Background: Chemotherapy alone has limited efficacy in treating advanced pancreatic cancer (APC). The addition of nimotuzumab (nimo) to gemcitabine had been shown to be more effective in our previous studies: the progression-free survival (PFS) was up to 5.1 months, 1.5 months longer than gemcitabine alone for 1st line treatment of APC, but its efficacy and safety in combination with other chemotherapy regimens are unknown.

Methods: In this study, patients with APC were treated with standard of care (routine chemotherapy) combined with or without nimo in a real-world data setting. Demographic and clinical data were collected from electronic medical records of First Affiliated Hospital of Xi'an Jiaotong University from April 2018 to May 2023. The primary efficacy endpoint was progression-free survival (PFS).

Results: We identified 282 APC patients, of which 36.8% received nimo combined with routine chemotherapy. After 1:1 propensity score matching (PSM), we created 65 pairs patients (median age was 62 years, range, 55-69) who received routine chemotherapy with or without nimo as first-line treatment. Among them, 55 pairs were treated with albumin paclitaxel-gemcitabine (AG), 3 pairs with gemcitabine-tegafur (GS) and 7 pairs with others. The median dosage of nimo was 400mg weekly. Up to May 2023, the median follow-up time was beyond 24 months. Survival analysis showed that nimo was associated with longer PFS (10.9 months vs 9.1 months; $p<0.05$, HR=0.5(95%CI, 0.29-0.88) after matching), but the OS was not evaluated due to the missing date of death. No grade 3 or above toxicities were observed.

Conclusions: Gemcitabine-based combination chemotherapy (eg, AG regimen, GS regimen) were commonly used as first-line treatment for APC in China. The addition of nimotuzumab to combination chemotherapy was a strong regimen and found to prolong the survival time for APC, with a manageable safety profile.

1679P Comparison of first-line chemotherapy regimens in unresectable locally advanced or metastatic pancreatic cancer: A systematic review and network meta-analysis

L. Mastrantoni[1], V. Beccia[1], M. Chiaravalli[2], A. Di Bello[2], A. Spring[2], D. Barone[2], F. Schietroma[2], M.G. Maratta[2], G. Trovato[2], C. Bagalà[2], M. Bensi[1], S. Alfieri[3], G. Quero[3], G. Tortora[2], L. Salvatore[2]

[1]Medical Oncology Department, Università Cattolica del Sacro Cuore, Milan, Italy; [2]Dipartimento di Oncologia Medica, Fondazione Policlinico Universitario Agostino Gemelli IRCCS, Rome, Italy; [3]Chirurgia Digestiva, Comprehensive Cancer Center, Fondazione Policlinico Universitario Agostino Gemelli IRCCS, Rome, Italy

Background: In patients with unresectable locally advanced (LAPC) or metastatic pancreatic cancer (MPC) gemcitabine-nab-paclitaxel (GEM-NAB) and FOLFIRINOX are standard first-line treatments. Recently, other combinations have shown to be associated with a survival advantage.

Methods: PubMed, CENTRAL, Embase and oncology meetings websites were searched to March 1st, 2023. We included phase II and III randomized controlled trials (RCTs) enrolling patients with unresectable LAPC or MPC which investigated gemcitabine-based (GEM) regimens, FOLFIRINOX, NALIRIFOX, PAXG or other first-line combinations. Efficacy outcomes were progression-free survival (PFS) and overall survival (OS). Hazard ratios (HRs) and 95% confidence intervals (95% CI) were computed using a random effects model. A frequentist network meta-analysis was conducted, and P-scores were used to rank treatments.

Results: 4412 records were screened, and 45 studies were included; 37 studies were evaluable for PFS and 43 for OS. Considering PFS, PAXG (P-score 0.9410), NALIRIFOX (P-score 0.8723) and FOLFIRINOX (P-score 0.8696) were among the top-ranked strategies, while GEM-NAB had a P-score of 0.6388. In terms of OS, PAXG (P-score 0.9585), GEM-NAB sequential strategies (GEM-NAB > FOLFOX, P-score 0.9350 and GEM-NAB > FOLFIRI, P-score 0.9117), FOLFIRINOX (P-score 0.8512) and NALIRIFOX (P-score 0.8461) were among the top-ranked strategies, while the P-score of GEM-NAB was 0.6998. No difference was observed between NALIRIFOX and FOLFIRINOX (PFS HR: 1.01, 95% CI 0.68-1.50; OS HR: 0.99, 95% CI 0.74-1.31). A significant difference was observed between FOLFIRINOX and GEM+NAB in terms of PFS (HR 0.71, 95% CI 0.53-0.95), while a non-significant trend was observed in OS (HR 0.82, 95% CI 0.66-1.04). No difference was observed between NALIRIFOX and PAXG (PFS HR 1.25, 95% CI 0.72-2.17; OS HR 1.40, 95% CI 0.87-2.24) and between FOLFIRINOX and PAXG (PFS HR: 1.26, 95% CI 0.72-2.22; OS HR: 1.38, 95% CI 0.84-2.27).

Conclusions: With the limitations of a network meta-analysis, our results suggest that combinations with three or four drugs, when feasible, could provide a greater survival benefit compared to GEM-NAB in unresectable LAPC or MPC.

1680P Meta-analysis of real-world survival outcomes of liposomal irinotecan in advanced pancreatic cancer patients with prior irinotecan exposure

A. Gupta, D. Laheru

Medical oncology, Johns Hopkins Medicine - The Sidney Kimmel Comprehensive Cancer Center, Baltimore, MD, USA

Background: Liposomal irinotecan (nal-IRI) plus 5-fluorouracil (5-FU)/leucovorin (LV) demonstrated survival benefits in advanced pancreatic cancer (APC) patients (pts) who progressed on gemcitabine-based therapy. The NAPOLI-1 demonstrated greater survival benefits from nal-IRI+5-FU/LV in IRI-naïve pts. Nal-IRI may be less effective in pts with prior irinotecan (IRI) exposure due to a potential cross-resistance to SN-38. This raised concerns about the relevance of nal-IRI + 5-FU/LV in clinical practice, as FOLFIRINOX is the recommended first-line regimen for APC pts with good performance status. Therefore, we evaluated the real-world survival outcomes of nal-IRI in patients with prior IRI exposure.

Methods: Real-world studies evaluating the outcomes of nal-IRI in pts with prior IRI exposure published up to April 2023 were searched using electronic databases including PubMed, Scopus, Cochrane CENTRAL, Web of Science, EBSCOhost. The meta-analysis was conducted using the R package v4.3.0 and RevMan v5.4.1. Random effects model was used to estimate the pooled hazard ratio (HR) and the 95% confidence interval (CI). I^2 statistics was obtained to evaluate the heterogeneity of the studies.

Results: Out of the total 470 pts from seven studies that are included in the meta-analysis, most pts with prior IRI exposure received nal-IRI at the third or later lines. The pooled median progression-free survival (PFS) and overall survival (OS) were 1.9 (95% CI: 1.4-2.4) and 4.1 months (95% CI 3.4-4.7), respectively. The pts with prior IRI exposure had comparable PFS (pooled HR 1.20, 95% CI 0.67-2.14, p= 0.53, I^2= 0%) and OS (HR 1.13, 95% CI 0.69-1.84, p= 0.63, I^2= 0%) to pts without prior IRI exposure. Pts who discontinued prior IRI due to progressive disease had comparable PFS (HR 1.60, 95% CI 0.34, 7.58, p=0.55, I^2= 0%) and OS (HR 2.09, 95% CI 0.29, 14.87, p=0.46, I^2= 0%) to pts with no progressive disease. Nal-IRI had a manageable safety profile across the included studies.

Conclusions: Prior IRI exposure had no impact on the survival outcomes of nal-IRI-containing regimen in APC pts. Thus, it is feasible to introduce nal-IRI in later lines of treatment in patients with prior IRI exposure. Further prospective studies are warranted.

1681P A retrospective real-world study for nimotuzumab plus postoperative adjuvant chemotherapy for resectable pancreatic cancer

S. Zou, Q. Zhan, C. Wen, F. Li, S. Zhao, L. Jiang, H. Chen, X. Deng, B. Shen

General Surgery, Ruijin Hospital Affiliated to Shanghai Jiao Tong University School of Medicine, Shanghai, China

Background: Adjuvant chemotherapy offers patients an improved chance of long-term survival, especially for those with R0/R1 resection. In APACT study, the median overall survival (mOS) of adjuvant chemotherapy for resectable pancreatic cancer (RPC) patients ranged from 36.2 to 40.5 months, but further improvement is still needed. As targeted therapy is still a blank in the treatment of RPC, we conducted this study, aiming to explore the clinical benefit of the addition of nimotuzumab to standard adjuvant chemotherapy.

Methods: RPC patients were treated with surgery, postoperative chemotherapy with or without nimotuzumab. Demographic and clinical data were collected from electronic medical records of Ruijin Hospital from May 2016 to July 2022. The primary efficacy endpoint was OS.

Results: We identified 795 patients who underwent surgical resection, of which 57 RPC patients received nimo. Propensity score matching (PSM) was performed to reduce the bias. After 1:1 PSM, we created 32 pairs RPC patients (stage I and II) who received adjuvant chemotherapy with nimo (study arm, Nimotuzumab 400mg, weekly, median exposure was 4 weeks) or without (control arm). Baseline characteristics were balanced after PSM. Median age was 63y, with 66% males. Barthel score 80-100. Median follow-up time was 35.2 (95%CI, 24.8-57.4) months and 37.3 (95%CI, 21.6-42.8) months in the control arm and study arm respectively. Survival analysis showed that study arm with a prolongation survival trend in OS (mOS: 24.5 months vs. 45.1 months) and disease-free survival (mDFS: 13.4 months vs. 15.4 months). Adverse events (AEs, Grade 1-2) were reported by 67% of patients (44 out of 64). The most frequently reported AEs were anemia (37.5%), leukopenia (7.8%), and diarrhea (4.7%), and there were no differences between the two groups. No Grade 3 or above adverse events were observed.

Conclusions: RPC patients were with a prolongation survival trend by the addition of nimotuzumab into current regimens in the postoperative program with good safety profile.

1682P Impact of metastatic site on survival in patients with synchronous metastatic pancreatic adenocarcinoma (PDAC): A national prospective BACAP study

E.L. Alouani[1], C. canivet[2], B. Bournet[2], J. Selves[3], L. Buscail[2], B. Napoleon[4], L. Palazzo[5], N. Flori[6], P. Guibert[7], A. Albucher[8], A-C. Brunac[3], C. Maulat[9], F-Z. Mokrane[10], S. Gourgou[11], L. Gauthier[11], R. Guimbaud[1], N. Fares[1]

[1]Digestive Oncology, Centre Hospitalier Universitaire de Toulouse - Hopital Rangueil, Toulouse, France; [2]Department of Gastroenterology and Pancreatology, Centre Hospitalier Universitaire de Toulouse - Hopital Rangueil, Toulouse, France; [3]Department of Pathology, Institut Claudius Regaud, Toulouse, France; [4]Department of Gastroenterology and Pancreatology, Hôpital privé Jean Mermoz, Lyon, France; [5]Service de gastro-entérologie, Clinique du Trocadéro, Toulouse, France; [6]Clinical Nutrition and Gastroenterology Department, ICM - Institut du Cancer de Montpellier, Montpellier, France; [7]Centre Léon Bérard, Endoscopy Unit, Centre Léon Bérard, Lyon, France; [8]Department of Gastroenterology, Centre Hospitalier Universitaire de Toulouse - Hopital Rangueil, Toulouse, France; [9]Department of Digestive Surgery, Centre Hospitalier Universitaire de Toulouse - Hopital Rangueil, Toulouse, France; [10]Radiology, Centre Hospitalier Universitaire de Toulouse - Hopital Rangueil, Toulouse, France; [11]Biostatistics, ICM - Institut régional du Cancer de Montpellier, Val d'Aurelle, Montpellier, France

Background: Advanced PDAC carries a dismal prognosis with a 5-year survival rate of 3%. While treated as an even population, previous retrospective studies suggested significant different survival rates for patients (pts) with lung-only metastases (mets) when compared to other pts. This study aims to explore prospectively the difference in survival outcome based on initial site of metastases in synchronous metastatic PDAC.

Methods: This is a prospective observational study including all adult pts with synchronous metastatic PDAC in BACAP (national Anatomo-Clinical Database on Pancreatic Adenocarcinoma). Data regarding pts demographics, tumor characteristics, and survival outcomes were analyzed. Primary endpoint was overall survival (OS), defined as the time from diagnosis to death or most recent follow-up.

Results: Overall, 504 pts were included [52.4% male, mean age 69 years] of which 31 (6.2%), 58 (11.5%), 363 (72%) and 51 (10.1%) pts had lung-only, peritoneal-only, liver-only and multi-site mets at diagnosis, respectively. Most patients (79.2%) received at least one line of chemotherapy. Patients with lung-only mets were older (38.7% were > 75 years old), mostly male (61.3%) and 22.6% received at least 3 lines of chemotherapy (vs 15.5% for other patients). Median OS was significantly different according to mets site (p=0.003) (Table), with a trend towards better PFS when lung-only mets: 6.3 vs 5.4, 4.5 and 2.4 mo when peritoneal-only, liver-only and multi-site mets, respectively (p=0188).

Table: 1682P

Group	N	Event (%)	OS (mo)	95% CI
Lung-only	29	25 (86.2)	11.7	[9.3; 14.6]
Peritoneal-only	58	49 (84.5)	9.2	[5.5; 12.9]
Liver-only	362	334 (92.3%)	7.2	[6.1; 8.1]
Multi-site	52	50 (96.2%)	4.1	[2.3; 5.0]
Total	501	458 (91.4%)	7.2	[6.1 ;8.1]

p=0.003

Conclusions: Pts with lung-only mets represented 6.2% of synchronous metastatic PDAC pts and exhibited improved survival. These results suggest that a subset of pts with synchronous metastatic PDAC could benefit from more aggressive locoregional treatments. Underlying biological mechanisms contributing to survival difference are under investigation.

Background: Pancreatic cancer has one of the worst outcomes of any tumor type, with a five-year survival rate of 12%. In patients undergoing upfront resection, up to 30% do not receive adjuvant chemotherapy due to surgical complications. The success of neoadjuvant chemotherapy in converting inoperable patients into operative candidates has resulted in more widespread use of it in early disease. In other cancer types, the addition of neoadjuvant immunotherapy has resulted in increased pathological response rates. The aim of the NEO-IMPACT study is to assess the safety and tolerability of neoadjuvant chemo-immunotherapy in pancreatic adenocarcinoma patients prior to definitive surgery.

Trial design: NEO-IMPACT is a phase II multi-centre, single arm, investigator-initiated trial in patients with upfront or borderline resectable pancreatic adenocarcinoma. This trial is sponsored by the Australasian Gastro-Intestinal Trials Group. Patients receive neoadjuvant durvalumab 1500mg iv q4weekly in combination with mFOLFIRINOX (5- fluorouracil, leucovorin, irinotecan and oxaliplatin) q2weekly over 12 weeks, followed by restaging and multidisciplinary team (MDT) review. Patients who remain surgical candidates will proceed to resection within 6-8 weeks of neoadjuvant therapy. A further 6 cycles of mFOLFIRINOX will be given in the adjuvant setting. The primary endpoint is the proportion of patients receiving 80% of planned neoadjuvant treatment. Secondary objectives include R0 resection rate, pathological complete response rate, objective response rate and treatment tolerability. Exploratory objectives include analysis of pre-treatment and post-treatment tumour tissue for gene expression profiling. A translational sub study is planned to investigate the evolution of the pancreatic microbiome when exposed to neoadjuvant chemo-immunotherapy. Trial recruitment commenced May 2022. 11 of a planned 20 patients are enrolled. ANZCTR registration number: ACTRN12622000378729. This study was awarded the 2018 AGITG 'New Concepts' award. Trial conduct is funded through AGITG Philanthropic Major Donor funding, with Study Drug support from AstraZeneca Pty Ltd.

Clinical trial identification: ACTRN12622000378729.

1684TiP PARPiPANC: A multicentric, single arm, phase II assessing niraparib as first line therapy for patients with metastatic homologous repair-deficient pancreatic cancer

P. Cassier[1], C. Cropet[2], C. Coutzac[3], P. Rochefort[1], A. Streichenberger[4], M. Chastenet[1], A. Buisson[4], G. Garin[2], D. Tatu[2], M. Bernardin[2], M. Chauvenet[5], F. Ghiringhelli[6], G. Roth[7], D. Perol[8]

[1]Medical Oncology Department, Centre Léon Bérard, Lyon, France; [2]Clinical Research platform, DRCI, Centre Léon Bérard, Lyon, France; [3]Digestive Oncology, Centre Léon Bérard, Lyon, France; [4]Centre Léon Bérard, Lyon, France; [5]Medical Oncology Department, Lyon Sud Hospital Center, Pierre Benite, France; [6]Medical Oncology, Centre Georges-François Leclerc (Dijon), Dijon, France; [7]Hepato-gastroenterology Department, CHU Grenoble-Alpes - Le site nord à La Tronche - Hopital Michallon, La Tronche, France; [8]Clinical Research Department, Centre Léon Bérard, Lyon, France

Background: PARP inhibitors are active in tumors with defect in homologous DNA repair by a mechanism known as synthetic lethality defined as defects in two or more separate proteins/pathways that induce cell death only when combined. Most studies of PARP inhibitors in pancreatic cancer have shown response rates of 20 to 25% in BRCA1/2 mutation carriers previously exposed to cytotoxic chemotherapy. Since mechanisms of resistance to platinum-based chemotherapy share some similarities with the mechanisms of resistance to PARP inhibitors, we hypothesize that PARP inhibitors may be significantly more active when used in chemotherapy-naïve patients and could represent a chemotherapy-free alternative for pancreatic cancers bearing defects in homologous recombination.

Trial design: This investigator initiated, multicentric, single arm, open-label, phase II aims to assess niraparib in chemotherapy-naïve biomarker-selected pancreatic cancer pts. Only pts with mutation and/or rearrangement, detected locally on tumor or liquid biopsy, leading to inactivation in at least one of the following genes BARD1, BRCA1, BRCA2, BRIP1, FANCA, FANCD2, FANCL, MRE11, NBN, PALB2, PPP2R2A, RAD51B, RAD51C, RAD51D, RAD54L are eligible. Included pts are treated with niraparib (300mg/d, orally) until loss of clinical benefit, unacceptable toxicity, withdrawal of consent, pt or investigator decision. Primary endpoint is objective response rate after 16 weeks of treatment according to RECIST V1.1 (ORR_{16W}). Secondary endpoints include duration of response, disease control rate, progression free survival, overall survival and safety. Using a Fleming-A'Hern single stage design with a target ORR_{16w} of 60% and an inefficacy bound of 30% (α=5% one sided and 90% power) a total of 25 evaluable pts are required. If at least 16 successes (CR or PR at 16 weeks) are observed, niraparib will deserve further investigation. Correlative studies include documentation of HR alteration at time of progression on optional *de novo* tumor biopsy as well as assessment of predictive value for niraparib resistance of existing or new variants using liquid biopsies. To date, 4 French hospitals are participating.

Clinical trial identification: NCT05442749.

1685TiP Perioperative or adjuvant mFOLFIRINOX for resectable pancreatic cancer (PREOPANC-3): A multicenter randomized controlled trial

J.L. van Dam[1], E.M.M. Verkolf[1], E.N. Dekker[1], G. van Tienhoven[2], M.Y.V. Homs[3], M.G. Besselink[4], H.W. Wilmink[5], B. Groot Koerkamp[1]

[1]Surgery, Erasmus MC Cancer Institute, Rotterdam, Netherlands; [2]Radiation Oncology, Amsterdam UMC - Location VUMC, Amsterdam, Netherlands; [3]Medical Oncology, Erasmus MC Cancer Institute, Rotterdam, Netherlands; [4]Surgery, Amsterdam UMC - Location VUMC, Amsterdam, Netherlands; [5]Medical Oncology, Amsterdam UMC - Location VUMC, Amsterdam, Netherlands

Background: Surgical resection followed by adjuvant mFOLFIRINOX is the current standard of care for patients with resectable pancreatic cancer. The main concern with adjuvant chemotherapy is that only half of patients actually receive adjuvant treatment. Neoadjuvant chemotherapy, on the other hand, guarantees early systemic treatment and may increase chemotherapy use and thereby improve overall survival. Furthermore, it may prevent futile surgery in patients with rapidly progressive disease. However, some argue that neoadjuvant therapy delays surgery, which could lead to progression towards unresectable disease and thus offset the potential benefits. Comparison of perioperative (i.e., neoadjuvant and adjuvant) with (only) adjuvant administration of mFOLFIRINOX in a randomized controlled trial (RCT) is needed to determine the optimal approach.

Trial design: This is a multicentre, phase III, RCT that will include 378 patients with resectable pancreatic ductal adenocarcinoma with a WHO performance status of 0 or 1. Patients are recruited from 20 Dutch centres and three centres in Sweden. Resectable pancreatic cancer is defined as no arterial contact and $\leq$90 degrees venous contact. Patients in the intervention arm are scheduled for 8 cycles of neoadjuvant mFOLFIRINOX (2-week cycle of oxaliplatin 85 mg/m^2, leucovorin 400 mg/m^2, irinotecan 150 mg/m^2 at day 1, followed by 46 hours continuous infusion of 5-fluorouracil 2400 g/m^2) followed by surgery and 4 cycles of adjuvant mFOLFIRINOX. Patients in the comparator arm start with surgery followed by 12 cycles of adjuvant mFOLFIRINOX. The primary outcome is overall survival by intention-to-treat. Secondary outcomes include progression-free survival, resection rate, quality of life, adverse events, and surgical complications. To detect a hazard ratio of 0.70 with 80% power, 252 events are needed. The number of events is expected to be reached after the inclusion of 378 patients in 36 months, with analysis planned 18 months after the last patient has been randomized. Accrual started on September 7, 2021, and as of May 10, 2023, all centres are open for inclusion and 138 patients have been randomized.

Clinical trial identification: NCT04927780.

Background: Patients with metastatic pancreatic cancer (mPC) and germline mutations in *BRCA1/2* genes benefit from PARP inhibitors. In addition, some studies have demonstrated that PDL-1 inhibitors therapeutically synergize with PARP inhibitors in tumours with DNA homologous repair deficiency. Our hypothesis is that patients with alterations in DNA damage repair genes (somatic or germline *BRCA1, BRCA2, PALB2, RAD51C, RAD51D* and other functional DDR genes) who have benefitted from platinum-based therapy might derive additional benefit from the combination of olaparib and durvalumab.

Trial design: This is an open-label, single-arm, phase II clinical trial opened to accrual in 15 Spanish hospitals attesting the combination of olaparib (300 mg (2x150 mg tablets) bid and durvalumab (1500 mg IV infusion Q4W) in patients with mPC. Patients are eligible for the study based on alterations in a panel of specific DDR genes including *BRCA1, BRCA2, PALB2, RAD51C, RAD51D* and other DDR genes, as determined by a local assay or by the central laboratory (if local assay is not available). Main inclusion criteria: age ≥18 years, alterations in DNA Damage Repair genes, up to 2 lines of prior chemotherapy for metastatic disease, have derived benefit from platinum-based chemotherapy and not presented progression to platinum-based chemotherapy, ECOG performance status 0-1 and adequate bone marrow, renal and liver function. Main exclusion criteria: other malignancies, unless curatively treated with no evidence of disease for ≥5 years. Patients with a history of uncontrolled clinically significant, symptomatic cardiovascular disease within 6 months before trial enrolment are excluded. Primary objective is to evaluate the efficacy of olaparib in combination with durvalumab in terms of overall response rate. Secondary objectives: progression-free survival, overall survival, duration of response, disease control rate and safety and tolerability. Exploratory objectives: impact of baseline and on treatment biomarkers predictive of the efficacy. The trial is in progress; 10 of up to 40 planned patients have been recruited at the end of April 2023 (first patient in November 2022).

Clinical trial identification: NCT05659914.

Legal entity responsible for the study: Spanish Cooperative Group for the Treatment of Digestive Tumors (TTD).

Background: Cancer is a major cause of mortality and high healthcare costs globally. Accurate and granular estimation of the number of patients requiring cancer care is crucial for healthcare planning and resource allocation. The PRIMCAT project provides evidence-based forecasts of the population health economic impact of new cancer treatments in Australia.

Methods: The PRIMCAT project takes a data-driven approach using real-world hospital and administrative data (RWD) for melanoma (MEL), non-small cell lung (NSCLC) and colorectal cancer (CRC). We analysed patterns of care for each cancer, refined using clinician-developed treatment algorithms. We estimated time-to-event analyses, treatment utilization, and progression rate based on retrospective data. We built a discrete event simulation (DES) model to forecast the number of individuals treated by line of treatment and stage of disease. To test the model, we identified the top 5 novel drugs through a systematic horizon scanning procedure and integrated scenario analyses to forecast the number of patients eligible for each drug.

