progression or relapse. 35.5% developed a grade 3 or 4 toxicity. 5 patients (16.1%) died, 4 due to disease progression and 4 of whom were seen by palliative care. The median time between first palliative care review and death was 133 days (range 78 - 309). Of the patients who did not proceed with CAR-T therapy, 100% (n=6) died, all due to disease progression, of whom 5 were seen by palliative care. The median time between first palliative care review and death was 18 days (range 1 - 99). In total 25 patients (67.6%) were seen by the palliative care team, of whom 40% had more than 1 consultation. The most frequent interventions were information provision (n=25), symptom control (n=13),

communication (n=10) and advance care planning (n=9). Pain was the most common symptom, followed by constipation, nausea and vomiting and anxiety.

Conclusions: An integrated palliative care service is feasible within a CAR-T oncology service and is an opportunity to provide patients with information about palliative care. Development of an earlier and more integrated service can be explored. Specialist palliative care input may be required to support symptom control and advance care planning.

1615P Investigation of status of lung cancer palliative care management and concept and practice in Chinese medical providers

L. Ma[1], M. Chen[2], H. Yu[1]

[1]Department of Geriatric Oncology and Department of Palliative care, Chongqing University Cancer Hospital, Chongqing, China; [2]Clinical nutrition, Chongqing Cancer Hospital, Chongqing, China

Background: This study aimed to investigate the current situation of lung cancer palliative care and the awareness of related issues among Chinese medical providers.

Methods: Doctors, nurses, pharmacists were investigated using an electronic questionnaire from January 14 to March 1,2022. The questionnaire addressed the current situation of lung cancer palliative care, most common accompanying symptoms in patients with lung cancer, the incidence of lung cancer-refractory cancer pain, the assessment of treatment satisfaction, usage of patient-controlled analgesia (PCA) drugs.

Results: Questionnaires from 2093 medical provides were collected from 706 hospitals in 28 provincial administrative units. 84.2% p of physicians believed that anti-tumor therapy and palliative care are equally important, while less than 50% of lung cancer patients received palliative care in most hospitals. The main obstacle affecting the palliative care of lung cancer patients is that patients and their families have concerns about the safety of long-term use of palliative care related drugs. Pain is the most common concomitant symptom of lung cancer. There were statistically significant differences in the proportion of obstacles to the treatment of cancer pain by PCA in different levels of hospitals (goodness-of-fit test result was: χ^2=620.022 , $P<0.001$). The top three ranking of response rate and penetration rate of secondary and tertiary hospitals were: worry about adverse reactions of drug overdose, worry about opioid addiction and increase the economic burden of patients. There is a serious lack of training for Chinese medical providers in terms of the timing of palliative care initiation, pain relief for refractory cancer pain by PCA, and basic understanding of symptom management.

Conclusions: The proportion of patients who were satisfied with the effect of palliative care is low. The medical staff have insufficient awareness of this. There was an urgent need to develop a consensus and standardize lung cancer palliative care and symptoms management in China.

Background: Both nab-paclitaxel plus gemcitabine and modified FOLFIRINOX are equivalently recommended as first-line treatment for metastatic pancreatic cancer in patients with good performance status. S-IROX (S-1, irinotecan, and oxaliplatin) showed activity in a phase Ib study in this population. We therefore aimed to compare the efficacy and safety of these three regimens directly.

Methods: This multicentred, randomized, open-label, phase II/III trial was done in 45 centres in Japan. Eligible patients were aged 20—75 years and an Eastern Cooperative Oncology Group performance status of 0 or 1 with pathologically confirmed metastatic or recurrent pancreatic cancer. Patients were randomly assigned (1:1:1) to receive nab-paclitaxel (125 mg/m^2) plus gemcitabine (1,000 mg/m^2) on days 1, 8, 15, every 4 weeks, modified FOLFIRINOX (oxaliplatin 85 mg/m^2, irinotecan 150 mg/m^2, l-leucovorin 200 mg/m^2, and fluorouracil 2,400 mg/m^2 on days 1—3, every 2 weeks), or S-IROX (oxaliplatin 85 mg/m^2, irinotecan 150 mg/m^2, and S-1 80 mg/m^2/day on days 1—7, every 2 weeks). The primary endpoint of the phase III portion was overall survival.

Results: Between Apr 2019, and Mar 2023, 527 patients were enrolled, and 426 patients were analyzed at the planned interim analysis in Mar 2023. The median overall survival was 17.1 months in the nab-paclitaxel plus gemcitabine arm, 14.0 months in the modified FOLFIRINOX arm (HR 1.31, 95% CI 0.97—1.77), and 13.6 months in the S-IROX arm (HR 1.35, 95% CI 1.00—1.82). The predictive probability for achieving superiority at the final analysis was 0.73% for the modified FOLFIRINOX arm and 0.48% for the S-IROX arm. Therefore, the study was terminated for futility. The most common grade 3—4 non-hematological toxicity of anorexia was more frequent in the modified FOLFIRINOX (23.3%) and S-IROX (27.5%) arm than the nab-paclitaxel plus gemcitabine arm (5.0%).

Conclusions: Nab-paclitaxel plus gemcitabine is recommended as the first-line treatment for patients with metastatic or recurrent pancreatic cancer compared to modified FOLFIRINOX or S-IROX.

Clinical trial identification: jRCTs031190009.

Background: Pancreatic carcinoma (PC) is an aggressive malignancy and the 4th cause of all cancer deaths worldwide. More than 30% of patients (pts) with PC are unresectable because of the local extension with a median overall survival (OS) of less than 1 year. FFX is superior to gem in the treatment of metastatic PC, in terms of OS and progression-free survival (PFS) but standard of care remains gem for LAPC.

Methods: Pts with histologically proven LAPC not suitable for surgery, WHO PS $\leq$1, no cardiac ischemia were eligible. Randomization was stratified by center, tumour localization (pancreas head yes/no), WHO PS (0 vs 1) and age ($\leq$60 vs $>$ 60 years [yrs]). Pts received FFX (every 14 days for 12 cycles) or Gem 1000 mg/m^2 on days 1, 8, and 15 for six 28-day cycles excepted for cycle 1 with an infusion at D22. Primary

endpoint was PFS. Secondary endpoints were OS, rate of secondary curative-intent surgery, objective response rate, disease control rate, time to treatment failure, quality of life (QoL) and safety. QoL outcomes and updated survival results since ESMO 2022 are presented here in the intent-to-treat population.

Results: A total of 171 pts aged 35-84 yrs were included and followed for maximum 5 yrs. With a median follow-up of 47.8 mo, 159 PFS events were observed. Median PFS was 9.7 mo (95% CI: 7.0; 11.7) vs 7.7 mo (95% CI: 6.2; 9.2) in FFX and gem arm respectively, stratified HR=0,71 (95% CI: 0.5; 1.00), p=.04 and median OS was 15.7 mo (95% CI: 11.9; 20.3) vs 14.9 mo (95% CI:11.7; 18.3), stratified HR=1.03 (95% CI: 0.73; 1.46), p=0.71. QoL was evaluated on 141 pts (68 in gem arm and 73 pts in FFX arm). No significant difference was observed between the two arms except on the diarrhea scale: rate of patients without deterioration was 50.4% (95% CI: 37.6.; 63.2) and 37.8% (95% CI: 25.9.; 51.5) in FFX arm vs 89,3% (95% CI: 78.5.; 95) and 63,2% (95% CI: 48.3.; 76) in Gem arm, at 3 and 6 mo respectively, p=0.002.

Conclusions: PRODIGE 29/NEOPAN trial results show that FFX yields significantly longer PFS compared to Gem and was well tolerated. No significant difference in OS and QoL was observed between both groups. More analysis are ongoing on QoL, and will be presented during ESMO meeting.

Background: *NRG1* fusions are rare oncogenic drivers of PDAC and other solid tumours. These chimeric proteins bind HER3, leading to HER2/HER3 heterodimerization and oncogenic transformation. Zenocutuzumab (MCLA-128; Zeno) is a bispecific antibody that overcomes HER3 mediated NRG1 signalling in NRG1+ cancer. Zeno is being evaluated in the ongoing pivotal phase II eNRGy study and early access program (EAP). Updated NRG1+ PDAC data are presented.

Methods: Patients (pts) with advanced NRG1+ PDAC determined by NGS, previously treated with or not candidate for standard therapy, age $\geq$ 18 y, ECOG PS $\leq$ 2, and measurable (RECIST v1.1) or evaluable disease were enrolled. Zeno (750 mg IV Q2W) was administered until disease progression or unacceptable toxicity. Tumour imaging was conducted Q8W. The primary endpoint is investigator-assessed objective response rate (ORR) per RECIST v1.1. Secondary endpoints include duration of response (DOR) and safety.

Results: As of 01 Feb 2023, 38 pts with NRG1+ PDAC (33 eNRGy/5 EAP) were enrolled. Efficacy was assessed in 27 pts who received $\geq$ 1 dose of Zeno and were enrolled by 01 Aug 2022 to allow for the opportunity for $\geq$ 6 months (mo) follow-up and met the criteria for the primary efficacy population. The median age was 49 y (range 21—72), 52% were male, 44%/52%/4% pts had ECOG PS 0/1/3. Pts had a median of 2 prior systemic therapies (range 0-5), 93% with FOLFIRINOX and/or gemcitabine-based therapy. All had liver metastases and measurable disease. Common fusion partners were *ATP1B1* (52%) and *SLC4A4* (11%). The confirmed ORR was 44% (95% CI 26-65), with 1 CR and 11 PRs. Most (22/27; 81%) pts had target lesion reduction and 16/19 (84%) pts had CA 19-9 decline $\geq$ 50% from baseline. Median DOR was 9.1 mo with responses ongoing in 4/12 (33%) pts. Kaplan Meier estimate of 6-mo DOR rate was 64%. Among 38 pts treated with Zeno, Grade $\geq$ 3 individual AEs irrespective of causality occurred in $<$ 5% pts. No pt discontinued Zeno for a treatment related AE.

Conclusions: In this updated analysis, Zeno continues to demonstrate unprecedented efficacy in pts with previously treated advanced/metastatic NRG1+ PDAC with robust and durable responses and a well-tolerated safety profile.

Clinical trial identification: NCT02912949.

Background: The phase III NAPOLI 3 trial (NCT04083235) included 770 patients with mPDAC who were randomized (1:1) to receive liposomal irinotecan + 5-fluorouracil/leucovorin + oxaliplatin (NALIRIFOX) or nab-paclitaxel + gemcitabine (Gem+NabP) in 28-day cycles. As previously reported, at a median follow-up of 16.1 months, NALIRIFOX demonstrated statistically significant improvements in overall survival and progression-free survival versus Gem+NabP. Here, we report EORTC QLQ-C30 results from NAPOLI 3.

Methods: The EORTC QLQ-C30 was completed at baseline, day 1 of each 28-day cycle and at the end of treatment. A mixed model repeated measures (MMRM) model was used to describe the global health status (GHS) evolution over time between treatment arms. Time until definitive deterioration (TUDD) was defined as the time between randomization and first occurrence of a decrease $\geq$ 10 points in QLQ-C30 score without further improvement of $\geq$ 10 points or further data due to discontinuation.

Results: Mean GHS scores at baseline were similar between treatment arms (NALIRIFOX 62.1; Gem+NabP 61.2); from week 16, there was a trend towards improvement in GHS scores in the NALIRIFOX arm relative to the Gem+NabP arm. The median TUDD of GHS was 15.7 months with NALIRIFOX and 12.2 months with Gem+NabP (stratified Cox hazard ratio 0.74 [95% confidence interval: 0.53−1.04]; nominal $p = 0.08$). At 6 months, 26.4% and 31.7% of patients NALIRIFOX and Gem+NabP arms, respectively, experienced definitive deterioration in GHS. The TUDD of physical, role and emotional functioning, pain, dyspnea and constipation were longer, with nominal $p \leq 0.05$, in patients who received NALIRIFOX versus Gem+NabP.

Conclusions: NALIRIFOX was associated with a trend towards improvement in GHS scores and longer TUDD in several EORTC QLQ-C30 subscales compared with Gem+NabP. However, these results should be interpreted with caution owing to the number of missing assessments.

Clinical trial identification: NCT04083235.

Pederzoli Casa di Cura Privata Spa, Peschiera Del Garda, Italy; [9]Pathology Unit, Azienda Ospedaliera Universitaria Integrata Verona, Verona, Italy

Background: The risk of positive surgical margins, poor recovery after surgery that impairs postoperative treatments, and a high risk of recurrence might limit the current standard treatment for rPDAC. This study evaluated the safety and the activity of perioperative liposomal irinotecan 50 mg/m^2 + 5-FU 2400 mg/m^2 + LV 400 mg/m^2 + oxaliplatin 60 mg/m^2 (NALIRIFOX) for patients with rPDAC.

Methods: nITRO was an investigator-initiated, Simon's two-stages, single arm study. Eligible patients had newly diagnosed rPDAC with $<180^\circ$ interface with major veins' wall and a Karnofsky status $\geq$60. Patients received 3 cycles before and 3 cycles after resection with NALIRIFOX, day 1 and 15 of a 28 day cycle. The primary endpoint was the proportion of patients undergoing an R0 resection. Plasma concentration of 25 different cytokines was measured by a multiplex xMAP/Luminex technology.

Results: 107 patients were enrolled and began preoperative treatment (ITT population). 9 patients discontinued the treatment in the preoperative phase because of treatment related or unrelated adverse events (AEs). The disease control rate was 92.9%. 87 (81.2%) patients underwent surgical exploration, 11 (10.3%) had intraoperative evidence of unresectable or metastatic disease, and 1 died due to surgical complications. 49 patients achieved an R0 resection, accounting for a rate of 65.3%, which largely exceeded the alternative hypothesis of 55%. The most common grade $>$3 AEs were neutropenia and diarrhea (10.3% and 13.1% in the preoperative, 10.2% and 5.1 in the postoperative phase). With an updated median follow-up time of 33·1 months (IQR 23·1-43·6), the median overall survival (OS) of the ITT population was 32.3 months (95% CI 27.8-44.3). The median disease-free and OS of resected patients were 19.3 (95% CI 12.6-34.1) and 44.3 months (95% CI 33.2-NA), respectively. TNF-α, a potent activator of the chemoresistance pathway TAK1/NF-κB, was the circulating factor most significantly correlated with response and survival outcomes.

Conclusions: NALIRIFOX was manageable and active for patients with rPDAC. Plasmatic TNF-α level allows for the selection of patients who may benefit the most from this perioperative strategy.

Clinical trial identification: NCT03528785.

Background: Erdafitinib (erda) is an oral selective pan-FGFR tyrosine kinase inhibitor approved for treatment of locally advanced or metastatic urothelial carcinoma in adults with susceptible FGFR3/2alt who have progressed during or after ≥1 line of platinum-based chemotherapy. Interim results from the RAGNAR study demonstrated tumor agnostic efficacy in patients (pts) with advanced solid tumors with predefined FGFRalt after failure of standard therapies (tx) (Loriot et al, ASCO 2022). Here we report results on pts with pancreatic cancer in RAGNAR.

Methods: Pts with advanced or metastatic pancreatic cancer with prespecified FGFR1-4alt (mutations or fusions), disease progression after ≥1 line of systemic tx, and who exhausted standard tx received oral erda until disease progression or intolerable toxicity. Primary end point is objective response rate (ORR) by independent review committee (IRC). Secondary endpoints include duration of response (DOR), disease control rate (DCR), progression-free survival (PFS), overall survival (OS), and safety.

Results: At data cutoff (median survival f/u 15.24 mo), 18 pts with pancreatic cancer received erda. Median age was 60.5 y (range 34-78); 17 (94.4%) had visceral metastases; median 3 prior lines of systemic tx (range 1-9); 1 (5.6%) responded to last line of tx. All 18-pts had FGFR fusions (14 FGFR2, 4 FGFR1); none had FGFR mutations. None of the pts had KRAS co-alterations. ORR by IRC was 55.6% (95% CI 30.8-78.5). Median time to onset of response was 1.45 mo. Responses were observed in pts with FGFR1 and FGFR2 fusions. Median DCR was 94.4%. Median DOR, PFS and OS were 7.1 mo, 7.0 mo, and 19.7 mo respectively. Investigator-assessed efficacy data were comparable to IRC. The most common adverse events (AEs) were dry mouth (72%), diarrhea (67%), stomatitis (67%), dry skin (67%), hyperphosphatemia (56%), and fatigue (50%); 5 (28%) had serious AEs; 2 (11%) discontinued erda due to AEs. No treatment-related deaths were observed.

Conclusions: Erda demonstrated robust and clinically meaningful activity in pancreatic cancer pts with FGFRalt. Safety data were consistent with erda safety profile.

1622P D-1553 in patients with KRAS G12C mutated advanced pancreatic cancer (pca)

S. Kondo[1], D. Yan[2], V. Ganju[3], G. Richardson[4], X. Hou[5], J. Shan[6], X. Liu[7], Y. Zhang[7], X. Xie[7], Z. Xiang[7], Z. Shi[7], Y. Wang[7], L. Zhang[7], N. Yamamoto[1]

[1]Department of Experimental Therapeutics, National Cancer Center Hospital, Tokyo, Japan; [2]Department of Oncology, Beijing Luhe Hospital Affiliated to Capital Medical University, Beijing, China; [3]Department of Medical Oncology, Peninsula Oncology Centre, Frankston, VIC, Australia; [4]Department of Medical Oncology, Cabrini Hospital - Malvern, Malvern, VIC, Australia; [5]Gastroenterology Ward 2, Henan Cancer Hospital, Zhengzhou, China; [6]Medical Oncology Department, The First Affiliated Hospital of Zhejiang University School of Medicine, Hangzhou, China; [7]R&D, InventisBio Co., Ltd, Shanghai, China

Background: KRAS mutations are found in approximately 90% of PCa, of which 1-2% are KRAS G12C. D-1553 has shown clinical activity in patients (pts) with KRAS G12C mutated non-small cell lung cancer and colorectal cancer. Here, we report preliminary data of D-1553 in KRAS G12C mutated advanced PCa.

Methods: Pts with KRAS G12C mutated advanced PCa (with no standard treatment available or refractory or intolerant to existing standard treatment) were enrolled and received D-1553 at the recommended phase II dose of 600 mg BID orally. Study endpoints included safety, pharmacokinetics (PK), and efficacy (RECIST, v1.1). Efficacy endpoints included objective response, disease control (defined as an objective response or stable disease) and progression-free survival. Safety was also assessed.

Results: As of 01 March 2023, a total of 10 pts with advanced PCa (median age 67.5 years [range 48—78]; 60% female; 70% Asian; 80%/20% ECOG PS 0/1; 100% stage IV disease at baseline; 40% with ≥ 2 prior lines of therapy [median 1]) were enrolled and treated with D-1553. At data cutoff, 5 (50%) pts remained on treatment. The median duration of treatment and follow-up were 7.15 months (range 1.22-8.94) and 8.10 (range 4.47-9.23) months, respectively. The objective response rate was 50.0% (5/10, including 1 confirmed complete response, 3 confirmed partial response [PR], and 1 unconfirmed PR) and disease control rate was 80.0% (8/10). Median progression-free survival was 8.54 (95% CI 1.25-NA) months. Treatment-related adverse events (TRAEs) of any grade occurred in 7 (70.0%) pts, with the most commonly (≥ 20%) reported as increased ALT, increased AST, decreased appetite, and diarrhoea. Grade 3 TRAEs occurred in 2 (20%) pts, including increased ALT, increased AST and increased alkaline phosphatase. There was no grade > 3 TRAEs, nor TRAEs leading to death or D-1553 permanent discontinuation.

Conclusions: D-1553 is well tolerated and has shown promising anticancer activity in pts with pre-treated KRAS G12C mutated advanced PCa. This study is ongoing, and more results will be presented at the meeting.

1623P Pelareorep (pela) + atezolizumab (atezo) and chemotherapy in first-line (1L) advanced or metastatic pancreatic ductal adenocarcinoma (PDAC) patients: Results from the GOBLET study

D. Arnold[1], E. Goekkurt[2], A. Stein[3], U.M. Martens[4], J. Chater[5], G. Ungerechts[6], H. Loghmani[7], M. Coffey[7], R. Trauger[8], T.C. Heineman[9]

[1]Oncology, Haematology, Palliative Care Dept., Asklepios Tumorzentrum Hamburg AK Altona, Hamburg, Germany; [2]Medical Oncology Department, Hämatologisch-Onkologische Praxis Eppendorf HOPE, Hamburg, Germany; [3]Oncology Hematology Department, Hematology Oncology Practice Hamburg, Hamburg, Germany; [4]Medical Oncology Department, SLK-Kliniken Heilbronn GmbH, Heilbronn, Germany; [5]Medical Oncology Department, Klinikum Chemnitz gGmbH, Chemnitz, Saxony, Germany; [6]Medical Oncology Department, NCT - Nationales Zentrum für Tumorerkrankungen, Heidelberg, Germany; [7]Translational Research, Oncolytics Biotech Inc, Calgary, AB, Canada; [8]Translational Medicine, Oncolytics Biotech, Inc., La Jolla, CA, USA; [9]Clinical Development Department, Oncolytics Biotech, Inc., La Jolla, CA, USA

Background: Pela is an intravenously delivered unmodified oncolytic reovirus that selectively replicates in cancer cells and induces innate and adaptive immune responses. The GOBLET study assesses the safety and efficacy of pela in combination with atezo +/- chemotherapy in multiple gastrointestinal cancers. Here, we report clinical and translational results for the PDAC cohort.