Results: We included 90,522 patients with either MEL, NSCLC or CRC to populate the model with RWD. Treatment patterns provide an overview of how cancer care is managed in Victoria, and the DES estimates the number of patients currently treated. Scenario analyses estimate the numbers of patients likely to be treated with novel drugs for each cancer type based on forecasted incidence, stage distribution, and uptake of treatment. For example, the availability of pembrolizumab for deficient mismatch-repair in metastatic CRC as first line treatment from 2021 onwards would result in a range of 656-867 patients per year receiving this drug, depending on uptake.

Conclusions: Our simulation model estimates the impact of introducing new treatments at applicable points in treatment pathways, decreasing uncertainty associated with the eligible patient population for novel cancer therapies. We provide an invaluable tool for health technology assessment, allowing policymakers to plan and support decision-making for new drugs. Our model aims to ensure effective, affordable, and sustainable cancer care services with equitable access to high-quality care.

1688O Informative censoring of surrogate end-point data in FDA-approved cancer drugs

T. Meirson[1], J. Ofer[2], G. Markel[1], Y. Pras[3], S. Gilboa[3]

[1]Davidoff Cancer Center, Rabin Medical Center, Petah Tikva, Israel; [2]Oncology, Davidoff Cancer Center - Rabin Medical Center, Petah Tikva, Israel; [3]Sackler Faculty of Medicine, Tel Aviv University, Tel Aviv, Israel

Background: The use of surrogate endpoints in oncology is widespread and increasing, but their association with survival is often weak. Since informative censoring can affect survival analysis, we sought to investigate the patterns of censoring in oncology randomised controlled trials (RCTs) FDA-approved based on surrogate endpoints and examine their association with overall survival.

Methods: In this cross-sectional study we reconstructed K-M curves of RCTs leading to FDA drug approval based solely on surrogate endpoints between 2010 and 2020. The reverse K-M method (i.e., events and censoring are flipped) was used to examine differential censoring with the analogous reverse hazard ratio and restricted mean survival time. Sensitivity analysis was performed by restoring the balance in censoring between study arms.

Results: Of the 65 eligible studies, 22 (34%) reported significant overall survival benefit (concordant trials), and 43 (66%) did not (discordant trials). The proportion of studies with significant differential censoring in surrogates was 51% (22/43) and 45% (10/22) in discordant and concordant trials, respectively. Although censoring imbalance occurred in both groups, after sensitivity analysis, 74% (32/43) of the discordant trials lost their statistical significance, compared to 9% (2/22) of concordant trials (OR $= 29.09$ 95% CI 5.83 $-$ 145.08, $P = 0.0018$).

Conclusions: Drugs approved based on surrogate endpoints frequently exhibit uneven dropout rates between study arms. Our analysis indicates that studies without survival benefit often fail to demonstrate improvement in surrogates after accounting for excessive censoring.

Background: A growing body of real-world evidence (RWE) aims to better reflect outcomes of cancer patients treated in real-world settings. We aimed to conduct a first comprehensive mapping review of the RWE produced over the past 3 years in terms of tumor type, treatment strategies, setting, and data sources, focusing on targeted therapies (TT) in solid tumors.

Methods: We conducted a systematic review in PubMed of RWE studies published between 01/2020 and 12/2022. We identified non-interventional studies using observational data, focusing on solid tumors exposure to targeted therapies, excluding immunotherapies. Abstract and full-text screening were performed by 11 independent reviewers.

Results: A total of 7,774 publications were retrieved with 1,251 considered eligible and extracted. The number of publications per year progressively increased during this period (328 in 2020; 421 in 2021; 502 in 2022). Most studies (50%) were performed in Asia, followed by Europe (25%) and North America (17%). Only 8% of studies had patients treated in more than one country. Treatment effectiveness and safety were assessed in 71% and 42% of studies respectively. Main data sources were medical records (60%), different types of registries (12%), and standardized data (9%). The majority were retrospective cohorts (87%), while 8% were prospective cohorts and 16% could be classified as population-based. Small molecules (62%) were the most frequently type of TT investigated. Most studies (30%) assessed gastrointestinal tract tumors, followed by lung (23%) and breast tumors (21%). In 17% of cases, study funding was industry-based.

Conclusions: RWE publications on TT for solid tumors are heterogeneous and mostly rely on retrospective data such as medical records. Population-based and international studies are rare. Collaborative efforts towards international representativeness and the use of routinely collected and/or standardized data sources must be encouraged to increase the relevance and future quality of publications and their potential impact on oncology practice.
Dr Perrat and Dr Grinda contributed equally to this study.

1690O Impact of the SARS-CoV-2 outbreak on the initial clinical presentation of new solid cancer diagnoses: A systematic review and meta-analysis

S. Marty[1], G. Lamé[2], E. Guével[3], S. Priou[4], G. Chatellier[5], C. Tournigand[1], E. Kempf[1]

[1]Medical Oncology, Centre Hospitalier Universitaire Henri-Mondor AP-HP, Creteil, France; [2]Laboratoire de Génie Industriel, CentraleSupélec - Paris-Saclay campus, Gif Sur Yvette, France; [3]Innovation and Data, IT Department, Assistance Publique - Hopitaux De Paris AP-HP, Paris, France; [4]LGI, CentraleSupélec - Paris-Saclay campus, Gif Sur Yvette, France; [5]Epidemiology, Assistance Publique - Hopitaux De Paris, Paris, France

Background: Sars Cov-2-related disruptions to health services might have impaired the initial clinical presentation of new solid tumor patients. The aim of this systematic review was to compare the initial tumor stage of solid cancer diagnoses before and after the Sars Cov-2 outbreak.

Methods: Following PRISMA and MOOSE guidelines, we systematically reviewed articles in MEDLINE and EMBASE on the tumor stage of new solid cancer diagnoses before and after the initial Sars Cov-2 pandemic waves. A random-effects meta-analysis was conducted to compare the rate of metastatic tumors at initial presentation. Subgroup analyses were performed per primary tumor site, and per study country. Interstudy heterogeneity and subgroup differences were assessed with I^2 and X^2 tests, respectively.

Results: From 2,013 studies published between January 2020 and April 2022, we included 58 studies including 109,996 patients. The rate of metastatic tumors was higher after than before the pandemic (OR: 1.29 (95% confidence interval (95%CI), 1.06-1.57) with a I^2 of 89% (95%CI, 86%-91%). OR (95%CI) were 1,51 (1.07-2,12) for breast cancers, 1.51 (1.04-2.18) for gynecologic cancers, 0.79 (0.18-3.52) for lung cancers, 1.15 (0.89-1.49) for colorectal cancers, 1.45 (0.62-3.42) for other digestive cancer, 2.26 (0.51-10,05) for prostate cancer, 12.07 (0.57-253,68) for genitourinary cancers and 1.01 (0.59-1.75) for other types of cancer ($X^2 = 24,60$, $p<0.01$). Only 2 countries out of 17 studied showed a significantly higher rate of metastasis after the pandemic: Italy (OR (95%CI) = 1.55 (1.01-2.39)) and Spain (1.14 (1.02-1.29)) Conversely, Taiwan and Canada showed a significantly lower rate of metastasis after the pandemic: OR (95%CI): 0,51 (0,28-0,93) and 0,14 (0,07-0,29).

Conclusions: Despite inter-study heterogeneity, our meta-analysis showed a higher rate of metastatic tumors at initial presentation after the Sars Cov2 outbreak. The burden of social distancing policies might explain those results, as patients may have delayed seeking care.

1691O Trends in new patient consultations during the COVID-19 pandemic at a comprehensive cancer centre in a public healthcare system

C.C. Barron[1], T. Pittman[2], W. Xu[2], M. Madunic[1], J. Brierley[1], M.K. Krzyzanowska[1]

[1]*Medical Oncology, UHN - University Health Network - Princess Margaret Cancer Center, Toronto, ON, Canada;* [2]*Biostatistics, Princess Margaret Cancer Centre, Toronto, ON, Canada*

Background: The impact of COVID-19 pandemic-related disruptions on cancer services is still emerging. We describe trends in new patient consultations in a comprehensive cancer centre before and during the pandemic.

Methods: New patient consultations were reviewed in the Princess Margaret Cancer Registry and grouped by Year=Y and quarter=Q1-Q4. Periods of interest were: baseline (Y2018-2019), pandemic declaration (Y2020Q1-Y2020Q2) and post-declaration period (PDP) (Y2020Q2-Y2021Q1). Logistic regression models were used to assess the effect of period before and during the COVID-19 pandemic on stage at presentation and adjusted for age, sex and diagnosis location (our hospital network vs. elsewhere).

Results: 53,759 new patient consultations took place from Jan 1, 2018-June 30, 2022. After pandemic declaration, new consultations decreased by 43.3% in Y2020Q2. During the PDP there were 2047 fewer overall, and 1618 new primary, consultations than expected which were not made up for at latest follow-up. The cancer sites with largest reduction in new primary assessments were neuroendocrine (84.6%), esophageal (62.1%) and colorectal (50.9%). Patients presenting with metastatic cancers were less likely to be diagnosed within our hospital network (aOR 0.70; CI 0.66-0.74, $p<0.001$), while patients with early-stage cancers were more likely (aOR 1.43; CI 1.34-1.52, $p<0.001$). After easing of pandemic restrictions in Y2020Q3, new patient assessments for metastatic cancers were higher than expected (aOR 1.23; CI 1.08-1.40, $p=0.002$). During the later periods of Y2021Q3-Y2022Q2 the odds of assessment for Stage 2/3 cancers were significantly lower than expected (aOR 0.81-0.90).

Conclusions: A large reduction in new patient consultations occurred during the COVID-19 pandemic; representing a gap in new cancer detection or change in care patterns with shift to other centres. The proportion of patients with stage 4 disease at consultation increased directly after the lockdown lifted, while the proportion of early-stage assessments remained below baseline during the later quarters, suggesting a protracted system recovery. Quantifying these changes are crucial for informing care delivery and recovery strategies.

1692MO Is project Orbis successful? The Swiss perspective

M. Pavic[1], Q. Li[1], E. Atiek[2], A. Wolfer[1], U-P. Rohr[1]

[1]*Clinical Assessment, Swissmedic Swiss Agency for Therapeutic Products, Bern, Switzerland;* [2]*Regulatory Assessment, Swissmedic Swiss Agency for Therapeutic Products, Bern, Switzerland*

Background: An expedited market access for novel, effective & innovative drugs is warranted for patients. Swissmedic (SMC, Swiss Agency for Therapeutic Products) has participated since 2020 in Project Orbis, an US FDA launched collaborative parallel-review program where regulatory agencies remain decision-independent. We present the impact of the first 2 Project Orbis years from a SMC perspective.

Methods: We compared submission gaps (time between submission to FDA [1st] and SMC [2nd]), approval rates, consensus decision rates, and the approved indication labels between SMC and FDA for the 31 market authorization applications (MAA) in oncology submitted through Project Orbis (Orbis MAA) and the 41 oncology applications submitted in a conventional way to SMC (non-Orbis MAA) during 2020-2021. Assessment times at SMC were evaluated for Orbis and non-Orbis MAA with a decision until 6/2022.

Results: The median gap between submission to the FDA and SMC was 33.0 days (range: 7, 337) for Orbis MAA versus 168.0 days (range: -359, 1593) for non-Orbis MAA. The median assessment time at SMC was 235.5 days (range: 52, 476) for Orbis MAA and 314.0 days (range: 115, 542) for non-Orbis MAA. Approval rate at SMC was consistent with 76.9% for Orbis and 75.6% for non-Orbis MAA compared to 96.2% and 100% at the FDA, respectively. Consensus decision between SMC and FDA was with 80.8% numerically higher for Orbis as compared to 75.6% for non-Orbis MAA. Divergent decisions in Orbis MAA were due to different interpretations on trial design (uncontrolled), lack of benefit in subgroups (histology, race), and lack of overall survival (OS) benefit or immature OS data. Less labels with differences in indication wording between SMC and FDA was observed in Orbis than in non-Orbis MAA (60% vs 67.7%). Similarly, stricter label indications at SMC were reduced with Project Orbis from 61.3% to 50% with non-Orbis.

Conclusions: Project Orbis is successful for SMC because (1) Submission gaps and review times for oncology applications submitted to SMC are significantly reduced by Project Orbis, fostering a faster patient access. (2) Consensus decision rates are increased and indication differences and strictness between SMC and FDA are reduced with Project Orbis, potentially due to joint discussion amongst agencies.

Background: Adolescents and young adults (AYAs), aged 18-39 years at primary cancer diagnosis, form a distinct population within the oncology community due to their spectrum of cancers, developmental life challenges, and care needs that differ from children and older adults. While the 5-year survival of AYAs is >80%, long-term and late effects can affect the quantity and quality of their life. We studied patient-reported long-term and late health-related problems among AYA cancer survivors.

Methods: Long-term AYA cancer survivors (5-20 years after primary cancer diagnosis) were identified by the population-based Netherlands Cancer Registry (NCR) and invited to participate in a questionnaire study. Participants reported their sociodemographic characteristics, and the occurrence and time of diagnosis of their long-term and late health-related problems. Clinical data were retrieved from the NCR.

Results: 3776 AYA cancer survivors (on average 31.6 years old at diagnosis; 12.4 years post-diagnosis) were included for analyses. Participants reported health-related problems with/of their digestive system (15.5%), vision (15.0%), back (14.6%), hormonal system (14.4%), cardiovascular system (12.6%), respiratory system (12.1%), urinary tract (11.0%), depression (8.6%), hearing (7.4%), osteoarthritis (6.9%), second primary cancer (6.4%), and anemia (5.1%). Of the 14 health-related problems that we examined, 35.1% of the participants reported none, 28.8% one and 36.1% reported two or more long-term and late health-related problems. Factors associated with an increased likelihood of long-term and late health-related problems include female sex, higher age at diagnosis, longer time since diagnosis, cancer of the colon/rectum, female genitalia, or thyroid, and treatment with stem cell therapy.

Conclusions: About two-thirds of the AYA cancer survivors experience at least one long-term or late health-related problem. If future research confirms that these problems are caused by cancer or its treatment, appropriate surveillance strategies to identify those at risk and interventions to mitigate those problems should be implemented preferably in AYA survivorship care programs.

Clinical trial identification: NCT05379387. IRB approval: Netherlands Cancer Institute Institutional Review Board NCI-IRBd18122. Approval date: February 6th, 2019.

1694MO Socio-economic consequences among adolescent and young adult cancer patients: A European perspective

S. Janssen[1], J. Vancoppenolle[1], N. Franzen[1], W.T.A. Van Der Graaf[2], O. Husson[1], V.P. Retel[1], W. van Harten[3]

[1]Psychosocial Research and Epidemiology, NKI-AVL - Netherlands Cancer Institute/Antoni van Leeuwenhoek Hospital, Amsterdam, Netherlands; [2]Medical Oncology, NKI-AVL - Netherlands Cancer Institute/Antoni van Leeuwenhoek Hospital, Amsterdam, Netherlands; [3]Department of Health Technology and Services Research, University of Twente, Enschede, Netherlands

Background: The effect of a cancer diagnosis is wide-ranging with potential negative impact on socioeconomic life such as high (in)direct treatment-related costs and income loss. These socioeconomic consequences differ per country, healthcare setting and patient population. Adolescents and young adults (AYAs), 18-39 years old at cancer diagnosis, are recognized as a distinct population within the oncology community with age-specific problems and needs. Insight into the socioeconomic consequences of cancer at this young age is of utmost importance to provide the best possible supportive care to this group. This study explores the socio-economic consequences among AYAs across 11 European countries.

Methods: This study presents a sub-analysis of the SEC-Study data, focusing on AYAs who were currently treated or treated before. Participants were included by hospitals of the Organization of European Cancer Institutes network and patient organizations in 11 countries (Belgium, Bulgaria, Cyprus, Denmark, Finland, France, Germany, Netherlands, Norway, Spain, Switzerland). Next to measuring financial distress through the Financial Index of Toxicity, our survey explored other socio-economic consequences like income loss, coping behaviour regarding treatment related expenses and access to financial services.

Results: 316 AYA cancer patients participated (median age: 35 years), of which 38% had to permanently quit their job due to their cancer (range: 19% (France, Norway); 71% (Spain)) and 70% suffered from income loss (range: 53% (Bulgaria); 89% (Belgium)). AYAs coped by using their savings (43%), spending less on luxury goods/leisure activities (37%), spending less on basic goods (29%), applying for financial assistance (26%), or borrowing money (20%), although differences exist between countries. Most AYAs (82%) were worried about their family's financial situation and 58% stated it's important to them to discuss the personal cost of treatment with their doctor.

Conclusions: This European study shows that many AYAs face serious socio-economic consequences, although differences exist between countries. Those AYA cancer patients at risk of impacted socio-economic outcomes require bespoke financial support.

1695MO Cancer care during armed conflict: Factors associated with adult patient transfer for treatment abroad during the war in Ukraine

I. Huivaniuk[1], D. Kizub[2], V.S. Kopetskyi[1], A. Dzhemiliev[3], A. Kacharian[1], V. Strilka[4], A. Beznosenko[5], N. Melnitchouk[6]

[1]Hepatopancreatobiliary Department, National Cancer Institute of the Ministry of Health of Ukraine, Kiev, Ukraine; [2]Division of Cancer Medicine, MD Anderson Cancer Center, Houston, TX, USA; [3]Surgery Dept., Brigham and Women's Hospital, Boston, MA, USA; [4]Medicine, National Cancer Institute of the Ministry of Health of Ukraine, Kiev, Ukraine; [5]Oncology Dept, National Cancer Institute of the Ministry of Health of Ukraine, Kiev, Ukraine; [6]Surgery, Harvard Medical School, Boston, MA, USA

Background: Because of Russian Federation's invasion of Ukraine, many patients with cancer are unable to receive treatment at home. We explored factors associated with transfer of cancer patients to the European Union (EU) for treatment through the joint program.

Methods: We conducted a retrospective review of data from the Ministry of Health (MOH) on patients who applied to be transferred abroad for cancer care from April 2022 to April 2023. Data was analyzed using descriptive statistics and standard tests of association.

Results: 336 (53.0%) of 634 patients were analyzed. We excluded children, patients without a cancer and with no available data. The mean age was 46.9 years (SD ± 13.5). 197 (58.6%) had ECOG 0-1, 94 (30%) ECOG 2, 14 (4.2%) ECOG 3-4, 31 (9.2%) ECOG unknown. The most common cancers were: 102 (30.4%) melanoma, 43 (12.8%) breast cancer, 31 (9.2%) chronic hematologic and 26 (7.8%) acute hematologic malignancies, 21 (6.3%) colorectal cancer, 20 (6.0%) lung cancer, 12 (3.6%) head and neck cancer. Of 336 patients, 280 (83.3%) were transferred for care abroad, 22 (6.5%) were pending, 28 (8.3%) transfers declined. Reasons for transfer were treatment not available, new diagnosis190 (56.5%), 105 (31.3%) for continuation of care, 19 (5.6%) cancer relapse, 32 (9.5%) bone marrow transplant, 15 (4.5%) radiotherapy, 13 (3.9%) surgery, 3 (0.9%) organ transplant. Factors independently associated with being transferred were breast cancer (OR 5.8, 95% CI: 2.7-5.7), melanoma (OR 2.6, 95% CI: 1.2-5.6), ECOG 3-4 (OR 0.1, 95% CI: 0.01-0.4). In univariate analysis, not having cancer treatment available in Ukraine (OR 2.5, 95% CI: 1.4-4.5), head and neck cancer (OR 0.2, 95% CI: 0.1- 0.6), and continuation of cancer care when drug was not available in Ukraine (OR 2.5, 95% CI: 1.4-4.5) were also associated with transfer.

Conclusions: The Ukraine-EU program for transferring cancer patients abroad is a strategy to mitigate issues with cancer care capacity during armed conflict, with almost all patients who applied currently receiving cancer treatment in the EU. Patient-related factors associated with transfer abroad for cancer care during war included patient condition, cancer type, and government treatment coverage.

1696MO Partial orphan cancer drugs: FDA approval, clinical benefit, trials, epidemiology, price, beneficiaries, and spending

D.T. Michaeli[1], C.T. Michaeli[2]

[1]Department of Medical Oncology, National Center for Tumor Diseases, Heidelberg University Hospital, Heidelberg, Germany; [2]Abteilung für Personalisierte Onkologie mit Schwerpunkt Lungenkarzinom, UMM - Universitaetsklinikum Mannheim, Mannheim, Germany

Background: The Orphan Drug Act (ODA) incentivizes drug development for rare diseases with limited sales potential. Yet, orphan drugs frequently turn into multi-billion-dollar blockbusters, particularly those used to treat rare and common diseases: partial orphans. This study analyses the development, US Food and Drug Administration (FDA) approval, epidemiology, and economics of full, partial, and non-orphan cancer drugs.

Methods: 170 drugs with FDA approval for 455 cancer indications were identified between 2000-2022. Full, partial, and non-orphan drugs were compared regarding their regulatory approval, clinical benefit, trials, epidemiology, price, beneficiaries, and spending with data extracted from FDA documents, Global Burden of Disease study, and Medicare & Medicaid.

Results: We identified 110 full, 22 partial, and 38 non-orphan cancer drugs. Time from first to second FDA approval was shorter for partial than non-and full orphans (median 1.3 vs 1.6 vs 2.3 years). Full orphans, relative to partial and non-orphans, were more frequently third-line (17% vs 8 vs 7, $p=.025$) monotherapies (74% vs 58 vs 58, $p=.002$) for hematologic cancers (66% vs 4 vs 0, $p<.001$) supported by smaller (median 154 patients vs 416 vs 536, $p<.001$) open-label (56% vs 64 vs 87, $p<.001$) single-arm trials (19% vs 23 vs 50, $p<.001$). Disease incidence was lower and disease severity higher for full than partial and non-orphans. Full orphans offered a significantly greater overall survival (median: 4.0 vs 2.8 vs 2.8, $p<.001$) and progression-free survival (median: 5.1 vs 2.5 vs 3.6, $p<.001$). Monthly prices were higher for full and partial than non-orphans (median $17177 vs 13284 vs 12457, $p<.001$). Beneficiaries (8790 vs 4390 vs 1730) and spending ($570 vs 305 vs 156 million) per drug were greater for partial than non-and full orphans.

Conclusions: The benefit, trials, and epidemiology of partial orphan cancer drugs are more similar to non-orphans than full orphans. Yet, partial orphans receive all of the ODA's incentives and are swiftly extended to new indications, resulting in greater prices, beneficiaries, and spending. Establishing a maximum revenue threshold for the ODA's benefits alongside indication-specific pricing could reduce expenditure on partial orphans.

1697MO Spending on and beneficiaries of orphan cancer drugs for ultra-rare, rare, and common diseases

J.C. Michaeli[1], C.T. Michaeli[2], D.T. Michaeli[3]

[1]Department of Obstetrics and Gynecology, LMU University Hospital, LMU Munich, Munich, Germany; [2]Abteilung für Personalisierte Onkologie mit Schwerpunkt Lungenkarzinom, UMM - Universitaetsklinikum Mannheim, Mannheim, Germany; [3]Department of Medical Oncology, National Center for Tumor Diseases, Heidelberg University Hospital, Heidelberg, Germany

Background: The Orphan Drug Act of 1983 not only incentivizes drug development for rare (200,000-6,600 affected US citizens), but also for ultra-rare (<6,600 US citizens) and subsets of common diseases (>200,000 US citizens). This study estimates Medicare & Medicaid spending on and beneficiaries receiving ultra-rare, rare, and common orphan cancer drugs to understand their budget impact and usage.

Methods: We identified 153 cancer drugs with FDA approval in the Drugs@FDA database (2000-2022). Drugs were group into non-orphan, common orphan (>200,000 patients), rare orphan (6,600 to 200,000), and ultra-rare orphan (<6,600) according to the number of affected US citizens as published by the Global Burden of Disease study. Drug spending and the number of beneficiaries for Medicare Part D and B & Medicaid were obtained from public documents. We calculated and compared total and average spending on and the total number of beneficiaries receiving non-, common, and rare orphan cancer drugs.