Methods: GOBLET is a phase I/2 Simon 2-stage basket study. PDAC patients must have locally advanced and/or metastatic disease evaluable by RECIST and be eligible for 1L therapy. Patients received pela, atezo and gemcitabine/nab-paclitaxel. The first stage enrolled 13 evaluable patients (at least one post-baseline tumor assessment). Primary objectives are safety and efficacy (objective response rate [ORR]). The Stage 1 success criterion for PDAC is $\geq$3 confirmed responses. T cell receptor sequencing (TCR-seq) was performed on blood samples collected at baseline (cycle 1 day 1 [c1d1]), c2d1 and c4d1 to assess treatment effects on the T cell repertoire.

Results: No safety signals were observed in treated patients. Median age was 61 years; 92% had metastatic disease (69% liver). Eight of 13 evaluable patients had a partial response and 3 had stable disease for an ORR of 62% (confirmed ORR 53%) and a CBR of 85%. At the data cut-off (January 19, 2023), median duration of response was 6.0 month; 6-month progression-free survival (PFS) rate was 72.9% (95% CI 36.8-90.5), and 6-month overall survival (OS) rate was 82.1% (95% CI 44.4-95.3). Final PFS/OS are pending. TCR-seq revealed an expansion of new and preexisting T cell clones. Updated efficacy and TCR-seq results will be presented.

Conclusions: Pela combined with atezo and chemotherapy was well-tolerated. The ORR exceeded the pre-specified success criteria and compares favourably to ORRs from prior PDAC clinical trials in 1L PDAC. The changes in T cell repertoire observed by c2d1 are consistent with previous pela/checkpoint inhibitor studies and will be evaluated at later study timepoints.

Background: Second line nanoliposomal irinotecan/5-FU/folinic acid (Nal-IRI/5-FU/FA) increases survival of unselected patients (pts) with metastatic PDAC after gemcitabine-based 1st-line therapy. It is not well defined, which parameters are predictive for the efficacy of a 2nd-line treatment.

Methods: In this prospective trial, 151 pts with locally advanced or metastatic PDAC were enrolled for treatment with biweekly Nal-IRI/5-FU/FA (70 mg/m^2, 2400 mg/m^2, 400 mg/m^2) after failure of gemcitabine/nab-paclitaxel. Primary end point was the time to treatment failure of the 2nd-line therapy (TTF2). Secondary endpoints were overall survival (OS) and quality of life. To evaluate the impact of 1st-line treatment, pts was divided into three cohorts: TTF1low, -medium and -high. Comparative analyses were performed for the TTF1low and TTF1high cohorts, and for a comprehensive set of potential predictive factors.

Results: 146 (97%) pts have received at least one dose of medication. Median treatment duration of 2nd-line treatment was 3.71 [95% CI: 2.50, 4.11] months, with 28.3% on treatment after 6 m. Analyses of the TTF1 low ($\leq$ 120 d, n=50) and TTF1high ($\geq$ 210 d, n=49) cohorts and predictive factors for TTF2 are summarized in the table.

Table: 1624P Selected predictive factors for TTF2 and OS

		TTF2 months (95% CI)	p-value	OS months (95% CI)	p-value
Baseline					
TTF1	high (N=50)	3.22 [1.77, 4.01]	0.790	6.41 [4.76, 9.99]	0.746
	low (N=49)	2.83 [2.10, 4.86]		8.08 [4.73, 10.02]	
CA19-9	<100 U/ml (N=36)	5.95 [2.10, 7.06]	0.005	9.26 [6.08, 11.89]	0.035
	≥100 U/ml (N=104)	2.86 [2.17, 3.91]		6.67 [5.45, 8.08]	
Leukocyte level	normal (N=111)	4.07 [3.45, 5.06]	<0.001	-	-
	abnormal (N=35)	2.14 [1.28, 2.69]		-	
Metastases	liver (N=106)	2.79 [2.17, 4.01]	0.047	-	-
	non liver (N=40)	4.40 [2.92, 6.24]		-	
During treatment					
CA 19-9 decrease (response)	≥ 50% (N=32)	6.05 [4.14, 8.94]	<0.001	-	-
	< 50% (N=81)	2.14 [1.84, 2.83]		-	

Conclusions: Duration, efficacy, or dose of 1st-line treatment did not correlate with the success of 2nd-line therapy. Significant predictive factors are CA19-9 levels and leucocytes, which correlated with TTF2 and OS. During 2nd line treatment CA19-9 response and reduced pain indicate a benefit from treatment.

Clinical trial identification: EudraCT 2016-005147-17.

Background: Metastatic pancreatic adenocarcinoma (PDAC) is an aggressive disease without third line standard-of-care treatment option. CBP501, a 12-amino acid G2 checkpoint abrogator and calmodulin-modulating peptide increases platinum influx into tumour cells, suppresses platinum-induced macrophage cytokine release and enhances anti-tumor activity with anti-programmed cell death-1 (anti-PD-1).

Methods: Patients with metastatic PDAC, who failed two lines of systemic therapy, with white blood cell count <10,000/mm^3 were stratified by ECOG (0 vs 1) and liver metastasis (present vs absent) and randomized 1:1:1:1 to arm 1 - CBP501 25 mg/m^2 + cisplatin 60 mg/m^2 + nivolumab 240 mg; arm 2 - CBP501 16 mg/m^2 + cisplatin 60 mg/m^2 + nivolumab 240 mg; arm 3 - CBP501 25 mg/m^2 + cisplatin 60 mg/m^2; or arm 4 - cisplatin 60 mg/m^2 + nivolumab 240 mg. Patients received 4 cycles of combination therapy then 6 cycles of nivolumab every 21 days if without disease progression (nivolumab arms only). The primary endpoint was 3-month progression-free survival rate (3M PFSR) in the ITT population. Secondary endpoints were safety, PFS, objective response rate (ORR) and overall survival (OS).

Results: As of October 17, 2022, efficacy was evaluable in 36 patients. 3M PFSR were 44%, 22%, 11% and 33% in arms 1, 2, 3 and 4, respectively. ORR were 22% in arm 1 (2 partial responses), 0% in arms 2, 3 and 4. Median PFS were 2.8, 2.1, 1.5 and 1.5 months, respectively. Median OS was not reached in arm 1 and 7.0, 2.7 and 3.8 months in arms 2, 3 and 4. Most common AEs were infusion-related reaction in 18/25 (72%; grade 1-2) during CBP501 infusion, and anemia in 2/33 (6%; both grade 3). SAEs occurred in 14/33 (42%); 13 SAEs were unrelated to CBP501. SAE acute renal failure (arm 3, after 1 cycle) was assessed as possibly related to CBP501 and definitely related to cisplatin.

Conclusions: Preliminary results indicate clinically meaningful improvement and tolerable safety of CBP501, cisplatin and nivolumab as 3rd line treatment for metastatic PDAC.

Clinical trial identification: NCT04953962.

Lauder Breast Center, New York, NY, USA

Background: Locally advanced pancreatic cancer (LAPC) accounts for 30% of pancreatic cancer (PC). LAPC incurs high mortality. We evaluated a novel extended-release siRNA targeting $KRAS^{G12D/V}$ (G12D/V) mutations (Loder) in combination with standard chemotherapy.

Methods: A two-cohort, phase II multicenter, open-label trial was conducted. Cohort 1: Patients (pts) with LAPC randomized to: Loder + gemcitabine/nab-paclitaxel (GnP); or GnP. Cohort 2: pts with Borderline Resectable (BR) PC or LAPC single arm, Loder + (modified)FOLFIRINOX ((m)FFX) or GnP. The Loder was inserted into primary tumor via endoscopic ultrasound (EUS 19G needle) q3 mo. for 2-3 doses. mITT, all patients $\geq$ 1 treatment. Key study endpoints: overall survival (OS), safety.

Results: N= 49 pts in mITT (6 BRPC, 43 LAPC, Loder n=38, control n=11). KRAS known for n=35: G12V, n=12; G12D, n=11; G12R, n=7; Q61R, n=2; wild-type, n=1. For mITT: no difference in OS for Loder + chemo vs. chemo (OS=21.1 vs. 22.2 mo.). However, in pts with G12D/V a non-statistically significant numerical advantage was seen in Loder + (m)FFX or GnP arm (n=18, Cohorts 1,2) median OS = 19.4 mo. vs. 13.8 mo. GnP arm.

Table: 1626P

Cohort/Arm	Median OS mo. (HR (95% CI))	RR (partial or complete)
All Patients, mITT n=49		
Arm 1: Loder + Chemo, n=38	21.1 (1.64 (0.78,3.8))	9/38 23.2% 2/11
Arm 2: GnP, n=11	22.1	18.2%
Cohort 1 (Randomized, LAPC)	22.8 (1.47 (0.64,3.4))	3/18 16.7% 2/11
Arm 1: Loder + GnP, n=18	22.1	18.2%
Arm 2: GnP, n=11		
Cohort 2 (Single arm, LAPC+BRPC)	17.4	6/20 30.0%
Loder + (m)FFX or GnP, n=20		
G12V and G12D Exploratory Subgroup		
Cohort 1+Cohort 2	19.4 (0.65 (0.21,2.0))	4/18 22.2% 0/5 0.0%
Arm 1: Loder + (m)FFX or GnP	13.8	
n=18 Arm 2: GnP, n=5		
Cohort 1 (Randomized, LAPC) Arm	22.8 (0.63 (0.19,2.1))	2/11 18.2% 0/5 0.0%
1: Loder + GnP, n=11 Arm 2: GnP,	13.8	
n=5		

Loder treatment was well tolerated. Safety events were primarily related to procedure, mainly reversible abdominal pain. Four Grade 5 events (visceral arterial ischemia, sepsis; 2 progression of disease), assessed as unrelated.

Conclusions: Loder with chemotherapy is feasible, safe, and shows a promising signal in KRASG12D/V BR, LAPC. Further evaluation is warranted.

Clinical trial identification: NCT01676259.

1627P First-line (1L) fuzuloparib plus mfolfirinox followed by maintenance fuzuloparib in patients (pts) with unresectable locally advanced or metastatic (LA/M) pancreatic cancer (PC): A phase Ib study

X. Yu[1], Y. Mou[2], X. Chen[3], C. Liu[4], X. Zhang[5], J. Xu[1], J. Zhang[6], S. Shi[1], M. Wei[1], J. Li[1], R. Liu[6], S. Gao[6], L. Xu[4], Z. Sheng[7], J. Lian[7], Q. Shi[7]

[1]Department of Pancreatic Surgery, Fudan University Shanghai Cancer Center, Shanghai, China; [2]Department of Gastrointestinal-Pancreatic Surgery, Zhejiang Provincial People's Hospital, Hangzhou, China; [3]Department of Internal Oncology, Henan Cancer Hospital, Zhengzhou, China; [4]Department of Hepato-Pancreato-Biliary Surgery, Sun Yat-sen Memorial Hospital, Guangzhou, China; [5]Department of Medical Oncology, The First Affiliated Hospital, Zhejiang University School of Medicine, Hangzhou, Zhejiang, China; [6]Phase I Clinical Trial Center, Fudan University Shanghai Cancer Center, Shanghai, China; [7]Clinical Research & Development, Jiangsu Hengrui Pharmaceuticals Co., Ltd, Shanghai, China

Background: Chemotherapy regimens remain the standard 1L treatment for PC, but with limited anti-tumor activity. We amid to explore the feasibility of adding the PARPi fuzuloparib to mFOLFIRINOX in pts with LA/M PC.

Methods: This was a dose escalation (ESC) and expansion (EXP) phase Ib study. Pts were given oral fuzuloparib at escalating doses starting at 30 mg bid plus intravenous mFOLFIRINOX q2w for 8–12 cycles, followed by maintenance fuzuloparib at 150 mg bid. Dose-limiting toxicities (DLTs) were observed during the first 2 cycles. At least 1 dose cohort would be selected for EXP to collect data supporting the determination of recommended phase II dose (RP2D). Primary endpoints were DLT, maximal tolerated dose (MTD), and RP2D.

Results: As of Jan 15, 2023, 39 pts were recruited. Of them, 12 pts were enrolled in ESC phase (30 mg [n=4]; 60 mg [n=6]; 100 mg [n=2]). DLT occurred in 1 pt in 60 mg cohort (grade 4 decreased platelet count and grade 4 decreased neutrophil count lasting for $\geq$5 d) and 1 pt in 100 mg cohort (grade 4 decreased neutrophil count lasting for $\geq$5 d). Based on the tolerability and safety data during ESC, 60 mg bid was determined to be the MTD. 60 and 30 mg cohorts were expanded to 22 and 15 pts, respectively. Overall, grade $\geq$3 treatment-related adverse events (TRAEs) were reported in 34 (87.2%) of 39 pts; the most common were decreased neutrophil count, decreased platelet count, decreased white blood cell count, and anemia. TRAEs led to discontinuation of any study agent in 5 (12.8%) pts. Efficacy in 60 mg cohort seemed to be most favorable, with ORR of 50.0%, DCR of 94.4%, median PFS of 7.2 mo, and median OS of 12.5 mo (Table).

Table: 1627P Efficacy outcomes

	30 mg	60 mg	100 mg	Overall
Confirmed ORR*, n/N (%; 95% CI)	2/12 (16.7%; 2.1—48.4)	9/18 (50.0%; 26.0—74.0)	0/2 (0.0%; 0.0—84.2)	11/32 (34.4%; 18.6—53.2)
Confirmed DCR*, n/N (%; 95% CI)	10/12 (83.3%; 51.6—97.9)	17/18 (94.4%; 72.7—99.9)	1/2 (50.0%; 1.3—98.7)	28/32 (87.5%; 71.0—96.5)
PFS#				
Events, n/N (%)	10/15 (66.7%)	12/22 (54.5%)	2/2 (100.0%)	24/39 (61.5%)
Median (95% CI), mo	7.5 (1.9—10.1)	7.2 (5.1—13.9)	7.2 (1.6—NR)	7.3 (5.3—10.1)
OS#				
Events, n/N (%)	10/15 (66.7%)	15/22 (68.2%)	1/2 (50.0%)	26/39 (66.7%)
Median (95% CI), mo	11.5 (4.0—NR)	12.5 (7.8—NR)	NR (2.0—NR)	11.5 (7.8—14.2)

*tumor response evaluable set;#full analysis set.

Conclusions: 1L fuzuloparib plus mFOLFIRINOX followed by maintenance fuzuloparib was generally safe, with no unexpected toxicities, and showed encouraging efficacy in pts with LA/M PC. The RP2D of fuzuloparib combination was 60 mg bid.

Clinical trial identification: NCT04228601.

1628P Anlotinib plus chemotherapy as first-line therapy for gastrointestinal tumor patients with unresectable liver metastasis: Preliminary results from a multi-cohort, multi-center phase II trial (ALTER-G-001)

J. Wu[1], J. Zhang[1], C. Zhou[1], J. Yan[2], L. Zhu[3], J. Jiang[1], C. Wang[2], J. Chen[4], Z. Han[5], C. Wang[6], M. Yong[7], X. Tang[8], Z. Qin[9], X. Wei[10], C. Shangguan[1]

[1]Department of Oncology, Ruijin Hospital - Shanghai Jiao Tong University School of Medicine, Shanghai, China; [2]Department of Oncology, Jiading Central Hospital, Shanghai, China; [3]Department of Oncology, Jiangsu Province Hospital/The First Affiliated Hospital of Nanjing Medical University, Nanjing, China; [4]Department of Oncology, Ningbo Yinzhou People's Hospital, Ningbo, China; [5]Department of Oncology, The Affiliated Hospital of Xuzhou Medical University, Xuzhou, China; [6]Department of Oncology, 3rd People's Hospital of Yancheng, Yancheng, China; [7]Department of Oncology, Affiliated Hospital of Jiangnan University (Wuxi Fourth People's Hospital), Wuxi, China; [8]Department of Oncology, Wuxi Branch of Ruijin Hospital, Wuxi, China; [9]Department of medical oncology, Zhejiang Provincial People's Hospital, Hangzhou, China; [10]Department of Oncology, Nanjing First Hospital, Nanjing, China

Background: Advanced gastrointestinal (GI) tumors, such as colorectal, gastric and pancreatic cancers (CRC, GC and PC), and esophageal squamous cell carcinoma (ESCC), 20%-50% with liver metastases (LMs) and have poor prognosis. Previous trials showed anlotinib plus chemotherapy (CT) has promising clinical activity and a tolerable safety profile for advanced CRC and ESCC, especially with LMs. In this phase II trial, we assessed the efficacy and safety of anlotinib plus CT as first-line (1L) treatment for LMs GI tumors.

Methods: Previous untreated pts with unresectable LMs GI tumors received induction therapy (6 cycles, q3w) in 3 cohorts: cohort A (CRC): anlotinib (12 mg, po, qd, d1-d14), oxaliplatin (130 mg/m^2, iv, d1), capecitabine (850 mg/m^2, po, bid, d1-14). B (ESCC): anlotinib, cisplatin (60-750 mg/m^2, iv, d1/d1-3), paclitaxel (135 mg/m^2, iv, d1) or docetaxel (75 mg/m^2, iv, d1). C (other GI tumors, e.g., PC, GC): anlotinib plus standard CT. Pts without PD and radical resection received anlotinib and metronomic capecitabine (500 mg, po, bid, d1-21, q3w) maintenance until PD or unacceptable toxicity. The primary endpoint was ORR (RECIST 1.1). Secondary endpoints were DoR, PFS, OS, DCR, radical resection rate for LMs and safety.

Results: As of May 8th, 2023, 74 pts were enrolled, 33 in cohort A, 3 in B and 38 in C (26 PC, 6 GC, 5 biliary tract cancer (BTC) and others), median age was 64 years (34-75), 70.3% male, 91.9% ECOG-PS 1 and 59.5% had LMs only. After induction therapy, 8 pts (5 CRC, 1 PC, 1 GC, 1 BTC) received surgical resection. Of 19 evaluable pts in cohort A, ORR and DCR were 57.9% and 100% (PR, n=11; SD, n=8, 5 SD had reduced tumor size). All 3 pts in cohort B were PR. Of 28 evaluable pts in cohort C, ORR and DCR were 39.3% and 85.7% (PR, n=11; SD, n=13, 6 SD had reduced tumor size). Of 16 evaluable PC pts, 7 had PR, 7 had SD, ORR 43.8%. The mPFS was not reached. 50 pts had TEAEs and grade 3/4 TEAEs (28.4%) mainly included neutropenia (13.5%), hypertension (6.8%) and white blood cell decreased (5.4%).

Conclusions: Anlotinib plus chemotherapy as 1L treatment has shown promising efficacy and acceptable safety and may be a favorable option for advanced LMs GI tumors, especially for PC.

1629P Modified-FOLFIRINOX-losartan followed by chemoradiotherapy for locally advanced pancreatic cancer: A phase II study

A.M. Alhanafy[1], N. Abd El Bary[1], O. Hegazy[2], A. Abd El Ghany[1], S.H. Soliman[1], R. Ahmed[1]

[1]Clinical Oncology Department, Menoufia University, Shebeen El-Kom, Egypt; [2]Hepato-Pancreatici-Biliary Surgery, National Liver Institute, Shebin El Kom, Egypt

Background: The management of pancreatic adenocarcinoma continues to be challenging. Surgical resection is the only modality for a cure, with an overall survival rate of 10—20% at 5 years. However, only 20% of the patients are surgical candidates because of locally advanced disease or systemic stage at presentation.

Methods: A phase II clinical trial was carried out on 50 patients with previously untreated locally advanced, surgically unresectable pancreatic adenocarcinoma. Patients had ECOG PS 0 or 1 and adequate hematologic, renal, and hepatic function. They arranged to receive 3 cycles of modified FOLFIRINOX prior to CCRT, with losartan taken orally every day followed by chemoradiotherapy.

Results: Response after completion CCRT was assessed. 6% of patients achieved complete response. 38% of the patients had a partial response, while twenty-four patients (48%) had stable disease and 8% had progressive disease. Of the 50 patients, thirteen (26%) underwent surgery, with R0 resection achieved in 6 of 13 patients. Median follow-up period was 20.25 months (range, 6.0-34.5). The median PFS was 12 months (95% CI, 9.647 — 14.353), while Median OS was 21 months (95% CI, (10.200—31.800). The patients who underwent resection had longer survival 24 months (95% CI, (16.363 — 27.637) compared to those who did not undergo resection; mean OS was 14 months (95% CI, (9.205 — 18.795)). (P=0.271). The patients who achieved CR after modified Folforinox-losartan had a longer median OS of 33 months (95% CI, 19.918 — 46.082) compared to patients who had PR and SD, each had median OS of 13 months (95% CI, 6.768 — 19.232), (11.718 — 14.282) respectively (P=0.040*). The patients who achieved CR after CCRT had longer OS (NR) compared to those who had PR, SD and PD. median OS was 24, 14 and 8 months, respectively (95% CI, 6.761 — 41.239), (11.022 — 16.978), and (95% CI, 4.080 — 11.920) (P=<0.001*). The patients who achieved CR after CCRT had longer PFS (NR) compared to those who had PR, SD and PD. Median PFS was 24 (95% CI, 13.191 — 34.809), 10(95% CI, 4.973 — 15.027) and 5 (95% CI,4.823-5.124) months, respectively (P=<0.001*).

Conclusions: Induction chemotherapy with modified-FOLFIRINOX-losartan, followed by CCRT improved patient outcomes.

1630P Phase I/Ib study of SHP2-ERK inhibition in KRASm pancreatic cancer (SHERPA trial) and preclinical identification of potential resistance markers

A.C. Kanhailal[1], A. Mulero-Sánchez[2], J.E. Knikman[3], A. Bosma[2], R. Bernards[2], A.D.R. Huitema[4], E.E. Voest[5], S. Mainardi[2], F. Opdam[1]

[1]Devision of Medical Oncology / Clinical Pharmacology, NKI-AVL - Netherlands Cancer Institute/Antoni van Leeuwenhoek Hospital, Amsterdam, Netherlands; [2]Division of Molecular Carcinogenesis, NKI-AVL - Netherlands Cancer Institute/Antoni van Leeuwenhoek Hospital, Amsterdam, Netherlands; [3]Division of Clinical Pharmacology, NKI-AVL - Netherlands Cancer Institute/Antoni van Leeuwenhoek Hospital, Amsterdam, Netherlands; [4]Department of Pharmacy & Pharmacology, Netherlands Cancer Institute/Antoni van Leeuwenhoek, Amsterdam, Netherlands; [5]Division of Molecular Oncology & Immunology, NKI-AVL - Netherlands Cancer Institute/Antoni van Leeuwenhoek Hospital, Amsterdam, Netherlands

Background: Pancreatic ductal adenocarcinoma (PDAC) patients have a 5-year survival rate of < 5%. Therapy options are limited. *KRAS* is mutated in >85% of PDAC and could be a key target. Preclinical studies have shown that SHP2 and ERK inhibition in *KRAS* mutant (*KRAS*m) PDAC models results in inhibition of proliferation. The aim of this phase I/Ib trial is to assess safety and efficacy of treatment with SHP2 inhibitor RMC-4630 and ERK inhibitor LY3214996 in *KRAS*m PDAC, non-small cell lung carcinoma (NSCLC) and colorectal carcinoma (CRC) patients. In the expansion phase, only PDAC patients will be included. In preclinical setting, potential resistance markers will be investigated to anticipate patient response.

Methods: In the dose escalation phase, patients with *KRAS*m PDAC, NSCLC or CRC were treated in a 28-day cycle with RMC-4630 on day 1 and 2 every week and LY3214996 daily. The main objective was to determine the Recommended Phase II Dose (RP2D). Other objectives included safety and tolerability assessed by the incidence of adverse events, efficacy determined by objective response rate (ORR) according to RECIST 1.1, pharmacokinetics (PK), and pharmacodynamics assessed by MAPK downstream protein expression levels. Resistance markers were explored by CRISPR.

Results: Eleven patients were enrolled in 2 cohorts: Cohort 1a 140 mg RMC-4630 and 100 mg LY3214996; cohort 1b 100 mg RMC-4630 and 200 mg LY3214996. Eight patients were evaluable for dose limiting toxicity (DLT). In cohort 1a, 2 out of 5 patients developed a DLT: grade 3 thrombocytopenia and renal insufficiency. No DLTs occurred in cohort 1b. PK analysis showed high interpatient variability. The exposure of LY3214966 was dose proportional. The ORR in both cohorts was 0%. In *KRAS*m tumor cell lines, PTEN downregulation, c-JUN hyperactivation and increased PI3K/AKT/mTOR pathways activation were identified as mechanisms of resistance.

Conclusions: Two DLTs out of 5 patients limited the tolerability of the combination in cohort 1a, no DLTs were identified in cohort 1b. Patient enrolment is ongoing in the next dose level. The RP2D has not been determined yet. Alterations in the PI3K/AKT/mTOR and the c-JUN pathways could be markers for drug resistance, which data are pending.

Clinical trial identification: NCT04916236.

1631P Phase I study of endoscopic ultrasound (EUS)-guided NBTXR3 delivery activated by radiotherapy (RT) for locally advanced or borderline resectable pancreatic cancer (LAPC or BRPC)

G. Fuentes[1], M.J. Rodriguez[1], A. Al-Sharfeen[2], M.H. Katz[3], N. Ikoma[3], C-W.D. Tzeng[3], M.J. Overman[4], S. Pant[5], M.S. Lee[5], R. Wolff[5], M. Javle[6], C.M. Taniguchi[2], E.B. Ludmir[2], P. Das[2], A.C. Koong[2], O.I. Vivar[7], S. Liu[8], E.P. Tamm[9], M.S. Bhutani[10], E.J. Koay[2]

[1]Radiation Oncology, MD Anderson Cancer Center, Houston, TX, USA; [2]Department of Radiation Oncology, MD Anderson Cancer Center, Houston, TX, USA; [3]Department of Surgical Oncology, MD Anderson Cancer Center, Houston, TX, USA; [4]Gastrointestinal Medical Oncology Department, The University of Texas MD Anderson Cancer Center, Houston, TX, USA; [5]Department of Medical Oncology, MD Anderson Cancer Center, Houston, TX, USA; [6]Gastrointestinal Medical Oncology, MD Anderson Cancer Center, Houston, TX, USA; [7]Medical Affairs, Nanobiotix, Paris, France; [8]Biostatistics, The University of Texas MD Anderson Cancer Center, Houston, TX, USA; [9]Abdominal Imaging Department, MD Anderson Cancer Center, Houston, TX, USA; [10]Gastroenterology, Hepatology and Nutrition, MD Anderson Cancer Center, Houston, TX, USA

Background: Patients with LAPC or BRPC often receive RT after chemotherapy (chemo) if no metastatic progression has occurred, and CA19-9 historically normalizes ~20% after all therapy. While escalated dose RT (EDR) has shown promising survival in selected patients, RT dose limitations of the bowel often prevent safe EDR. To overcome this challenge, we are investigating NBTXR3, a functionalized hafnium oxide radio enhancer administered by a single intratumoral injection, locally amplifying the RT dose. The primary objective is to determine NBTXR3 recommended phase II dose (RP2D) and secondary objective is to measure anti-tumor effects.

Methods: The study uses a Bayesian optimal interval design (BOIN) with two parts: dose-finding for RP2D (NBTXR3 at [level 1] 33% of gross tumor volume [GTV] or [level 2] at 42% of GTV) and cohort expansion at RP2D. In part 1, eligibility criteria included only LAPC patients with no evidence of metastatic disease after 2-6 months of chemo, part 2 allows BRPC. NBTXR3 is given once prior to RT via EUS-guided intratumoral injection. All patients receive 45 Gy in 15 fractions to GTV. Target tumor response is per RECIST v1.1 criteria. CA19-9 is measured serially.

Results: As of January 12, 2023, 12 LAPC patients (median age 61 years [range 43-81], 8 males, 4 females) received protocol therapy. The first patient (level 1) and subsequent 11 patients (level 2) had no dose limiting toxicities (DLTs). At 4 weeks post RT, 11 had stable disease (SD) locally (1 had progressive disease [PD] overall) and 1 had radiographic complete response (CR). At 3 months post RT, 11 had SD locally (1 PD overall), and 1 had surgery with negative margins and no residual viable tumor. 6 patients had elevated CA19-9 before NBTXR3/RT, 5 of these 6 (83%) had a decrease in CA19-9 subsequently, and 2 of these 6 (33%) had CA19-9 normalization eventually. 9 patients had elevated CA19-9 at diagnosis, and 5 out of 9 patients (56%) had normalization of CA19-9 after all therapy.

Conclusions: The RP2D of NBTXR3 for LAPC is 42% of GTV. The successful CR and shift to resectability in this patient population, along with the response and CA19-9 decrease and normalization suggest promising anti-tumor efficacy of NBTXR3/RT.

1632P Organoids as tools for functional precision oncology in advanced pancreatic cancer

A. Boileve[1], J. Cartry[1], N. Goudarzi[1], S. Bedja[1], J. Mathieu[1], A. Mouawia[1], C. Nicotra[2], V. Boige[3], D. Malka[4], M. Valery[3], A.A. Tarabay[3], M.A. Bani[5], P. Dartigues[5], T. de Baere[6], A. Italiano[2], M. Gelli[7], C. Smolenschi[3], M.P. Ducreux[3], A. Hollebecque[3], F. Jaulin[1]

[1]U1279, Gustave Roussy - Cancer Campus, Villejuif, France; [2]DITEP, Institut Gustave Roussy, Villejuif, France; [3]Medical Oncology, Institut Gustave Roussy, Villejuif, France; [4]75, Institut mutaliste Montsouris, Paris, France; [5]Pathology, Institut Gustave Roussy, Villejuif, France; [6]Interventional radiology, Gustave Roussy, Villejuif, France; [7]Surgery, Institut Gustave Roussy, Villejuif, France

Background: Pancreatic ductal adenocarcinoma (PDAC) has a steadily increasing incidence and a poor prognosis. Patient (pts) tumors' derived organoids (PDO) are promising models for functional precision oncology (FPO). This study aims to evaluate whether PDO can be implemented in clinical practice for the management of PDAC pts.

Methods: During 2021-2022, pts were prospectively enrolled in an IRB-approved protocol (NCT04932525). Main inclusion criteria were histologically confirmed PDAC, at least one tumor accessible site (biopsy, surgery or effusions) and ECOG performance status 0-1. The efficacy of 25 antitumor therapies was tested (=chemogram) (ATP luminescence test). A scoring system was developed to rank drugs and to find hits.

Results: Overall, 81 patients were included (median age 61 years; median previous treatment lines 2 [range: 0-5]). 91% pts had previously received FOLFIRINOX, 61% gemcitabine and 49% (nab)-paclitaxel. PDO take-on rate was 62% (n=50/81) (notably, liver biopsy: 64%, ascites: 93%). Mean turnaround-time to chemogram was 6.7 weeks. Main PDO molecular alterations were *KRAS* (98%), TP53 (72%), CDKN2A/B (17%) and SMAD4 (17%) with good concordance rate (88%) with initial tumor. Median patients' overall survival from PDO sampling was shorter when PDO were established ($p<0.01$). Median number of hits was 3 (range 0-12). In 89% of cases, at least 1 hit

was identified, and in 84% of cases, at least one of the hits was not a Standard-of-Care (SOC, i.e., 5-FU, irinotecan, oxaliplatin, gemcitabine, or paclitaxel). Main identified hits were gemcitabine (n=17/50), docetaxel (n=16/50), olaparib (n=15/50), and vinorelbine (n=15/50). Evaluable pts that received a treatment that was a hit after PDO biopsy had a longer growth modulator index (GMI) (p= 0.0007) disease control rate (p=0.001) and progression-free survival (p=0.07, NS) than others. Sensitivity and specificity of PDO to predict pts response were 80% and 95.7% respectively.

Conclusions: We report a large prospective study that aims to implement PDO-based FPO for PDAC. In a clinically relevant turnaround time, at least one putative hit was identified in 89% of cases with good sensitivity and specificity. The benefit of PDO-based FPO warrant to be confirmed in a prospective randomized trial.

Clinical trial identification: NCT04932525.

1633P Development and clinical validation of news transcriptomic tools for predicting the response to individual drug of the mfolfirinox regimen in patients with pancreatic ductal adenocarcinoma

N. Fraunhoffer[1], C. Teyssedou[1], M. Bigonnet[2], P. Pessaux[3], J.L. Iovanna[4], N. Dusetti[1]

[1]CRCM - Centre de Recherche en Cancérologie de Marseille, Marseille, France; [2]Predicting Med, Marseille, France; [3]Hopitaux Universitaires de Strasbourg - Nouvel Hopital Civil, Strasbourg, France

Background: Current therapeutic options for patients with a pancreatic ductal adenocarcinoma (PDAC) implicate monotherapy (gemcitabine) or combined therapies (modified FOLFIRINOX). mFFX treatment is accompanied by a high toxicity and therefore, administration of mFFX is conditioned by the performance of the patients, rather by rational criteria. In this work, we developed transcriptomic signatures for each drug of the mFFX regimen and validate their clinical interest.

Methods: To extract biologically relevant signatures for 5FU, oxaliplatin and irinotecan, we integrated transcriptomic data from patient-derived primary cell cultures (PDC), patients-derived organoids (PDO) and patient-derived xenografts (PDX) with their corresponding chemo-response profiles to capture the biological components responsible for the response to each drug. The genes displaying the highest levels of contribution defined the signatures 5FUCore, OxaCore and IriCore. We further validated the signatures in a pooled cohort of 167 patients with advanced and metastatic PDAC (94 patients from the COMPASS cohort and 73 from the Angers-Strasbourg cohort).

Results: All three signatures captured high responder patients for overall survival (OS) and progression-free survival (PFS) in the mFFX arm exclusively. We then studied the response of patients to 0, 1, 2 and 3 drugs and we identified a positive correlation between the number of drugs predicted as sensitive and the OS and PFS, and with the objective response rate. We next evaluated the level of association between the PurIST classifier and our signatures. We found an association between both OxaCore and IriCore and the classical subtype, but none with 5FUCore. However, we observed in a multivariate Cox regression that our model based on independent signatures displayed higher predictive value for the OS and PFS.

Conclusions: We developed three novel transcriptome-based signatures which define sensitivity for each mFFX components that can be used to rationalize the administration of the mFFX regimen and could help to avoid unnecessary toxic effects.

1634P Extensive molecular profiling of KRAS wild-type versus KRAS mutant pancreatic ductal adenocarcinoma on 233 patients

J. Lena[1], M. Alamé[2], A. Italiano[3], I. Soubeyran[2], L. Blouin[2], E. Khalifa[2], S. Cousin[1], S. Pernot[4], L-J. Palmieri[4]

[1]Medical Oncology Dept., Institute Bergonié - Centre Régional de Lutte Contre le Cancer (CLCC), Bordeaux, France; [2]Biopathology Department, Institute Bergonié, Bordeaux, France; [3]Early Phase Trials Unit, Institute Bergonié, Bordeaux, France; [4]Digestive Medical Oncology Unit, Institut Bergonié, Bordeaux, France

Background: Molecular profiling is increasingly implemented to guide treatment of pancreatic ductal adenocarcinoma (PDAC), especially if enrolment in clinical trials is considered. The aim of our study was to describe actionable alterations detected in *KRAS* mutant (*KRASm*) versus *KRAS* wild-type (*KRASwt*) PDAC, as the latter is considered as harboring more molecular alterations.

Methods: This monocentric prospective study included patients with locally advanced or metastatic PDAC who underwent next-generation sequencing (NGS) on liquid biopsy and/or tissue sample between 2015 and 2022 (FoundationOne® CDx, Liquid CDx or Oncomine Comprehensive Assay), as part of the BIP study (NCT02534649).

Results: 233 patients with a PDAC underwent NGS: 63 on tissue samples alone, 95 on liquid biopsies alone, and 75 on both tissue and liquid. Among 170 liquid biopsies, 90 were informative (52.9%). Among 196 patients with informative NGS, 172 patients (87.8%) had a *KRASm* PDAC, and 24 a *KRASwt* PDAC (12.2%). Median overall survival (OS) in the *KRASwt* group was 27.8 versus 20.3 months for *KRASm* patients (HR 0.58, CI (0.39-0.87), p=0.02). ESCAT alterations were found in 17.3% of total population, 25.0% in *KRASwt* group and 16.3% in *KRASm* group. All 7 *BRCA1/2* germline mutations were detected in the *KRASm* group. 1 *NTRK* fusion was found in a *KRASwt* PDAC. *BRCA1/2* somatic mutations, *PIK3CA* hotspot mutations, *MDM2* amplifications and *ERRB2* alterations were found similarly in both groups. We detected 5 *KRAS* G12C mutations. Patients harboring ESCAT alterations had a median OS of 25.0 versus 19.6 months for those without (HR 0.85, 95%CI (0.58 − 1.23), p=0.40). 66 patients (33.7%) were eligible to early-phase trials according to the molecular tumor board and 10 patients (5.1%) were effectively enrolled, with a range of time to progression between 22 days and 11 months.

Conclusions: Although actionable mutations are more prevalent in the *KRASwt* group, 16.3% of *KRASm* patients harbored ESCAT alterations, underlying the need for molecular profiling regardless of *KRAS* status.

Background: Assessment of germline BRCA1-2 pathogenic variants (gPV) is routinely recommended in Pancreatic Ductal Adenocarcinoma (PDAC) patients (pts), due to clinical-epidemiological relevance. Limited data are available on the prevalence of gPV

in other cancer predisposition genes, including the DNA Damage Response (DDR) system.

Methods: Clinical data of consecutive PDAC pts, of any age and stage, tested with a multigene germline panel between January 2018 and March 2023 in five Italian Institutes were collected. A descriptive analysis of gPV (class 4 and 5) frequency, clinical variables and risk factors, was performed. Since gene panels did not overlap across all Institutes, it was difficult to properly estimate the real prevalence of gPV and to compare the clinical characteristics of all wild type with any-PV population, as screened pts/gene also varied (291-1200). Herein we report the best scenario that may result in rates underestimation.

Results: Among the 1200 pts included in the analysis, 169 (14%) had a gPV (any-PV). 23/73 genes had a gPV in $\geq$ 1 patient. Genes with a gPV in >1% of tested pts were ATM (36/1200 - 3.0%), BRCA2 (35/1200 - 2.9%), CDKN2A (23/942 - 2.4%), BRCA1 (18/1200 - 1.5%), CHEK2 (11/838 - 1.3%), and COL7A1 (5/447 - 1.1%). Characteristics of the main cohorts are shown in the table. The risk of having a genomic gPV was $\geq$9% in all the subgroups of pts considered for the different variables, including >73 years old pts (11%). Moreover, 25% of pts with age 41-50, 18% of obese pts and 21% of pts with PDAC/breast/ovarian/prostate cancer/melanoma family history harbored a gPV.

Table: 1635P Patients' characteristics [N (%)]

NA: not available

Conclusions: Our study highlighted a remarkable prevalence of gPV in cancer predisposition and DDR genes in a large cohort of PDAC pts. These findings endorse the implementation of an extended multigene germline panel to be offered to all PDAC pts, irrespective of age, stage, and personal/family history.

Background: Pts with advanced PC have limited treatment (Tx) options. Research has focused on identifying a subset of pts who may benefit from targeted therapies. ctDNA genomic profiling by NGS is an emerging non-invasive diagnostic tool. We show the genomic landscape of advanced PC pts using ctDNA.

Methods: We conducted a retrospective multicentre analysis of PC pts that underwent ctDNA blood sample testing 10 days after any Tx line progression. Samples were analysed by standardised Guardant360 assay covering microsatellite instability (MSI) evaluation and somatic alterations among 74 genes reported as pathogenic or non-pathogenic. Hereditary syndromes genes with VAF $\geq$ 30% were confirmed by Sanger. Demographic data were obtained from medical records. Potential therapeutically relevant alterations (pTRA) were classified according to OncoKB and ESCAT levels of evidence (LE), consulted 05/2023. Negative ctDNA reports were interpreted as absence or low levels of detectable mutations (mut).

Results: We collected blood samples of 242 PC pts from 07/2017 to 08/2022 from 7 hospitals in Spain. Most pts were diagnosed with metastatic PC; 52% were male, 56% were <65 yrs. old and 45% were Tx naïve. Median turnaround for molecular reports was 6 days. A total of 736 gene alterations were detected, 78% pathogenic and 18% pTRA. Negative ctDNA was reported in 48 pts (20%). *TP53* (67%) was the most frequently altered gene, followed by *KRAS* (62%). Additionally, we identified incidental germline cancer predisposition mut detected in 9 pts (4%), 3 *ATM* and 6 *BRCA2*. Description of pTRA according to OncoKB and ESCAT LE in the table. Only 4 (2%) pts with *BRCA2* mut received PARP inhibitors Tx.

Table: 1636P Number of potential therapeutically relevant alterations according to OncoKB and ESCAT levels of evidence

	Pathogenic	Non-Pathogenic	OncoKB	ESCAT
MSI-High	2	0	1	IC
BRAF^{V600E}	1	0	1	IIIA
BRCA1 BRCA2	3 13	8 6	2	Germline IA Somatic IIIB
KRAS^{G12C} *KRAS*^{G12D}	2 18	0 0	3 4	IIB IIIA
ARID1A	15	9	4	IVA
CDKN2A	34	3	4	IIIA
PIK3CA	8	1	4	IIIA
TP53^{Y220C}	6	0	3	IIIA
Others	474	133	-	-

Conclusions: ctDNA is a feasible and non-invasive tool for identifying pTRA in advanced PC pts and adds value by detecting hereditary syndromes. Even though very few pts receives molecular targeted therapy. We highlight a clinical practice gap and the unmet medical need for new treatment options.