Results: Medicare & Medicaid data were available for 118 on-patent drugs. Overall spending increased from $8.8 to $26.5 bn (2016-2020). In 2020, 2% ($0.5 bn) were spent on ultra-rare, 31% ($8.2 bn) on rare, 30% ($8.1 billion) on common, and 37% ($9.7 bn) on non-orphan drugs. In 2020, average spending was lower for ultra-rare and rare than common and non-orphan drugs ($70 vs 155 vs 323 vs 295 million, p=0.005). A total of 171,260 and 357,464 beneficiaries received novel cancer drugs under Medicare & Medicaid schemes in 2016 and 2020, respectively. Of these, 2% (6560) suffered from ultra-rare, 27% (97,319) from rare, 31% (111,125) from common, and 40% (142,460) from non-orphan diseases. The average number of beneficiaries per drug was lower for ultra-rare and rare than common or non-orphans (1093 vs 1098 vs 4445 vs 4452 beneficiaries, p=0.015) in 2020.

Conclusions: Significant resources are spent on orphan drugs for diseases affecting more than 200,000 US citizens, whilst shifting the FDA's and taxpayers' resources away from truly rare or ultra-rare diseases. Congress could either create three distinct special orphan designations (ultra-rare, rare, and common) or differentially tie the Orphan Drug Act's incentives to the treated disease's prevalence.

1698MO E-cigarette use among us ever-smoking cancer survivors and its implications on lung cancer screening

Q. Wang[1], M.L. Hsu[1], C. Wen[2], A. Dowlati[1], Y. Zhang[3], C. Jiang[4], D. Bruno[1], Y. Li[5], L. Deng[4], L. Chiec[1], G. Dutcher[1], C.Y. Kong[6]

[1]Department of Hematology and Oncology, University Hospitals Seidman Cancer Center and Case Western Reserve University, Cleveland, OH, USA; [2]Quality Operations, Icahn School of Medicine at Mount Sinai, New York, NY, USA; [3]Department of Surgery, Ascension Providence Hospital, Southfield, MI, USA; [4]Department of Medicine, Roswell Park Comprehensive Cancer Center, Buffalo, NY, USA; [5]School of Population and Public Health, UBC - The University of British Columbia, Vancouver, BC, Canada; [6]Division of General Internal Medicine, Icahn School of Medicine at Mount Sinai, New York, USA

Background: E-cigarettes are increasingly used as a perceived safe alternative for smoking cessation, despite evidence of increased lung cancer risk. Young cancer survivors (<40 years old) use e-cigarettes 1.5 times more than their non-cancer survivor peers. Long-term cancer survivors have a higher risk of developing second primary lung cancer than the general population. However, lung cancer screening (LCS) guidelines that focus on cigarette smoking may overlook the cancer risk of using e-cigarettes. We aimed to study e-cigarette use in LCS-ineligible long-term cancer survivors.

Methods: Smokers aged 50-79 years were obtained from the 2017-2018 & 2020-2021 US Behavioral Risk Factor Surveillance System Ineligibility for LCS was defined using the US Preventive Service Task Force (USPSTF) 2021 criteria: smokers with <20 pack-year smoking history or former smokers quit >15 years. The prevalence of current e-cigarette use in LCS-ineligible smokers was calculated and compared between long-term cancer survivors (cancer diagnosed > 5 years ago) and non-cancer survivors. All calculations were weighted.

Results: Out of 11,431,095 smokers, 62.6% were ineligible for LCS. Ineligible cancer survivors had a significantly lower prevalence of e-cigarette use than their peers without a history of cancer (p<0.01) (Table). E-cigarette use was comparable between cancer survivors and non-cancer survivors who were current, heavy, or recently quit smokers (p>0.05).

Table: 1698MO

E-cigarette use prevalence % (95%CI)	LCS ineligible smokers (62.6%; N=7,159,703)		
	Non-cancer survivors (95.2%)	Long-term cancer survivors (4.8%)	p-value
Overall	9.7 (8.0-11.3)	4.2 (1.1-7.3)	<0.01
Gender			
Women	11.8 (9.4-14.2)	5.2 (0.1-10.3)	0.02
Men	7.3 (5.0-9.5)	3.0 (0.2-5.7)	0.03
Smoking status			
Current	15.4 (11.8-19.0)	14.7 (0.5-28.9)	0.93
Former	6.5 (4.9-8.1)	1.9 (0.1-3.6)	<0.001
Pack-years			
<20	10.6 (8.7-12.4)	5.0 (1.2-8.8)	0.01
≥20	4.2 (1.4-7.0)	1.3 (0.0-3.7)	0.14
Years since quitting (former smokers)			
>15	3.8 (2.3-5.3)	1.6 (0.0-3.2)	0.05
≤15	17.1 (12.1-22.1)	4.7 (0.0-13.7)	0.07

Conclusions: Nearly 0.8 million LCS-ineligible long-term cancer survivors currently use e-cigarettes in the US. While the overall prevalence of e-cigarette use among cancer survivors was relatively low, current/heavy smokers use e-cigarettes at rates comparable to non-cancer survivors. Given that cancer survivors already face an increased risk of lung cancer, the use of e-cigarettes may further heighten this risk. Future lung cancer risk assessment and screening studies may need to take e-cigarette use into consideration.

1699MO Intervening factors for participation and non-participation in colorectal cancer screening in Spain

M.L. Amador[1], D. de Haro[2], B. Fernández Sánchez[1], M. Lopez[1], M. Blanco Álvarez[1], A. Fernández Marcos[3]

[1]Medical Department, Headquarters Spanish Association Against Cancer (AECC), Madrid, Spain; [2]Medical Department, AECC - Asociación Española Contra El Cáncer, Madrid, Spain; [3]Incidencia Política, Headquarters Spanish Association Against Cancer (AECC), Madrid, Spain

Background: The Spanish Ministry of Health introduced a population-based colorectal screening program within its common services portfolio in 2014. The program targeted adults from 50 to 69 years. They receive a personal invitation letter asking them to perform the fecal occult blood test (FOBT). To achieve public health benefits on incidence, mortality, and cost-effectiveness from this screening program 65% participation in the program is needed[1]. Although participation rates have been improved since 2014, there is still room from improvement as only 56% of the Spanish regions reach the participation threshold[2]. In this study, we examined attitudinal and social factors impacting on participation in the target population.

Methods: A survey of the target population of the screening program was conducted using a national online panel representative of the Spanish population. A representative program's target population sample, with a size of 5131 valid responses, was obtained. The data collection was conducted from June to July 2022. The data was analyzed using a descriptive analysis for the entire sample as well as the logistic regression technique.

Results: We found that 62.5% of the target population in Spain has had the FOBT effectively carried out, 72.5% have received the information letter to participate in the screening program and 86.8% were familiar with the test. Furthermore, receipt of the information letter (OR 7.35, p<0.01) and knowledge of the FOBT (OR 6.32, p<0.01) are the main variables that increase the probability of the actual completion of the test. Other variables with a high contribution are the frequency with which one visits a doctor (OR 1.71, p<0.01) and the fact of belonging to higher age brackets (OR 1.52, p<0.01).

Conclusions: Alongside the universal implementation of the invitation to the program, researchers must work with attitudinal variables which act as barriers to the population's participation — such as prior knowledge of the test or the normalization of regular visits to a doctor — if we hope to achieve truly equal access to the screening program.

1700MO Knowledge of cancer risk factors and risk-reduction in 20 high- and middle-income countries

P. Carrera[1], S. Calderazzo[2]

[1]*Digital Cancer Prevention, DKFZ - German Cancer Research Center, Heidelberg, Germany;* [2]*Biostatistics, DKFZ - German Cancer Research Center, Heidelberg, Germany*

Background: The incidence of preventable cancers especially among adults younger than age 50 years in high-income countries (HIC) is increasing. This underscores the significance of disseminating prevention recommendations as it raises concerns about risk modification by individuals and individuals' knowledge of cancer risk factors that enable primary prevention. We explored relations between risk-reduction behavior and self-perceived knowledge of cancer risk factors in 20 countries using data from the International Public Opinion Survey on Cancer 2020.

Methods: We focused on selected risk factors in the survey which had a total sample of 15,427 adults and fit an ANCOVA model to evaluate the effect of knowledge, as well as its interaction with country and risk factor on risk reduction behavior engagement. Non-response options were graphically inspected.

Results: Every unit increase in the proportion of the population knowledgeable about a cancer risk factor, on average across risk factors and countries, significantly increases the proportion of people engaging in risk reduction by approximately 16.91% (95% CI 1.77 % to 32.05 %; $p=0.029$) in 10 HIC, and 32.94% (95% CI 16.22 to 49.66; $p<0.001$) in 10 middle-income countries (MIC), respectively. A significant interaction effect was found between knowledge and country, but not between knowledge and risk factor. France showed an estimated decreased engagement in overall risk-reduction activity of about 27.73% (95% CI -46.05, -9.42; $p<0.001$) compared to the overall average. Risk factors such as sugary drinks, and red and processed meat show a steeper positive linear relationship with risk reduction compared to alcohol and excess weight in HIC and MIC.

Conclusions: Knowledge of cancer risk factors is positively associated with risk reduction in HIC and MIC. Improved dissemination of cancer prevention recommendations including the European Code Against Cancer, World Cancer Research Fund and national clinical recommendations is crucial to address potential gaps in or inadequate knowledge of cancer risk factors in the population.

[1]*Department Of Clinical Oncology, Cairo University, Giza/Egypt;* [2]*Department Of Surgery, Cairo University, Giza/Egypt;* [3]*National Cancer Institute, Cairo University, Giza/Egypt;* [4]*Department Of Surgical Oncology, Mansoura University, Mansoura/Egypt;* [5]*Department Of Radiology, Cairo University, Giza/Egypt;* [6]*Presidential Women's Health Initiative, Ministry of Health and Population, Cairo/Egypt;* [7]*Department Of Clinical Oncology, Ain Shams University, Cairo/Egypt;* [8]*Department Of Pathology, Cairo University, Giza/Egypt;* [9]*Department Of Clinical Oncology, Alexandria University, Alexandria/Egypt;* [10]*Department Of Clinical Oncology, Menoufia University, Shebeen El-Kom/Egypt;* [11]*Department Of Clinical Oncology, Assiut University, Assiut/Egypt*

Background: Screening mammography is the standard approach for early detection of breast cancer (BC). Clinical breast examination (CBE) may serve as an alternative screening tool in limited resource countries where the late presentation of BC and young age at diagnosis prevail.

Methods: We designed a nationwide screening program with a multistep approach based on two-stage CBE. All Egyptian women $\geq$18 years (ys) were invited to participate in one of the 3538 primary health care (PHC) units across Egypt. Women who were 18-35 ys of age with predefined risk factors and all women $>$35 ys underwent CBE. Those with abnormal CBE were subsequently referred to one of 102 tertiary cancer clinics (TCC) for a confirmatory breast examination conducted by a BC oncologist/surgeon. Diagnostic imaging was requested for those with clinically suspicious findings in the confirmatory CBE. Here we report the outcomes of the first 2 ys of the program.

Results: From July 2019 to June 2021, 10,832,447 women participated in the program. Of those, 5,987,485 women met the criteria for CBE. Abnormal CBE was detected in 598,252 (10%) women. Of those, 390,633 (65.3%) presented to TCC for a confirmatory CBE with a median age of 43 ys. A total of 196,509 (50.3%) women had abnormal confirmatory CBE warranting breast imaging. The majority (162,898 (82.9%)) attended diagnostic imaging, with 14,794 cases reported as BIRADS 4 or 5 (9.1%). Among the 10,128 women who successfully performed a biopsy, 5,335 (52.6%) had malignant findings; of these, 5112 had mammary carcinoma. 270 women (5.1%) of the BC cases were $\leq$ 35 ys old. Stages 0-II were diagnosed in 80.5%, reflecting significant downstaging from prior historical cohorts. Risk factors for BC in Egyptian women were estimated for the first time on a nationwide scale (Table).

Table: 1759MO

Risk factor	Relative risk (95% CIs)	Cases/Controls (5,112/5,389,233)
Oral contraceptive pills use $\geq$ 5 ys	1.16 (1.10-1.22)	1,082/984,086
BMI $\geq$ 30 kg/m^2	1.59 (1.58-1.60)	4,860/3,217,506
Diabetes mellitus	1.82 (1.67-1.99)	460/266,495
Age of menopause $\geq$ 50 ys	2.12 (1.93-2.32)	422/209,822
Family history of breast/ovarian cancer	2.50 (2.36-2.64)	1,032/435,658
Prior breast biopsy	7.67 (6.80-8.65)	254/34,903

Conclusions: Personalized-risk CBE, as adopted in our program, is effective in downstaging BC. This is the largest study to report successful BC downstaging via CBE, meeting the WHO pillar 1 key performance indicator of $\geq$60% of stages 0-II.

1701P Cancer premium: Explaining differences in prices for cancer vs non-cancer drugs with efficacy and epidemiological endpoints in the US, Germany, and Switzerland

M. Serra-Burriel[1], G. Perényi[2], Y. Laube[2], A. Mitchell[3], K.N. Vokinger[2]

[1]*Epidemiology, Biostatistics and Prevention Institute (EBPI), University of Zurich (UZH), Zurich, Switzerland;* [2]*Institute of Law, University of Zurich, Zurich, Switzerland;* [3]*Department of Oncology, Memorial Sloan Kettering Cancer Center, New York, NY, USA*

Background: High treatment prices of new cancer drugs are a global public health challenge to patients and healthcare systems. Policymakers in the US and Europe are debating reforms to drug pricing. The objective was to assess whether drug efficacy or epidemiological characteristics (prevalence, incidence, mortality) explain the gap in treatment prices between cancer and non-cancer drugs in the US, Germany, and Switzerland.

Methods: This cross-sectional study identified all new drugs approved in the US, Germany, and Switzerland between 2011 and 2020. Drug efficacy was extracted from the pivotal trials, drug prices from public and commercial databases, and epidemiological characteristics from the Global Burden of Disease (GBD) 2019 study. We used regression models to explain drug prices with drug efficacy and epidemiological characteristics (prevalence, incidence, mortality).

Results: The cohort included 181 drugs, including 68 (37.5%) drugs approved for treatment of cancer. A significant negative correlation was found between incidence/prevalence and treatment prices, and a significant positive correlation was observed between mortality and treatment prices for both, cancer and non-cancer drugs. A significant association between relative drug efficacy and treatment prices of drugs was observed, however, less pronounced for cancer drugs. Our regression estimates indicated that after adjusting for efficacy and epidemiological characteristics, cancer drugs were on average approximately three times more expensive compared to non-cancer drugs in all three countries, indicating a cancer premium. Our model explained 72% of the variance in observed prices (R2).

Conclusions: Drug pricing reforms should target the cancer premium to improve access of patients to cancer drugs as well as to achieve equity across the different therapeutic areas and sustainability in the health care systems.

1702P Real-world evidence contributions to European medicines agency's safety and efficacy evaluations of oncology targeted therapies between 2018-2022

J.W.G. Derksen[1], D. Martins Branco[2], A. Pellat[3], S.C.M.W. van Nassau[4], A. Valachis[5], A. Aggarwal[6], M. Koopman[4], G. Pentheroudakis[7], L. Castelo-Branco[7], S. Delaloge[8]

[1]Dept. Julius Center for Health Sciences and Primary Care, UMC-University Medical Center Utrecht, Utrecht, Netherlands; [2]Clinical Trials Support Unit, Institute Jules Bordet, Brussels, Belgium; [3]Medical Oncology, Hopital Saint-Antoine, Paris, France; [4]Medical Oncology, UMC - University Medical Center Utrecht, Utrecht, Netherlands; [5]Dept. of Oncology, Faculty of Medicine & Health, Örebro University, Örebro, Sweden; [6]Institute of Cancer Policy, KCL - King's College London, London, UK; [7]Scientific and Medical Division, ESMO - European Society for Medical Oncology, Lugano, Switzerland; [8]Breast Oncology Department, Institut Gustave Roussy, Villejuif, France

Background: While Real-world Evidence (RWE) has documented value for safety monitoring and disease epidemiology, its objective contribution to safety and efficacy evaluations for regulatory purposes is still unclear. Here, we aim to describe the prevalence and type of RWE considered by European Medicines Agency (EMA) as contribution to efficacy and safety-related evidence generation among approved oncology targeted therapies.

Methods: On March 10, 2023, we screened the medicines listing of EMA to identify all anti-cancer targeted therapies for solid malignancies with a decision date (initial marketing authorizations and extension of indications) between 2018-2022. We screened the European public assessment reports (EPARs) using a standardized approach to collect data on RWE. When generated pre-authorization, the RWE contribution to the final regulatory decision was classified as definitive, supportive, or non-supportive. For published RWE studies, we collected their main characteristics.

Results: Out of a total of 1976 medicines, we identified 55 oncology targeted therapies, corresponding to 75 EPARs (indications), which are described in the table. The use of RWE in regulatory deliberations occurred in 24/75 (32%) EPARs, increasing from 30% in 2018-2020, to 34% in 2021-2022. Pre-authorization RWE was described in 20/24 (83%) EPARs, among which none were definitive, 8 RWE studies (in 7 EPARs) non-supportive, and 20 RWE studies (in 15 EPARs) were supportive of the decision. Published RWE (n=14) originated from data aggregators (n=5), patient registries (n=3), health records (n=3), standardized cohort data (n=2), or from combined sources (n=1).

Table: 1702P

Characteristic	Total EPARs (n=75)	EPARs w/ no RWE (n=51)	EPARs w/ RWE (n=24)
Year: n, %			
2018-2020	43	30 (70%)	13 (30%)
2021-2022	32	21 (66%)	11 (34%)
Targeted therapy type: n, %			
Small molecule	50	34 (68%)	16 (32%)
Monoclonal antibody	20	15 (75%)	5 (25%)
Antibody-drug conjugate	5	2 (40%)	3 (60%)
EPAR type: n, %			
Initial Marketing Authorization	42	27 (64%)	15 (36%)
Extended indication	33	24 (73%)	9 (27%)
First drug in class (Yes): n, %	19	11 (58%)	8 (42%)
Generic (Yes): n, %	3	3 (100%)	0 (0%)
Biosimilar (Yes): n, %	13	12 (92%)	1 (8%)
Accelerated assessment (Yes): n, %	9	4 (44%)	5 (56%)
Orphan medicine (Yes): n, %	4	3 (75%)	1 (25%)
Conditional approval (Yes): n, %	15	8 (53%)	7 (47%)
Additional monitoring (Yes): n, %	50	34 (68%)	16 (32%)

Conclusions: Over the past 5 years, RWE involvement in the approval of oncology targeted therapies in Europe tends to increase, with the majority being supportive for EMA regulatory decision making complementary to traditional clinical trials.

1703P Value of molecular targets and genome-targeted cancer therapies FDA-approved, 2015-2022

A. Tibau[1], T.J. Hwang[2], M. Consolacion[3], J. Avorn[4], A. Kesselheim[4]

[1]Medical Oncology Department, Hospital de la Santa Creu i Sant Pau, Barcelona, Spain; [2]Division of Urological Surgery, Brigham and Women's Hospital, Boston, TX, USA; [3]Medical Oncology Department, Princess Margaret Cancer Centre, Toronto, Canada; [4]PORTAL Program on Regulation, Therapeutics, And Law, Brigham and Women's Hospital - Pharmacoepidemiology and Pharmacoecomonics Division, Boston, MA, USA

Background: Genome-targeted cancer drug approvals have increased, offering personalized therapy at high cost. We assessed genome-targeted cancer drugs to determine the validity of the targets and clinical benefits identified in the pivotal clinical trials.

Methods: We identified trials FDA-designated as pivotal that supported genome-targeted cancer drug approvals between 2015-2022. From drug labeling and publications, we extracted characteristics of the trials. Strength of evidence supporting molecular targetability was assessed by the European Society for Medical Oncology (ESMO) Scale for Clinical Actionability of molecular Targets (ESCAT). Clinical benefit for approved indications was evaluated by the ESMO-Magnitude of Clinical Benefit Scale (ESMO-MCBS) with substantial benefit defined as grade A or B for curative and 4 or 5 for noncurative intent. Molecular targets qualifying for ESCAT level I-A and I-B associated with substantial clinical benefit were rated as high benefit.

Results: Among 50 molecular-targeted drugs approved for 84 indications, 45 (54%) were based on phase I/II trials and 45 were supported by single-arm studies. The most common primary endpoint (46, 55%) was response rate (median 57%, median duration of response 11.1 months). Among the 84 pivotal trials, 38 (45%) had I-A and 32 (38%) had I-B ESCAT targetability score; 24 trials (29%) demonstrated substantial clinical benefit via ESMO-MCBS. Overall, 24 indications (29%) were high-benefit genomic-based cancer treatments.

Conclusions: Fewer than one-third recently approved molecularly-targeted cancer therapies demonstrated high patient benefits. Data often evolve after marketing, but when new cancer treatments are first approved based on exploratory analyses and anti-tumor activity alone, benefit frameworks like ESMO-MCBS and ESCAT can help identify the minority of therapies with the best clinical potential.

1704P Clinical benefit of cancer drugs approved by the US food and drug administration based on appropriateness of control arm and its change over time

C. Molto[1], A.P. Restrepo[2], A.J. Templeton[3], A. Tibau[4], A. Mittal[1], F.T. Tamimi[1], D. Malon Gimenez[1], E. Amir[1]

[1]Division of Medical Oncology & Hematology, Department of Medicine, Princess Margaret Cancer Centre and University of Toronto, Toronto, ON, Canada; [2]Medical Oncology Department, Hospital San Pedro De Alcantara, Caceres, Spain; [3]Medical Oncology Department, St. Claraspital AG, Basel, Switzerland; [4]Medical Oncology Department, Hospital de la Santa Creu i Sant Pau, Barcelona, Spain

Background: Value frameworks such as American Society of Clinical Oncology Value Framework (ASCO-VF) and European Society for Medical Oncology Magnitude of Clinical Benefit Scale (ESMO-MCBS) can be sensitive to control arms of randomized trials (RCTs). Standard of care changes over time. We explored clinical value based on appropriateness of control arm and its change over time.

Methods: We searched Drugs@FDA to identify new cancer drugs approved based on RCTs between January 2012 and December 2021, excluding trials with overlap between experimental and control arm. Appropriateness of control arm was based on published ESMO and NCCN guidelines both 1 year prior to start of accrual (as defined by ClinicalTrials.gov) and at time of drug approval. Control arm was defined as suboptimal if the strength of recommendation was 2B-3 for NCCN, III-V / C-E for ESMO guidelines and/or if prior RCT data showed that the control arm was inferior to an available alternative. Substantial clinical benefit was defined as ASCO-VF threshold score $\geq$45 and ESMO-MCBS grade A or B (curative intent) and 4 or 5 (palliative intent).

Results: We identified 55 RCTs supporting the approval of 32 drugs. Substantial benefit was observed in 65% and 55%, using ESMO-MCBS and ASCO-VF. Prior to accrual, appropriate control arm therapy was associated with non-significantly higher odds of clinical benefit using ESMO-MCBS with NCCN (OR 3.19, P=.23), but not ESMO guidelines (OR 1.29, P=.79). At the time of drug approvals associations were similar (OR 3.03, P=.06 and 1.17, P=.80). For ASCO-VF, appropriate control arm therapy was associated with non-significantly increased odds of clinical benefit (OR 5.52, P=.14) for both guidelines. These associations were not observed at the time of drug approval (OR 0.81, P=.69 for NCCN and 0.81, P=.72 for ESMO). Results were similar for RCTs performed exclusively in palliative intent.

Conclusions: ASCO-VF appears sensitive to change in appropriateness of control group therapy over time. ESMO-MCBS appears more consistent. Heterogeneity was observed based on scale, guideline and timepoint. Further exploration of impact of control group therapy on value frameworks is warranted.

1705P Therapeutic value of first vs supplemental indications of drugs in the US and Europe (2011-2020): Retrospective cohort study

K.N. Vokinger[1], C. Glaus[1], A. Kesselheim[2], M. Serra-Burriel[3], J. Ross[4], T. Hwang[5]

[1]Institute of Law, University of Zurich, Zurich, Switzerland; [2]PORTAL Program On Regulation, Therapeutics, And Law, Brigham and Women's Hospital - Pharmacoepidemiology and Pharmacoecomonics Division, Boston, MA, USA; [3]Epidemiology, Biostatistics and Prevention Institute (EBPI), University of Zurich (UZH), Zurich, Switzerland; [4]General Internal Medicine, Yale School of Medicine, New Haven, CT, USA; [5]Urologic Surgery, Brigham and Women's Hospital and Dana-Farber Cancer Institute, Boston, MA, USA

Background: After first approval of a new drug, it may subsequently be approved for additional indications. The number of drugs approved for such supplemental indications has increased, however, their added therapeutic benefit is unclear. We analyzed the therapeutic value of supplemental indications compared to first indications for drugs approved in the US and Europe (2011-2020).

Methods: We identified first and supplemental indications that were approved by the FDA and EMA. Therapeutic value ratings were obtained from France and Germany. We used descriptive statistics to analyze the unadjusted proportion of first and supplemental indications rated highly by the French or German health authorities. To obtain adjusted estimates of the probability for supplemental indications to be rated highly, we used Poisson regression analyses.