1637P Early retention of KRAS mutations in cfDNA is an ominous sign for pancreatic cancer patients during chemotherapy: A prospective cohort study

C-J. Huang[1], W-Y. Huang[2], N-J. Chiang[3], M-Y. Lin[1], C-J. Yen[4], Y-S. Shan[5]

[1]Division of Gastroenterology and Hepatology, Department of Internal Medicine, NCKUH - National Cheng Kung University Hospital, Tainan City, Taiwan; [2]Institute of Clinical Medicine, NCKUH - National Cheng Kung University Hospital, Tainan City, Taiwan; [3]Department of Medical Oncology, Taipei Veterans General Hospital, Taipei, Taiwan; [4]Department of Medical Oncology, NCKUH - National Cheng Kung University Hospital, Tainan City, Taiwan; [5]Department of Surgery, NCKUH - National Cheng Kung University Hospital, Tainan City, Taiwan

Background: Pancreatic ductal adenocarcinoma (PDAC) has a notoriously poor prognosis after treatments without precise biomarkers. The traditional biomarker, carbohydrate antigen 19-9 is not suitable for timely checking treatment responses for all PDAC patients. The usage of low-invasive liquid biopsies, e.g., cell-free DNA (cfDNA) from blood, has shown to improve prognostication for several cancers, but not precisely for PDAC, especially for predictive prognosis by longitudinal sampling. This study aims to address the issue that the dynamic occurrence of oncogenic mutations in cfDNA from serial monitoring could be served as a predictive indicator of disease outcomes in PDAC patients after chemotherapy.

Methods: A total of 65 advanced-staged PDAC patients were enrolled. The plasma cfDNA were subjected to next generation sequencing with a panel of tumor-associated genes and confirmed by digital PCR. Patients were grouped by three risky levels which were designated by the quantities of cfDNA and presence of the oncogenic mutations in cfDNA after treatment (post-cfDNA). Association of different risk factors with progression-free survival (PFS) and overall survival (OS) was assessed in Kaplan-Meier curves and Cox regression analyses.

Results: In the prospective cohort, high-risk patients who had high levels of cfDNA over the threshold showed the worst PFS and OS [HR= 8.83 (3.99-19.51) in PFS, $p<0.001$; HR=4.25 (2.24-8.06) in OS, $p<0.001$]. The medium-risk patients, whose cfDNA levels were lower than the threshold but contained KRAS mutants in post-cfDNA, demonstrated moderately worse PFS and OS than low-risk patients without elevated levels and KRAS mutants in post-cfDNA [low risk as reference, HR= 6.08 (2.42-15.27) in PFS, $p<0.001$; HR=2.64 (1.18-5.91) in OS, p=0.018]. However, patients with TP53 mutants in cfDNA after treatments showed no significance correlations to either PFS (p=0.144) or to OS (p=0.098), respectively.

Conclusions: Early retention of oncogenic KRAS mutants in cfDNA after chemotherapy is an independent factor in predicting worse OS and PFS in PDAC patients. The serial molecular response of oncogenes in post-cfDNA could serve as a leading biomarker in monitoring clinical outcomes in PDAC patients.

1638P The prognostic and predictive role of class III β-tubulin and hENT1 expression in patients with advanced pancreatic ductal adenocarcinoma

T.K. Sahin[1], A. Isik[2], D.C. Guven[3], F. Ceylan[4], B. Babaoglu[5], A. Akyol[5], S. Yalcin[3], O. Dizdar[3]

[1]Department of Internal Medicine, Hacettepe University Faculty of Medicine, Ankara, Turkey; [2]Transgenic Animal Technologies Research and Application Center, Hacettepe University, Ankara, Turkey; [3]Department of Medical Oncology, Hacettepe University Cancer Institute, Ankara, Turkey; [4]Department of Medical Oncology, Ankara City Hospital, Ankara, Turkey; [5]Department of Pathology, Hacettepe University Faculty of Medicine, Ankara, Turkey

Background: FOLFIRINOX and gemcitabine-nabpaclitaxel (GnP) are both standard first-line treatment regimens for advanced pancreatic ductal adenocarcinoma (PDAC), however, predictive biomarkers are currently lacking to guide treatment selection. We aimed to investigate the prognostic and predictive value of class III β-Tubulin (TUBB3) and human equilibrative nucleoside transporter 1 (hENT1) expression, which have previously been shown to be associated with taxane and gemcitabine resistance in advanced PDAC.

Methods: We conducted a retrospective analysis of 106 patients with advanced PDAC at Hacettepe University Cancer Institute. TUBB3 and hENT1 immunohistochemical staining were analyzed in tumor specimens and scored jointly according to the intensity of expression: high score ($TUBB3^{low}/hENT1^{high}$) and low score ($TUBB3^{high}/hENT1^{high}$, $TUBB3^{low}/hENT1^{low}$ or $TUBB3^{high}/hENT1^{low}$). Response rates and progression-free survival (PFS) rates were compared based on TUBB3 and hENT1 expression.

Results: The median age was 60 years (range; 38-80 years) and 65% were male patients. The median progression-free survival (PFS) and overall survival (OS) of patients were 6.83 and 12.06 months, respectively. In patients who received the GnP regimen (n=68), a high combined score ($TUBB3^{low}/hENT1^{high}$) was associated with a higher disease control rate (DCR) (84.2% vs. 39.6%, p=0.001) and longer PFS (8.76 months vs. 3.1 months, $p<0.001$) compared to those with low score. In the multivariate analysis, a high combined score was an independent predictor of higher DCR (OR: 11.96; 95% CI: 2.61-54.82; p=0.001) and longer PFS (HR: 0.33; 95%CI: 0.18−0.60; $p<0.001$). However, there was no difference in response rates or PFS based on TUBB3 and hENT1 expression among patients receiving FOLFIRINOX regimen.

Conclusions: Our findings suggest that tumor TUBB3 and hENT1 expression may predict the efficacy of GnP regimen, and low TUBB3 and high hENT1 expression are associated with a higher DCR and longer PFS in patients with advanced PDAC.

1639P Feasibility of tumor genomic sequencing on tissue obtained from endoscopic ultrasound in patients with pancreatic cancer

V. Florou, J. Smith, J. Morris, C. Ko, C.D. Nevala-Plagemann, K. Barber, L. Olson, H.P. Soares, I. Garrido-Laguna

Internal Medicine, University of Utah Health- Huntsman Cancer Institute, Salt Lake City, UT, USA

Background: Endoscopic fine needle biopsy (EUS-FNB) is an effective tissue sampling modality for diagnosing pancreatic cancer. Genomic sequencing is becoming essential with the emerging targeted therapies in pancreatic cancer. However, the feasibility of commercial comprehensive next-generation sequencing on tissue obtained from EUS-FNB is unknown. We aimed to examine the success rate of genomic sequencing utilizing tissue from EUS-FNB and correlate it with procedural characteristics.

Methods: We retrospectively reviewed a consecutive cohort of patients who underwent a diagnostic EUS-FNB during the workup of a pancreatic mass, over five years, at our institution. Genomic results, patient demographics, tumor characteristics, and technical aspects of the EUS-FNB were reviewed. The successful completion of sequencing was defined as the generation and reporting of DNA sequencing results.

Results: A total of 396 patients underwent endoscopic ultrasound with pancreatic mass biopsy as part of the routine diagnostic workup. Tumor sequencing from the pancreatic EUS-FNB was requested from 101 patient samples. The remaining samples had no sequencing performed, or sequencing was requested on pancreatectomy samples and/or metastatic sites. Of the 101 patients, sequencing was successful in 88 samples (87%). The median number of needle passes to obtain sufficient tissue for completion of sequencing was 3 (range 1-5). Tumor purity information was available in 71 samples; the average purity was 32% (range 20-90%). Genomic sequencing was unsuccessful in the remaining 13 samples (13%) due to inadequate tissue. The median number of needle passes for these patients was 2 (range 1-5). The cancer stage distribution for patients whose tumor sequencing was requested from pancreatic biopsies was the following: I (9%), II (10%), III (14%), and IV (67%). Genomic sequencing results will be presented at the meeting.

Conclusions: Comprehensive genomic sequencing of all stages of pancreatic cancer is feasible on EUS-FNB. Increasing the number of needle passes can increase the yield for tumor genomic sequencing. This is particularly important for locally advanced, unresectable pancreatic cancers without alternative sites for tissue sampling.

1640P Response monitoring with ctDNA in metastatic pancreatic cancer

J. Ahn, K. Jung, J. Lee, B. Kim, J-C. Lee, J. Kim, J-H. Hwang

Department of Internal Medicine, Seoul National University Bundang Hospital, Seongnam, Republic of Korea

Background: Various studies about clinical usefulness of serial monitoring with liquid biopsy are being conducted actively in many types of cancer. However, there is not much in pancreatic cancer. We explored whether serial ctDNA monitoring in metastatic pancreatic cancer (MPC) can be beneficial for evaluating treatment response and predicting prognosis.

Methods: A total of 76 MPC patients were prospectively enrolled. Blood samples were collected at every response evaluation until progression of disease (PD) or 5th evaluation. Quantitative ctDNA were measured by droplet digital polymerase chain

reaction using *KRAS G12/G13* screening multiplex Kit (Bio-Rad) and reported as variant allele fraction (VAF). Percent change of ctDNA VAF (DctDNA(%) = (current VAF - previous VAF)/previous VAF*100) were correlated to radiographic responses by RECIST 1.1 and tumor volume. Furthermore, Progression free survival (PFS) and overall survival (OS) were analyzed by DctDNA.

Results: Among the 76 enrolled patients, baseline ctDNA were detected in 65 patients. Patients with hepatic metastasis had higher baseline ctDNA level than other metastasis (p=0.038). During a median follow-up of 11.3 months, PD by radiographic response was observed in 43 patients. As expected, PD group showed higher DctDNA compared with non-PD group (p=0.013). The group with increased tumor volume exhibited higher DctDNA levels than the other groups (p=0.028). DctDNA for PD yielded Area Under Curve of 0.839 (p<0.001) with 73.3% sensitivity at 90% specificity. Patients who showed early ctDNA clearance had longer PFS (8.2 m vs 4.8 m; HR 0.45; 95% CI 0.20 to 1.03; p=0.059) and OS (16.6 m vs 10.8 m; HR 0.22; 95% CI 0.07 to 0.75; p=0.013) than those who did not. In multivariable analysis, early ctDNA clearance was still associated with significantly longer PFS (HR 0.29; p=0.036) and OS (HR 0.11; p=0.014).

Table: 1640P

Prognostic Factor	PFS HR	P value	OS HR	P value
ctDNA clearance	0.29 (0.11-0.93)	0.036	0.11 (0.04-0.57)	0.014
Age	0.97 (0.92-1.03)	0.326	1.02 (0.95-1.10)	0.629
Sex male	1		1	
female	0.58 (0.18-2.04)	0.410	0.24 (0.03-1.85)	0.171
Primary site Head	1		1	
Body	1.92 (0.62-5.97)	0.260	7.80 (1.17-51.87)	0.034
Tail	1.08 (0.30-3.91)	0.906	0.44 (0.04-5.54)	0.525
Metastatic site Liver	1		1	
Lung	0.81 (0.08-8.19)	0.859	0.78 (0.05-13.23)	0.860
Peritoneum	1.15 (0.34-3.91)	0.823	5.87 (0.79-43.64)	0.084
Multiple	1.03 (0.36-2.95)	0.962	1.38 (0.22-8.78)	0.081
Chemotherapy FOLFIRINOX	1		1	
GNP	1.43 (0.51-4.03)	0.495	4.09 (0.84-19.95)	0.081
CA 19-9 < 1900	1		1	
≥ 1900	1.08 (0.45-2.60)	0.873	1.44 (0.27-7.87)	0.671

Conclusions: Serial monitoring with ctDNA in MPC has considerable clinical potential in monitoring treatment response and predicting prognosis.

1641P ABCG transporter and SRPK1 kinase inhibition of chemotherapy resistance: A phase Ib clinical trial of safety and maximum tolerated dose for SCO-101 in combination with gemcitabine and nab-paclitaxel in inoperable pancreatic cancer

M. Ladekarl[1], S. Shim[1], T.J. Ettrich[2], A. Kestler[2], P. Pfeiffer[3], L.S. Tarpgaard[3], A. Reinacher-Schick[4], A-L. Kraeft[4], J. Stenvang[5], A. Zurlo[5], N. Lindland Roest[5]

[1]Department of Oncology, Aalborg University Hospital, Aalborg, Denmark; [2]Department of Internal Medicine I, University Hospital Of Ulm - Oberer Eselsberg, Ulm, Germany; [3]Experimental research in medical cancer therapy, OUH - Odense University Hospital, Odense, Denmark; [4]Dept. of Hematology, Oncology and Palliative Care, St. Josef-Hospital, Bochum, Germany; [5]Scandion Oncology A/S, Scandion Oncology A/S, Copenhagen, Denmark

Background: Gemcitabine (Gem) and nab-paclitaxel (Nab) is a standard treatment for pts with inoperable pancreatic cancer (iPC), but a high frequency of chemoresistance is observed clinically. SCO-101 is a compound for oral use that was shown to revert drug resistance in preclinical studies: In taxane-resistant cancer cells SCO-101 resensitized tumor cells to taxane and reduced the active efflux of ATP Binding Cassette G2 substrate molecules from irinotecan resistant colon cancer cells. Moreover, SCO-101 inhibits Serinine-Arginine Protein Kinase 1, which may increase sensitivity of tumor cells to Gem. In clinical phase I studies, SCO-101 was well tolerated after single (up to 200 mg) and multiple (up to 150 mg daily for 14 days) doses.

Methods: This open-label, phase Ib study was conducted at four centers in Denmark and Germany as a standard 3+3 dose escalation study with increasing doses of SCO-101 and 80% dose of Gem-Nab in pts with iPC. Here we report on the primary objective to determine safety and Maximum Tolerated Dose (MTD) by evaluation of Dose-Limiting Toxicities (DLTs) related to SCO-101 during the first treatment cycle.

Results: 22 pts were included. Median age was 65 years (range 51-77) and 16 had ECOG PS=0. 11 pts had prior PC-related surgery and 19 had previously received chemotherapy. SCO-101 was dosed once daily for 6 days on days 1-6 and 15-20 on a bi-weekly schedule and chemotherapy given on day 6, 13 and 20. MTD was determined to be 200mg (Table). DLTs included increased conjugated bilirubin and decreased platelet count.

Table: 1641P Results of dose escalation

Cohort	No of pts	No of DLTs	*Type and grade of DLT (*Graded according to CTC ver. 5.0)
50 mg of SCO-101	3	0	
100 mg SCO-101	3	0	
150 mg SCO-101	6	1	Conjugated bilirubin gr. 3
200 mg SCO-101	6	0	
250 mg SCO-101	4	2	Decreased platelet count gr. 4
Total	22	3	

Conclusions: The combination of SCO-101 and Gem-Nab was generally well tolerated. DLTs were observed in 2 pts in the cohort treated with 250mg of SCO-101, hence MTD for SCO-101 concurrent with Gem-Nab was determined to be 200mg once daily for 6 days on a bi-weekly schedule. A full description of toxicities is pending.

Clinical trial identification: NCT04652206.

Background: Pancreatic ductal adenocarcinoma (PDAC) is marked by a desmoplastic stroma and poor prognosis. Current pathological or molecular classifications are discordant and not applied in routine clinical practice. In order to predict relapse-free survival (RFS), we aimed to develop an immunohistochemical (IHC) signature involving immune, fibroblastic, tumor markers in a cohort of 217 resected PDAC patients.

Methods: Tumors were collected for tissue microarrays construction and characterized by digital pathology with 13 IHC stains at the tumor epithelial, immune and stromal compartments. Cox proportional hazard models were performed to estimate hazard ratio and CI95% for factors associated with RFS.

Results: Multivariate Cox analysis showed that loss of membrane localization of β-catenin on tumor cells (HR=1.54, 95%CI=1.08-2.20, p=0.02), a low density of tumor infiltrating CD8+ T-cells (HR=1.72, 95%CI =1.23-2.41, p<0.01) and a high percentage of HSP47-positive Cancer-Associated Fibroblasts (CAF) (HR=1.41, 95%CI =1.03-1.96, p=0.03) were independent predictors of reduced RFS. Based on the expression of these three markers, we constructed a scoring system to classify resected PDAC into three distinct prognostic groups (p<0.001): 0/1+ (mRFS=8.4, 95%CI=6.7-9.9), 2+ (mRFS=13.1, 95%CI=10.7-16.4) and 3+ (mRFS=22.5, 95%CI=17.1-131.7). The discriminative ability of the three-group model was confirmed in overall survival analysis. Furthermore, with the exception of neoadjuvant therapy (p=0.03) and the presence of lymphovascular invasions (p=0.04), the score developed was not related to other clinicopathological data.

Conclusions: We propose a novel RFS prediction model based on three independent prognostic IHC markers evaluating tumor epithelial, immune and fibroblastic compartments. These results highlight considerable heterogeneity in the survival of patients with resected PDAC. Moreover, this is the first demonstration of the prognostic character of HSP47 by IHC in PDAC.

1643P Clinical outcomes of FOLFIRINOX as front-line therapy in patients with localized pancreatic adenocarcinoma: Asian retrospective study of 781 patients

K. Bang[1], H. Yoon[2], J.H. Lee[3], D.W. Hwang[3], K.B. Song[3], S.C. Kim[3], B-Y. Ryoo[2], K-P. Kim[2], C. Yoo[2]

[1]Division of Hemato-Oncology, Department of Internal Medicine, Chung-Ang University, Gwangmyeong Hospital, Gyeonggi-do, Republic of Korea; [2]Department of Oncology, Asan Medical Center - University of Ulsan, Seoul, Republic of Korea; [3]Division of Hepatobiliary and Pancreatic Surgery, Department of Surgery, Asan Medical Center - University of Ulsan, Seoul, Republic of Korea

Background: Neoadjuvant (m)FOLFIRINOX has been established as one of standard therapy for borderline resectable (BRPC) and locally advanced pancreatic cancer (LAPC). Recently, its use has been expanded to resectable pancreatic cancer (RPC), but large pragmatic studies, particularly in Asia, to show the implication of localized pancreatic adenocarcinoma are still lacking.

Methods: This retrospective study included 781 patients with localized pancreatic adenocarcinoma who received (m)FOLFIRINOX as initial therapy in Asan Medical Center, Seoul, Korea, between DEC 2017 and DEC 2020.

Results: The median age was 62 years, and 341 (43.8%) patients were female. According to the NCCN criteria, 131 (16.8%), 326 (41.9%), and 321 (41.3%) patients had RPC, BRPC and LAPC, respectively. The objective response rates were 22.1%, 16.3%, and 15.0%, respectively. The curative-intent resection (R0 or R1) was performed in 94 (71.8%) patients of the RPC group, 137 (42.0%) patients of the BRPC group, and 40 (12.5%) patients of the LAPC group; patients who underwent curative resection, the R0 resection rates were similar among three groups (86.2%, 86.1%, and 80.0%, respectively). There were 11 patients who achieved surgery following salvage chemotherapy after progression on initial (m)FOLFIRINOX. The median overall survival (OS) was 28.1 months (95% CI, 22.7—33.5) for RPC, 22.0 months (95% CI, 19.8—24.1) for BRPC, and 20.3 months (95% CI, 18.7—21.9) for LAPC ($p<0.001$). In each resectability group, median OS was significantly better in patients with surgical resection (RPC, 41.6 *vs* 14.5 months, $p<0.001$; BRPC, 37.3 *vs* 14.7, $p<0.001$; LAPC, 51.4 *vs* 18.5 months, $p<0.001$). In multivariate analysis, female gender, RPC, baseline CA 19-9 $<$ median (118.7 U/mL), objective response (CR or PR), and curative-intent surgery were significantly associated with better OS.

Conclusions: This large retrospective cohort study provides the realistic key clinical outcome data such as resection rates, survival outcomes and prognostic factors in RPC, BRPC and LAPC treated with front-line (m)FOLFIRINOX.

1644P The mutation landscape and evolution pattern of liver or peritoneal metastasis in pancreatic cancer

G. Yao[1], Q. Zhang[2], Y. Tan[2], Q. Duan[2], D. Chen[2]

[1]Department of Hepatobiliary Surgery, The First Affiliated Hospital of Henan University of Science and Technology - Kaiyuan Campus, Luoyang, China; [2]The Medical Department, Jiangsu Simcere Diagnostics Co., Ltd., Nanjing, China

Background: Pancreatic ductal adenocarcinoma (PDAC) has been found to metastasize in more than 50% of patients at the time of their initial diagnosis. This is considered to be the main reason for mortality. The liver and peritoneum are frequently observed as metastatic locations in cases of PDAC. The mutational profile and evolutionary patterns of metastatic lesions in the liver and peritoneum in pancreatic cancer remain poorly understood.

Methods: Whole exome sequencing (WES) was performed on 47 samples from 30 treatment-naïve, synchronously resected hepatic or peritoneal metastatic PDACs. The present study examined 10 primary tumours that did not metastasize within a year after surgery (non-PTs), 8 matched pairs of liver-metastatic primary (LiM-PTs) and metastatic (LiM-MTs), 9 matched pairs of peritoneal-metastatic primary (PeM-PTs), and 3 unpaired primary and metastatic tumours.