Results: 124 first and 335 supplemental indications approved by the FDA, and 88 first and 215 supplemental indications by the EMA were included, the largest subset for cancer disorders. Therapeutic ratings were available for 107 (86%) first and 179 (53%) supplemental indications in the US, and 87 (99%) first and 184 (86%) supplemental indications in Europe. Among FDA-approved indications with available ratings, 41% (44/107) had high therapeutic value ratings for first, compared with 34% (61/179) for supplemental indications. In Europe, 47% (41/87) of first and 36% (67/184) of supplemental indications had high therapeutic value ratings. Among FDA approvals, when the sample was restricted to the first three approved indications, second indication approvals were 36% less likely to have a high value rating (RR=0.64, 95%CI, 0.43-0.96) and third indication approvals were 45% less likely (RR=0.55, 95%CI, 0.29-1.01) when compared to the first indication approval. Similar findings were observed for Europe and when weighting by the inverse number of indications for each drug.

Conclusions: The proportion of supplemental indications rated as having high therapeutic value was substantially lower compared to first indications. When indications do not offer added therapeutic value over other available treatments, that information should be clearly communicated to patients and physicians.

1706P Time to full approval of novel anticancer medicines granted accelerated approval and implications for reform of the accelerated approval pathway

T. Hwang[1], C. Molto[2], M. Borrell Puy[3], A. Tibau[2]

[1]Urologic Surgery, Brigham and Women's Hospital and Dana-Farber Cancer Institute, Boston, MA, USA; [2]Dept. Medical Oncology, Hospital de la Santa Creu i Sant Pau, Barcelona, Spain; [3]Dept. Medical Oncology, Hospital Universitario Vall d'Hebron, Barcelona, Spain

Background: The Accelerated Approval (AA) pathway was established to speed development and approval of drugs for life-threatening conditions with limited treatment options. In December 2022, the US Congress enacted new policies to ensure that confirmatory studies for AA medicines are completed in a timely fashion. Here, we evaluate factors associated with conversion of AA to regular approval by the US FDA, including magnitude of clinical benefit as measured by European Society for Medical Oncology Magnitude of Clinical Benefit Scale (ESMO-MCBS).

Methods: We included all anticancer drugs that had received AA from the US FDA from 1992 to 2020, with follow up on approval status through January 2022. FDA drug labels and clinical trial reports were reviewed to apply ESMO-MCBS v1.1 grades to both initial and confirmatory studies. High clinical benefit was defined as a grade of A or B for trials of curative intent and 4 or 5 for those of palliative intent. Withdrawn AA indications, as determined by FDA, were considered as low benefit.

Results: From 1992 to 2020, the FDA granted AA to 46 anticancer solid drugs for 74 indications. The median time between AA and regular approval of oncology drugs was 3.7 years (range: 0.8-12.6 years). Of these 74 indications, 42 (57%) had clinical benefit confirmed in post-approval clinical trials and were converted to regular approval. Indications with high clinical benefit according to ESMO-MCBS were associated with shorter times to conversion to regular approval (median 2.5 vs 4.8 years; P=0.007). Similarly, indications with overall survival benefit were associated with shorter times to regular approval (median 2.6 vs 3.7 years; P=0.04).

Conclusions: Anticancer medicines with greater clinical benefit were associated with faster conversion to full FDA approval. New policy reforms to the AA pathway in the USA should prioritize further expediting market access of therapies with high clinical benefit as well as expedited completion of confirmatory studies.

1707P Cancer drug prices in the US: Efficacy, innovation, clinical trial evidence, and epidemiology

C.T. Michaeli[1], D.T. Michaeli[2]

[1]Abteilung für Personalisierte Onkologie mit Schwerpunkt Lungenkarzinom, UMM - Universitaetsklinikum Mannheim, Mannheim, Germany; [2]Third Department of Medicine, Medizinische Fakultät Mannheim der Universität Heidelberg, Mannheim, Germany

Background: Rising cancer drug prices pose a challenge for patients and healthcare systems in the US. Whilst prices are routinely assigned to a drug's original indication receiving US Food and Drug Administration (FDA) approval, the influence of supplemental indication approvals on prices remains uncertain. This study identifies and quantifies factors associated with cancer drug prices, distinctly analyzing original and supplemental indications.

Methods: Clinical trial evidence supporting each indication's FDA approval was collected from the Drugs@FDA database (2003-2022). Disease incidence and disability-adjusted life years (DALYs) were obtained from the Global Burden of Disease

study. Indication-specific monthly treatment costs were calculated for patients covered under Medicare Part B and D. The association between log-prices and collected variables was assessed in univariate regression analyses.

Results: We identified 145 drugs approved across 373 cancer indications. Drugs were priced at $24,444 per month on average (median $16,013; IQR 14,648 to 22,348). For original indications, prices were only weakly correlated to improvements in overall survival ($\hat{\beta}$=0.28, 95%CI 0.02 to 0.54, p=0.037) and progression-free survival ($\hat{\beta}$=0.16, 95%CI 0.07 to 0.25, p=0.001). Original indications' prices were: (1) negatively associated with disease incidence ($\hat{\beta}$=-0.21, 95%CI -0.28 to -0.13, p<0.001) and prevalence; (2) positively correlated for first-in-class drugs (26%, 95%CI -1 to 60, p=0.057), gene & cell therapies (176%, 95%CI 79 to 324, p<0.001), hematologic cancers (52%, 95%CI 28 to 106, p<0.001), and severe diseases with substantial unmet needs (6% per DALY, 95%CI 3 to 8, p<0.001); and (3) negatively correlated to indications with randomized controlled phase III trials. Prices were only poorly associated with supplemental indications' efficacy, clinical evidence, and epidemiology.

Conclusions: Cancer drug prices are set based on the original indication's characteristics, thereby omitting the value of supplemental indications. *Indication-specific* pricing, coverage, and reimbursement policies considering each indication's safety, efficacy, innovativeness, and unmet needs are necessary to align a drug's value and price.

1708P The registration pathways in China for globally developed novel anticancer drugs

D-W. Wu, H.Y. Huang, S. Jia, Y. Tang, N. Li

Clinical Trials Center, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China

Background: Since China implemented the regulations on adjusting the approval process of imported drugs in 2017, the integration of China into the global development of novel anticancer drugs has accelerated. The changing registration pathways for these products inspire us to present this data analysis.

Methods: Based on the review reports of approved global anticancer drugs from the database of the Center of Drug Evaluation of China, the cancer type, scope and timeline of pivotal supporting trials for each indication were extracted by the end of 2022. The distribution of registration pathways was explored using the number of indications as the key indicator.

Results: A total of 83 approved indications were retrieved. Participating in synchronous global studies (39, 47.0%) was the most common registration pathway, which was divided into dose expansion/phase II (4, 4.8%) and confirmatory studies (35, 42.2%). Launching China-dominant studies was another main pathway (35, 42.2%), including bridging (26, 31.3%) and confirmatory studies (10, 12.0%). Clinical studies in China were exempted in 15 (18.1%) indications. Multiple pathways were used to support 7 (8.4%) indications. The number of indications supported by China-dominant studies decreased from 19 (2017-2019) to 15 (2020-2022), while that of synchronous global studies increased from 15 (2017-2019) to 23 (2020-2022). Among the 9 indications for esophageal, gastric and hepatocellular cancer, eight (88.9%) were approved by global studies. The median days between China and the first global approval was 371 in indications supported by global studies, compared with 1326 in that supported by China-dominant studies.

Conclusions: Participating in synchronous global studies is the most common and time-saving registration pathway in China for globally developed novel anticancer drugs in recent years, especially for Chinese high-prevalent cancers. Efforts should be made to help China join more global early-phase studies in the future.

1709P Influence of censoring on conclusions of FDA-approved cancer drugs using the modified time to treatment failure

J. Ofer[1], S. Gilboa[2], Y. Pras[2], G. Markel[1], T. Meirson[1]

[1]Davidoff Cancer Center, Rabin Medical Center, Petah Tikva, Israel; [2]Sackler Faculty of Medicine, Tel Aviv University-Sackler Faculty of Medicine, Tel Aviv, Israel

Background: Time-to-treatment failure (TTF), in which both disease progression and treatment interruption are regarded as events, is a common measure in clinical trials that can be used as a sensitivity analysis for informative censoring. However, TTF is inappropriate for excessive censoring in the control group as it exaggerates the effect size instead of penalizing the bias. We propose a novel measure, the modified TTF (mTTF), that considers censoring as events only for excessive censoring in the intervention group. Here we examine whether excessive censoring in the intervention could affect the results of randomized controlled trials (RCTs) leading to FDA-approved drugs using mTFF.

Methods: We conducted a cross-sectional study collecting data from phase II and phase III RCTs of FDA drugs approved based on surrogate endpoints between 2010 and 2020. We reconstructed individual patient data from the published Kaplan-Meier curves of the primary surrogate endpoint. The reverse Kaplan-Meier method (i.e., events and censoring are flipped) was used to quantify excess censoring between study groups. The mTTF sensitivity analysis was conducted and statistical significance was calculated using the log-rank test.

Results: One hundred and one RCTs comprising 60,697 patients were included. The most common surrogate endpoint was progression-free survival with 86 (85.1%) of the studies. The median HR for surrogate endpoints was 0.54 (IQR [interquartile range], 0.41 to 0.63) and the median p-value was $3.0*10^{-5}$ (IQR, $2.8*10^{-8}$ to $1.5*10^{-3}$). Following adjustment for excess censoring using the mTTF the median HR was 0.68 (IQR, 0.52 to 0.84) and the median p-value was $4.2*10^{-3}$ (IQR, $2.5*10^{-6}$ to 0.12). Across all trials, 35 (34.6%) lost statistical significance using the mTTF.

Conclusions: We introduce mTFF as a practical clinical endpoint that is less conservative than the TTF and is sensitive to excessive censoring in the intervention group. Our findings suggest that some studies are associated with an excessive drop-out rate favouring the intervention group that may lead to a false conclusion regarding the efficacy of FDA-approved treatments. Meaningful shared decision-making requires careful consideration of informative censoring.

Background: Although eligibility criteria are an essential component of clinical trial design, overly restrictive criteria contribute to low accrual and poor generalizability of study results. To make trials more inclusive, there has been an increasing interest in broadening eligibility criteria, but how this affects patient safety remains unclear. In the Drug Rediscovery Protocol (DRUP, NCT02925234), protocol exceptions that were granted by the study team, taking into account the balance of potential benefits and risks, were analyzed. Here we describe the impact of these protocol waivers on patient safety and treatment efficacy.

Methods: DRUP is a Dutch multicentred, non-randomized, pan-cancer platform trial in which treatment-refractory patients are treated with targeted- and immunotherapies outside their registered indications, based on their tumor molecular profile. We collected data of all included patients for whom a waiver was granted and analyzed them in terms of treatment safety and efficacy. Also, safety and efficacy outcomes of these patients were compared to those of patients that did not need a waiver to participate.

Results: Between September 1, 2016, and September 1, 2021, 1019 patients were included in DRUP. In total, 88 protocol waivers were granted for 82 patients (8%). Most waivers were granted for general- or drug-related eligibility criteria (44%). For 32 of 82 patients that received a waiver (39%), 49 SAEs regardless of relationship to study treatment, were reported. For the included patients without a waiver (n=937), 666 SAEs were reported in 385 patients (41%, $p = 0.81$). The clinical benefit rate (CBR; either objective response or stable disease (SD) $\geq$ 16 weeks) of patients for whom a waiver was granted was 40% (14 patients (17%) with a partial response and 19 (23%) with SD $\geq$ 16 weeks), compared to a CBR of 33% in the non-waiver population ($p = 0.43$).

Conclusions: Safety and clinical benefit were preserved in patients for whom a waiver was granted in DRUP. Our data advocate omittance of 'old' unnecessarily strict safety criteria when setting up molecularly driven trials and support a more personalized approach in assessing eligibility criteria, especially in trials with therapeutic intent for patients without other treatment options.

Background: While the promise of personalised cancer medicine (PCM) is clear, implementation remains challenging. In the European Union (EU), healthcare systems fall under national responsibility and differ greatly in structure, financing and capacity. Furthermore, EU countries are predominantly small, limiting generated evidence from national trials. The family of DRUP-like clinical trials (DLCTs) addresses this challenge: as a bottom—up, clinician-initiated initiative, DLCTs share the pragmatic core clinical trial design of the original Drug Rediscovery Protocol (DRUP), anchored into national context and financed independently. The result is a distributed DLCT network that addresses local priorities while collaborating internationally for scale and impact.

Methods: In 2022, the DLCT community successfully applied for two projects funded by the EU that will expand the network by supporting investigators to establish national DLCTs in additional countries. At the same time, the projects will build shared cross-DLCT capacity in molecular diagnostics and education (PCM4EU) as well as cross-trial data analytics, initiate shared cohorts and provide Health Technology Assessments (HTA) (based on the EUnetHTA core model) and Health Economic Evaluations (PRIME-ROSE). To ensure successful implementation, the projects involve various national and European decision-makers as well as the cancer patient community.

Results: Our approach demonstrates the feasibility of a novel type of pragmatic clinical trial networks that rely on distributed rather than centralized leadership. This way ensures wide and equitable patient inclusion and building national capacity in PCM diagnostics and treatments. Further, the set-up of a shared core, but variable side modules, allows for parallel experimentation and fast implementation of successful findings by adding these to the common DRUP core model.

Conclusions: This Europe-wide PCM deployment will address key scientific and methodological questions to accelerate broad and equitable access to new and effective cancer treatments. The ongoing effort is leading to standardization and pragmatic consensus, thereby anticipating the benefits of the upcoming European Health Data Space.

1712P Implementation of a molecular pre-screening program (MPP) in a network of public cancer centres for phase I clinical trial (Ph1-CT) candidates: The PREICO program

J.J. Soto Castillo[1], L. Notario Rincon[2], D. Azuara[3], J.C. Ruffinelli[1], A. Stradella[1], M. Oliva Bernal[1], M. Calvo Campos[1], M. Jové[1], S. Llop Serna[1], R. Villanueva Vazquez[1], C. Cuadra Amor[1], M.A. Bergamino[2], E. Teixidor Vilà[3], S. Villatoro Gómez[3], M. González Acosta[3], C. Fina Planas[4], C. Hierro[2], M. Gil Martín[1], C. Lazaro[3], J. Martin-Liberal[1]

[1]Medical Oncology - Phase I Functional Unit, Catalan Institute of Oncology (ICO), Hospitalet De Llobregat, Spain; [2]Medical Oncology - Phase I Functional Unit, Catalan Institute of Oncology (ICO), Badalona, Spain; [3]Molecular Diagnostic Lab Core - Bellvitge Biomedical Research Institute (IDIBELL), Catalan Institute of Oncology (ICO) - Bellvitge University Hospital (HUB), Hospitalet De Llobregat, Spain; [4]Medical Oncology - Phase I Functional Unit, Catalan Institute of Oncology (ICO), Girona, Spain

Background: Next-generation sequencing (NGS) and molecular tumor boards (MTB) might optimize patient (pt) selection for Ph1-CT. Here we report the first-year results of the PREICO Program, a coordinated and histology-independent NGS MPP in a network of public cancer centres in Catalonia, Spain.

Methods: Multicentre retrospective study of adult pt with advanced solid tumors candidates for Ph1-CT but ineligible for standard practice NGS. Pt underwent a centralised in-house tumor NGS panel (Illumina TruSight Oncology 500) at 3 different Catalan Institute of Oncology (ICO) centres: Hospitalet, Badalona, Girona. Molecular results were weekly reviewed by an MTB and pt were offered treatment accordingly within Ph1-CT or Special Medication Situation (SMS) program if available. The aim of the study was to analyze clinical outcomes and MPP utility for access to molecularly targeted agents (MTA).

Results: From Feb2022 to Mar2023, 120 pt were included: NGS results were available in 112 (93.3%) pt, 5 (4.2%) pt had no quality sample and 3 (2.5%) pt died before the analysis. Median age was 62 y (34-78), 60 (53.5%) pt were female and 101 (90.2%) pt had ECOG $\leq$1. Most common tumor sites were central nervous system (14.3%), colorectal (CRC) (12.5%) and pancreatobiliary (9.8%). Sixty-four (57.1%) pt had received $\geq$2 prior lines and 57 (50.9%) pt had no alternative standard of care. On average, 13 MTA Ph1-CT were recruiting per month during study period. After NGS results, 73 (65.2%) pt were not eligible for any Ph1-CT, while 12 (10.7%) pt harbored alterations eligible for at least one MT Ph1-CT. Nine (8%) pt received MTA based on actionable alterations: 7 within Ph1-CT (3 RAS/RAFwt, 2 KRAS G12Cmut, 1 ARID1A-mut, 1 METmut) and 2 within SMS program (MSI-H glioblastoma, HER2-amplified CRC). ORR and median PFS/OS for these pt were 33.3% and 2.8 (.7-5.4)/5.1 (1.9-7.9) months, respectively. According to prior therapy ($\leq$2 vs $\geq$3 prior lines), 3 and 6 pt received MTA, respectively.

Conclusions: Our results suggest that implementation of a coordinated MPP within a public network of cancer centres helps to identify potentially actionable alterations and increases the chances of receiving personalised therapies in a wide range of cancer types.

1713P Non-inferiority oncology clinical trials in major journals: Purposes, methods and results

R.B. Barreto, M.H. Furlanetto Miranda, B.A. Uliana, L.H.D.A. Lazzari, D. Bodnar, C.M. Blatt, M.D.S. Cadore

Departamento de Oncologia, CEPON - Centro de Pesquisas Oncológicas, Florianopolis, Brazil

Background: Non-inferiority (N-I) trials in oncology aim to prove that an experimental intervention is not significantly worse than a reference treatment, while offering other advantages. Clear explanation of the trial design and chosen margins is crucial.

Methods: We searched in leading oncology and general medical journals (Annals of Oncology, Journal of Clinical Oncology, JAMA, JAMA Oncology, Lancet, Lancet Oncology and New England Journal of Medicine) for N-I randomized clinical trials on solid tumours. We included phase II/III trials published in the last five years (since April/2018) and analyzed the primary N-I endpoint, margin of N-I, reasons for the margin, results and funding.

Results: The search yielded 637 articles, 367 were excluded after title/abstract screening, 190 after full-text screening, resulting in 80 analyzed articles (44 on cancer drugs, 19 radiotherapy, 11 surgery, 5 diagnostics, 1 follow-up). N-I design reasons: less intense drug treatment (22), less intense or hypofractionated radiotherapy (n17), less aggressive or no surgery (16) and less toxic/more convenient drug schedules (16). The primary sites were breast cancer (28), head/neck and gastric cancers (9 each) and

colon (7). Main scenarios: neo/adjuvant protocols (32) curative (20) and first-line (17). Most common primary endpoints: recurrence/disease free survival (25), progression free survival (21) and overall survival (17). 25 received support from for-profit organizations, mainly drug trials from pharmaceutical industries (18/25). Most primary outcomes were within the non-inferiority margin (60), however 27 (33%) did not explicitly state the reasons for choosing such margin. Median N-I margin for time-to-event outcomes was 1.27 (95% CI 1.2−1.32; hazard ratio), while for binary outcomes, it was 8% (95% CI 5.4%−10%). No significant differences were observed between the results (positive or negative) or the chosen margin according to funding or type of trial (drug or not).

Conclusions: Most oncology N-I clinical trials reported in major medical journals are about less intense, less toxic or more convenient drug schedules and are positive. A considerable part is funded by pharmaceutical industries and another sizable part lacks reporting the reasons for the chosen margin.

1714P Geographical disparities in access to cancer clinical trials in Korea

S. Kang[1], M-H. Kim[2]

[1]Ilsan-gu Madu-dong, National Cancer Center Hospital, Goyang, Republic of Korea; [2]Gyencologic Oncology, Korea Cancer Center Hospital, Seoul, Republic of Korea

Background: Ensuring equal opportunity to participate in clinical trials is important. We analyzed the effectiveness of efforts to ensure geographically equal access to cancer clinical trials in Korea.

Methods: Clinical trials registered between 2012 and 2023 in Korea were captured from the Ministry of Food and Drug Safety database. To measure geographic disparity, we calculated the ratio of clinical trials conducted in local areas compared to those conducted in metropolitan areas and called it the trial geographical disparity index (TGDI). Regression analysis was used to analyze the annual trend of the TGDI.

Results: From 191 hospitals, 9424 cancer clinical trials were identified. The mean TGDI was 46%, indicating that cancer patients living in local areas can only access 46% of cancer clinical trials available to patients living in metropolitan areas. The disparities did not increase or decrease over 12 years. The situation varies among cancer sites, however. There was an improvement in the geographical disparity in lung cancer ($p = 0.019$), whereas a deterioration existed in pancreatic and prostate cancer ($p = 0.035$ and 0.016, respectively). Additionally, TGDI has worsened in clinical trials for domestically developed drugs (R-squared 0.58). In contrast, it has significantly improved for trials initiated by global pharmaceutical companies (R-squared 0.61), especially in lung and breast cancer ($p = 0.016$ and 0.005).

Conclusions: Although geographical disparities in access to cancer clinical trials seem to have been fixed in Korea, our data suggest that sponsor-initiated phase II/III trials conducted by global pharmaceutical companies may have a significant role in lowering the geographical barrier and ensuring equal access.

Pascale, Naples, Italy; [7]Oncology Department, University of Turin, Ordine Mauriziano Hospital, Turin, Italy; [8]Immuno-Oncology Dept., UNIL - Ludwig Institute for Cancer Research - Lausanne Branch, Epalinges, Switzerland; [9]Medical Oncology, Fondazione Policlinico Universitario Agostino Gemelli IRCCS, Rome, Italy; [10]Dipartimento di Oncologia Medica, IRCCS Ospedale San Raffaele, Milan, Italy; [11]Department of Oncology, University of Turin, Azienda Ospedaliera Universitaria San Luigi Gonzaga, Orbassano, Italy; [12]Oncology Department, University of Turin, Turin, Italy; [13]Department of Oncology, EOC - Ospedale Regionale Bellinzona e Valli - Istituto Oncologico della Svizzera Italiana (IOSI), Bellinzona, Switzerland

Background: Randomized controlled trials (RCTs) are usually considered the highest level of evidence for clinical practice. Patients assigned to control arm in RCTs should always receive the best available treatments to protect participants while also allowing for proper interpretation and applicability of study results. Here we analyzed RCTs published in oncology between 2017 and 2021, to describe the frequency of suboptimal control arms.

Methods: We identified phase III studies testing active treatments in patients with solid tumors among 11 major oncology journals. Each control arm was analyzed, and the standard of care was determined according to international guidelines and scientific evidence at accrual beginning and until accrual completion. We identified studies with suboptimal control arm from the beginning (type 1) and studies with an initially optimal control arm which became outdated during the accrual period (type 2).

Results: This analysis included 387 studies. 43 (11.1%) control arms were judged as suboptimal: 24 (6.2%) type 1 and 19 (4.9%) type 2. Suboptimality rates were higher in industry-sponsored compared to academic trials: 9.3% vs 1.9% for type 1 ($p=0.003$); 7.9% vs 0.6% for type 2 ($p= 0.001$). Suboptimality rates were higher in studies with positive results: 8.1% vs 4.0% for type 1 ($p=0.09$); 7.6% vs 1.7% for type 2 ($p=0.007$).

Conclusions: A non-negligible percentage of control arms, even in journals with high impact factor, was suboptimal according to our criteria. Many patients were treated with suboptimal control treatments in those trials, and the interpretation and applicability of study results can be challenging.

1716P Addressing clinical trial disparities in Spain: A digital solution

M. Hardy-Werbin[1], J.J. Garcia Mosquera[2], S. González Gallardo[3], D. Lepke[4], T. Espinosa[4], A.M.D. Degrave[3], M. Sánchez Calleja[3], M. Szarfer Barenblit[4], A. Llopart Babot[3], E. Arriola[5]

[1]Medical Department, Trialing Health, Barcelona, Barcelona, Spain; [2]Medical Oncology Department, Dr. Rosell Oncology Institute (IOR), Barcelona, Spain; [3]Medical Department, Trialing Health, Barcelona, Spain; [4]Data Analytics, Trialing Health, Barcelona, Spain; [5]Medical Oncology Dept., Hospital del Mar - Parc de Salut Mar, Barcelona, Spain

Background: In Spain, many eligible patients do not participate in clinical trials (CT) due to the lack of reliable information about trial availability. Trialing, created in 2021, is an artificial intelligence-based CT search engine that enables oncologists to directly refer their patients to available trial sites.

Methods: We analyzed aggregate data in Trialing, including information from public registries of CT (clinicaltrials.gov, reec.aemps.es), public data from the Spanish Ministry of Health, and data from the Trialing platform itself.

Results: Of the 561 Spanish oncology centers, 23% (131) offer CT. Of these, 69% centers offer <20 CT (small), 21% between 21 and 75 CT (medium), 8% between 76 and 150 CT (large), and 2% >150 CT (giant). Through Trialing: (i) all large and giant centers receive referral requests, 75% of medium centers and 27% of small centers; (ii) oncologists from 55% of small centers, 80% of medium centers, 83% of large centers and 60% of giant centers request referrals. We found that only two of the 17 administrative regions in Spain account for more than 50% of available CT, while most communities have no more than 10% of the CT available in Spain. The pathology for which there are most CT is non-small cell lung cancer, followed by breast cancer and colorectal cancer (28%, 16% and 12% of the total number of clinical trials,

respectively). More than 2,500 CT searches are performed each month on the Trialing platform, and the pathology for which most referrals are requested through Trialing is lung cancer, followed by breast and colorectal cancer.

Conclusions: Our findings show that the distribution of CT in Spain is highly concentrated, with only certain regions offering a significant number of trials. Trialing provides real-time information on CT availability, referral patterns, and potential solutions to increase patient access to CT and improve treatment equity. The acceptance of Trialing in the Spanish oncology community suggests that it can be replicated in other countries with similar challenges.

1717P Management of patients during a digital healthcare record system transition: A phase I unit experience

L. Del Rosario, B. Rao Baikady, S. Rodney, S. Gurung, S. Hammond, F. Cortes, S. MohamedKhan, C. Livings, T. Clark, R. Daly, G. Silva Fortes, K. Horvath, P. Lamb, A. Little, J.S. de Bono, U. Banerji, A.R. Minchom, J.S. Lopez, A. Sharp, A. Paschalis

Drug Development Unit, The Institute of Cancer Research and Royal Marsden Hospital, Sutton, UK

Background: Digitalisation of healthcare delivery enhances security, efficiency, and cost-effectiveness. The challenges of transitioning to a modern electronic healthcare system with multiple workflows remain poorly described, especially for early phase trial units. We present our recommendations for digital healthcare transition based on our experiences and outcomes. The Royal Marsden (RM) and Institute of Cancer Research (ICR) Drug Development Unit (DDU) is one of the largest early phase centres in Europe, enrolling ∼300 patients across >60 trials per year, with a dedicated ward, day unit and outpatient clinic.

Methods: In March 2023, RM transitioned to a new healthcare system. DDU adopted a patient centric approach, as per table, with emphasis on safe treatment delivery for patients within the dose-limiting toxicity (DLT) period.

Results: All planned trial activities were completed during weeks 1-4; though late IMP dosing up to 21:00 were experienced. Over these weeks, 36 patients were treated within the DLT period, and no safety issues raised. Adaptation pace among staff varied, with reports of fatigue from learning new workflows, improving from Week 4. From Week 5, the number of attendances returned to pre-transition levels.

Table: 1717P Planning aims

a) Virtual walk-through trial pathways from referral to discharge b) Patient visits planning and forecast for first 4 weeks. For Week 1, targeted reduction in planned patient attendance by 10% with no patients starting on trial and on-site attendance is prioritised for those within DLT period. c) Staff training < 8 weeks in advance and absences minimised during the transition period d) Managing expectations of patients, staff, and partners e) Daily team meetings to feedback and escalate issues

Conclusions: Major digital transformation projects can be undertaken safely within a phase I trial setting whilst maintaining service delivery, with investments in implementation beyond the technology itself. Staff digital literacy assessments, training, pathway walkthrough, interface familiarisation, managing staff morale are critical for managing such transitions. Extensive planning and focus on the end users are vital in ensuring both short-term delivery and long-term benefits of digital transformation.

1718P Impact of the economic status of the patient's country of residence on the outcome of oncology clinical trials

S. Nishiyama, M. Narukawa

Graduate School of Pharmaceutical Sciences, Kitasato University - Shirokane Campus, Minato-ku, Japan

Background: Prolongation of overall survival (OS) is commonly evaluated as a primary endpoint in confirmative oncology clinical trials; however, it is potentially affected by the healthcare environment, which often varies from country to country. We compared progression-free survival (PFS) and OS between the Organisation for Economic Co-operation and Development (OECD) and non-OECD countries. We also investigated the causes of the survival difference.

Methods: Individual patient data from industry-sponsored multi-regional phase III oncology trials were obtained from the Project Data Sphere. Cox regression analysis was conducted to estimate the hazard ratio (HR) for PFS and OS between the different subgroups such as race and country in each trial, and summary HR was estimated. Patients' demographic data such as performance status (PS) and ratio of the elderly were compared between the subgroups by calculating the odds ratio. The incidence of serious adverse events (SAEs) was calculated by the subgroups, and median survival time in patients with SAEs was estimated using the Kaplan-Meier method. The rate of post treatment in each subgroup was calculated.

Results: Eleven arms from 10 clinical trials were eligible for the analysis. No statistically significant difference was observed in PFS and OS between races. A prolongation of OS was observed in patients enrolled in the OECD, while no statistically significant difference was observed in PFS. Patients enrolled in the OECD were older and showed favorable PS. Although incidence of SAEs was higher in the OECD, the median PFS and OS in patients with SAEs were longer in the OECD. The rate of post treatment was higher in the OECD.

Conclusions: The economic status and healthcare environment of countries where patients were enrolled had an impact on the outcome of OS. Differences were observed in patients' demographic data such as PS and age as well as in the management of SAEs depending on the patients' country of residence. Clinical trial sponsors are recommended to consider carefully how to design and conduct oncology clinical trials including the selection of countries, provision of appropriate AE management guidelines and related training, and data management of subsequent treatments.

1719P Decentralized clinical trials: Is there a space in Italy?

C. Cagnazzo[1], F. Mannozzi[2], S. Stabile[3], C. Sgarbossa[4], D. De Cesare[4], A. Carrera[4], S. Testoni[5]

[1]Trial Department, AOU Città della Salute e della Scienza - Presidio Ospedaliero Infantile Regina Margherita, Turin, Italy; [2]Unità di Biostatistica e Sperimentazioni Cliniche, IRCCS Istituto Romagnolo per lo Studio dei Tumori "Dino Amadori" - IRST S.r.l., Meldola, Italy; [3]Trial center, ASST Grande Ospedale Metropolitano Niguarda, Milan, Italy; [4]Life Science Innovation, Politecnico di Milano, Milan, Italy; [5]UBSC Department, IRST - Istituto Scientifico Romagnolo per lo Studio e la Cura dei Tumori IRCCS S.r.l., Meldola, Italy

Background: The need to identify appropriate formulae to decentralize the clinical trials (DCTs) and enabling their implementation outside hospitals became a dramatic priority during COVID-19 pandemic. However, many obscure points remain concerning DCTs, starting from the regulatory definition.

Methods: In June 22, Life Science Innovation shared an anonymous online survey with the Italian Group of Data Manager to investigate how DCTs' elements were widespread in Italian clinical research centers. The final survey was structured with 14 questions and remained open for 15 days.

Results: The survey was completed by 35 study coordinators, mostly (54.3%, n=19) from public hospitals, with a median work experience of 8 years. Just over half (48.6%, n=17) declared they could count on Electronic Medical Records, while Electronic Case Report Forms were widely (74.2%, n=26) used. Only in 2 cases (5.7%) these tools are integrated. Over 60% of respondents (n=22) declared no experience in conducting DCTs but the vast majority (72.7%, n=16) expressed interest for the future. The lack of interest is mainly (50%) due to the need of specific skills. Analyzing the answers on the specific digital solutions (n=24, multiple answers option), the most used ones, regardless of the pandemic emergency, are devices (eg sensors) for remote parameter collection (60%), tools for collecting patients' data like apps for monitoring the therapeutic adherence (60%) and for delivering Electronic Patient Reported Outcomes (60%). More than half of the respondents (60%) declare a future interest in the remote informed consent process. On a 1-10 scale (strongly disagree - strongly agree), DCTs are considered not fully useful to increase patient adherence (mean score 6.6) or to reduce research time (5.8) and costs (5.9). Even lower (5.5) the suggestion that DCTs could increase patient involvement. There is a convergent thinking that DCTs can increase the amount of Real-world data collected (7.5) and that they require very specific skills (8) as well as address key data privacy and security (8) issues.

Conclusions: Despite the pandemic experience, the interest in a greater diffusion of studies with a partial or total digital component remains limited and crucial aspects should be addressed regarding Italy's ability to implement DCTs in short run.

1720P Experience in the provision of oncology services immediately after a major disaster

B.Y. Aktas[1], C. Karacin[2], M.A.N. Sendur[3], M. Dincer[3], N. Karadurmus[3]

[1]Department of Medical Oncology, Hacettepe University - Faculty of Medicine, Ankara, Turkey; [2]Medical Oncology, Dr. Abdurrahman Yurtaslan Ankara Oncology Training and Research Hospital, Ankara, Turkey; [3]Medical Oncology, Turkish Society of Medical Oncology (TTOD), Istanbul, Turkey

Background: On February 6, 2023, an earthquake occurred in Turkey that affected 11 provinces, many hospitals and millions of people. In Hatay, one of the provinces most affected by the earthquake, all 4 oncology centers in were partially or completely destroyed. So, a new unit was established in Dörtyol District Hospital, one of the few standing hospitals. On February 27, 2023, the first oncologist was assigned to the new oncology unit in Dörtyol Hospital. On 01 March 2023, the oncology outpatient clinic started to work and with the arrival of drugs, the first intravenous systemic anticancer treatment was administered on 03 March 2023. The aim of this abstract is to share our experience on how oncology services continue in the event of a major disaster.

Methods: In this abstract, the attempts made to provide oncology services after the earthquake in Hatay and the results of the first 100 patients followed in the new facility are summarized. The patients followed at the oncology outpatient clinic had their age, gender, primary diagnosis, and causes for admission retrospectively analysed.

Results: Between 01 and 10 March 2023, 100 patients applied to the oncology unit. A total of 62 of the patients were women. The median age of the group was 54. The most common diagnosis was breast cancer (N=46), followed by GIS (N=17) and lung (N=14) malignancies. The numbers of local, locoregional and metastatic diseases were 20, 33 and 47, respectively. Most common admission purpose was routine follow up (N=38), followed by scheduled systemic therapy (N=34). A total of 38 patients received systemic therapy while 9 had hormonotherapy and 3 had palliative treatment. Respectively, 5 patients were referred to different cities for PET scan, 3 patients for radiotherapy, and 7 patients due to the absence of drugs in the hospital.

Conclusions: Oncology is not a suitable field to delay or cancel active or palliative treatments. For this reason, it is inevitable to continue oncological services under all conditions, as has been seen in the recent COVID pandemic. On the other hand, due to the treatments applied, oncology centers have to meet some basic requirements in terms of infrastructure and work force. As in the Hatay experience, it is vital to take quick actions and ensure coordination after a disaster.

1721P Self-assessment tool and best-practice sharing to support hospitals in improving the quality of multi-disciplinary teams in lung cancer care

E. Nadal[1], M. Gallego Llorente[2], Y.P. Cui[2], L. Verbaas[3], A. Moucquot[4], H. Moses[5], T. Finazzi[6], T.O. Halvorsen[7], I. Opitz[8], D. Dellamonica[9], B. Amesz[2]

[1]Medical Oncology Department, ICO - Institut Català d'Oncologia l'Hospitalet (Hospital Duran i Reynals), L'Hospitalet De Llobregat, Barcelona, Spain; [2]Life Sciences, Vintura, Baarn, Netherlands; [3]Healthcare, Vintura, Baarn, Netherlands; [4]Global Digital Healthcare, AstraZeneca PLC, Cambridge, UK; [5]Medical Affairs, AstraZeneca PLC, Cambridge, UK; [6]Klinik für Strahlentherapie und Radioonkologie, Universitatsspital Basel, Basel, Switzerland; [7]Department of Clinical and Molecular Medicine, NTNU - Norwegian University of Science and Technology, Trondheim, Norway; [8]Department of Thoracic Surgery, University Hospital Zürich, Zurich, Switzerland; [9]Global Digital Healthcare, AstraZeneca AG, Zug, Switzerland

Background: Regular meetings of multi-disciplinary teams (MDTs) constitute a key moment in the care pathway in lung cancer, where physicians discuss patient cases and decide on treatment plans. MDTs increase the volume of patients treated, improve diagnosis, and positively impact survival. However, the way MDTs are organized is variable across hospitals and countries. These variations may lead to suboptimal outcomes, reflected by inconsistencies on the numbers of patients treated with curative intent and variable 5-year survival rates. The importance of MDTs keeps increasing, as the therapeutical landscape becomes more complex and evolves towards personalization.

Methods: Here we share a self-developed MDT maturity model and support hospitals to self-assess the performance of their MDTs in six dimensions: access to the MDT, processes, technology, quality, culture and capabilities. Once performance is self-assessed, gaps in hospitals' current MDT practices are identified. The maturity model is accompanied by 40+ best practices covering each of the six key dimensions. This way identified gaps are matched to actionable best practices which can be implemented by hospitals.

Results: We have supported various hospitals to identify gaps in their current MDTs by leveraging this MDT maturity model and have used our identified best practices to address those gaps. Hospitals across Europe and Canada have this way been able to improve their MDTs along the model's six identified dimensions in a measurable way. This process has been led by a network of 20 hospitals where the 40+ best practices were identified and is resulting in improved MDTs across other hospitals in Europe and Canada.

Conclusions: As MDTs become a standard part of patient care, inter-hospital collaboration should become standard to provide a platform for improvement. This work shows that self-assessment tools, best-practice sharing, support from leading hospitals, and change management can help hospitals improve the way their MDTs are organized and managed, which ultimately benefits patients' lives. Optimization of MDTs should be a key part of a continuous improvement cycle for every hospital, and this work ultimately facilitates this process.

1722P Factors contributing to differences in evidence compliance rate in cancer treatment among second opinion cases

T. Sanomachi, T. Shimoi, A. Kawachi, H.S. Okuma, M. Hoshino, M. Ito, A. Saito, S. Kita, A. Maejima, Y. Kojima, T. Nishikawa, E. Nakamura, K. Sudo, K. Yonemori

Department of Medical Oncology, NCCH - National Cancer Center Hospital, Chuo-ku, Japan

Background: Adherence to guidelines is linked to favorable prognosis in various cancer types. Nevertheless, the increasing complexity and sophistication of cancer drug therapy have posed challenges in identifying evidence-based treatment options. Thus, patients with cancer and local physicians are increasingly resorting to the cancer center's second opinion (SO) system for advice on treatment strategies. Integrating academic opinions from multiple physicians via SOs is expected to improve the evidence compliance rate (ECR). However, it remains unclear which cases would benefit from SOs to enhance the ECR. This study aimed to identify the factors contributing to the differences in ECR in patients with cancer.

Methods: A single-center retrospective study was conducted at the Department of Medical Oncology, National Cancer Center Hospital (Tokyo, Japan), analyzing electronic medical records of 305 patients with cancer who received SOs between January and June 2022. Two medical oncologists evaluated ECR according to the latest international standard guidelines for each cancer and classified them into two levels (Compliance: ECR is ≧50%, Non-compliance: ECR is <50%).

Results: Of 305 cases referred from 130 hospitals, 247 (81%) were female; the median age was 56 years (range: 15—85). Among them, 150 (49.2%)/152 (49.8%) were common/rare cancers, with 95 (31%) having gynecological cancers, 84 (28%) having breast cancers, and 66 (22%) having mesothelial and soft tissue cancers as major groups. After excluding cancer types for which no guidelines existed, 214 cases were eventually analyzed. Japan had a significantly higher ECR with designated core or designated hospitals for cancer genomic medicine (p=0.036). No significant relationship was found between ECR and hospital types, such as oncology, university, or urban hospitals. Moreover, no significant relationship was found between ECR and cancer types and who requested the SO.

Conclusions: This study highlights differences in ECR based on referral hospital type. The findings may aid in the appropriate allocation of medical resources between cancer centers and local hospitals as online medical care networks become more prevalent in the future.

1723P Improving access to molecular tumour boards for complex genomic profiles: A healthcare policy from the Netherlands

S. van Waalwijk van Doorn-Khosrovani[1], C. Reparon[2], S. Koole[3], A. Huisman[4], C. Louis[5], M. van Aart[6], W. Groenen[7], K. Grunberg[8], E. Schuuring[9], V.T.H.B.M. Smit[10], K. Monkhorst[11], H. Gelderblom[12], S. van der Flier[13]

[1]Medical Department, CZ Health Insurance Company, Tilburg, Netherlands; [2]Medical Department, Zilveren Kruis, Leiden, Netherlands; [3]Medical Department, ONVZ Health Insurance, Houte, Netherlands; [4]Department of Medicine's Policy, Zorgverzekeraars Nederland, Zeist, Netherlands; [5]Diagnostics Advocacy, NFK - Dutch Federation of Cancer Patient Organisations, Utrecht, Netherlands; [6]Healthcare Transformation, Strategy and Policy, CZ Health Insurance Company, Tilburg, Netherlands; [7]Specialized Care, CZ Health Insurance Company, Tilburg, Netherlands; [8]Department of Pathology, Radboud University Medical Center, Nijmegen, Netherlands; [9]Department of Pathology, UMCG - University Medical Center Groningen, Groningen, Netherlands; [10]Department of Pathology, LUMC-Leiden University Medical Center, Leiden, Netherlands; [11]Department of Pathology, NKI-AVL - Netherlands Cancer Institute/ Antoni van Leeuwenhoek Hospital, Amsterdam, Netherlands; [12]Department of Medical Oncology, LUMC - Leids Universitair Medisch Centrum, Leiden, Netherlands; [13]Medical Department, VGZ Health Insurance, Arnhem, Netherlands

Background: The role of Molecular Tumour Boards (MTBs) is becoming increasingly important in the interpretation of complex genomic profiles; for instance, in pinpointing the most optimal (targetable) therapy for rare or uncommon variants or in situations when more than one actionable aberration is detected, in rejecting suboptimal treatment strategies and in finding matched clinical trials based on genomic insights. In general, only academic hospitals and large cancer research institutes can facilitate an in-house MTB, as expertise in medical oncology, pathology, molecular biology, genetics and bioinformatics is required. As a result, patients treated in general hospitals may have limited or delayed access to expert interpretation of complex molecular diagnostics and relevant therapeutic guidance. One of the major barriers is the absence of reimbursement for such remote consultations.

Methods: In the Netherlands, health insurance companies have created a specific payment code for MTBs to be able to reimburse the consultations directly and monitor access.

Results: Empowering MTBs enhances their potential to gain and disseminate knowledge in the highly dynamic field of precision medicine due to an increased number of consultations. Moreover, it stimulates development and maintenance of guidelines and further standardisation of the recommendations for more frequent aberrations based on the evidence and the outcomes.

Conclusions: From a national health perspective, it is essential to ensure access to MTB's recommendations, thereby providing equal treatment opportunities (including enrolment in clinical trials) but also reducing the unjustified costs and clinical burden of ineffective treatment strategies. Eventually, a national data infrastructure and an umbrella organisation of the MTBs will facilitate better and equal options for patients and creates a true learning health system for precision oncology.

1724P Improving access to breast cancer diagnosis and treatment through navigation: Evaluation of a one-year pilot project in Botswana

A. Migeotte1, I. Soares de Pinho[2], N. Ngwako[3], T. Leselwa[4], T. Lethloma[5], T. Ralefala[6], I. Setlhako[6], N.C. Swart[7], J. Khutjwe[7], T. Gaolathe[8], R. Lebelonyane[9], K.M. Chalegwa[10], P. Moanakwena[11], R. Marlink[12], K. Sharma[13], P. Vuylsteke[14]

[1]Oncology Department, Centre Hospitalier Jolimont-Lobbes, Haine-Saint-Paul, Belgium; [2]Oncologia Médica, Faculdade de Medicina da Universidade de Lisboa, Lisbon, Portugal; [3]Faculty of Medicine, University of Botswana, Gaborone, Botswana; [4]Assistant Program Coordinator, Botswana Rutgers Partnership for Health, Gaborone, Botswana; [5]Princess Marina Hospital - Outpatient Clinic, Ministry of Health, Gaborone, Botswana; [6]Princess Marina Hospital - Oncology Department, Ministry of Health, Gaborone, Botswana; [7]School of Nursing, University of Botswana, Gaborone, Botswana; [8]Senior Advisor, Botswana Rutgers Partnership for Health, Gaborone, Botswana; [9]Program Manager, Botswana Rutgers Partnership for Health, New Brunswick, Botswana; [10]University of Botswana, Gaborone, Botswana; [11]Teaching and Learning Unit, University of Botswana, Gaborone, Botswana; [12]Global Health - Director, Rutgers Global Health Institute, New Brunswick, United States of America; [13]Rutgers Global Health Institute, Rutgers Global Health Institute, New Brunswick, United States of America; [14]Internal Medicine Dept., University of Botswana, Gaborone, Botswana

Background: In Botswana, 65% of breast cancers present at an advanced stage due to multifactorial delays. The WHO Global Breast Cancer Initiative recommends a maximum of 60 days of lead time in diagnostic workup and strongly advocates for the use of patient Navigation. A Patient Navigation Project was created to improve the timely diagnosis and treatment of breast cancer patients around Gaborone, the capital.

Methods: A 2-day theoretical and practical course was delivered in March 2022 to 15 clinical navigators (nurses from 6 district Hospitals and from the Referral Hospital) and 7 non-clinical navigators (advocacy groups). A navigation coordinator served as the point of contact, reported on program outcomes and provided smartphone airtime.

Different virtual communication groups were created with navigators to accelerate patient flow and facilitate problem solving.

Results: Between April 2022 and July 2023, 75 patients were included in the navigation program: 21 were in early stages (stages I and II) (28%) and 53 in advanced stages (stages 3 and 4) (71%). From those patients, 46% received neoadjuvant chemotherapy, 17% adjuvant chemotherapy and 25% palliative therapy. Navigation enabled faster access to CT-scan staging, unveiling more stage IV disease (23%), thus avoiding inappropriate curative treatments.

Table: 1724P Key navigation challenges and improvements

Key persistent challenges	Key improvements
Delays in biopsy (needle shortages)	Biopsies and staging done locally, avoiding referral delays for diagnostic workup
Delays in obtaining biopsy and IHC results (pathology backlogs, loss of sample, reagent shortages)	Fast referral pathway for patients in need of urgent consultation
Patient transport issues	Closer tracking of patients and tests results
Treatment delays: Stock-outs of drugs (hormone therapy, chemotherapy) and radiation therapy delays	Facilitated access to counselling and transport services
Time constraints: Limited time allocated to navigation	Increased multidisciplinary collaboration

Conclusions: The Botswana Breast Cancer Navigation project succeeded in implementing Cancer Navigation in accordance with international guidelines. It improved management of breast cancer patients through a smoother access to diagnosis and treatment, and it addressed barriers to care for specific situations. Many navigation sites referred patients with upfront biopsy diagnosis and minimal staging, and this reduced the time from first consultation in breast clinic to treatment (median delay 22 days). Dr Migeotte and Dr Soares de Pinho contributed equally to this work.

1725P Genetic counselling for cancer in EU member states: Review and foundation for consensus recommendations

J.M. McCrary[1], E. Van Valckenborgh[2], J. van Rooij[3], K. Van Steen[4], M. Vaht[5], A. Metspalu[5], A. Uitterlinden[3], M. Genuardi[6], H.A. Poirel[2], A.K. Bergmann[1]

[1]Institute of Human Genetics, Hannover Medical School, Hannover, Germany; [2]Cancer Centre, Department of Epidemiology and Public Health, Sciensano, Brussel, Belgium; [3]Department of Internal Medicine, Erasmus MC, Rotterdam, Netherlands; [4]Department of Human Genetics, KU Leuven, Leuven, Belgium; [5]Institute of Genomics, University of Tartu, Tartu, Estonia; [6]Istituto di Medicina Genomica, Università Cattolica del Sacro Cuore - Fondazione Policlinico Universitario Agostino Gemelli IRCCS, Rome, Italy

Background: Somatic and germline genetic alterations are significant drivers of cancer development, with new technologies to profile these alterations a major asset for personalized diagnosis, prognosis, and therapy, as well as prevention. Effective integration of genomic medicine into cancer care requires high-quality genetic counselling to facilitate informed decision-making by patients and their families. However, timely delivery of genetic counselling is complex, with rapidly increasing usage of clinical genetic services necessitating alternative delivery and reimbursement strategies. Further, common standards are needed to ensure consistent quality across the EU. This project aims to survey genetic counselling legislation and practice across EU Member States to provide a foundation for consensus genetic counselling recommendations.