Results: KRAS mutations were found in 89.65% (26/29) of primary tumours, 70% (7/10) of liver metastases, and 100% (8/8) of peritoneal metastases. Interestingly, PCDHB14 and PXDN mutations were only detected in non-PTs, MUC16 were only detected in LiM-PTs, and ZNF594 were only detected in PeM-PTs, although there was no statistical difference. Meanwhile, the LiM-MTs group had higher TMB than PeM-MTs group (P=0.048). Mutation pattern analysis found that transitions outnumbered transversions in all samples. The paired LiM-PTs and PeM-PTs samples underwent GO and KEGG analyses. The ECM-receptor interaction signaling pathway that has been linked to metastasis in other cancer types was found to be distinct in LiM-PTs as compared to other groups. On the other hand, the proteoglycans and calcium signaling pathway was found to be unique to LiM-MTs when compared to PeM-MTs. Phylogenetic relationships analysis found that neither the LiM group nor the PeM group has a unified evolutionary pattern.

Conclusions: This research reveals that PDAC liver metastasis and peritoneal metastasis differ in mutated genes and evolutionary pattern. These results suggest that different biological mechanisms may exist in metastasis to different sites, and also highlights the need for more precise personalized treatment for PDAC in clinical practice.

1645P STAT3, ACTA2, and SPARC stromal markers predict response to Gemcitabine/Cisplatin/Nab-paclitaxel (GCN) in patients with advanced pancreatic adenocarcinoma (apdac)

H.J. Mahadevia[1], U. Majeed[2], J. Starr[2], J.C. Jones[3], D. Ahn[4], S. Wu[5], J. Andring[5], H. El Shawa[5], J. Xiu[5], G. Sledge[6], I. Astsaturov[7], S. Goel[8], P.A. Philip[9], M. Borad[10], T. Bekaii-Saab[11], H. Babiker[2]

[1]Internal Medicine, UMKC (University of Missouri Kansas City), Kansas City, MO, USA; [2]Hematology/Oncology, Mayo Clinic, Jacksonville, FL, USA; [3]Oncology Department, Mayo Clinic - Florida, Jacksonville, FL, USA; [4]Hematology/Medical Oncology Department, Mayo Clinic Cancer Center, Phoenix, AR, USA; [5]Clinical and Translational Research, Caris Life Sciences - Headquarters, Irving, TX, USA; [6]Precision Oncology, Caris Life Sciences - Headquarters, Irving, TX, USA; [7]GI Oncology, Fox Chase Cancer Center - Main Campus, Philadelphia, PA, USA; [8]Medical Oncology Dept., Rutgers Cancer Institute of New Jersey, New Brunswick, NJ, USA; [9]Oncology Department, Karmanos Cancer Institute, Detroit, MI, USA; [10]Oncology Department, Mayo Clinic Cancer Center, Scottsdale, AZ, USA; [11]Medical Oncology Department, Mayo Clinic Cancer Center, Phoenix, AR, USA

Background: GN is front-line therapy for aPDAC. Addition of Cisplatin showed high overall response rate, progression free survival (PFS), and median overall survival (mOS) in aPDAC patients in a phase II study. However, biomarkers predicting response or resistance to GCN are lacking. We hypothesize that addition of cisplatin alters the aPDAC tumor microenvironment.

Methods: Analysis of 1379 aPDAC patients using Next-Gen sequencing (NGS) of the DNA (NextSeq, 592 genes or NovaSeq, WES) and RNA (NovaSeq, WTS) (Caris Life Sciences, Phoenix, AZ) was done to determine biomarkers of response to GCN versus GN (DNA damage repair mutations/DDRMs and stromal gene markers). Real-world mOS was extracted from insurance claims data and calculated using Kaplan-Meier estimates for molecularly defined cohorts from first treatment of GN or GCN to last contact. Time on treatment (ToT) was obtained similarly as the time of first treatment of GN or GCN to last treatment.

Results: 1204 aPDAC patients received GN therapy among which 47% were female. 175 aPDAC patients received GCN regimen (47.5% were female). GCN was associated with higher mOS (534 vs 275 days(d), HR:0.61, $p<0.001$) and longer ToT (238 vs 105 d, HR:0.43, $p<0.001$) compared to GN. No difference in mOS and ToT was seen with either regimen in patients harboring somatic DDRMs (BRCA, CHEK, FANC, MSH, MLH and others). High STAT3 (957 vs 421 d, HR:0.44, p=0.017), ACTA2 (957 vs 421 d, HR:0.45, p=0.019) and SPARC (1029 vs 421 d, HR:0.49, p=0.038) gene expressions were associated with improvement in mOS on GCN whereas STAT2 had no association. Several stromal genes including TGFB1, TGFB2, HAS-2 and IL-6 correlated with worse mOS following GN therapy. High MMP-2 expression was associated with better mOS (p=0.007) and longer ToT (p=0.006) in patients who received GN.

Conclusions: GCN demonstrated higher mOS and ToT compared to GN. There was no difference in outcome among patients with somatic DDRMs. High expression of STAT3, ACTA2, and SPARC was associated with significant mOS benefit in patients who received GCN. In patients who received GN, MMP-2 was associated with better outcome. Analysis of stromal markers STAT3, ACTA2, and SPARC in a prospective trial is ongoing.

1646P Genomic and prognostic differences in patients with different KRAS mutations in pancreatic cancer

C. Xu[1], W. Wang[2], X. Li[3], Y. Zeng[4], F. Pang[3]

[1]Respiratory Medicine, Affiliated Jinling Hospital, Medical School of Nanjing University, Nanjing, China; [2]Department of Chemotherapy, Zhejiang Cancer Hospital, Hangzhou, China; [3]Medical Department, Shanghai OrigiMed Co., Ltd., Shanghai, China; [4]Operational Department, Shanghai OrigiMed Co., Ltd., Shanghai, China

Background: Approximately 90% of pancreatic cancer patients carry *KRAS* mutations, and about 80% of pancreatic cancer patients are diagnosed at advanced stage with poor efficacy of first-line treatment. Currently, several anti-tumor small molecule drugs targeting *KRAS* are under clinical investigation. Exploring the genomic and prognostic information of *KRAS*-mutated patients can help identify suitable pancreatic cancer patients for targeted therapy.

Methods: From 2017 to 2020, a total of 487 tumor samples were collected from pancreatic cancer patients across China. The laboratory Origimed, certified by the College of American Pathologists (CAP) and Clinical Laboratory Improvement Amendments (CLIA), conducted next-generation sequencing (NGS) of 450 cancer-related genes (YUANSU™) in Shanghai, China.

Results: In this study, we found that among 487 patients with pancreatic cancer, the percentages of *KRAS* G12, non-G12 *KRAS* mutations, and *KRAS* wild-type were 79.9%, 7.8%, and 12.3%, respectively. Furthermore, we found that pancreatic cancer patients with *KRAS* mutations were more likely to have *TP53* mutations (82.2% vs 78.4% vs 48.3%, $p=9.7x10^{-8}$), while *BRAF* (23.3% vs 2.6% vs 0.5%, $p=3.0x10^{-11}$) and *CTNNB1* (21.7% vs 5.3% vs 1.3%, $p=1.2x10^{-8}$) were more common mutated genes in *KRAS* wild-type patients. We found that patients with non-G12 mutations had significantly higher TMB than those with G12 mutations and *KRAS* wild-type (4.1 vs 2.3, p=0.0008), and this group of patients had significantly lower OS after receiving first-line chemotherapy in our cohort (249 days VS 352 days VS NA, p=0.013), but no difference was observed in PFS.

Conclusions: In this study, we elucidated the genomic differences among pancreatic cancer patients with *KRAS* G12, non-G12, and KRAS wild-type mutations. Furthermore, we found that patients with non-G12 KRAS mutations had lower OS after receiving first-line chemotherapy compared to other patients, and these patients had higher TMB levels.

1647P Cancer-associated endocrine cell: A novel component of tumor microenvironment in pancreatic cancer

Y. Chen, X. Yin, R. Ruzi, R. Xu, J. Song, Q. Xu, C. Wang, Y. Zhao

General surgery, Peking Union Medical College Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Beijing, China

Background: Pancreatic cancer is a highly fatal and aggressive disease due to its discouraging mortality and clinical treatment efficacy. Pancreas is composed of endocrine and exocrine parts, and the interlacing structure of them reminds us of the potential interaction between endocrine and exocrine cells in the oncogenesis and development of pancreatic cancer.

Methods: We depicted the changes of pancreatic endocrine cells in pancreatic cancer tissues by single-cell transcriptome sequencing, spatial transcriptome sequencing and multiplexed immunohistochemistry in human as well as in mouse models. After that, the interaction and sequence between pancreatic cancer oncogenesis and endocrine changes was explored in orthotopic transplantation mice and KPC mice. Finally, we proved the mechanism of the interaction between endocrine and exocrine parts of the pancreas through islet isolation, co-culture in vitro and co-injection in vivo.

Results: We found that, compared with normal pancreatic tissue, pancreatic endocrine cells displayed significantly different transcriptomic characteristics and increased interaction with exocrine part in pancreatic cancer tissues. Specifically, pancreatic polypeptide positive (PP+) cells showed a sharp increment accompanied with the progression of the cancer lesion. From an evolutionary perspective, the increased PP+ cells might be derived from the trans differentiation of α and β cells. Interestingly, in vivo and in vitro experiments proved that pancreatic cancer cells were able to induce the trans differentiation of α cells and β cells into GCG+PP+ and INS+PP+ double-positive cells, which further promoted pancreatic cancer proliferation in a paracrine-dependent manner and formed a positive feedback loop.

Conclusions: Our study systematically mapped the changes of pancreatic endocrine cells in pancreatic cancer and elucidated their relationship with pancreatic cancer oncogenesis and development. Meanwhile, we first time defined and characterized cancer-associated endocrine cells (CAE), which indicated that pancreatic endocrine cells should be an important component of pancreatic cancer microenvironment, thereby providing novel ideas for early diagnosis and targeted therapy of pancreatic cancer.

1648P Association between circulating tumor cell count and thrombosis in pancreatic cancer

M. Benavente[1], N. Gutierrez Alonso[1], M. Bringas Beranek[1], J. Soto Alsar[1], M. Palma[1], M.A. Cañete Muñoz[1], C. López Jiménez[1], A. Gutierrez Ortiz[1], D.S. Juliao Caamaño[1], A. Lopez Alfonso[2], L. Ortega Morán[1], G. Torres Perez-Solero[1], D. Megias[3], P.A. Calvo Ferrandiz[1], M. Del Monte-Millan[1], P. Rahimi Mousavi[1], M. Roche-Molina[1], P. García Alfonso[1], M. Martin Jimenez[1], A.J. Munoz Martin[1]

[1]Medical Oncology Dept., Hospital General Universitario Gregorio Maranon, Madrid, Spain; [2]Medical Oncology, Hospital Infanta Leonor, Madrid, Spain; [3]Confocal Microscopy, CNIO - Centro Nacional de Investigaciones Oncologicas, Madrid, Spain

Background: Cancer patients have a risk up to nine times higher of suffering from venous thromboembolism (VTE) compared to those without cancer, which makes VTE the second preventable cause of mortality in cancer patients. Pancreatic carcinoma is a high thrombotic risk tumor, being its incidence of thrombosis of up to 30% in outpatient patients. It has been suggested that circulating tumor cells (CTC) may be related to thrombosis, as they can alter blood coagulation and due to their pro-inflammatory and pro-coagulant properties.

Methods: We conducted an observational, prospective, cohort study in a two Spanish centers. CTC were isolated from a blood sample of newly diagnosed patients of pancreas carcinoma before starting chemotherapy treatment. CTC count was determined by using Isoflux® technology followed by counting via confocal microscopy. Patients were followed up according to routine practice. Clinical and analytical data were collected up to death. We analyzed the relation between CTC and VTE, and between CTC and VTE scores.

Results: This analysis included a total of 63 patients newly diagnosed before chemotherapy was given. 39 (61,9%) patients were metastatic, 16 (25,4%) locally advanced and 8 (12,7%) borderline tumors. Median follow up was 11,63 months. 25 episodes of VTE occurred in 23 patients during follow up (11 pulmonary embolism, 5 deep vein thrombosis, 6 visceral thrombosis, 3 catheter-related thrombosis). Median value of CTC was 397 (range 33-21697). For a cut off of CTC 500, we found no relation between CTC and VTE (p=0,298). However, when we analyzed CTC>500 and VTE excluding visceral and catheter-related thrombosis, it was found to be associated (p=0.006, p=0.002 in those metastatic). We found no relation between CTC and thrombosis scores (Khorana, Viena, Protech, Conko nor CAT).

Conclusions: This study shows that CTC detection before first-line chemotherapy could be a predictor marker for VTE.

1649P Comprehensive genomic profiling contributes to the prognosis of patients with advanced pancreatic cancer

E. So[1], H. Hayashi[2], K. Shimozaki[1], S. Horie[1], S. Kishimoto[1], A. Chida[1], Y. Saito[1], K. Tsugaru[1], K. Hirata[1], H. Nishihara[3], T. Kanai[1], Y. Hamamoto[3]

[1]Division of Gastroenterology and Hepatology, Department of Internal Medicine, Keio University School of Medicine, Tokyo, Japan; [2]Keio Cancer Center, Keio University School of Medicine, Tokyo, Hokkaido, Japan; [3]Keio Cancer Center, Keio University School of Medicine, Tokyo, Japan

Background: Precision medicine for pancreatic cancer (PC) is one of the promising treatment strategies. However, only a few patients can receive genotype-matched treatments for the low detection rate of actionable genomic alterations, therefore the clinical utility of comprehensive genomic profiling (CGP) is still unknown. On the other hand, CGP gives us a lot of information such as prognosis, future eligibility for genotype-matched clinical trials, and it may affect physician's treatment strategies. The present study was to investigate the contribution to prognosis of CGP, and its appropriate timing in the treatment of advanced PC.

Methods: This was a single-center, retrospective cohort study. Patients who were diagnosed as recurrent or metastatic PC with adenocarcinoma or adenosquamous carcinoma and underwent systemic chemotherapy between April 2018 and March 2022 were recruited. We reviewed the medical records and collected data of patient characteristics, survivals, and genomic information. We compared overall survival (OS) according to those who had received CGP (CGP group) or not (non-CGP group), and those who had performed CGP before or after initial chemotherapy.

Results: A total of 107 patients were eligible, in which 47 patients had received CGP. Patient characteristics were not statistically different between two groups except for age. OS was significantly longer in CGP group than non-CGP group (median, 29.7 vs 13.4 months; hazard ratio [HR], 0.51; 95% confidence interval [CI], 0.30—0.89; $P < 0.017$). OS tended to be longer in patients who had received CGP before the initiation of systemic chemotherapy than those who had received CGP after initial chemotherapy (median, 40.1 vs 24.0 months; HR, 0.29; 95% CI, 0.085—1.02; P=0.054). Actionable genomic alterations were detected in 16 patients (34.0%), whereas genotype-matched treatments were implemented for five patients (10.6%).

Conclusions: In the present study, OS was prolonged in patients who had undergone CGP irrespective of implementation of genotype-matched treatments, suggesting that CGP could help physicians to select the optimal treatment strategies for advanced PC in clinical practice. Given the extremely poor prognosis of the disease, earlier timing of CGP is considered.

1650P Identification of potential targets in pancreatic adenocarcinoma: The KRAS Wild-Type subset

D.A. Acosta Eyzaguirre[1], C. Fabregat-Franco[1], F. Castet[1], D.E. López Valbuena[2], G. Castillo[3], S. Vega[2], S. Aguilar Izquierdo[4], A. Sierra[1], T. Tian[5], A. Vivancos[6], R. Dienstmann[7], T. Macarulla[1]

[1]Gastrointestinal Cancer Unit, Vall d'Hebron University Hospital, Barcelona, Spain; [2]Medical Oncology, Vall d'Hebron University Hospital, Barcelona, Spain; [3]VHIO, Vall d'Hebron Institute of Oncology (VHIO), Barcelona, Spain; [4]VHIOTECA & Prescreening Program, Vall d'Hebron Institute of Oncology (VHIO), Barcelona, Spain; [5]Upper GI Cancer Translational Research Group, Vall d'Hebron Institute of Oncology (VHIO), Barcelona, Spain; [6]Cancer Genomics Group, Vall d'Hebron Institute of Oncology (VHIO), Barcelona, Spain; [7]Oncology Data Science (ODySey) Group, Vall d'Hebron Institue of Oncology (VHIO), Barcelona, Spain

Background: Pancreatic ductal adenocarcinoma (PDAC) is a lethal disease with limited treatment benefits. However, about 10% of cases are *KRAS* wild-type (WT) which are enriched in potentially actionable molecular alterations (MA). We aim to shed light on the clinical and molecular features and explore the survival benefit from precision medicine in these patients (pts).

Methods: We conducted a comprehensive retrospective analysis of PDAC pts treated at Vall d'Hebron University Hospital from 2016 to 2022 and included those with *KRAS* WT and a molecular profile using next-generation sequencing (NGS). We classified MA using the ESMO Scale of Clinical Actionability for molecular Targets (ESCAT) and compared those in Tiers I-III treated with matched therapy to those who did not or without actionable MA. We used the Kaplan-Meier method and the log-rank test to compare overall survival (OS).

Results: We identified 45 *KRAS* WT pts with a median age of 57 years (range 29 - 75), 69% were male and 56% were metastatic at diagnosis. Among metastatic cases (n=36) median OS was 23.7 months (95% confidence interval (95CI) 18.4-43.4). Ten pts presented DNA damage repair (DDR) gene alterations (24%) and two presented deficient mismatch repair alterations (4.4%). Moreover, we identified pathogenic germline mutations in 8 pts and gene fusions in 8 pts (18%). The table outlines MA according to the ESCAT and matched therapy. Metastatic pts who received matched therapy (n=9) had longer OS compared to those who did not receive matched therapy (n=9) [(HR 0.49 (95CI 0.17-1.45) 34,3 vs 19 months p=0.2] or those without actionable MA (n=18) [(HR 0.86 (95CI 0.31-2,32) 21,8 months p=0.76].

Table: 1650P

ESCAT (n)	Genomic alteration	Therapy (n)	Non-therapy (n)
IA (5)	g*BRCA*1, g*BRCA*2	PARPi (3)	2
IB (3)	s*BRCA*1, s*BRCA2*, s*PALB2*, g*PALB2*	PARPi (1), ATMi (1)	1
IC (3)	MSI	AntiPD1(0)	1
	RET fus	RETi (1)	1
IIB (5)	*NRG1* fus	Anti-HER2/HER2 (3)	1
	BRAF V600E	BRAFi+MEKi (0)	1
IIIA (8)	Other DDR	PARPi (0)	3
	ALK fus	ALKi (0)	1
	*HER*2 mut	AntiHER2 (0)	1
	PIK3CA mut	PIK3CAi (0)	3
IV (1)	*BRAF* fus	NA	NA
X (10)		NA	NA

Conclusions: Our findings suggest that *KRAS* WT PDAC tumours are enriched in potentially targetable MA and could benefit from precision-oncology approaches. These results highlight the relevance of performing a complete NGS analysis in these pts.

1651P Comparison of surgical outcome and prognostic factors between pancreaticobiliary and intestinal types of periampullary adenocarcinoma following pancreaticoduodenectomy

S. Anwar, K. Parasar, U. Anand, B. Singh

Surgical Gastroenterology, AIIMS - All India Institute of Medical Sciences - Patna, Patna, India

Background: The exact origin and associated prognosis of periampullary adenocarcinoma might be challenging to determine, especially in bulky tumours, due to the destruction of normal periampullary anatomy and the extension of the tumour beyond a single periampullary structure. Periampullary carcinomas are typically divided into pancreatobiliary and intestinal types according to histological differentiation. The aim of this study was to determine the prognostic value of this histological differentiation by comparing various clinic-pathological prognostic factors and surgical outcome in periampullary carcinoma cases that underwent pancreaticoduodenectomy.

Methods: From May 2018 to April 2021, 60 consecutive cases of periampullary carcinoma who underwent pancreaticoduodenectomy were included in this study. Cases were divided into two groups: pancreatobiliary and intestinal types. Various clinical and histopathological prognostic variables were analysed, and the association of these variables with pancreatobiliary and intestinal variants of periampullary carcinoma was determined using Chi-square and Fischer's exact tests.

Results: 20 cases were included in the pancreatobiliary group, and 40 cases were included in the intestinal group. These groups were comparable in terms of age, sex, nutritional status, and bilirubin levels. Pancreatobiliary type was more frequently associated with nodal disease (**p<0.01**), lymphovascular invasion (**p<0.01**) and perineural invasion (**p = 0.018**). Post-operative morbidity was significantly higher in the pancreatobiliary group (**p = 0.043**).