Methods: National legislation databases of all 27 Member States were searched using terms relevant to genetic counselling, translated as appropriate. Interviews with relevant experts (*medical geneticists/counsellors, oncologists*) from each EU Member State are being conducted to validate legislation search results and provide detailed insights into genetic counselling practice in each country.

Results: Genetic counselling is included in legislation as a mandatory component of clinical genetic services in 22/27 (81%) Member States. Legislation in 9/27 (33%) Member States prescribes the personnel, content, and timing of genetic counselling; legislation in 13/27 (48%) Member States generally mandates the inclusion of genetic counselling. Interviews reveal that current clinical workflows consistently lead to suboptimal patient waiting times across Member States, driven by limited availability of genetics expertise. Specialized genetic counsellors and cooperative interdisciplinary approaches are sparsely utilized.

Conclusions: The inclusion of genetic counselling in legislation of most EU Member States underscores its importance. Forthcoming consensus recommendations will aim to propose strategies to ensure this importance is reflected by sustainable EU-wide integration of high-quality genetic counselling into cancer care.

1726P Optimizing oncology drug spending in a cancer centre in Ireland

R. Kieran[1], K. Coakley[2], T. Cronin[2], C.S. Weadick[1], B. Macanovic[1], R.J. Keogh[1], D. Lynch[3], M.A. Hennessy[4], K. Cooke[5], E. Mulroe[3], H.M. O'Sullivan[1], D.C. Collins[1], S. O'Reilly[1]

[1]Medical Oncology Dept., CUH - Cork University Hospital, Cork, Ireland; [2]Medicine, CUH - Cork University Hospital, Cork, Ireland; [3]Trials, Cancer Trials Ireland, Dublin, Ireland; [4]Cancer Research @UCC, University College Cork, Cork, Ireland; [5]Pharmacy, CUH - Cork University Hospital, Cork, Ireland

Background: The rising costs of innovative oncology agents is a global challenge. In Ireland, despite rising per capita spending, access to new agents is delayed compared to other European states. A strategy to optimise existing drug spending nationally in not in place. We aimed to review how existing prescribing in a cancer centre could be optimised to accelerate access to new agents.

Methods: We performed a retrospective review of expanded access programmes (EAPs, 2011-21, 3 hospitals) and biosimilar use (2020-22, 4 hospitals) within the southwest of Ireland, and a review of clinical trial availability nationally (2022). We surveyed oncology patients receiving treatment in 3 centres, and healthcare professionals (HPCs) nationally on their view on barriers to biosimilar integration (survey 1, 2020-22) and other potential mechanisms of cost optimisation (survey 2, 2023).

Results: Our review found 193 patients accessed EAPs over 10 years (33 agents, 50 indications & 189 programmes). No national database to ensure equity of access was in place; an increasing trend of availability over time was noted. Immune checkpoint inhibitors (55%); targeted therapies (35%) and antibody drug conjugates (6%) were available through EAPs, treating lung (28%), breast (17%) and ovarian (9%) cancers. Of the 287 patients accrued to clinical trials in 2022, 48% participated in immunotherapy trials. Biosimilar use of trastuzumab and rituximab ranged from 39-100%, and 0-89% respectively among 4 hospitals. Cost savings by using biosimilars compared with reference products ranged from 28% to 73%.

Table: 1726P Results of surveys on (1) barriers to biosimilar use & (2) other methods of optimisation

Survey 1	Patients (n=16)	Pharmacists (n=205) & students (n=33)	Doctors (n=11) & students (n=64)
Biosimilar awareness	37% (n=61) †	97% (n=231) †	45% (n=34) †
Agreeableness to biosimilar switching	85% (n=141)	N/A	N/A
Support pharmacist-led biosimilar substitution	N/A	37% (n=87) †	9% (n=7) †
Support consistent nomenclature of biosimilars	N/A	84% (n=200)	80% (n=60)
Survey 2	Patients (n=53)	HPCs (n=60)	
Support split fill dispensing initially	82% (n=42)	75% (n=45)	
Support split fill dispensing long term	60% (n=28)†	30% (n=18)†	
Support redispensing unused oral agents	29% (n=14)*	22% (n=13)*	

*$p<0.05$, † $p<0.01$

Conclusions: Multiple disparate mechanisms are in place to optimise drug costs. We found biosimilar use and split fill dispensing was acceptable to both patients and HCPs but the majority of HCPs do not approve of pill sharing. Additional optimisation could occur through prioritisation of biosimilar substitution and education of prescribers on their benefits, a national registry of EAPs, expansion of clinical trial portfolios, and modified drug dispensing.

1727P Barriers and facilitators of physician involvement in clinical oncology database management in Ukraine

I. Huivaniuk[1], D. Kizub[2], A. Dzhemiliev[3], N. Melnitchouk[4], A. Beznosenko[5], V.S. Kopetskyi[1]

[1]Hepatopancreatobiliary Department, National Cancer Institute of the Ministry of Health of Ukraine, Kiev, Ukraine; [2]Division of Cancer Medicine, MD Anderson Cancer Center, Houston, TX, USA; [3]Surgery, Brigham and Women's Hospital, Boston, MA, USA; [4]Surgery, Harvard Medical School, Boston, MA, USA; [5]Oncology Dept, National Cancer Institute of the Ministry of Health of Ukraine, Kiev, Ukraine

Background: Oncology databases/cancer registries can help facilitate quality cancer care and novel research. Their maintenance remains challenging in low and middle-income countries (LMICs). We explored barriers and facilitators of oncology database maintenance in Ukraine.

Methods: We conducted semi-structured interviews with a purposeful sample of oncology physicians at the Ukraine National Cancer Institute (NCI) to explore barriers and facilitators of oncology database data entry and use. Interviews were audio-recorded, transcribed, and analyzed via hybrid analysis.

Results: 13 physicians were interviewed, including 6 (46%) junior and 7 (54%) senior NCI faculty. All were aware of local or international oncology databases. 10 (77%) entered patient data into them, including 7 (54%) to international and 8 (62%) to local databases. 6 (69%) thought that most of their oncology colleagues in Ukraine are not aware of the existence or value of cancer databases. The following themes have been identified: perceived benefits of cancer databases included improving patient care, research, standardizing clinical practice, care monitoring, and quality improvement. Obstacles of data entry included: time required, low quality of medical documentation, complex online interface. Some thought that physicians should be responsible for data entry, while others thought it should be done by nonmedical providers. Facilitators of data entry included appointing a physician leader to oversee quality and engagement, direct direction from supervisor, use for research publication or as part of a project of personal interest, monetary compensation, collaborating with colleagues abroad, data entry training.

Conclusions: Factors affecting data entry into and use of local and international cancer databases by oncology physicians in Ukraine included perceived benefits for career and patient care, required time, requirements from leadership, database technology characteristics. Given limited resources for local and population-based cancer registry maintenance in Ukraine and other LMICs, novel low-cost strategies for this are urgently needed.

1728P Implementation of a comprehensive oncology unit: Needs detected in cancer survivors during follow-up

F.J. Jimenez-Ruiz, M.Y. Rodriguez Garces, J.L. Bayo Calero

Oncology, Hospital Juan Ramon Jimenez, Huelva, Spain

Background: The prevalence of oncology survivors is increasing exponentially. More than half of them experience difficulty in returning to their pre-disease socio-familial role. Comprehensive Oncology Units are infrequent in our environment. In our center we have implemented this novel Unit in order to improve the quality of life of our cancer survivors during follow-up.

Methods: Prospective quasi-experimental study. From March 2022 to March 2023. A total of 232 patients were included in the Comprehensive Oncology Unit of the Juan Ramón Jiménez Hospital in Huelva. The aim of our study is to describe the psycho-social, nutritional and physical needs of cancer survivors during follow-up and the impact of the intervention on their quality of life.

Results: The median age of the patients was 53 years (33 - 78). Ninety-six percent were women. Ninety percent had been diagnosed with breast cancer, followed by 6 % CRC, 2 % other digestive tumors and 2 % gynecological tumors. 67.1% required assessment for nutrition, 62.9% for rehabilitation, 59.28% for psycho-oncology and 4.8% for social intervention. Of the patients who were evaluated by psycho-oncology, 50% improved their fear of recurrence with only 3 sessions. Regarding nutrition assessment, the median BMI in the population with BMI $>$ 25kg/m2 was 30.7 Kg/m2 at baseline and 29.71 Kg/m2 (22.7 - 40) 6 months after nutrition intervention ($p<0.001$).

Conclusions: The results of our study reveal that there is a high demand of needs to be covered in cancer survivors beyond the purely clinical aspects that impact on their quality of life. Implementing a Comprehensive Oncology Unit could help to detect these needs and improve their healthy lifestyle habits as well as improve their quality of life.

Legal entity responsible for the study: Comprehensive Oncology Unit.

1729P Targeted interventions in registration and reporting of multidisciplinary team meetings (MDT) in oncology help to improve tumor board decisions

L. Galonska[1], S. Mertins[2], S. Kluge[1], M. Justen[1], W. Koester[1], M. Korell[2], M. Sabel[3], N. Gattermann[4]

[1]Internal Medicine / Oncology, Johanna Etienne Krankenhaus, Neuss, Germany; [2]Oncology, Johanna Etienne Krankenhaus, Neuss, Germany; [3]Neurosurgery, Uniklinik Duesseldorf, Duesseldorf, Germany; [4]Hemato-oncology, UKD - Universitätsklinikum Düsseldorf, Düsseldorf, Germany

Background: MDTs are a central institution of decision making in oncological centres. Good recommendations are comprehensible, follow guidelines, are consistent to following treatment and responsibility for this case must be made explicit. In order to constantly improve our performance, we examined key factors influencing MDT recommendations. After this analysis, structural intervention was performed to exclude the main factors influencing our performance negatively. Here we report the outcomes and results of this intervention.

Methods: After examining our MDT performance retrospectively in 488 tumor board decisions, we changed the registration process, including definition of required input for aspects of patient history and the protocol of our MDT for GI cancers. We also made sure that personal responsibility was provided for case presentation as well as for further action. Analysis of MDT recommendation after this intervention was performed using the same questionnaire as in the first analysis prospectively in 488 tumor board presentations and decisions of the complete following year. We correlated input-factors of MDT registration to output-factors defining reasonable MDT recommendations. Simple comparison was performed using chi-square testing between individual factors, group of factors and outcome variables.

Results: Following our intervention, we measured significant increase of all factors considered to be most influential for good recommendations (Table).

Table: 1729P

Input factor	Before (%)	After (%)	p-value
Presence of core team members	54,7	62,8	$<$ .0001
Clear indications of patient wishes	85,96	96,93	$<$ .0001
Complete case information	80,12	89,55	$<$ .0001
Information of thorough discussion	5,7	17,2	.095
Good recommendations	65,16	84,63	$<$ .0001

Conclusions: Oncological treatment is often based on MDT recommendations. Therefore, high quality of MDT must be ensured, transparency and understandability of the protocol must be clear and responsibility for further action needs to be addressed. We hereby demonstrate that changing infrastructural factors in registration and protocol of recommendations lead to improved tumor board decisions.

1730P Dealing with digital paralysis: Surviving a cyberattack in a cancer centre

R.J. Keogh[1], H.M. Harvey[2], C. Brady[1], E. Hassett[3], S.J. Costelloe[4], M.J. O'Sullivan[5], M. Twomey[6], M.J. O'Leary[7], M.R. Cahill[8], A. O'Riordan[9], C.M. Joyce[10], A. Flavin[11], R. Bambury[1], D. Murray[12], K. Bennett[13], M. Mullooly[14], S. O'Reilly[3]

[1]Medical Oncology Dept., CUH - Cork University Hospital, Cork, Cork, Ireland; [2]Oncology Department, St James's Hospital, Dublin, Ireland; [3]Cancer Trials Cork, CUH - Cork University Hospital, Cork, Ireland; [4]Department of Clinical Biochemistry, CUH - Cork University Hospital, Cork, Ireland; [5]Department of Surgery, CUH - Cork University Hospital, Cork, Ireland; [6]Radiology, CUH - Cork University Hospital, Cork, Ireland; [7]Palliative Care, Marymount University Hospital & Hospice, Cork, Ireland; [8]Haematology, CUH - Cork University Hospital, Cork, Ireland; [9]Unscheduled Care Directorate, CUH - Cork University Hospital, Cork, Ireland; [10]Biochemistry, CUH - Cork University Hospital, Cork, Ireland; [11]Department of Radiotherapy, Bons Secours Hospital Cork, Cork, Ireland; [12]National Cancer Registry Ireland, National Cancer Registry Ireland, Cork, Ireland; [13]Division of Population Health Sciences, RCSI - Royal College of Surgeons in Ireland, Dublin, Ireland; [14]School of Public Health, RCSI - Royal College of Surgeons in Ireland, Dublin, Ireland

Background: A constellation of a large attack surface of interconnected devices and cyberimmaturity renders healthcare ripe to cybercrime. These vulnerabilities and their consequences will be magnified by the exponential growth in artificial intelligence. We assess the impact and implications of a cyberattack on a national cancer centre.

Methods: On 14 May 2021 (day 0), the first national healthcare ransomware attack occurred within which all hospitals including Cork University Hospital (CUH) Cancer Centre was implicated. Contingency plans were only present in laboratory services who had previously experience information technology (IT) failures. Departmental handwritten logs of activity and responses for 700 days after the attack were reviewed.

Results: Following the attack, all IT systems were shut down. No hospital cyberattack emergency plan was in place. Within CUH, on day 0, all radiotherapy (RT) treatment stopped, outpatient activity fell by 50%, and elective surgery stopped. Haematology, biochemistry and radiology capacity fell by 90% (daily sample deficit (DSD) 2700 samples), 75% (DSD 2,250 samples), and 90% (100% mammography/PETscan) respectively. Histopathology reporting times doubled (7 to 15 days). or paused IT links. Outsourcing of radiology and radiotherapy (RT) commenced, alternative communication networks (e.g., proton mail; Siilo) were utilised and national conference calls for RT and clinical trials were established. 136 patients had interrupted RT: median gap day 6 days category 1, 10 days for remaining patients. By day 28, e-mail communication was restored. By day 210, reporting and data storage backlogs were cleared and over 2000 computers were checked/replaced by the Irish Army. Notification of patients and staff whose data was compromised is ongoing (day 720).

Conclusions: Cyberattacks have rapid, profound and protracted impacts. While laboratory and diagnostic deficits were readily quantified, the impact of disrupted/delayed care on patient outcomes is less readily quantifiable but likely to be much greater. As criminals and nation states weaponize the internet, cyberawareness and cyberattack plans need to be embedded in healthcare.

1731P Providing access to anticancer drugs within an armed conflict: The experience of Mission Kharkiv (MK) and Medecins Sans Frontieres (MSF) in Ukraine

S. Polozov[1], H. Marijon Jourdier[2], R. Shkavron-Filippenko[1], M. Boulay[3], A. Taconet[3], C. Bouillat[1], A. Brousse[2], D. Kocheharova[1], D. Vulpian[2], L. Averkova[1], Y. Bennadji[4], C. Ngo[2], C.M. Rieux[2]

[1]Oncology Program, Mission Kharkiv, Kharkiv, Ukraine; [2]Paris Onco, MSF, Paris, France; [3]Emergency Department, MSF, Paris, France; [4]Pharmacy, MSF, Paris, France

Background: Since the outbreak of the Russian Federation invasion, the border city of Kharkiv has come under bombardments leading to disruptions of the medical supply chain. Mission Kharkiv (MK) is a non-governmental organization (NGO) created in 2022 by Ukrainian volunteers to organize a consistent supply of chronic medications, especially anticancer drugs, in the area of Kharkiv.

Methods: A partnership was created between MK and MSF in June 2022. MSF decided a donation of 12 anticancer drugs, all registered on the World Health Organization list of essential medicines. The supplies were dispensed to MK by MSF teams in Ukraine. MK was in charge of the storage and the distribution of the drugs to patients meeting eligibility criteria determined with Ukrainian oncologists. Digital database was created to allow traceability of every medication from its donation to its dispensation.

Results: From October 2022 to April 2023, platinum compounds, taxanes, fluorouracil, trastuzumab, doxorubicin and hormone therapies were given to MK. Drugs were stocked in a warehouse unit equipped with cold chain facilities. 749 patients met eligibility criteria and were registered on the database to receive a whole course of treatment prescribed by Ukrainian oncologists. >99% of patients were ECOG 0-2. The largest types of cancers were digestive cancers (200 patients with gastrointestinal cancer, 21 with pancreatic cancer and 2 with biliary tract cancer representing 29.7% of all patients), breast cancers (206 women — 27.5%), gynaecologic cancers (151 women — 20.2%) followed by lung cancers (49 patients — 6.5%), hematologic malignancies (44 patients — 5.7%) and head and neck cancers (44 patients — 5.4%). Disease stage was reported in 723 patients. 32% were diagnosed with stage I-II, 33% with stage III and 35% with stage IV. Included patients received an average of 4.5 cycles of chemotherapy.

Conclusions: This model of humanitarian cancer medication release, coupled with cooperation between NGOs and a high level of digital traceability, has proven to be efficient. This approach could be scaled up in the future, enabling more cancer patients suffering from the consequences of war to benefit from this humanitarian program.

1732P War and the fragility of anticancer drug supply networks in Ukraine

O. Kostenchak-Svystak[1], D. Kizub[2], A. Dzhemiliev[3], I. Huivaniuk[4], V. Kopetskiy[5], L. Rieutova[6], H. Uzlova[6], I. Matiushenko[6], M. Kasianchyk[7], A. Beznosenko[8], N. Melnitchouk[3]

[1]Oncology Department, UzhNU - Uzhhorod National University, Uzhorod, Ukraine; [2]Division of Cancer Medicine, MD Anderson Cancer Center, Houston, TX, USA; [3]Division of General and GI Surgery, Department of Surgery, Brigham and Women's Hospital, Center for Surgery and Public Health, Harvard Medical School, Boston, MA, USA; [4]Hepatopancreatobiliary, National Cancer Institute of the Ministry of Health of Ukraine, Kiev, Ukraine; [5]Department of Hepato-Pancreato-Biliary Surgery, National Cancer Institute of the Ministry of Health of Ukraine, Kiev, Ukraine; [6]Oncology patient org., Inspiration family, Kyiv, Ukraine; [7]Internal medicine, Texas Tech University Health Sciences Center El Paso, El Paso, TX, USA; [8]Oncology Dept, National Cancer Institute of the Ministry of Health of Ukraine, Kiev, Ukraine; [9]Division of General and GI Surgery, Department of Surgery, Brigham and Women's Hospital, Center for Surgery and Public Health, Harvard Medical School, Boston, MA, USA

Background: Systemic therapy availability in Ukraine is fluid due to the war. This information is key to optimizing cancer care.

Methods: Online surveys assessing cancer treatment capacity were distributed to physicians in Ukraine through cancer-focused social media in April 2023. Results were analyzed with descriptive statistics and Fisher's exact test.

Results: 15 oncologists from 14 oncology centers and 12 hematologists from 9 hematology centers completed surveys, including 3 (25%) and 4 (27%), respectively, from the more war-affected Northern, Southern, and Eastern Ukraine. Of the 36 drugs used for solid tumors, limited availability (half of the time, rarely available, or unavailable) was reported for 11 (31%) drugs by 2-4 (14-29%) respondents: cisplatin, cyclophosphamide, doxorubicin, etoposide, fluorouracil, ifosfamide, methotrexate, vincristine, filgrastim, dexamethasone, tamoxifen. 7 (19%) had limited availability per 5-6 (36-42%): capecitabine, irinotecan, mesna, anastrozole, leuprolide, zoledronic acid, erlotinib. 12 (33%) drugs were limited per 7-8 (50-57%): abiraterone, bleomycin, carboplatin, docetaxel, gemcitabine, oxaliplatin, paclitaxel, vinblastine, vinorelbine, folinic acid, bicalutamide, trastuzumab. 7 (19%) were limited per 8-13 (57%-93%): nivolumab, diethylstilbestrol, bevacizumab, palbociclib, trastuzumab emtansine, sorafenib. Of 31 drugs used for hematologic malignancies, 4 (21%) were limited in availability per 2-4 respondents: vincristine, bortezomib, imatinib, azacitidine. 5 (16%) were limited per 5-6: bendamustine, filgrastim, doxorubicin, lenalidomide, hydroxycarbamide. 10 (32%) were reported to be limited by 7-8: rituximab, thalidomide, vinblastine, chlorambucil, bleomycin, methotrexate, daunorubicin, nilotinib. 10 (32%) were limited per 9-12: ibrutinib, mercaptopurine, eltrombopag, erythropoietin, thrombopoietin, ruxolitinib, venetoclax, brentuximab, gemtuzumab, obinutuzumab. Drug availability did not differ by country region ($p > 0.05$).

Conclusions: Shortages of essential anticancer drugs are a continued challenge in Ukraine during the war. Results are limited by small sample size and limited sampling from regions affected by active hostilities.

1733P Two wars at time: Fight against cancer during war time - experience of Ukraine

V. Patsko[1], K. Bolharina[2], A. Shudrak[3], A.V. Lukashenko[1], A. Beznosenko[4]

[1]Department of minimally invasive and endoscopic surgery, interventional radiology, National Cancer Institute of the Ministry of Health of Ukraine, Kyiv, Ukraine; [2]Pediatric oncology Department, National Cancer Institute of the Ministry of Health of Ukraine, Kyiv, Ukraine; [3]Department of proctology, National Cancer Institute of the Ministry of Health of Ukraine, Kyiv, Ukraine; [4]Oncology Dept, National Cancer Institute of the Ministry of Health of Ukraine, Kyiv, Ukraine

Background: On 24th of February 2022 reality in Ukraine changed. Ukraine became a victim of unfair attack of the neighbouring county. It influenced civilian population hugely, including the most vulnerable - children, elderly and patients. Since then, cancer patients became fighters of two fights - malignant disease and external aggressor. After more than a year of this reality Ukrainian oncologists would like to remind international society that the problem is not solved, and Ukrainians desperately need support.

Methods: It is generalized description of situation in the sphere of oncology in Ukraine since 24th of February 2022.

Results: According to Ukraine's Minister of Health, Victor Lyashko, during the first year of the war in Ukraine 1218 hospitals were damaged, 540 - partially destroyed and 173 destroyed completely. Among them - oncological hospitals. More than a million (∼1.2) Ukrainians currently stay on temporary occupied territories of the country and do not have access to qualified medical care. Around 7 million people had to move to safer areas of the country to stay safe and thousands of cancer patients had to move abroad for further treatment. It influenced the oncological landscape significantly. Oncological centers currently have to deal with 70% more patients than before the war. Moreover, the quantity of advanced stage disease has risen dramatically because a lot of people just couldn't get medical help in time. Therefore, it caused bigger pressure on the medical system, requiring even more resources when they are so limited. At the same time, all clinical trials were put on pause leaving patients with advanced and rare diseases with no options for further treatment. Luckily, international society is extremely friendly to Ukraine providing Ukrainians with shelters and supplies, both material and intellectual. It helped and is helping a lot. But unfortunately, war is not over, and help is still needed.

Conclusions: The aim of the work is to show how things were going during this year of war and how they are actually going now for word to realize that even during the hardest time there is a place for high quality medical care. That only became possible thanks to huge support of international society, but there is still a lot to do to rebuild and improve reality that was destroyed on 24th of February.

Background: Screening for lung cancer (LC) with Low-Dose Chest Computed Tomography (LDCT) reduces LC specific mortality. Interception-Lung is a French, soon to be nationally deployed, community-hospital and digital-physical personalized pilot LC screening and prevention program with an ultimate objective of reducing the incidence of advanced LC.

Methods: After physician (or self-) referral, men and women aged $\geq$ 50, active or former smokers (quit $\leq$ 10 years), are invited to attend a dedicated "One Stop Shop" that includes personalized prevention consultations, counselling on smoking cessation, lung cancer screening with LDCT on the basis of a shared medical decision in addition to educational group workshops on smoking, LC, nutrition and physical activity. As per the European position statement on LC screening recommendations, screening outcome is either positive, negative or indeterminate. A shared personalized prevention plan is handed to the participants and sent to their physicians. A follow-up visit is scheduled after each screening round.

Results: Between May 2021 and 2023, 276 persons (187 females, median age 57) attended the One Stop Shop. Fifty-four percent had post high school training or college education, 37% had a previous history of another cancer (mainly breast). Two hundred and two (73%) were active smokers, 15% had a regular cannabis consumption and 16% reported any use of vape. Median 6-year lung cancer risk as per the PLCOm2012noRace prediction model was 1.4% (0.7-2.9). Results of the first screening round were negative, indeterminate and positive in 65%, 31% and 4% of the participants, respectively. Five participants had surgery; 3 had lung cancer (stage 1 adenocarcinoma) and 2 a benign histology. The proportion of indeterminate screenings decreased from 31% to 8% at the second round. Out of 56 initially active smokers with already available extended follow-up data, 12 (21%) were abstinent at one year from the One Stop Shop.