Table: 1651P

S.No.	Variable		Periampullary Carcinoma		x2	p-value
			Pancreatobiliary Type	Intestinal Type		
1	Age (years)	<60	15	32	0.196	0.658
		>60	5	8		
2	Sex	Male	12	19	0.834	0.361
		Female	8	21		
3	Comorbidity	Yes	6	16	0.574	0.449
		No	24	24		
4	Bilirubin (mg/dl)	<5	8	8	2.73	0.099
		>5	12	32		
5	Albumin (g/dl)	< 3	8	11	0.96	0.326
		> 3	12	29		
6	Pancreas Texture	Firm	10	21	0.03	0.855
		Soft	10	19		
7	MPD	<3mm	6	5	2.73	0.99
		>3mm	14	35		
8	Tumor size	>2cm	8	21	0.834	0.361
		<2cm	12	19		
9	Nodal status	Positive	12	10	7.03	0.008
		Negative	8	30		
10	Lymphovascular Invasion	Present	12	9	8.24	0.004
		Absent	8	31		
11	Perineural Invasion	Present	7	4	5.57	0.018
		Absent	13	36		
12	Grade	1	10	15	0.857	0.355
		2/3	10	25		
13	Post-operative Morbidity	Yes	11	08	4.10	0.043
		No	9	32		

Conclusions: After pancreaticoduodenectomy, periampullary cancer of the pancreatobiliary type is linked to worse post-operative outcome and unfavourable histopathological prognostic markers. Therefore, after surgery, these cases should follow management algorithms with aggressive adjuvant therapy protocols.

1652P Interaction between enhanced cytokine signalling and ferroptosis defence fuels obesity-associated pancreatic ductal adenocarcinoma oncogenesis

R. Ruzi, J. Song, Y. Chen, R. Xu, X. Yin, Q. Xu, C. Wang, Y. Zhao

General Surgery, Peking Union Medical College Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Beijing, China

Background: Obesity amplifies the risk for various cancers, including pancreatic cancer (PC). Due to limited early screening methods, this study seeks to investigate the effects of obesity-related metabolic disorders on PC initiation and offer novel insights into early detection and diagnosis in obese populations.

Methods: Human pancreatic Nestin-expressing ductal cells (HPNE) were cultured with human serum obtained from obese patients and healthy individuals. Transcriptomics, untargeted metabolomics, and joint-pathway analyses were conducted to examine the impacts of obesity-related metabolic disorders on pancreatic carcinogenesis. Multiomics analysis results were validated using cells of varying genetic backgrounds, while their mechanisms and roles in PDAC development were explored in obese transgenic mouse models. Clinical relevance and translational value were also corroborated using public databases and human samples.

Results: Multiomic assessment revealed heightened cytokine signalling and ferroptosis defence in HPNE cells exposed to obesity serum. *In vitro* tests showed that upregulated interleukin 34 (IL-34) strengthens ferroptosis defence through oxidative stress, while the enhanced ferroptosis defence reciprocally raises IL-34 levels. Our study demonstrated that augmented IL-34 signalling and ferroptosis defence hasten PDAC initiation in diet-induced obese mice by increasing immunosuppressive macrophages infiltration. Public databases revealed a strong correlation between elevated IL-34 and glutathione peroxidase 4 (GPX4) expression in pancreatic tumors vs. normal tissues. Gene signature expression displayed substantial correlations as well. Cohort validation and single-cell analysis suggested a positive association between IL-34 signalling and ferroptosis defence enhancement with PDAC patients' body mass index (BMI).

Conclusions: Obesity elevates IL-34 signalling and ferroptosis defence, thereby promoting PDAC development via macrophage-induced immunosuppression. The observed positive correlations between IL-34 and BMI, as well as GPX4 and BMI in PDAC patients underscore their potential roles in early PC screening among the obese population.

1653P The activated thermogenesis of intra-pancreatic fat fuels the progression of pancreatic cancer

X. Yin[1], Y. Chen[2], R. Xu[2], J. Song[2], R. Ruzi[2], C. Wang[2], Y. Zhao[2]

[1]General Surgery, PUMCH - Peking Union Medical College Hospital/Beijing Xiehe Hospital - Dongdan Campus, Beijing, China; [2]General surgery, Peking Union Medical College Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Beijing, China

Background: The presence of minimal intra-pancreatic fat deposition (IPFD) in the healthy human pancreas has been demonstrated in numerous studies. But excess IPFD, leads to a wide array of diseases, including but not limited to diabetes, pancreatitis, and pancreatic cancer (PC). Remarkably, PC patients with excessive intra-pancreatic fat accumulation are commonly associated with a poor prognosis compared to those with minimal IPFD. However, the interaction between tumor and IPFD remains elusive. Here, we evaluated the pancreatic fat infiltration in normal people and patients with PC respectively, and explored how intra-pancreatic fat accelerates tumor progression.

Methods: Magnetic resonance imaging (MRI) and clinical biopsy specimens were used to assess the degree of pancreatic fat infiltration in PC patients and healthy control individuals. The KC, KPC, KCO, and AAV8-ADIPOQ-DTA mice were established to demonstrate that IPFD promoted tumor progression. The single-nucleus sequencing of pancreatic fat tissue and proteomic of PC cell lines were performed to identify the mechanism of interaction between cancer cells and adipocytes.

Results: We found that patients with PC presented excess intra-pancreatic fat deposition more frequently than control individuals, and the degree of fat infiltration was positively correlated with the tumor size of PC patients. High-fat diet KPC mice or KCO mice showed a higher degree of IPFD, which contributed to tumor growth and low survival rates of mice. Besides, the expression of uncoupling protein 1 (UCP1) was upregulated in PC patients or spontaneous tumor mice compared to normal controls. Constantly, the single-nucleus sequencing of pancreatic fat tissue of PC patients demonstrated the increase in thermogenesis features. Specifically, we revealed that PC cells improved the thermogenesis of intra-pancreatic adipose tissue, which in turn promoted PC cell proliferation.

Conclusions: We demonstrated that excess intra-pancreatic fat infiltration fuels the progression of PC, and selectively eliminating fat in the pancreas inhibits tumor growth. Mechanistically, PC cells promote the browning of adipocytes, and then the activated adipocytes enhance the proliferation and migration of cancer cells in response.

Del Monte-Millan[2], D. Megias[6], Á. García Pérez[7], L.A. Mullor Delgado[7], L. Ortega Morán[1], G. Torres Perez-Solero[1], B.I. Morón[8], P.A. Calvo Ferrandiz[1], P. García Alfonso[1], M. Martin Jimenez[9], A.J. Munoz Martin[1]

[1]Medical Oncology Dept, Hospital General Universitario Gregorio Marañon, Madrid, Spain; [2]Medical Oncology Dept., Hospital General Universitario Gregorio Marañon - Fundación Investigación Biomedica, Madrid, Spain; [3]Medical Oncology Dept., Hospital Infanta Leonor, Madrid, Spain; [4]Oncología Traslacional, Hospital universitario gregorio marañon, Madrid, Spain; [5]Servicio Oncología medica, Hospital General Universitario Gregorio Marañon - Fundación Investigación Biomedica, Madrid, Spain; [6]Confocal Microscopy, CNIO - Centro Nacional de Investigaciones Oncologicas, Madrid, Spain; [7]Radiodiagnosis, Hospital General Universitario Gregorio Maranon, Madrid, Spain; [8]Medical Oncology Department, Hospital Universitario Ramon y Cajal, Madrid, Spain; [9]Servicio de Oncologia Médica Department, Hospital General Universitario Gregorio Marañon, Madrid, Spain

Background: CTCs have been extensively studied in different neoplasms. There are several techniques for their identification, however, it is not clear which is the most effective. In pancreatic cancer (PC) their significance in different stages of the disease and correlation with tumor markers are poorly understood.

Methods: Prospective, observational, cohort study in two Spanish centers. We analyzed CTCs at day 0 (before chemotherapy). Isolation was carried out with Isoflux technology, combining cell separation by immunomagnetic particles (positive selection) with a microfluidic system. Four different markers were used, including two mesenchymal markers, EpCAM and EGFR. The count of CTCs was done in a confocal microscope using the iMSRC (intelligent Matrix Screen Remote Control). Primary endpoint was the correlation of CTCs with overall survival (OS). Secondary endpoints: correlation between CTCs with Ca19.9/CEA values and the difference in the median value of CTCs in metastatic compared to locally advanced disease were secondary endpoints.

Results: Sixty-three patients were analyzed. Clinical characteristics: (Table) Median follow up was 11.6 months. Median value of CTC-0 was 343 (range 33 - 6259) for metastatic patients while it was 436 (81 - 1082) for locally advanced patients ($p = 0.380$). Correlation coefficient for Ca 19.9 was 0.03 ($p = 0.824$); CEA correlation coefficient was 0.121 ($p = 0.366$). Kaplan-Meier analysis showed an estimated median OS of 9.9 months for > 500 CTCs (95% confident interval [95% CI] 8.1 — 11.6) vs 14.7 (95% confident interval [95% CI] 6.7 — 22.6) for < 500 CTCs ($p = 0.021$).

Table: 1654P

Clinical characteristics	Results
Median age (range) - yr	65 (45 — 85)
Sex — no. (%) Male Female	35 (55.67) 28 (44.4)
Stage at diagnosis — no. (%) Borderline Locally advanced Metastatic	8 (12.7) 16 (25.4) 39 (61.9)
BMI — no. (%) Underweight Normal Overweight Obesity	2 (3.1) 34 (54) 21 (33.4) 6 (9.5)
PS - no. (%) 0 1 2	12 (19) 43 (68.3) 8 (12.7)
CEA — median (range)	4.8 (0.5 — 381)
Ca 19.9 — median (range)	1131 (2 -6627800)

Conclusions: With an increased number of patients there is still absence of differences of CTC-0 between metastatic and non-metastatic patients as well as no correlation of CTCs with tumor markers at diagnosis. 500 CTCs continues to be a significant cutoff for overall survival.

1655P Nampt inhibitors re-sensitize MAP17 expressing pancreas tumors

J. Martinez Perez[1], E.M. Verdugo Sivianes[2], L. Eufemia Navas[2], C. Saez[3], A. Carnero[2]

[1]Medical Oncology, Hospital Universitario Virgen del Rocio, Seville, Spain; [2]Laboratorio Biología Molecular del Cáncer, IBIS - Instituto de Biomedicina de Sevilla - Campus Hospital Universitario Virgen del Rocío, Seville, Spain; [3]Pathology, Hospital Universitario Virgen del Rocio, Seville, Spain

Background: The overexpression of MAP17, a small non-glycosylated membrane protein, has been described in a wide variety of human carcinomas, correlating with worse prognosis and response to different therapies. Pancreatic cancer (PC) has been the seventh major cause of cancer-related deaths worldwide in 2020, associated to a high mortality with a life expectancy of ∼5% at 5 years. Its aggressiveness makes necessary to identify new targets/biomarkers of response. The aim of this study was to assess the prognostic and predictive value of MAP17 expression in PC.

Methods: We evaluated MAP17 expression by immunohistochemistry in a cohort of 97 paraffin-embedded tissue samples of patients. We overexpressed MAP17 in two PC cells lines and tumorigenesis was analyzed using different functional assays and measuring several stem cell markers. We performed IC50 assays with different drugs and correlated them with MAP17 expression. Finally, we explored the effect of some of those treatments in vivo.

Results: High expression of MAP17 was detected only in pancreatic tumor cells. Also, we found that the overexpression of MAP17 increased the tumorigenic and stemness properties of cells as PC cell lines with high levels of MAP17 grew faster, formed higher number of colonies, holoclones, tumorspheres and a higher proportion of CD133+ cells. We explored whether the response to different antitumoral agents could be dependent on MAP17 expression, detecting that MAP17-expressing PC cells showed better response to gemcitabine, 5-FU, cisplatin and osimertinib, as well as resistance to docetaxel, bortezomib and ixazomib. However, in tumor xenografts in vivo, MAP17 expression confers resistance to all treatments. Next, we detected that the levels of total NAD, an essential metabolite implicated in many cellular processes, were higher in cells that overexpress MAP17. Finally, we found that the use of different inhibitors of NAMPT, the limiting enzyme of the synthesis of NAD, re-sensitize pancreatic tumor xenografts to classic chemotherapy.

Conclusions: MAP17 could serve as a prognostic and predictive biomarker in PC. Moreover, our findings could open new options of coadjuvant to current therapy with cisplatin or gemcitabine in PC that may eventually improve patients' outcomes.

1656P Targeting NPC1L1 rescues anti-tumor immunity and improves immunotherapeutic efficacy in pancreatic cancer

H. Liang[1], J. Ou[1], Z. Chen[2], R. zi[1], K. Shen[3], P. Zheng[4], X. Su[2]

[1]Department of Oncology and Southwest Cancer Center, Southwest Hospital, Third Military Medical University (Army Medical University), Chongqing, China; [2]Department of Hepatobiliary Surgery, Southwest Hospital, Third Military Medical University, Chongqing, China; [3]Department of Oncology, Fuling Hospital of Chongqing University, Chongqing, China; [4]College of Pharmacy, The Third Military Medical University, Chongqing, China

Background: The dysfunction of anti-tumor immunity of pancreatic adenocarcinoma (PAAD) is critically attributable to the failure of multi-therapies. Cholesterol is an essential component of mammalian cell membranes essential to the proliferation and TCR activation of $CD8^+$T cells, and it has been revealed that cholesterol metabolism plays an important role in sustaining the antitumor activity of $CD8^+$T cells. Although the cholesterol metabolism reprogramming has been implicated in carcinogenesis, including PAAD, how tumors reprogram cholesterol metabolism to sustain their survival and suppress anti-tumor immunity remains largely unknown.

Methods: RNA-seq, CyTOF, $CD8^+$ T cell isolation and cultivation, flow cytometry analysis etc. biological experimental techniques.

Results: PAAD cells ectopically express NPC1L1 to suppress the activation and proliferation of antitumor $CD8^+$ T cells in tumor microenvironment. NPC1L1 overexpression promotes PAAD cells to evade the immunosurveillance of $CD8^+$T cells and

is responsible for PAAD development and progression. And pancreatic npc1l1-silencing KPC mice led to a marked decrease in late-stage intraepithelial neoplasia lesions and malignant tumor formation. Our findings demonstrated that PAAD cell-expressed NPC1L1 functions as a checkpoint molecule to suppress the cytotoxicity of antitumor $CD8^+$T cell via NPC1L1-ITGAL interaction. Moreover, NPC1L1-ITGAL interaction promotes the efflux of intracellular cholesterol from antitumor $CD8^+$ T cells, consequently leading to a suppression of TCR activation and proliferation of antitumor $CD8^+$ T cells. The NPC1L1 inhibitor ezetimibe promotes the antitumor response mediated by $CD8^+$ T cells and synergizes with PD-1 blockade to enhance its therapeutic efficacy in PAAD.

Conclusions: Ectopically overexpressed NPC1L1 on cell membrane as a metabolic-immunologic two-pronged checkpoint is an ingenious trick of pancreatic cancer cells to gain at the expense of $CD8^+$ T cells.

1657P Understanding the role of SAGA and mediator in the resistance to Pdk1 deletion in PDAC

K. Ondrejkova, K. Sleiman, C. Veltkamp, F. Wang, G. Schneider, D. Saur

II. Medizinische Klinik und Poliklinik, Klinikum Rechts der Isar - Technische Universitaet Muenchen, Munich, Germany

Background: Pancreatic ductal adenocarcinoma (PDAC) represents the fourth highest rate of cancer-related deaths worldwide. The absence of early symptoms, early metastasis, and inefficient systemic therapies lead to a fatal prognosis for PDAC patients. Currently, surgical resection is the only curative option. However, it is often linked to severe postoperative complications and a considerable tumor recurrence rate. Therefore, identifying the resistance mechanisms of PDAC and developing targeted therapies is crucial.

Methods: Mutant KRAS and its effector Pdk1 play a major role in PDAC carcinogenesis. Previous works showed that Pdk1 deletion causes impairment of PDAC cell proliferation in vitro and in vivo. However, a minor subpopulation of cells continues to proliferate. To investigate this resistance, a genome wide CRISPR/Cas9 knockout screen was performed. Members of SAGA and Mediator complexes were among the top hits of the screen. The CRISPR knockouts of these genes were generated in the bulk PDAC epithelial cell line and in two single cell clones - one resistant and one sensitive to Pdk1 deletion. Clonogenic assays were performed to analyze the proliferation of the knocked-out cells, while RNA sequencing was conducted to investigate the differentially expressed genes.

Results: In the CRISPR/Cas9 knockout screen, members of SAGA and Mediator complexes showed enrichment in Pdk1 deletion resistant clones. Amongst all hits, significant proliferation of the Usp22- and Atxn7L3- as well as Med13- and Med16-knockout in the Pdk1 deleted PDAC cells was observed, with the strongest effect in the resistant clone. Several enhanced or downregulated hallmark pathways were observed in the knocked-out cells, providing insight into possible resistance mechanisms of the PDAC.

Conclusions: The results of the RNA sequencing of both SAGA and Mediator knocked-out cells showed an enhancement of the Hedgehog signalling, a pathway reported in the initiation of a growing number of cancers. The results of this research suggest furthermore, that the loss of the connecting units Atxn7L3 and Med16 promotes an unhinged transcription activity of the enzymatically active SAGA and Mediator complexes and leads to an enhanced PDAC cell proliferation.

1658P Molecular subtyping of familial pancreatic ductal adenocarcinoma identifies novel pathogenic germline variants

J. Earl[1], E. Barreto[1], M. Rodriguez[2], J. Villalon López[1], R. Fuentes Mateos[2], A. Garcia García de Paredes[3], A. Sanjuanbenito[4], E. Lobo[4], I. Ruz-Caracuel[5], M. Muñoz Beltran[6], E. Ramos[1], J. Blaquez[6], A. Carrato Mena[2]

[1]IRYCIS, Hospital Universitario Ramon y Cajal, Madrid, Spain; [2]Medical Oncology, Hospital Universitario Ramon y Cajal, Madrid, Spain; [3]Gastroenterology, Hospital Universitario Ramon y Cajal, Madrid, Spain; [4]General Surgery, Hospital Universitario Ramon y Cajal, Madrid, Spain; [5]Pathology, Hospital Universitario Ramon y Cajal, Madrid, Spain; [6]Radiology, Hospital Universitario Ramon y Cajal, Madrid, Spain

Background: The 5-year survival rate of pancreatic ductal adenocarcinomas (PDAC) is around 7.2% in spite of recent advances in therapeutics, as most patients are diagnosed at an advanced stage. 10-15% of pancreatic ductal adenocarcinoma (PDAC) cases cluster in families with an unknown genetic basis, known as familial pancreatic cancer (FPC). Targeted panel and exome sequencing of FPC cases was performed to identify new variants related to PDAC risk.

Methods: Targeted panel sequencing of 60 genes associated with hereditary cancer was performed in germline from 85 PDAC cases, 53 from families with an apparent familial pancreatic cancer syndrome and 32 cases with sporadic PDAC. Exome sequencing was also performed in 11 PDAC cases that were negative for a germline mutation by panel sequencing. The presence of a somatic mutation in KRAS codons 12, 13, 59, 61, 117 and 146 was determined in cfDNA in 54 PDAC cases.

Results: By panel sequencing, pathogenic variants were identified in 4 FPC cases (7.5%) in the MLH1 and CDKN2A and none of the sporadic cases via panel sequencing. Likely pathogenic variants were found in 5 FPC cases (5.7%) in POLQ, CHEK2 and FANCM and in 3 sporadic cases (9.4%) in MUTYH, TERT and ATM. By exome sequencing, missense variants with a damaging effect were found in all 11 FPC cases tested. However, stop gain, stop loss or frameshift variants were found in 5 FPC cases (45.45%), affecting WWOX, C2orf83, CYP3A5 and TANGO2. KRAS somatic mutations in codons 12 and 13 were more frequently detected in sporadic PDAC cases (70%) compared to familial cases (16%). Interestingly, the median overall survival for sporadic and familial PDAC cases was 10.2 vs. 21.7 months ($p=>0.01$), respectively, even though all patients are treated the same in the clinic.

Conclusions: Familial pancreatic cancer cases harbor pathogenic germline mutations in DNA repair genes and other genes related with tumorigenesis that could explain the aggregation of PDAC in these families. FPC seems to show a different molecular and clinical profile to the sporadic form of the disease.

1659P The use of liquid biopsy in patients with advanced pancreatic cancer (PDAC) to guide enrollment in phase I clinical trials

O. Letissier[1], C. Smolenschi[2], A. Hollebecque[2], D. Vasseur[3], S. Champiat[4], R. Bahleda[4], A. Gazzah[2], J-M. Michot[2], F-X. Danlos[2], K. Ouali[2], C. Henon[4], L. Mahjoubi[4], V. Goldschmidt[2], Y. Loriot[2], C. Massard[1], A. Bayle[2], A. Italiano[4], C. Baldini[2], S. Ponce Aix[2]

[1]Medical Oncology, Centre Eugène Marquis, Rennes, France; [2]Drug Development Department (DITEP), Gustave Roussy - Cancer Campus, Villejuif, France; [3]Molecular Biology, Gustave Roussy - Cancer Campus, Villejuif, France; [4]Drug Development Department (DITEP), Institut Gustave Roussy, Villejuif, France

Background: Therapeutic possibilities in PDAC remain poor and access to tumor tissue for molecular profiling is still a challenge. The era of circulating tumor DNA (ctDNA) or liquid biopsy facilitated molecular screening and treatment orientation in selected patients (pts).