Conclusions: A combined intervention mixing LC screening and prevention is feasible and could increase the benefit of LDCT screening and long-term smoking cessation rates. Reducing false-positives and improving risk-based identification and referral for screening is a major challenge.

1735P Impact of revised US Preventive Services Task Force (USPSTF) 2021 lung cancer screening guideline on long-term cancer survivors in the United States

Q. Wang[1], C. Wen[2], M.L. Hsu[1], C. Jiang[3], L. Deng[3], H. Xie[4], Y. Li[5], Y. Zhang[6], A. Dowlati[1], D. Bruno[1], L. Chiec[1], G. Dutcher[1], C.Y. Kong[7]

[1]Department of Hematology and Oncology, University Hospitals Seidman Cancer Center and Case Western Reserve University, Cleveland, OH, USA; [2]Quality Operations, Icahn School of Medicine at Mount Sinai, New York, NY, USA; [3]Department of Medicine, Roswell Park Comprehensive Cancer Center, Buffalo, NY, USA; [4]School of Public Health, University of Wisconsin-Milwaukee Joseph J Zilber School of Public Health, Milwaukee, WI, USA; [5]School of Population and Public Health, UBC - The University of British Columbia, Vancouver, BC, Canada; [6]Department of Surgery, Ascension Providence Hospital, Southfield, MI, USA; [7]Division of General Internal Medicine, Icahn School of Medicine at Mount Sinai, New York, NY, USA

Background: Among long-term cancer survivors (i.e., survived $>$ 5 years since most recent cancer diagnosis) with a non-lung primary cancer, second primary lung cancer (SPLC) has the highest incidence (19%) and mortality (32%) rate among all secondary primary cancers. There are currently no separate screening guidelines for SPLC, though most providers have adopted the general USPSTF recommendation for lung cancer screening (LCS) in cancer survivors. We aimed to assess the differences in LCS eligibility rates among long-term cancer survivors under the USPSTF 2013 vs revised 2021 guidelines.

Methods: Smokers aged 50-79 years were selected from the 2017-2021 US Behavioral Risk Factor Surveillance System data. We assessed the eligibility of LCS using USPSTF 2013 criteria: current or former smokers (quit $\leq$ 15 years), 55-80 years of age and $\geq$ 30 pack-year smoking history, and the revised 2021 criteria (expanding age to 50-80 and pack-year to 20) in long-term cancer survivors. Weighted chi-square tests were used with SAS (9.4).

Results: A weighted total of 17,544,768 smokers were selected (2.7% were cancer survivors). The LCS eligibility rate of long-term cancer survivors using the 2013 criteria was similar to the non-cancer survivors (21.1% vs 22.4%; p=0.62) but lower when using the 2021 criteria (31.5% vs 38.0%; p=0.03). The 2021 criteria increased eligibility for long-term cancer survivors across all groups (Table). However, the degree of increase in eligibility rate in cancer survivors was lower than in non-cancer survivors.

Table: 1735P

Weighted eligibility rate % (95%CI)	Long-term cancer survivors (CS)		Δ % in CS	Δ % in non-CS	p-value*
	2013 USPSTF	2021 USPSTF			
Overall	21.1 (16.0-26.2)	31.5 (26.0-37.1)	10.4	15.6	<0.01
Gender					
Women	20.5 (13.9-27.1)	34.3 (27.3-41.5)	13.8	15.8	0.43
Men	21.6 (14.0-29.2)	29.1 (20.9-37.4)	7.5	15.4	<0.001
Race					
Non-Hispanic White	23.2 (17.4-29.0)	34.0 (27.8-40.1)	10.8	16.1	<0.01
Non-Hispanic Black	9.9 (0.2-19.6)	16.6 (4.3-29.9)	6.7	14.2	0.08
Other races	9.0 (0.0-19.0)	21.5 (2.4-40.5)	12.5	13.5	0.90

*P-value compares non-cancer survivors vs cancer survivors in the change of eligibility rate from 2013 to 2021 USPSTF criteria.

Conclusions: The increase in eligibility from the revised 2021 USPSTF appears to be less in long-term cancer survivors than in non-cancer survivors. Cancer survivors are facing a significant burden from SPLC due to their prior diagnostic tests and treatments (e.g., chest irradiation), genetic susceptibility, and shared risk factors. Tailored LCS eligibility criteria are urgently needed in the growing cancer survivor population.

1736P Young adult lung cancer demands more attention in a low-resource area: Bangladesh perspective

M.R. Islam[1], S. Siddiqua[2], M.R. ISLAM[3], B. Saha[3], M. Rahman[1], S.B. Al Ayub[1], A.A.M. Khan[4], A.T.M.K. Hasan[1], A. Hossain[1], M.J. Alam[1], N. Khatun[1], M.N. Karim[5]

[1]Medical Oncology, NICRH - National Institute of Cancer Research & Hospital, Dhaka, Bangladesh; [2]Medicine, Unity Through Population Service, Dhaka, Bangladesh; [3]Radiotherapy, Mymensingh Medical College, Mymensingh, Bangladesh; [4]Medical Oncology, Shaheed Suhrawardy Medical College & Hospital, Dhaka, Bangladesh; [5]School of Public Health and Preventive Medicine, Monash University Caulfield Campus, Melbourne, VIC, Australia

Background: Young adult lung cancer's socioeconomic and clinical implications make it a unique disease. However, in Bangladesh, the status and features of early-onset lung cancer are not well understood. This study aimed to investigate the socio-demographic status and clinical characteristics of lung cancer in young adults in Bangladesh.

Methods: A retrospective review of patients with lung cancer was performed in our institute from January 2018 and December 2022. Young adults were defined as individuals between 18 and 45 years old. Demographic, clinicopathological and prognostic data were systematically analysed.

Results: Of the 6310 patients, 819 (12.98%) were young adults, and 780 were included in this study. The average age of young adult lung cancer patients was 38.92 years, and the average BMI was 20.46. Of all adult lung cancer patients, 29.49% were female, 58.97% were illiterate, and 87.56% had poor or below-average economic status. Among young adults, 23.08% did not use tobacco, while 41.41% had more than one tobacco-related habit. 33.52% of young patients with right-sided dominant lung cancer had a previous respiratory disease. At the time of presentation, 43.85% of patients had a score of $\geq$2 on the ECOG scale, and 33.52% had comorbidities, with hypertension being the most frequent (37.36%) and DM (33%) being the second most common. Adenocarcinoma was the most prevalent subtype (58.97%), followed by squamous (24.74%), small cell varieties with undifferentiated (14.74%), and others like sarcoma and mesothelioma. Stage 4 was diagnosed in 28.46% of patients, and the most frequent metastatic site was the lung (14.42%), followed by the pleura (12.5%) and the liver (11.06%). Young lung cancer patients in Bangladesh significantly differed from older adults regarding higher BMI, lower education, more female patients, fewer tobacco users, adenocarcinoma, and different metastatic sites (p 0.05).

Conclusions: The high prevalence of young adult lung cancer in Bangladesh necessitates specialized attention to this vulnerable group during treatment. These patients face unique challenges, making the management of their cancer complex and resulting in poor outcomes. A personalized and comprehensive approach is essential to manage young lung cancer effectively.

1737P Use of the predictive risk model LungFlagTM for lung cancer screening in screening in a Spanish reference center: A cost-effectiveness analysis

M.E. Olmedo Garcia[1], L. Gorospe[2], L.M. Seijo Maceiras[3], V. Pajares[4], M. Marzo Castillejo[5], J.B. Soriano[6], J.C. Trujillo[7], N. Arrabal[8], A. Flores[9], F. Garcia Verdes-Montenegro[9], M. Crespo[10], D. Carcedo[10], C. Heuser[8], N. Olghi[11], E.N. Choman[12], O. Higuera Gomez[13]

[1]Oncology Dept., Hospital Universitario Ramon y Cajal, Madrid, Spain; [2]Radiology Deparment, Hospital Universitario Ramon y Cajal, Madrid, Spain; [3]Pneumology Deparment, Clinica Universidad de Navarra, Pamplona, Spain; [4]Pneumology Deparment, Hospital de la Santa Creu i Sant Pau, Barcelona, Spain; [5]Primary Care Department, Grupo de Investigación del Cáncer en Atención Primaria, Barcelona, Spain; [6]Pneumology Deparment, Hospital Universitario de la Princesa, Madrid, Spain; [7]Thoracic surgery Department, Hospital de la Santa Creu i Sant Pau, Barcelona, Spain; [8]Access Roche Farma Spain, Roche Farma Spain, Madrid, Spain; [9]Medical Affairs, Roche Farma Spain, Madrid, Spain; [10]Hygeia Consulting, S.L., Madrid, Spain; [11]Commercial Deparment, Roche Farma S.A., Madrid, Spain; [12]RAQACA, Medial EarlySign, Hod Hasharon, Israel; [13]Dept. Medical Oncology, Hospital Universitario La Paz, Madrid, Spain

Background: Lung cancer screening programs using low dose computed tomography (LDCT) reduce mortality by early detection. LungFlag is an artificial intelligence-based predictive model of non-small cell lung cancer (NSCLC) risk, evaluating routine clinical and laboratory data to improve selection of individuals at-risk for enrollment in screening programs. The aim of this analysis was to assess the cost-effectiveness of LungFlag in the area of a Spanish reference center.

Methods: A combination of a decision tree and a Markov model was adapted to the Spanish setting. A multidisciplinary group of experts validated all the parameters and assumptions used in the model. Demographic characteristics were in line with those reported by Gould et al. (2021) . We defined 2 hypothetical cohorts, a broader cohort of 3000 ever-smokers aged 55-80 years, and another cohort of 1000 individuals meeting 2013 USPSTF criteria. A lifetime horizon was used, and only direct medical costs were considered. Sensitivity and specificity values were obtained from Gould et al. (2021) , and unit costs were obtained from local databases (€ 2023). Results were expressed in life-years (LYs), quality-adjusted life-years (QALYs), and incremental cost-effectiveness ratio (ICER). Sensitivity analyses were performed to assess the consistency of the model results.

Results: LungFlag provides a higher number of LYs and QALYs with a lower cost (dominant) compared to non-screening, as shown in the table. Sensitivity analyses confirmed the robustness of base case results.

Table: 1737P Results for the hypothetical cohorts

	LungFlag		Non-screening		LungFlag vs non- screening	
	EvSm (n=3.000)	USPSTF (n=1.000)	EvSm (n=3.000)	USPSTF (n=1.000)	EvSm (n=3.000)	USPSTF (n=1.000)
LYs	67.402	62.321	66.702	61.552	+700	+769
QALYs	59.244	53.753	58.875	53.316	+369	+437
Total cost	5.752.233€	7.584.866€	9.291.237€	12.154.655€	-3.539.015€	-4.569.799€
ICER (€ / QALY gained)					dominant	dominant

Conclusions: The implementation of LungFlag as a risk model for NSCLC screening in a Spanish reference center would be cost-effective compared to no screening for the 2 hypothetical cohorts analyzed, providing savings and a higher clinical benefit.

1738P Impact of digital platforms on exposure to tobacco and new smoking devices: A survey approach

D. de Haro, B. Arranz Álvarez, M. Lopez, K. Ramírez Cervantes, B. Fernández Sánchez, M.L. Amador

Medical Department, Headquarters Spanish Association Against Cancer (AECC), Madrid, Spain

Background: Tobacco remains the leading preventable risk factor for cancer in the world. Although the prevalence of tobacco use has a decreasing trend in most European countries, the availability of new smoking devices is causing an increase in smokers, especially among the younger population. Several studies have confirmed the relationship between this increase and indirect or covert advertising, carried out on social media and VOD platforms, through product placement, etc. This study aims to measure the impact of tobacco and new smoking devices in these digital spaces on the young Spanish population; and how this impact is related to increased consumption.

Methods: A survey has been conducted on the young Spanish population (aged between 16 to 21 years old) using a representative online panel of this population. The final sample obtained was 1730 interviews, and the data collection was conducted in December 2022. A questionnaire with an average duration of 10 minutes was administered, in which questions related to tobacco and new smoking devices use, and the recall of having seen content related to traditional tobacco and new smoking devices were collected. Descriptive and logistic regression analyses have been performed, taking the habitual consumption (last month) of tobacco and new smoking device as dependent variables.

Results: 82.5% of young people remember having had some impact related to traditional tobacco, and 83% with new smoking forms. Among young people who have had this impact, there are twice as many smokers (53.1%) as among those who have not (24.5%). Having seen someone smoking cigarettes on these platforms (AOR 1.56), cigarette product placement (AOR 1.71), or recalling e-cigarette brands (AOR 1.58) are the variables that most increase the risk of regularly consuming traditional cigarettes. The same happens in the risk of habitual consumption of new devices, with the recall of having seen specific brands or logos taking special relevance (AOR 2.47).

Conclusions: There is a correlation between the recall of these types of consumption and the regular consumption of tobacco or new forms of smoking. It is necessary to continue researching this avenue of normalization of consumption and to ensure the protection of young people from the promotion of new devices.

1739P Lung cancer mortality patterns of tobacco users in the United States: A 21-year analysis (1999-2020)

S. Bugazia[1], M. Boshnaf[2]

[1]Department of Internal Medicine, Henry Ford Hospital - Henry Ford Health System, Detroit, MI, USA; [2]Department of Internal Medicine, Baptist Health Medical Center-Little Rock, Little Rock, AR, USA

Background: According to the American Cancer Society, lung cancer is the leading cause of cancer-related deaths globally, and tobacco use is the 1ry cause of the disease. The association between tobacco use and lung cancer is well recognized, with smoking cigarettes accounting for approximately 85% of all lung cancer cases. Despite significant public health efforts to reduce tobacco use, it remains a prevalent issue, with an estimated 14% of the U.S. adult population being current smokers. Therefore, there is a continued need to investigate the relationship between tobacco use and lung cancer to better establish public health interventions and policies that can reduce the burden of this deadly disease.

Methods: Using the CDC multiple causes of death database (ICD-10 revision codes), we identified all patients with history of tobacco use who died of lung cancer (C34.x registered as the underlying cause of death) in Caucasian, African American, Asian, American Indian races, between 1999 and 2020 in the United States. Age-adjusted mortality rates were calculated per 1,000,000 persons (PMP), standardized to the U.S. census data from 1999, and stratified by gender.

Results: Between 1999 and 2020, 1,084,140 deaths were due to lung cancer in persons with history of tobacco use (age-adjusted mortality= 144.6 PMP). We identified a total of 970,370 Caucasian, 96,001 African American, 11,279 Asian, and 6,490 American Indian deaths in each population (total age-adjusted mortality was 151.5 PMP, 129.5 PMP, 38.3 PMP, and 117.7, respectively). Over 21 years, age-adjusted mortality increased by 782% in Caucasians (19.5 PMP in 1999 to 152.4 PMP in 2020), 575% in African Americans (21.2 PMP in 1999 to 121.9 PMP in 2020), 724% in Asians (5 PMP in 1999 to 36.2 PMP in 2020), and 351% in American Indians (27.2 PMP in 1999 to 95.5 PMP in 2020).

Conclusions: The study's results show a significant and consistent rise in the mortality rates of tobacco-related lung cancer among all ethnicities, ranging from 351% in American Indians to 782% in Caucasians. These findings emphasize the urgent need for effective public health interventions and policies that can address the destructive impact of tobacco use on lung cancer mortality across all racial groups in the U.S.

1740P Geolocation of respiratory tract cancer and its relationship with chronic exposure to PM2.5 pollutants

M. González-Escamilla[1], F. Alcorta-Nuñez[1], L.E. Reyes-Arreguín[2], D.C. Pérez-Ibave[1], C.H. Burciaga Flores[1], M. Hurtado-Díaz[2], H. Riojas-Rodríguez[2], J.L. Texcalac Sangrador[2], R. Piñeiro-Retif[1], A. Alcorta-Garza[1], J.F. Gonzalez[1], O. Vidal-Gutierrez[3], M.D.L. Garza Rodriguez[4]

[1]Oncology Service, CUCC - Centro Universitario Contra el Cáncer - Universidad Autónoma de Nuevo León (UANL), Monterrey, Mexico; [2]Epidemiology, Instituto Nacional de Salud Pública, Cuernavaca, Mexico; [3]Departamento de Oncologia, Hospital Universitario Dr José Eleuterio Gonzalez, Monterrey, Mexico; [4]Oncology, UANL - University Autonomous of Nuevo Leon, Monterrey, Mexico

Background: About 55% of the population worldwide lives in urban areas, and agreeing to WHO (World Health Organization), 91% of people in cities do not breathe safe air. There is evidence of a positive correlation between PM2.5 and lung cancer mortality. The Metropolitan Area of Monterrey, México, is the country's third most significant and most polluted, with an annual average of 23 $\mu g/m^3$ PM2.5, equivalent to 2.3 times the value established by the WHO. Objective. This study aimed to identify if spatial exposure patterns to PM2.5 correlate to respiratory tract cancer incidence.

Methods: Daily concentrations of PM2.5 were estimated considering the PM10/PM2.5 ratio in local stations that measured both fractions. Subsequently, the available fraction per station was calculated, considering the fractions of all available station data. Finally, the general fraction of the entire study period was calculated. The morbidity data for this study came from an individual-level database that contained the geographical coordinates of the residences of the airway cancer cases (bronchi, lung, larynx, and paranasal sinuses).

Results: The average concentration of PM2.5 was 32.4 $\mu g/m^3$, 3.24 times the limit established by the WHO. We identified that the increase in PM levels was associated with the number of cancer cases. The mean age of the cases was 70 years. There were 76.77% ($n = 476$) patients with a lung cancer diagnosis, followed by laryngeal cancer at 21.77% ($n = 135$). Interestingly, we detect that 44.35% ($n = 275$) has never smoked. On the other hand, there were 44.67% ($n=277$) heavy smokers in the cancer cases.

Conclusions: Implementing preventive measures to reduce emissions and exposure to PM2.5 and other air pollutants in polluted cities is necessary. High concentrations of PM2.5 are related to cancer cases, and it is essential to implement preventive cancer detection measures in polluted areas, not only in smokers' cases. In addition, spatial analyses are valuable to describe, quantify and explain the geographical variations of diseases associated with particulate matter exposure.

1741P Are physicians aware of lung cancer screening benefits and the importance of implementing this? Data from two public hospitals in Buenos Aires province, Argentina

V. Vidal[1], F. Durante[1], A. González Saénz[1], J. Hernández[1], E. Carinci[2], L.V. Fornero[1], A. Daza[1], M. Lavezzaro[1], M.D. Aguiar[1]

[1]Oncología, HIGA San Roque, Manuel B. Gonnet, Argentina; [2]Oncología, Hospital San Juan De Dios La Plata, La Plata, Argentina

Background: Lung cancer is the third most common cancer in Argentina in both sexes and the leading cause of cancer death, being smoking the most significant risk factor. Despite the effectiveness of a low dose computed tomography (LDCT) as a screening method, more than 70% of cases are still diagnosed at advanced stages, limiting patients' survival chances.

Methods: Observational, descriptive, and cross-sectional study. An anonymous online survey with closed-ended questions was conducted among physicians from San Roque and San Juan de Dios hospital, to assess their knowledge of lung cancer screening, its implementation, and possible barriers related to accessibility.

Results: The final sample of the study consisted of 102 physicians, with a median age of 33 years-old and a median of 6 years of practice. 70% of physicians knew about lung cancer screening methods, but 40% considered the risk-benefit balance to be

negative. Only 8 physicians knew the criteria for selecting the high-risk population, and 78 were not familiar with the NLST and NELSON trials. Although 61.8% knew about LDCT, 82.4% did not use it as a screening test, and 69.6% were unaware of its availability at their hospital. 31.4% were not confident in using LDCT as a screening tool, and 12.7% would not use it at all.

Conclusions: The results indicate that most physicians surveyed are not familiar with the criteria for selecting the high-risk population and do not routinely recommend lung cancer screening. Additionally, there was a significant lack of knowledge about the NLST and NELSON trials and the availability of LDCT at their hospitals. Urgent training, updates on the application of a lung cancer screening program and the dissemination of current scientific information on the topic are of paramount importance for local healthcare professionals in order to Improve patient outcomes.

1742P Gender differences in incidence trends of early-onset GI cancer: The European perspective

I. Ben-Aharon[1], H.W.M. van Laarhoven[2], M.G. Guren[3], I. Baraibar Argota[4], N. Gordon[1], T.G. Goshen - Lago[5], R.H.A. Verhoeven[6], T. Sokop[7], R. Obermannova[8], F. Lordick[9]

[1]Division of Oncology, Rambam Health Care Campus, Haifa, Israel; [2]Medical Oncology Dept., Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands; [3]Oncology Department, Oslo University Hospital, Oslo, Norway; [4]Oncology Department, Vall d'Hebron University Hospital, Barcelona, Spain; [5]Division of Oncology, Rambam Medical Center, Haifa, Israel; [6]Research and Development Department, IKNL - Netherlands Comprehensive Cancer Organisation, Utrecht, Netherlands; [7]Oncology Department, Masaryk Memorial Cancer Institute, Brno, Czech Republic; [8]Department Of Comprehensive Cance Care, Masaryk Memorial Cancer Institute, Brno, South Moravian, Czech Republic; [9]Medicine Department, Universitätsklinikum Leipzig - Universitäres Krebszentrum Leipzig, Leipzig, Germany

Background: The US Surveillance, Epidemiology and End Result (SEER) data indicate an increasing incidence of early-onset cancer across the GI tract. A female predominance has been shown for early-onset pancreatic cancer (EOPC) in the US. Due to environmental factors which may underlie the pathogenesis of early-onset cancer, incidence across the globe may differ. However, data regarding the incidence of gastrointestinal cancers in young patients in Europe is scarce. Therefore, we aimed to investigate patterns of GI cancers in young patients across various European countries.

Methods: National cancer registries of seven European countries - Germany, Netherlands, Spain, Slovenia, Norway, Czech Republic and Israel - were approached for absolute number of cancer incidences per age group (15-50 years in 5-year intervals) and the size of the population for each age group yearly from 2008-2018. Data was analyzed to calculate year-by-year the Average Annual Incidence Rate Change (AARC) and Average Annual Percent Change (AAPC).

Results: We observed heterogeneous patterns in different GI cancers across countries. An increase was noted in oesophageal cancer in females in the Czech Republic and Germany (AAPC 11.65% and 1.11% respectively) and slightly in males in the Netherlands (AAPC 0.88%) and Slovenia (AAPC 0.40%). Gastric cancer increased in females in Norway (AAPC 15.00%) and Slovenia (AAPC 11.90%). An increase in incidence of EOPC in men and women was noted in Germany, Norway and Netherlands and in females in Israel and Slovenia (AAPC 6.0%, 4.30% respectively). Early-Onset Colorectal cancer (EOCRC) is on the rise in men and women in Israel, Netherlands and Norway, while increasing only in males in the Czech Republic (AAPC 1.50%) and only in females in Slovenia (AAPC 5.40%). In Spain, only EOCRC showed an increased incidence.

Conclusions: The incidence of early-onset cancer along the GI tract displays differential patterns across countries, which differs from the trends observed in SEER data. In some GI cancers the incidence is stable between 2008-2018 and some are increasing mainly in women. Due to the environmental role in the pathogenesis of early-onset GI cancer, future studies should unravel potential etiologies especially with regard to gender-related factors.

1743P Bridging the gender gap in oncology: GEORGiNA'S quest for equality in academic research

K. El Bairi, on behalf of the GEORGiNA study collaborators

Faculty of Medicine and Pharmacy, Mohammed First University, Oujda, Morocco

Background: Gender disparities in academic research in oncology remain a persistent global challenge. There is a significant lack of research on gender inequity in Africa. GEORGiNA ("Gender Equity in Oncology Research" Group of North Africa) is a gender focusing bibliometric study that reviewed cancer research of North-African countries intending to build policy, recommendations, and gender equality actions in the field of cancer research.

Methods: A Pubmed-based bibliometric analysis was conducted over 2018-2022 period. Eligible articles had at least one author from a North-African country in the first or last position. Cancer researchers reviewed articles with authors from their own country to determine their gender accurately. A manual data extraction guide was developed and shared with collaborators to ensure consistent and accurate reporting. Factors associated with gender distribution were studied as appropriate.