Methods: Data from PDAC pts who underwent liquid biopsy at the Drug Development Department (DITEP) at Gustave Roussy were collected. The primary objective was to assess the ability of liquid biopsy to find molecular alterations (MA), orient and include pts in early phase clinical trials. We evaluated the progression-free survival (PFS) on matched therapy (PFS2) compared to PFS on prior therapy (PFS1). Treatment efficacy was considered by focusing on the percentage of patients with a PFS2 that was 1.5 times greater than the PFS1, based on a standard calculation (PFS2/PFS1), and a modified formula (mPFSr) with mPFSr = postPFS/prePFS with postPFS = PFS2 if PFS2 $<$ 6 months and postPFS = 24 months if PFS2 $>$ 6 months; prePFS = PFS1 if PFS1 $>$ 2 months and prePFS = 2 months if PFS1 $<$ 2 months.

Results: Between January 2020 to November 2022, a total of 31 pts were included in the study. The main characteristics were as follow: median age of 62 years (32-81), median number of previous lines of treatment of 2 (0-4) and median ECOG Performance Status of 0 (0-2). Finally, 30 patients had a liquid biopsy at progression on their

last treatment line. Targetable MA (FGFR, KRAS…) were found in 8 pts (27%), and 5 patients (17%) received a matched targeted therapy in an early phase clinical trial. FGFR alterations were the most frequent and 3 patients (60%) received FGFR inhibitors. From the 5 patients matched and treated, one patient (20%) had a PFS2/PFS1 ratio > 1.5 and three pts (60%) had an mPFSr > 1.5. With a median follow-up time of 12.3 months (9.2-NR), the overall response rate was 20%, the overall control rate was 100% and the median overall survival was not reached (8.5-NR months).

Conclusions: These results suggest that molecular profiling-matched therapy assessed by liquid biopsy could improve the therapeutic field in pancreatic cancer. However, only a small proportion of patients are matched and treated. Randomised trials are needed to confirm the value of this treatment method in pancreatic cancer.

1660P Squalene epoxidase promotes pancreatic cancer growth by attenuating ER stress and activating lipid rafts-regulated Src/PI3K/Akt signalling pathway

R. Xu[1], J. Song[1], R. Ruzi[1], Y. Chen[1], X. Yin[1], C. Wang[2], Y. Zhao[1]

[1]General Surgery, Peking Union Medical College Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Beijing, China; [2]General Surgery Dept., PUMCH - Peking Union Medical College Hospital/Beijing Xiehe Hospital - Dongdan Campus, Beijing, China

Background: Pancreatic cancer (PC) is among the deadliest malignancies with a 5-year survival rate of nearly 12%. Malignant proliferating cancer cells usually exhibit metabolism reprogramming, which is distinct from their normal counterparts, resulting in therapeutic vulnerabilities. However, the underlying mechanisms of aberrant cholesterol metabolism regulating PC progression are poorly understood. In the present study, we aimed to identify and investigate the role of a key cholesterol metabolic enzyme squalene epoxidase (SQLE) in tumorigenesis of PC.

Methods: Integrating analysis of The Cancer Genome Atlas (TCGA) cohort and multiple Gene Expression Omnibus (GEO) datasets was used to find the top up-regulated cholesterol homeostasis-related gene in PC. The IHC staining of tissue microarray composed of human PC samples were used to identify the clinical significance of SQLE in PC patients. The biological functions of SQLE and the potential therapeutic efficiency of SQLE inhibitors were assessed both in vitro and in vivo. Transcriptome analysis, untargeted metabolomics analysis, and related lipid detection were further performed to clarify the molecular mechanism of SQLE on PC development.

Results: We found *SQLE* expression was highly expressed in PC tissues compared with normal pancreatic tissues, and the upregulated *SQLE* predicted poor outcomes in PC patients. Additionally, we demonstrated that SQLE promoted the growth of PC both in vitro and in vivo. Mechanistically, inhibition of SQLE caused squalene accumulation-induced endoplasmic reticulum (ER) stress occurrence and subsequent cell apoptosis. Moreover, SQLE increased cholesterol de novo biosynthesis and maintained the stability of lipid rafts, which in turn activated Src/PI3K/Akt signalling. Finally, we found that pharmacological blockade of SQLE with terbinafine or NB-598 profoundly suppressed PC cell proliferation and xenograft tumor growth.

Conclusions: Our findings demonstrated the oncogenic role and tumor promoting mechanism of SQLE in PC. SQLE promotes PC growth by attenuating ER stress and promoting lipid rafts-regulated Src/PI3K/Akt signaling pathway, suggesting SQLE as a potential therapeutic target for PC.

1661P Precision medicine for pancreatic cancer: A clinical study validating EUS biopsies

J. Lundy[1], O. McKay[2], A. Perry[3], T. Wilson[4], D. Croagh[5]

[1]Medical Oncology, Peninsula Health, Frankston, VIC, Australia; [2]Gastroenterology, Monash University, Clayton, VIC, Australia; [3]Bioinformatics, Monash University, Clayton, VIC, Australia; [4]Hudson Institute, Monash University, Clayton, VIC, Australia; [5]Surgery, Monash University, Clayton, VIC, Australia

Background: Pancreatic cancer (PC) has a high mortality rate and treatment options remain very limited. While there is great appeal in improving patient outcomes by implementing precision medicine in this disease, there are significant barriers including challenges in accessing adequate biopsy material to analyse. Endoscopic ultrasound (EUS) biopsy is a common diagnostic procedure and often the only source of tissue for patients with PC, but the utility of these biopsies to provide high quality biopsy material for clinically relevant molecular profiling remains lacking.

Methods: This study enrolled 135 patients undergoing diagnostic EUS biopsy as standard of care in PC to perform molecular analysis using a commercial 500-gene panel which also provides data on clinically relevant gene fusions, tumour mutation burden (TMB) and microsatellite status. No interventions were provided, but data was analysed and discussed at a Molecular Tumour Board meeting and relevant findings fed back to treating oncologists. Patients were followed for treatment data and survival.

Results: 7 patients were unable to be analysed due to a lack of available biopsy material (n=2), withdrawal of consent (n=1) or inadequate QC metrics (n=4). We detected common oncogenes at expected frequencies, with KRAS in 114 (90%), TP53 in 85 (66%), SMAD4 in 13 (10%) and CDKN2A in 11 (9%). Targetable molecular findings were detected in 28 (22%), with RNF43 variants in 11 (9%), high TMB in 10 (8%), BRCA1/2 mutations in 4 (3%), BRAF V600E mutations in 2 (2%), CHEK2 mutation in 1 (1%) and BARD1 mutation in 1 (1%). No microsatellite instability was detected. Median TMB in this cohort was low, as expected, at 3.1Mut/Mb. However, of the 10 patients with high TMB (>10Mut/Mb), 5 of these had markedly hypermutated profiles (TMB >150Mut/Mb). To date, 8 patients (6%) have commenced targeted therapies and survival follow up is ongoing.

Conclusions: This study validates EUS as a reliable and accurate source of biopsy material for clinically relevant tumour profiling and adds to the body of literature highlighting the potential to improve patient outcomes in PC through routine genomic analysis, despite the many challenges.

1662P Targeting stress granule formation as a synthetic lethality strategy for kras-induced pancreatic cancer initiation

P. Santofimia[1], N. Fraunhoffer[1], X. Liu[1], I. Fernandez-Bessone[1], M. Pasca di Magliano[2], S. Audebert[1], L. Camoin[1], M. Modesti[1], G. Lomberk[3], R. Urrutia[3], P. Soubeyran[1], J.L. Neira[4], J.L. Iovanna[5]

[1]Pancreatic Cancer, CRCM - Centre de Recherche en Cancérologie de Marseille, Marseille, France; [2]University of Michigan, University of Michigan, Ann Arbor, MI, USA; [3]Medical College of Wisconsin, Froedtert Hospital & Medical College of Wisconsin, Milwaukee, WI, USA; [4]UMH, UMH - Universidad Miguel Hernández de Elche, Elche, Spain; [5]Pancreatic Cancer, University of Palermo, Palermo, Italy

Background: Stress granules (SGs) are membrane-less organelles formed by liquid-liquid phase separation (LLPS) that play a critical role in regulating RNA metabolism, and protein synthesis, in a wide range of stress responses. These granules are required to support pancreatic cancer (PDAC) transformation, cell survival, growth, and chemotherapy resistance, making them an attractive target for new cancer therapies. Here we report a novel mechanism for SG formation, which is induced by NUPR1 (an intrinsically disordered stress-associated protein), in response to *Kras*^{G12D} oncogenic stress. We provide a preclinical proof of concept for using SG inhibition as an efficient strategy for targeting PDAC initiation and development, by using NUPR1 inhibitors.

Methods: We have used recombinant proteins for in vitro tests (LLPS tests), PDAC-derived cell lines, and doxycycline-inducible transgenic cell lines (cell viability tests, evaluation of gene expression, and SGs quantification), a transgenic *Pdx1*-Cre; LSL-*Kras*^{G12D} mouse model.

Results: In this study, we show that NUPR1, has the capacity to produce droplets through LLPS, but not its mutants or under the treatment of its inhibitor (ZZW-115). We observed that LLPS induced by rNUPR1 is essential for SGs formation since genetic or pharmacological inhibition of NUPR1 activity hampers SGs formation in pancreatic cancer cells. In addition, we found that *Kras*^{G12D} mutation causes significant oncogenic stress which in turn induces a strong overexpression of NUPR1, promoting the formation of SGs as a stress-dependent mechanism of cell survival.

Consistently, forced Kras^{G12D} expression in pancreatic cells elicits a strong sensitivity to NUPR1 inactivation by genetic or pharmacological means. Finally, inhibition of SGs formation with the NUPR1 inhibitor ZZW-115 in *Pdx1*-Cre; LSL-*Kras^{G12D}* mice blocks the transformation process indicating that SGs formation is necessary for PDAC development.

Conclusions: In this work, we provide a preclinical proof of concept showing that SG formation is a targetable step in the *Kras^{G12D}*signaling pathway, thus suggesting that inhibiting NUPR1 or SG formation can be utilized as a synthetic lethality therapeutic strategy for *Kras^{G12D}*-dependent tumors.

1663P Role of next-generation sequencing somatic assays in patients with advanced pancreatic cancer

R. Naves, M. Naves, T.S.C.D. Almeida, R. Colombo Bonadio, C. Motta Venchiarutti Moniz, P.M. Hoff

Medical Oncology, Instituto D'Or de Pesquisa e Ensino, São Paulo, Brazil

Background: Recently, the use of Next-Generation Sequencing (NGS) somatic assays has increased aiming the identification of potentially targetable molecular alterations for the treatment of advanced malignancies that progressed after standard therapies. Pancreatic cancer (PC) remains a challenging disease, with poor outcomes, for which novel therapeutic strategies, are largely warranted. Nevertheless, the impact of NSG for the treatment and outcomes of this neoplasia is unclear. The aimed to assess the impact of NGS somatic assays for patients (pts) with advanced pancreatic cancer.

Methods: In this cohort, we evaluated pts with advanced PC (metastatic or locally advanced unresectable) treated in a private cancer network from 2014 to 2021. Electronic records were reviewed for data collection. The study endpoints were the pattern of somatic alterations, the frequency of potentially targetable alterations and the use of targeted therapy directed by the NGS somatic assay.

Results: Among 446 pts with advanced PC, 51 underwent a NGS somatic panel; 44 of them had the panel results available and were evaluated in this study. All pts with panel available had at least one somatic alteration. Most pts (95%) had KRAS mutations; the most common were KRAS G12D (52%), KRAS G12V (17%), KRAS G12R (9%), KRAS G12A (7%), and KRAS Q61H (5%). No patient had a KRAS G12C mutation that could be targeted with anti-KRAS G12C agents. Other frequent molecular alterations were found in the following genes: TP53 (52%), CDKN2A/B (41%), SMAD4 (18%), ARID1A (11%), PTEN (7%), and ATM (4%). Two pts had a BRCA2 mutation that was known to be germline. No patient had microsatellite instability-high or high tumor mutational burden. Overall, 11% had potentially drugable alterations. Only one patient (2%) received a treatment guided by the result of the somatic panel, with a median progression-free survival of 1.6 months.

Conclusions: Unfortunately, NGS somatic panel seems to have limited role for the PC treatment nowadays, with few pts receiving treatment guided by the panel. The development of new targeted therapy directed to the most frequently molecular alterations, including KRAS-directed therapy other than KRAS G12C, are urgently needed to improve outcomes.

Background: The present analyses from the GARIBALDI was aimed to addressing the role of oncology center volume, type and accrual rate on the prognosis of patients (pts) with metastatic Pancreatic Ductal Adenocarcinoma (mPDAC).

Methods: Consenting treatment-naïve pts $\geq$ 18-year with pathological diagnosis of mPDAC were enrolled. Participating centers were categorized according to the self-declared expertise, the type and the accrual rate. Survival curves were estimated by the Kaplan—Meier method and compared by the log-rank test. Overall Survival (OS) was defined as the time from the date of medical therapy start to death for any cause.

Results: Between July 2017 and October 2019, 475 pts enrolled in 44 centers were eligible for these analyses. Median age was 69 (range 36-90); 46% females; 90% ECOG PS 0-1; 38% overweight/obese; 66% with liver metastases; median CA19.9 789 (range 0-1,374,500); 8% with prior PDAC resection; 17% with prior cancer history. Median time from diagnosis to treatment was 33 days. 65.2% of pts started therapy >25 days from baseline CT; 70.7% of pts received nab-paclitaxel+gemcitabine; 16.7% gemcitabine alone; 7.7% FOLFIRINOX; 37% received a second-line therapy. The median follow-up was 50 months and 405 pts died. The table provide the median OS estimates.

Table: 1664P

	Deaths/N	Overall survival (Median [95%CI])	Log-rank p-value
Self-declared expertise			0.24483
Low-volume (<25 pts/year)	50/58	7.3 [5.6-9.0]	
Medium-volume (25-50 pts/year)	101/125	8.8 [6.7-11.5]	
High-volume (>50 pts/year)	234/267	10.1 [9.1-11.2]	
Type			0. 3610
Community hospitals	183/224	7.9 [6.7-9.6]	
Academic centers	222/251	10.1 [9.1-11.2]	
Accrual rate			0.6348
Low-accrual (<10 pts/year)	173/210	7.9 [6.7-9.5]	
Medium-accrual (10-50 pts/year)	173/201	9.6 [8.5-11.2]	
High-accrual (> 50 pts/year)	59/64	12.0 [9.7-14.9]	

Conclusions: Although not statically significant, the GARIBALDI survey detected a clinical difference in OS based on center volume, type, and accrual rate.

1665P Prognostic impact of diabetes and antidiabetic medication in pancreatic cancer patients

A. Friedrich[1], J.M. Berger[1], L. Berchtold[1], P. Wolf[2], M. Leutner[2], G. Prager[1], M. Preusser[1], A.S. Berghoff[1], E.S. Bergen[1]

[1]Department of Medicine I, MedUni Wien - Medical University of Vienna, Vienna, Austria; [2]Department of Medicine III, MedUni Wien - Medical University of Vienna, Vienna, Austria

Background: Diabetes mellitus (DM) is associated with pancreatic cancer (PC) as insulin is produced in the pancreatic beta cells. Whereas large epidemiological studies are available investigating the risk and prevalence of DM patients developing PC, only little is known about the impact of DM on the outcome of PC patients.

Methods: PC patients treated at the Medical University of Vienna between 1997 and 2020 with available information about their diabetic status at initial diagnosis of PC were identified from the PC database of our institution. We investigated the association of DM, antidiabetic drugs as well as random blood glucose and HbA1c levels with overall survival (OS, interval from initial diagnosis to death or last date of contact) in the overall patient cohort and subgroups of early and metastatic PC patients.

Results: Among 667 patients included into this analysis, 221 (33.1%) presented with DM at PC diagnosis, 53 (8.0%) developed DM later during the course of disease and 393 (58.9%) never developed DM. Presence of DM at initial diagnosis was significantly associated with a shorter OS in the overall patient population (13 vs. 17 months, hazard ratio (HR): 1.23, 95% confidence interval (CI 9.3 - 12.8; 6.6 - 11.3), $p=0.024$) as well as in patients with resectable disease (20 vs. 29 months, HR: 1.44, CI (13.4 - 31.1; 22.2 - 35.1), $p=0.034$). but showed no association in metastatic patients (8 vs. 11 months, HR: 1.21, CI (6.6 - 11.3; 9.3 - 12.8), $p=0.200$). Median OS was comparable between DM PC patients receiving metformin, insulin or other antidiabetic drugs (13 vs 15 vs 8 months, $p=0.221$, log-rank test). A random blood glucose at diagnosis of >300mg/dl compared to <200mg/dl (HR 2.29, 95%CI 0.06-3.53; $p=0.005$) as well as an HbA1c of >8% compared to <6.5% (HR 1.88, 95%CI 1.03-3.44; $p=0.040$) was associated with a significantly shorter OS.

Conclusions: Within this large cohort of PC patients, one third presented with DM at initial diagnosis. We observed a negative prognostic impact of DM especially in the subgroup of early PC patients. Different antidiabetic drugs thereby did not influence prognosis substantially. Only highly elevated levels of blood glucose and HbA1c seem to impact prognosis, whereas moderately elevated levels did not.

Background: The GARIBALDI study investigated the impact of oncology center volume, type, and accrual rate on the prognosis of the overall therapeutic management of patients (pts) with non-metastatic Pancreatic Ductal Adenocarcinoma (nmPDAC).

Methods: Consenting treatment-naïve pts ≥ 18-year with pathological diagnosis of nmPDAC were eligible. Participating centers were categorized according to the self-declared expertise, the type and the accrual rate. Survival curves were estimated by the Kaplan—Meier method and compared by the log-rank test. Overall Survival (OS) was defined as the time from the date of medical therapy start to death for any cause.

Results: Between July 2017 and October 2019, 402 pts with nmPDAC from 44 centers were enrolled. Median age was 69 (range 36-89); 50% females; 93% ECOG PS 0-1; 33% overweight/obese; 17%, 38.7%, 44.3% with stage I, II, III, respectively; median CA19.9 177 (range 0-350,933); 17% with prior cancer history. Median diagnosis to treatment interval was 26 days. 68.4% had baseline CT >25 days before treatment start. 64% received chemotherapy upfront mainly consisting of nab-paclitaxel+gemcitabine (55%), gemcitabine alone (12%) or FOLFIRINOX (27%); 50% were submitted to surgery; 32% received radiotherapy. The median follow-up was 43.7 months and 274 pts died. The table provides the median OS estimates.

Table: 1666P

	Deaths/N	Overall survival (Median [95%CI])	Log-rank p-value
Self-declared expertise			0.0036
Low-volume (<25 pts/year)	46/61	15.5 [11.7-21.8]	
Medium-volume (25-50 pts/year)	48/69	21.6 [16.9-24.5]	
High-volume (>50 pts/year)	174/260	23.2 [19.2-27.1]	
Type			0.0714
Community hospitals	108/154	20.6 [16.6-23.2]	
Academic centers	166/248	22.0 [18.7-26.9]	
Accrual rate			0.0238
Low-accrual (<10 pts/year)	114/161	18.7 [15.8-23.6]	
Medium-accrual (10-50 pts/year)	107/149	21.6 [18.6-25.1]	
High-accrual (> 50 pts/year)	53/92	29.3 [18.1-35.6]	

Conclusions: A statistically significant difference in OS was found based on center volume and accrual rate, while a clinical difference was highlighted based on center type.

Background: Pancreatic adenocarcinoma (PDAC) has a poor prognosis and a growing incidence, especially in patients (pts) $\leq$ 50 years (e.g., young onset YoPA). We aim to describe clinical and molecular features (genomic and transcriptomic) of YoPA.

Methods: A retrospective chart review (demographics, systemic therapies, and outcomes) was performed in consecutive PDAC pts followed in our institution between 2012-2022. Tumor molecular profiling was performed as part of MATCH-R (NCT02517892) or STING (NCT04932525) trial (mostly Foundation Medicine® on tumor tissue (56.4%) or liquid biopsy (43.6%)). RNA sequencing was performed as part of MATCH-R trial.

Results: Overall, 878 pts were included, of them 113 were YoPA, with similar performance status at diagnosis. YoPA were more often diagnosed at metastatic (met) stage (69.7% vs 58.3%, p=0.024). In particular, hepatic mets were more present at diagnosis in YoPA (60.2% vs 43.9%, p=0.002). Conversely, lung and bone mets tended to be less frequent in YoPA. Location of the primary tumor (head vs tail) was not different between groups. Regarding treatment outcomes, among the 239 pts with resectable or borderline disease, 217 (91%) underwent surgery (22 YoPA and 195 nYoPA). The median recurrence-free survival (RFS) was 12.0 months (mos) (95CI: 10.6-14.8) (similar between YoPA and nYoPA). Among the 746 pts with mets, 96% received at least 1 line of systemic therapy. YoPA received more lines (41.6% vs 31.0% received $\geq$ 3 lines, p = 0.045). 1st line PFS was not different between groups. The median overall survival (OS) was 18.2 mos, with no difference between YoPA and nYoPA (HR=1.01, 95%CI= 0.81-1.26). In mets, OS was 12.8 mos (95%CI: 11.8-14.0) and was similar between groups. 312 pts had molecular profile including 49 YoPA. Mean TMB was lower in YoPA (1.42 vs 2.95 mut/Mb, p<0.002). YoPA and nYoPAs had similar prevalence of mutations in *KRAS (*88%) and *BRCA1/2* (6.3%). Conversely, YoPA displayed fewer alterations in *CNKN2A/B* (p=0.03). RNA sequencing data is available for 84 pts and the analysis is in progress.

Conclusions: YoPA were more often diagnosed at the metastatic stage with a higher prevalence of hepatic mets and had similar OS to nYoPA. They displayed a different molecular profile with lower TMB and fewer alterations in *CDKN2A/B*.

1668P Prevalence and management of pancreatic ductal adenocarcinoma (PDAC) over a decade in France: A population-based study

L. Mas[1], C. Castelli[2], A. Coffy[2], D. Piquemal[3], J-B. Bachet[1]

[1]Gastroenterology and Digestive Oncology, Hopital Pitié Salpetrière AP-HP, Paris, France; [2]Beau Soleil Clinic, AESIO Santé Research Team, Montpellier, France; [3]Scientific Officer, ACOBIOM, Grabels, France

Background: Significant progress has been made in the management of PDAC in recent years, with the development of new chemotherapy regimens validated in both adjuvant and metastatic settings, as well as neoadjuvant/induction therapy (N/IT). In this population-based study, we aimed to compare prevalence, therapeutic strategies, and survival outcomes of PDAC patients in France over a decade encompassing these advances.

Methods: This study was performed on SNDS (Système National des Données de Santé) data, including nationwide French data on the consumption of medical care. All patients managed for PDAC during years 2009, 2014 and 2018 were included. Treatment modalities and survival outcomes were analyzed.

Results: A total of 8143/10267/12089 patients were included during years 2009/2014/2018, respectively. Prevalence increased mainly among patients aged 60-75 (62% over the study period) and >75 (53%) while a lesser trend was seen in patients <60 (13%). In localized PDAC, the proportion of patients receiving best supportive care (BSC) decreased at 43.6/37.7/33.5%. More patients received chemotherapy +/- radiotherapy alone over time (27.8/28.5/33.4%), and surgical resection after N/IT increased at 0.9/2.5/5.5%. The rate of upfront surgery remained stable at about 28%. Among metastatic patients, 45.0/49.2/51.3% received BSC. In the overall population, no relevant difference in survival outcomes were seen over time, but median overall survival (OS) and 1-year OS improved significantly both in localized patients and treated metastatic patients (Table). The 1-year OS was 85.7/85.9/91.7% among patients receiving N/IT before surgery, vs 76.3/79.0/80.0% for upfront resection.

Table: 1668P Survival outcomes

Population	Median OS (months) / 1-year OS (%)			p-value log-rank
	2009	2014	2018	
Overall	7.0 / 36.1	6.9 / 36.9	7.5 / 39.4	0.0067
Localized	11.4 / 48.4	12.5 / 51.3	Not reached / 55.0	<0.0001
Metastatic (treated)	7.3 / 30.3	8.4 / 36.1	8.9 / 38.2	<0.0001

Conclusions: This study confirms an increase in the prevalence of PDAC in France. Improved survival outcomes were seen in localized PDAC, with a wider use of chemotherapy and an increase in neo-adjuvant/induction strategies, and in treated metastatic patients.

1670P Tumoral and non-tumoral thrombosis associated with pancreatic ductal adenocarcinoma (PDAC): Survival impact, assessment of predictive scales and rethrombosis

A.R. Cardozo[1], R. Teres Lleida[1], A. Villalba[2], J. Gavira Diaz[1], J. Sanz Beltran[1], M.A. Molina Pérez[1], F. Bosma[1], S. Sanchez Del Rio[1], J.C. Tapia[1], A. Piedra[1], M. Aguado Sorolla[1], F.J. Pelegrín Mateo[1], B. Martin Cullell[1], D. Paez[1], P. Cerda Serda[1]

[1]Medical Oncology Dept., Hospital de la Santa Creu i Sant Pau, Barcelona, Spain; [2]Dept. Radiodiagnosis, Hospital de la Santa Creu i Sant Pau, Barcelona, Spain

Background: PDAC is highly associated with thrombotic risk, with reported incidences up to 40%. Although tumoral (TT) and non-tumoral thrombosis (nonTT) are frequently treated equally, they might have different impact in prognosis and survival. Khorana and ONKOTEV score can predict thrombotic risk in this scenario.

Methods: Retrospective study that includes 204 patients with PDAC treated with chemotherapy and visited in the Medical Oncology Department of a third-level hospital in Barcelona between January 2014 and December 2021. The main objective was to describe the frequency of TT and nonTT, the ability to predict thrombotic risk by predictive scores using ROC curve and to analyze survival associated with thrombosis and rethrombosis.

Results: We identified 62 patients with thrombosis (30.4%) of a total of 204. Median age was 70 years (48-92), 54.8% were males, and 62% presented stage IV at diagnosis. TT involved 71% of thrombotic events being the most frequent in all stages (80% in

resectable, 83.3% in borderline, 75% in locally advanced and 66.7% in metastatic disease). Predominant thrombotic events were splenic (39%) and superior mesenteric vein (32%) for TT and deep vein thrombosis (DVT) in lower extremities and pulmonary embolisms in non-tumoral scenario (56% and 22.2% respectively). The ONKOTEV score presented better predictive capacity compared to Khorana for nonTT (AUC 0.731 vs 0,670 in ROC curves). Neither of both scores demonstrated predictive capacity for TT (AUC 0.540 vs 0.495). Thromboembolic events were associated with reduced overall survival (OS; HR 0.71, p 0.034). Median OS was 12.5 months in patients who presented nonTT vs 7.2 months for those with TT (HR 0.48, p=0.326). Rethrombosis occurred in 8% (5 cases), 2 of them being on anticoagulant therapy. All were in the same location as previously.

Conclusions: TT was more frequent than nonTT in our cohort. Thromboembolic events, including TT and nonTT, were detrimental for survival without statistically significant differences between them. ONKOTEV score has a greater capacity to predict nonTT compared to Khorana, in order to identify patients who could potentially benefit from prophylactic anticoagulation.

Background: Pancreatic carcinoma (PC) remains one of the deadliest cancers, with late detection and a complex, still unknown biology as the main factors driving its lethality. Chemotherapy and surgery are the primary options for PC, however, only 15-20% are eligible for surgery and two thirds relapse after. Novel diagnostic strategies are an urgent need for an earlier diagnosis, particularly in pt at higher risk for PC. We aimed to characterize real-world pt management for PC and the prevalence of molecular profiling in routine oncology practice.

Methods: A retrospective chart review of pt from the Spanish RETUD registry diagnosed with PC between 1 January 2019 and 31 December 2022 was conducted. Demographic, clinical characteristics, molecular profiling, systemic treatments, and outcomes were described.

Results: The registry included 1,438 evaluable pt. The median age was 66.8 years, 55.4% were men. Cancer family history was reported in 53.1% of pt. Main histology was ductal adenocarcinoma (97.8%). It was located in the head (59.5%) or body/tail (39.4%). Overall, 56.1%,19.0%,18.5% and 6.5% pt were diagnosed metastatic (met) locally advanced (LA), resectable and borderline PC respectively. Only 24.1% of pt underwent pancreatic surgery. Germline molecular analysis was performed in 135 pt where 17.8% had *BRCA1* or *BRCA2* mutations. *KRAS* mutation in tissue was assessed in 264 pt, and it tested positive in 68.9%. Most (70.2%) pt received first-line systemic treatment, mainly the gemcitabine-based combination NabPGEM (65.9%) or FOLFIRINOX (26.0%). At the database cut-off, 81.3% pt died. Median overall survival (OS) was 24.3 (95% confidence interval [95CI] 20.3-28.7), 13.4 (95CI 12.1-15.0) and 6.4 (95CI 5.7-7.3) months (m), for resectable, LA and met setting, respectively. Met PC median OS was 11.3 m (95CI 10.0-12.3) when treated with frontline NabPGEM and 13.1 m (95CI 11.5-16.5) with FOLFIRINOX (p=0.01).

Conclusions: Our study provides an overview of routinely recommended treatments and their effectiveness in a large multicenter real-world cohort of PC in Spain. Our findings suggest that FOLFIRINOX improves clinical outcomes of pt with met disease, when compared to NabPGEM. Molecular assessment must be enhanced at diagnosis in our environment.

1673P Trajectories of immune-related serum proteins and quality of life in patients with pancreatic and other periampullary cancer: The champ study

S. Olsson Hau, M. Svensson, A. Petersson, J. Eberhard, K. Jirström

Clinical Sciences, Lund University - Faculty of Medicine, Lund, Sweden

Background: There is still a profound lack of efficient therapeutic strategies against pancreatic or other periampullary adenocarcinoma. Surgery is seldom possible, leaving palliative chemotherapy the only option for most patients. Chemotherapy treatment is however often accompanied by serious side-effects, and the identification of biomarkers for early prediction of disease and treatment-associated symptoms could help alleviate patient suffering. This study investigated the dynamic interrelationship between immune-related serum proteins, routine biomarkers and health-related quality of life (HRQoL) factors during chemotherapy treatment of patients enrolled in the prospective, observational study Chemotherapy, Host response And Molecular dynamics in Periampullary cancer (CHAMP).

Methods: Proximity extension assay was applied to analyse 92 immune-associated proteins in longitudinal serum samples from 75 patients, 18 being treated with adjuvant and 57 with palliative intent. HRQoL data were available from all patients at baseline (BL), from 41 patients at three months, and from 23 patients at six months.

Results: Levels of 8 proteins; CCL23, CD4, CD28, DCN, Gal-1, GZMB, GZMH and MMP7 were strongly correlated (Spearman's Rho $\leq$-0.6 or $\geq$0.6) with various symptoms (insomnia, dyspnea, cognitive and emotional functioning) during treatment. Associations between routine laboratory parameters albumin, CA19-9, CEA and CRP and HRQoL were overall weaker. None of the investigated proteins were associated with pain.

Conclusions: This is, to our knowledge, the first study exploring associations between serum biomarkers and HRQoL in patients with pancreatic or other periampullary cancer, and some findings merit further validation. The proteoglycan decorin (DCN) is of particular interest as it has been linked to conditions such as Alzheimer's disease and schizophrenia. Chemotherapy is known to cause persistent cognitive dysfunction with effects on memory and executive function, referred to as "chemo brain". It would therefore be of great value to identify biomarkers for early detection and management of this debilitating condition.

Clinical trial identification: NCT03724994.

1674P VILP registry of patients with metastatic pancreatic cancer treated with pegylated liposomal irinotecan plus 5-fluoroucil and leucovorin in the Czech Republic

S. Batko[1], M. Vocka[2], B.M. Duchoňová[3], M. Liberko[4], P. Májková[5], T. Buchler[1], L.B. Petruzelka[2], B. Melichar[3], R. Soumarova[4], K. Hejduk[5]

[1]Department of Oncology, Second Faculty of Medicine, Charles University and Motol University Hospital, Prague, Czech Republic; [2]Department of Oncology, First Faculty of Medicine, Charles University and General Faculty Hospital, Prague, Czech Republic; [3]Department of Oncology, Faculty of Medicine and Dentistry, Palacky University and University Hospital, Prague, Czech Republic; [4]Department of Oncology, Third Faculty of Medicine, Charles University and Královské Vinohrady University Hospital, Prague, Czech Republic; [5]Institute of Biostatistics and Analyses, Masaryk University Brno, Brno, Czech Republic

Background: Following the NAPOLI-1 trial, pegylated liposomal irinotecan (nal-IRI), in combination with 5-fluorouracil (5-FU) and leucovorin (LV) (nal-IRI + 5-FU/LV), is a standard treatment for advanced pancreatic ductal adenocarcinoma (PDAC) patients progressing after gemcitabine-based chemotherapy. The VILP registry captured real-world data on metastatic PDAC patients in Czech Republic receiving nal-IRI + 5-FU/LV.

Methods: Data were collected on all metastatic PDAC patients that received nal-IRI + 5-FU/LV, had an Eastern Cooperative Oncology Group performance status 0 or 1, and had progressed on gemcitabine-based chemotherapy, first line or (neo)adjuvant. Treatment was until progression or unmanageable toxicity. For the final evaluation of data, endpoints correspond to those published in the NAPOLI-1 trial; primary endpoint was overall survival (OS), calculated as the time from the treatment initiation to the date of death. Secondary endpoints included progression-free survival (PFS), objective response rate (ORR) and treatment toxicity.

Results: As of April 6, 2023, 142 PDAC patients were enrolled, of which 129 were evaluable. Patients had a median age of 66 years, 95 (73.6%) received nal-IRI + 5-FU/LV as second line therapy and 101 (78.3%) had ECOG PS 1. A total of 93 (72.1%) patients discontinued treatment and median treatment duration was 2.3 months (range: 0.0-18.8) with the principal reason for discontinuation being disease progression (n=45, 48.4%). Median and 6-months OS were 10.1 months (95% CI 6.0—not reached) and 57.1% (95% CI 47.4—68.7), respectively. Median and 6-months PFS were 3.5 months (95% CI 3.1—5.7) and 35.5% (95% CI 27.1—46.6), respectively. ORR was 10.1% (12 cases of partial response and 1 complete response). A total of 19 adverse events (AEs) occurred in 17 (13.2%) patients, with the most frequent AEs being diarrhoea (n=9; grade 3 n=3) and fatigue (n=3; grade 3 n=1).

Conclusions: The VILP register confirms the effectiveness of nal-IRI + 5-FU/LV as a well-tolerated treatment option for patients with PDAC in real-world practice.

1675P Diagnostic performance of blood-based DNA methylation assay using epigenetic-specific peptide nucleic acid in pancreatic adenocarcinoma

H. Kim[1], J. Chu[2], I-G. Do[2], H.K. Kim[1], Y. Yang[1], K.H. Lee[1], H.S. Han[1]

Background: Pancreatic adenocarcinoma (PA) is an aggressive tumor with a poor prognosis and is difficult to diagnose with traditional tissue-based techniques. Cancer-associated DNA methylation biomarkers are promising for cancer diagnosis and have potential as non-invasive methods, as they can be detected not only in tissues but also in the blood. In the present study, we aimed to evaluate the diagnostic performance of a DNA methylation assay using epigenetic-specific peptide nucleic acid (Epi-sPNA) for PA.

Methods: An Epi-TOP pancreatic assay (Seasun Biomaterials, Daejeon, Korea) was used to detect PA-specific epigenetic and genetic biomarkers. The assay using Epi-sPNA enabled the accurate and quick analysis of methylation without sample processing using bisulfate. A total of 92gDNA samples collected from normal pancreatic and PA tissues of 46 patients who underwent surgical resection for PA were tested to evaluate the diagnostic performance of epigenetic biomarkers for PA. Further validation was performed on cell-free DNA isolated from the plasma samples of 10 individuals each from the PA, benign pancreatic disease, and normal groups.

Results: The combination of seven epigenetic biomarkers, *HOXA9*, *TWIST*, *WT1*, *RPRM*, *BMP3*, *NPTX2*, and *BNC1* showed high sensitivity of 93.5% and specificity of 96.7% in discriminating between normal pancreatic and PA tissues. There were no significant differences in the methylation levels according to age, sex, or cancer stage. Plasma cell-free DNA collected from patients with PA and benign pancreatic disease and normal individuals was tested using a combination of epigenetic seven biomarkers with *KRAS* somatic mutations in codons 12, 13, and 61. Plasma-based DNA methylation analysis confirmed the diagnostic performance, with a sensitivity of 90.0%, specificity of 95.0%, and accuracy of 93.3%, whereas the accuracy of traditional serum biomarkers cancer antigen 19-9 and carcinoembryonic antigen was both 90.0%.

Conclusions: Our study suggests that seven differentially methylated genes, in combination with *KRAS* somatic mutations using Epi-TOP pancreatic assay, can be used as potential blood-based biomarkers for the diagnosis of PA.

1676P Clinical outcomes of first-line chemotherapy in locally advanced and metastatic pancreatic adenocarcinoma patients: Real-world experience

N. Umpawan[1], P. Termsinsuk[2], U. Kaosombatwattana[2], C. Akewanlop[1], K. Korphaisarn[1]

[1]Division of Medical Oncology, Department of Medicine, Faculty of Medicine Siriraj Hospital, Mahidol University, Bangkok, Thailand; [2]Gastroenterology, Faculty of Medicine Siriraj Hospital, Mahidol University, Bangkok, Thailand

Background: Pancreatic cancer has a poor prognosis compared to many other malignancies. This study evaluated the clinical outcomes of systemic chemotherapy (CMT) in patients with locally advanced and metastatic pancreatic ductal adenocarcinoma (LA/M-PDAC).

Methods: A retrospective, observational chart review was conducted on patients with LA/M-PDAC who underwent CMT between January 2012 and November 2022. The efficacy data (objective response rate [ORR], disease-control rate [DCR], progression-free survival [PFS], and overall survival [OS]) were evaluated and compared using Pearson's chi-square tests, Kaplan—Meier plots, and log-rank tests.

Results: Out of the 998 patients diagnosed with LA/M-PDAC, 332 (33.3%) received systemic CMT. Among the treatment regimens used, gemcitabine (GEM) was administered most frequently (33.7% of cases). The next most commonly utilized therapies were (m)FOLFIRINOX and GEM plus capecitabine (GEMCAPE), accounting for 27.4% and 26.2% of cases, respectively. Platinum doublets (PlatD) were administered in 9.3% of cases. The ORRs and DCRs of the four regimens differed significantly (for GEM, GEMCAPE, (m)FOLFIRINOX, and PlatD, the ORRs were 4.5%, 10.3%, 23.1%, 19.4%, respectively, with $P < 0.0001$; the DCRs were 38.4%, 52.9%, 73.6%, and 54.8%, respectively, with $P < 0.0001$). Patients who received combination CMTs had significantly longer median PFSs than those who received GEM alone (PFS = 4.93 months for GEMCAPE, 9 months for (m)FOLFIRINOX, 9.43 months for PlatD, and 3.87 months for GEM). When comparing GEMCAPE with (m)FOLFIRINOX, the median PFS was significantly lower in the GEMCAPE group (PFS = 4.93 vs 9.0 months; HR = 0.53; $P < 0.0001$). However, no significant differences were observed in the median OS rates of the four regimens in a multivariate Cox proportional-hazards model analysis. The frequency of treatment-related grade 3 or 4 adverse events was higher in the (m)FOLFIRINOX group, followed by the GEMCAPE group.

Conclusions: This study revealed that FOLFIRINOX exhibited higher ORR, DCR, and PFS rates than GEM or GEMCAPE. Nevertheless, no survival advantage was detected in the FOLFIRINOX groups, suggesting the influence of subsequent therapies.

1677P Pancreatic enzyme replacement therapy improves survival in patients receiving nab-paclitaxel plus gemcitabine as first-line treatment for advanced pancreatic adenocarcinoma

D. Lavacchi[1], C. Winchler[1], E. Giommoni[2], I.A. Vascotto[1], S. Romano[1], F. Scolari[2], A. Taddei[3], S. Pillozzi[1], A. Galli[4], L. Antonuzzo[2]

Background: Pancreatic ductal adenocarcinoma (PDAC) is one of the big killers with a 5-year-survival rate of less than 2% in metastatic disease. Limited treatment options and early clinical deterioration often affect outcome. Exocrine pancreatic insufficiency (EPI) is often underestimated in patients with advanced PDAC and a large proportion of patients (60-80%) does not receive pancreatic enzyme replacement therapy (PERT). This study aims to optimize the clinical selection of patients with advanced PDAC treated with gemcitabine/nabpaclitaxel and to develop models to predict benefit from first-line therapy and duration of second-line therapy.

Methods: In this observational study we prospectively enrolled patients with advanced PDAC treated with gemcitabine/nabpaclitaxel as first-line therapy at the Medical Oncology Unit of Careggi University Hospital from 2015 to 2022. Clinical and laboratory data were collected and associated with survival outcomes, duration of second-line therapy and treatment exposure.

Results: A total of 107 patients were enrolled, 54 (50.5%) were women and 53 (49.5%) were men. Disease stage was classified as locally advanced in 42 (39.3%) and metastatic in 65 (60.7%). Median progression-free survival (PFS) was 5.6 months and median overall survival (OS) was 7.4 months. Among the baseline clinical variables, a trend towards a worse prognosis was observed in patients with a high tumor burden (OS p=0.065). Overall, 66.0% of patients received PERT at baseline or within 3 months from first-line treatment start. PERT-users had a significantly longer OS than non-PERT-users (9.5 months vs 5.5 months, respectively, HR 95%CI 2,1 [1,2-3,7], p=0.008). In addition, the probability to receive a second-line treatment for at least 2 months was higher in the PERT-user group than in the non-PERT-user group (X-squared=7.6558, p-value=0.005659).

Conclusions: The clinical management of patients with advanced PDAC is challenging and requires a multidisciplinary strategy to prevent EPI-related symptoms and optimize treatment adherence. PERT could play a crucial role in preventing weight loss, maintaining dose intensity and improving survival.