Results: A total of 7,109 articles (2018-2022) published by North-African oncologists were included in the bibliometric analysis. Females represented 51% of first authors, with a notable women's presence in Tunisia (71.9%). Morocco, Algeria, and Egypt demonstrated a fair distribution of female first authors with ratios close to 0.5, while Sudan and Libya exhibited male dominance with percentages of 62% and 70%, respectively. Among 37,019 of co-authors, 44.13 % (n=16,333) were females. Male oncologists were found to have significantly higher representation as principal investigators (PIs) in all countries ($p < 0.001$). Notably, there has been a remarkable increase in women taking lead authorship roles in recent years, including during the period of the COVID-19 pandemic. Male researchers dominated original articles as PIs ($p < 0.001$). Indeed, male had received more funding than females and published more open access science ($p<0.01$). There was a significant difference observed in the involvement of male authors (both first and last positions) in international collaboration compared to females in equivalent positions.

Conclusions: While women in cancer research appear to achieve a fair position, there are still barriers such as insufficient funding and limited international collaboration to drive progress towards gender equity.

1744P Socioeconomic inequalities in the diagnosis and treatment of colon cancer: A population-based English cancer registry study

B.A. Pickwell-Smith[1], L. Paton[2], I. Soyiri[1], M. Lind[1], U. Macleod[1]

[1]Hull York Medical School, University of Hull, Hull, UK; [2]Hull York Medical School, University of York, York, UK

Background: Patients with colon cancer from more deprived areas may face barriers to accessing timely, quality healthcare. These barriers may contribute to socioeconomic inequalities in survival. We examined differences in treatment and time to diagnosis and treatment between socioeconomic groups.

Methods: The English Cancer Registry identified a retrospective cohort of patients diagnosed with colon cancer in England between 2016-2017. Cancer Registry data were linked to Hospital Episode Statistics, Cancer Pathway, Systematic Anti-Cancer Dataset and Diagnostic Imaging Datasets. Lasso logistic regression identified predictors of colon cancer treatment. The secondary care diagnostic interval (SCDI) was used to calculate the time to diagnosis and treatment, analysed using quantile regression. All analyses were conducted using STATA. The study was registered on ClinicalTrials.gov (NCT05185388).

Results: A total of 35,248 patients were included in the analyses. Area deprivation was a significant predictor of receipt of surgery and chemotherapy. The adjusted odds of treatment were reduced for patients from the most deprived quintile: surgery (OR 0.78), chemotherapy in stage IV (OR 0.88), and chemotherapy in stage II-III (OR 0.79). The median SCDI was 20 days for patients from the most and least deprived areas. However, patients from the most deprived area had a significantly longer time to diagnosis after adjusting for other factors (median difference 0.73 days [95% CI 0.09-1.36]). Meanwhile, the median treatment interval was 55 and 57 days for patients from the least and most deprived areas, respectively. The treatment interval was significantly longer for patients from the most, compared with the least deprived areas after adjusting for important factors (median difference 2.29 days [95% CI 1.28-3.31]).

Conclusions: In this large cohort of patients with colon cancer in England, we demonstrated that patients from more deprived areas are less likely to receive surgery or chemotherapy and wait longer to commence treatment. Further research is needed to understand why and what evidence-based actions can reduce these inequalities in treatment and timeliness.

1745P Why do adult patients with cancer abandon treatment in India? A nationwide qualitative study to understand the perspectives of healthcare workers

R. Ayiraveetil[1], M. Chittem[2], S. Lakshminarayanan[3], S. Veeraiah[4], P. Penumadu[5], J. Pandjatcharam[6], S. Kayal[1], B. Dubashi[1], P. Ganesan[1]

[1]Medical Oncology, JIPMER - Jawaharlal Institute of Postgraduate Medical Education and Research, Puducherry, India; [2]Liberal Arts, IIT-Indian Institute of Technology Hyderabad, Hyderabad, India; [3]Preventive and Social Medicine, Jawaharlal Institute of Postgraduate Medical Education and Research, Puducherry, India; [4]Psycho-oncology, Cancer Institute (WIA), Chennai, India; [5]Surgical Oncology Department, JIPMER - Jawaharlal Institute of Postgraduate Medical Education and Research, Puducherry, India; [6]Radiation Oncology Department, JIPMER - Jawaharlal Institute of Postgraduate Medical Education and Research, Puducherry, India

Background: Treatment abandonment (TA) is a major challenge in cancer care leading to poor outcomes and wastage of resources. Reasons for TA are multi-factorial and country specific. Understanding these complexities is the first step toward developing effective strategies for the prevention of TA. Insights and experiences of healthcare workers (HCWs) can provide valuable information about the factors contributing to TA; hence we conducted a qualitative study to understand the issues.

Methods: The participants were purposively selected, experienced HCWs (N=30) treating cancer patients from high-volume cancer centres nationwide. In-depth interviews (semi-structured, open-ended) were conducted by a person trained and experienced in qualitative interviews to understand the perspectives of HCWs on TA among adult cancer patients. We used the grounded theory approach to thematically analyze the data using inductive analysis.

Results: The HCWs (oncologists=17, nurses=6, psycho-oncologists=3, counselors=4) were selected from 9 states of India representing all geographical regions and working in both private (paid services, N= 14) and government (free services, N=16) sectors. The average duration of the interview was 30 minutes, and the reasons for TA perceived by the HCWs were classified under 6 themes: 1) Socio-demographic, 2) Patient-specific, 3) Clinical, 4) Psychological, 5) Health system related, and 6) Economic factors. Catastrophic health expenditure, direct medical and/or non-medical costs, indirect medical costs, poor socio-economic status, lack of specific knowledge about disease and treatment, poor patient-provider communication, accessibility, psychological distress, and toxicities of treatment were the common reasons for TA cited by the HCWs.

Conclusions: The study is one of the first studies reporting on HCWs' perspective on TA among cancer patients in India. In addition to well-known socio-economic factors, this study identified important themes such as lacunae in communication and psychological issues (e.g., distress) causing TA. The results of this study will help plan quantitative research into the complex issues of TA and interventions to counter the problem.

1746P Unintended consequences: Working time directives and oncology staff implications

S. Barry[1], M.L. O'Connor[1], C. Moloney[1], M. Colfer[1], C. O'Leary[1], A. Doolan[1], A. Reilly[1], G. Lavelle[1], K. Mckendry[1], N. Pierce[1], K. Skehan[1], C. Kinsella[1], O.S. Breathnach[1], W.M. Grogan[1], B. Hennessy[1], P.G. Morris[1], K. Egan[2], A.G. Murphy[1], P. Bredin[1]

[1]Medical Oncology, Beaumont RCSI Cancer Centre, Dublin, Ireland; [2]Cancer Clinical Trials Unit, Beaumont RCSI Cancer Centre, Dublin, Ireland

Background: On-call work is an inherent component of Oncology care. Managerial models focus on length of stay in calculating efficiency within hospitals. Ensuring compliance with the European Working Time Directives (EWTD) for doctors is a legal requirement for Hospitals. Calculations of required physician staff to provide overnight care is not necessarily based on numbers of patients to be cared for, nor the complexity of care. The acute oncology service (AOS) after-hours has to date been provided by the day-time medical team in whole. To improve safety and quality of the AOS for patients being seen after hours, as well as to comply with the EWTD, a change to shift-work for the 1st-on-call oncology doctor is planned in 7/23. We sought to quantify the impact on the service.

Methods: The numbers of non-consultant hospital doctors (NCHDs), with allowances for full staff and also allowing for annual and educational leave entitlements were gathered for 1) pre-shift work implementation and 2) post-implementation of shift work. The number of NCHDs multiplied by the hours available to the ambulatory services (day unit and outpatient clinics) were calculated per week for both service structures to produce the "available NCHD hours".

Results: Assuming the normal working day is 8am to 5pm, this change would result in the reduction of available NCHDs to the ambulatory oncology service from 270 available NCHD hours per week to 171 available NCHD hours once vacation and study leave are factored into the equation, despite the addition of one NCHD to the medical oncology team. This represents a 36% reduction in available staff yet with a likely continued increase in patient activity.

Conclusions: While modifying the after-hours service to shift-work augments availability of medical staff for the acutely unwell patient with cancer and achieves compliance with EWTD, it reduces the numbers of doctors available for a significant part of the day, placing more strain on those doctors trying to manage a similar number of patients in a safe and patient-focused manner. Changes to the after-hours service inadvertently has knock-on effects on the "Oncology Ecosystem" and may impact on future service quality. Adjustments to NCHD numbers to cover the predicted significant staff fall short of those required.

1747P The need for a better discussion between doctors and patients with regards to fertility preservation and vaginal rehab after anti cervical cancer treatments

B. Levy, V. Ben Hur Peer, O. Shaul, O. Erlich, Z. Magen

Management, HaBait Shel Bar - Israel's Women's Cancer Association (RA), Tel Aviv, Israel

Background: Cervical cancer patients' age is relatively young (considering only 35-39 and not 60-64). At this young age, patients might consider birth planning and other sexual health considerations such as vaginal rehabilitation.

Methods: A call for answers to a survey was published and patients and verified survivors were invited to respond voluntarily and anonymously through a coded and encrypted web form.

Results: 116 women responded to the survey (age 21-72, median=42, age range at diagnosis 18-65). 8% were diagnosed with CIN1-2, 43% with CIN3, 20% with stage 1, 7% with stage 2, 10% with stages 3-4, 12% did not know how to answer. Past treatments were recorded. 84% of those required to use a vaginal dilator did not do so (results were modified in accordance to guidelines). At childbearing age [67 women, ages 21-45, median=37; 55.22% CIN3, 19.4% stage 1, 5.97% stage 2, 5.97% stages 3-4, 13.43% did not know how to answer; 77.61% were sexually active with a single known partner], only 58.2% recall having a discussion with their physician regarding fertility preservation, before beginning treatments. 32.83% recall such a discussion afterwards. 11.94% give birth after illness or had a child thanks to a surrogate mother.

Conclusions: This study underscores the need for greater attention to patients' sexual health and fertility aspects before and after completion of treatments. There is a need in coordinate patients' expectations regarding birth planning and in making the information regarding vaginal dilator accessible. Research involving a larger sample size may help to better support the information needs of survivors.

1748P Tackling childhood obesity epidemic on southern Europe through soft drink advertisement policies: Should oncology societies have a say?

K.V. Kamposioras[1], K. Marti[1], S. Droufakou[2], D. Spiteri[3], P. Marti[4], P. Kountourakis[5], L. Lorioli[6], M. tolia[7], D. Mauri[8], R. Alves[9]

[1]Medical Oncology Dept., The Christie NHS Foundation Trust, Manchester, UK; [2]5th Medical Oncology Dept, IASO S.A. - Private Clinic, Maroussi, Greece; [3]Sports Medicine, Sports and Exercise Medicine, Malta, Msida, Malta; [4]Facultad de Medicina, Universidad CEU San Pablo, Madrid, Spain; [5]Medical Oncology Dept., Mediterranean Hospital of Cyprus, Limassol, Cyprus; [6]Neonatal Intensive Care Unit, ASST Papa Giovanni XXIII, Bergamo, Italy; [7]Clinical Oncology Dept., University General Hospital of Heraklion, Heraklion, Greece; [8]Medical Oncology, University Hospital of Ioannina, Ioannina, Greece; [9]NOVA University Lisbon, NOVA University Lisbon, Lisbon, Portugal

Background: Obesity has been recognised as one of the main risk factors for non-communicable diseases including cancer. WHO European report suggests that obesity affects 30% of children in Europe. Unhealthy diet is one of the most important determinants of childhood obesity, a condition that has become very prevalent in the south of Europe. Consumption of sugar-sweetened beverages (SSBs) influence childhood obesity and food advertisement is one of the strongest determinants of SSB consumption.

Methods: A multidisciplinary panel of clinicians from the South of Europe (Cyprus, Greece, Italy, Malta, Spain and Portugal) critically reviewed the available legislation and recommendations on SSB advertisements, in native language. The website of relevant national societies (Cardiovascular, Diabetic, Oncology, Paediatric and Stroke) was reviewed. Herein we present the recommendations from Oncology national societies.

Results: The countries in study have national legislations on SSB advertisements following EU directives with Spain having the most comprehensive regulatory framework. None of the oncology societies had recommendations on SSB consumption from children. The Spanish oncology society (SEOM) recognised obesity as risk factor for developing cancer and a close collaboration with the Spanish Association for the study of obesity is suggested. The Portuguese Society of Oncology (SPO) provides general guidance on the role of food and nutrition in cancer development. In Greece and Cyprus sporadic publications from the oncology society (HeSMO) on the preventive role of diet was noticed with no concrete guidance. Italian Oncology society (AIOM) has published on the role of nutritional support for cancer patients but the preventive role of healthy diet on childhood obesity is not available. European society of Medical Oncology links to IARC prevention strategies in the society website.

Conclusions: Recommendations on healthy diet to tackle childhood obesity, including SSB advertisement, from national medical societies in South Europe is fragmented. Oncology societies should join forces with other medical societies to increase awareness of childhood obesity and implement measures to address the phenomenon.

1749P Prevention of modifiable cancer risks in informal family caregivers of cancer patients: Implementation and evaluation of a personalised primary prevention intervention (PREV-AIDANT)

B. Fervers, C. Bouffay, O. Pérol, M. Bac, J. Lesage, M. Mazeron, P. Vidican, N. Moumjid

Prévention Cancer Environnement, Centre Léon Bérard, Lyon, France

Background: The situation of caregiving can lead the informal family caregiver to neglect his or her own health, develop "risky" behaviours (smoking, alcohol consumption), adopt an unbalanced diet, encourage a sedentary lifestyle, and thus increase the risk of cancer. The sharing of the same lifestyle, including the same risk factors, within the informal family caregivers-patients dyad can also increase this risk. In addition, compared to the general population, informal family caregivers have a better perception of their risks and a greater motivation to change their behaviour. The objectives of the present study are to evaluate the feasibility and acceptability of a personalised primary prevention intervention for modifiable cancer risk factors in informal family caregivers of cancer patients.

Methods: The study is being conducted at the Léon Bérard Cancer Centre (Lyon, France), since April 2022, among informal family caregivers (first-degree relative or partner/spouse) who are adults and cancer-free. The personalised intervention was co-constructed with the representatives of informal family caregivers. It targets 6 risks factors (tobacco, alcohol, diet, physical activity, overweight/obesity, ultraviolet exposure) and screening. The intervention consists of an initial consultation (quantification of exposure, information on recommendations, drafting of a personalised primary prevention programme), support for the implementation and a four-month follow-up consultation (assessment of the actions taken, readjustment of the programme, exchanges to perpetuate the changes).

Results: To date, out of the 50 informal family caregivers expected, 26 have been seen at the initial consultation and 7 at the follow-up consultation. Inclusion will end in August 2023, the study looks feasible and acceptable, more results will be presented at the Congress.

Conclusions: The PREV-CARE transferability study of this intervention at the Institut Gustave Roussy (Paris, France) began in December 2022. Its objectives are to analyse the transferability of the intervention, to meet the challenges of territorial diversity, before considering evaluation on a larger scale.

Clinical trial identification: NCT05310045.

1750P Knowledge and awareness of hepatitis B and C virus reactivation among oncologists in Dutch-speaking Belgium: The CHOICe trial (Chronic Hepatitis B/C screening in patients on immunosuppressive therapy and chemotherapy)

M. Coessens[1], C. Van de Bruaene[2], W. Verlinden[3], A. Geerts[2], V. Kruse[4], M. Aerts[5], S. Bourgeois[6], I. Colle[7], J. Maus[8], H. Orlent[9], L. Van Overbeke[10], C. Van Steenkiste[11], J. Schouten[3]

[1]Laboratory of Experimental Medicine and Pediatrics (LEMP), University of Antwerp, Wilrijk, Belgium; [2]Gastroenterology and Hepatology, Ghent University Hospital, Ghent, Belgium; [3]Gastroenterology and Hepatology, Vitaz, Sint-Niklaas, Belgium; [4]Medical Oncology, Vitaz, Sint-Niklaas, Belgium; [5]Gastroenterology and hepatology, University Hospital Brussels, Jette, Belgium; [6]Gastroenterology and Hepatology, Stuivenberg ZNA, Antwerp, Belgium; [7]Gastroenterology and Hepatology, ASZ Aalst, Aalst, Belgium; [8]Gastroenterology and hepatology, Middelheim ZNA, Antwerp, Belgium; [9]Gastroenterology and hepatology, AZ Sint-Jan Brugge-Oostende AV, Bruges, Belgium; [10]Gastroenterology and hepatology, AZ Sint-Maarten, Mechelen, Belgium; [11]Gastroenterology and hepatology, AZ Maria Middelares, Ghent, Belgium

Background: Hepatitis B and C virus (HBV, HCV) reactivations are an emerging problem. Several societies have composed screening guidelines, but HBV reactivation still occurs in daily practice. This survey aims to assess knowledge and awareness of HBV/HCV reactivation in oncologists.

Methods: A questionnaire was designed to assess descriptive variables (i.e., subdiscipline, years of experience, working in an academic center, and having witnessed an HBV reactivation in clinical practice) and nine content questions (four background and five clinically oriented). The survey was disseminated in spring 2022 in 11 hospitals in Belgium (3 university, 8 non-university).

Results:

Table: 1750P Characteristics of responding oncologists

		N = 64	%
Subdiscipline	Solid tumours	33	52.4
	Haematological malignancies	21	33.3
	Gastrointestinal tumours	9	14.3
Years of experience	<5 years	20	31.2
	>5 years	44	68.8
Working in an academic center	Yes	26	40.6
	No	38	59.4
Already witnessed a HBV reactivation in clinical practice	Yes	24	37.5
	No	40	62.5

The table provides an overview of characteristics of responding oncologists. Mean overall scores were 33.7%, and mean scores for background and clinical questions were 20.3% and 44.4%, respectively. Less than half of participating oncologists was aware of universal HBV screening prior to initiation of chemotherapy (48.4%) and immunosuppression (37.5%). Only 7.8% of them was aware of the high reactivation risk that comes with administration of anthracyclines. Moreover, oncologists that have already witnessed a hepatitis B reactivation in clinical practice, are better aware of hepatitis B screening guidelines prior to administration of chemotherapy ($p=0.005$) and immunosuppression ($p=0.033$).

Conclusions: Knowledge of HBV/HCV reactivation is insufficient in oncologists. In addition, HBV screening guidelines prior to initiation of chemotherapy and immunosuppression are poorly implemented, given that over one third of responding oncologists already witnessed an HBV reactivation in clinical practice. Encouragingly, these respondents are also better aware of HBV screening guidelines. Oncology organisations play an important role in raising awareness and providing clear guidance.

1751P Re-ranking cancer mortality using years of life lost

C. Radkiewicz[1], T.M-L. Andersson[2], J. Lagergren[1]

[1]Molecular Medicine and Surgery, Upper GI Surgery, Karolinska Institutet, Stockholm, Solna, Sweden; [2]Medical Epidemiology and Biostatistics, Karolinska Institutet, Stockholm, Sweden

Background: Standardized incidence and mortality rates are the default measures to describe cancer trends while survival assesses advances in cancer detection and treatment. Mortality compounds both incidence and survival but does not fully address age at death or long-term survival, both essential to quantify the cancer burden on society.

Methods: Using Swedish National Cancer and Cause of Death Register data together with publicly accessible projections of life expectancy, we calculated *years of life lost* (YLL) as the difference between age at cancer death and expected age at death for an individual of the corresponding age, sex, and birth year in the general population. All adults (18-95 years) with death reported as caused by one of the 10 solid tumors causing most deaths (lung, colorectal, prostate, pancreatic, breast, hepatobiliary, urinary, central nervous system, gastric cancer, or melanoma) in Sweden from 2010-2019, were included.

Results: When YLL were related and compared to mortality estimates in 2019 (Table), lung cancer (43,152 YLL) and colorectal cancer (32,340 YLL) remained at the top. Pancreatic cancer was up-ranked from 4th to 3rd place (22,592 YLL) and breast cancer from 5th to 4th place (21,810 YLL), while prostate cancer was down-ranked from 3rd to 5th place (17,380 YLL). In the table, a traditional approach ranking the 10 most common causes of cancer death in number of deaths and mortality rate (A), and new ranking using years of life lost approach (B), Sweden 2019.

Table: 1751P

	A. Traditional approach			B. Years of life lost approach	
Cancer site	Deaths	Mortality rate	Rank	Years of life lost	New rank
Lung	3144	38.7	1	43152	1
Colorectal	2543	31.3	2	32340	2
Prostate	2063	25.4	3	17380	5
Pancreatic	1600	19.7	4	22592	3
Breast	1335	16.5	5	21810	4
Hepatobiliary	998	12.3	6	14568	6
Urinary	740	9.1	7	7435	8
Central nervous system	548	6.7	8	11628	7
Gastric	510	5.8	9	7159	9
Melanoma skin	472	6.3	10	6973	10

Assessing YLL trends over the period from 2010-2019, women consistently lost more life years due to lung and pancreatic cancer than men. A downward trend in colorectal cancer mortality was reflected as a YLL decline only among women but not men.

Conclusions: Although all vital statistics have inborn advantages and disadvantages, this study demonstrates that YLL is simple to calculate, intuitive to interpret, and is as a meaningful measure to be added to the statistical toolbox box when presenting and comparing cancer trends within and between populations.

1752P Clinical benefit of immunotherapies in advanced cancer in France: A population-based estimate from 2014 to 2021

I. Borget[1], F-E. Cotté[2], E. Giroux-Leprieur[3], A-F. Gaudin[2], C. Lebbe[4], V. Grumberg[2]

[1]Biostatistic And Epidemiology, Institut Gustave Roussy, Villejuif, France; [2]Health economics and outcomes research, Bristol Myers Squibb, Rueil-Malmaison, France; [3]Respiratory Diseases and Thoracic Oncology Department, Hopital Ambroise Pare AP-HP, Boulogne-Billancourt, France; [4]Dermatology Dept., Hopital Saint Louis AP-HP, Paris, France

Background: In France, new treatments' benefit is evaluated by the *Haute Autorité de Santé* (HAS) to inform on reimbursement and pricing, but they are rarely evaluated afterwards. Although immunotherapies (ITs) considerably improved patients' survival, few data are available on their clinical benefit at the population-treated level. The objective of this study was to retrospectively quantify the clinical benefit of ITs compared to previous standard of care (SoC) in France from 2014 to 2021.

Methods: Analysis covers all ITs marketed in early access and/or reimbursed in France between 2014 and 2021, regardless of indication, with a cost-effectiveness (CE) model validated by HAS. For year between 2014 and 2021, the number of patients having initiated an IT, per drug and per indication, was retrieved from the French Hospital Reimbursement database. The clinical benefit was expressed as the number of deaths prevented (DP), life years gained (LYG) and quality-adjusted life years (QALYs) of ITs versus their comparators until 2021. DP and LYG were calculated thanks to extrapolated overall survival curves from randomized clinical trials, validated by the HAS. The number of additional QALYs was calculated using utility scores from the HAS CE opinion. Sensitivity analyses were performed according to the population size, survival, utility values and the period of availability.

Results: From 2014 to 2021, 5 ITs (atezolizumab, avelumab, durvalumab, nivolumab and pembrolizumab) were available in monotherapy or in combination in France corresponding to 8 tumor types and 21 indications. Overall, 132,924 patients initiated an IT, mainly in non-small cell lung cancer (66.5%) and melanoma (12.3%). By Dec 31st of 2021, 16,173 [13,803 − 17,141] deaths were prevented compared to previous SoC, representing 12.2% of patients initiating an IT. Compared to previous treatments, ITs allowed 37,318 [33,583 − 41,053] LYG and 27,710 [23,785 − 30,451] QALYs. Nivolumab contributed in 64.6% of LYG and 63.1% of QALYs. Early access of ITs participated in 14.7% of DP, 6.1% LYG and 6.0% QALYs.

Conclusions: Immunotherapies allowed significant clinical benefits for French cancer population in term of DP, LYG and QALYs. This type of analysis should be replicate in other countries.

1753P Universal DPYD genotyping in patients with gastrointestinal malignancies: Real-world data from a single institution in Italy

C. Cardone[1], S. Facchini[1], F. Collina[2], M.R. Brogna[2], A. Daniele[1], R. Casaretti[1], A. Cassata[1], A. De Stefano[1], A. Nappi[1], F. Foschini[1], L. Silvestro[1], C. Romano[1], N. Zanaletti[3], F. Tatangelo[2], S. De Franciscis[4], A. Belli[5], F. Izzo[5], G. Ferrara[2], P. Delrio[4], A. Avallone[1]

[1]Experimental Clinical Abdominal Oncology, Istituto Nazionale Tumori IRCCS - Fondazione G. Pascale, Napoli, Italy; [2]Patology Unit, Istituto Nazionale Tumori IRCCS - Fondazione G. Pascale, Naples, Italy; [3]GI unit, Istituto Nazionale Tumori IRCCS - Fondazione G. Pascale, Naples, Italy; [4]Colorectal Surgery, Istituto Nazionale Tumori IRCCS - Fondazione G. Pascale, Naples, Italy; [5]Hepatobiliary Surgery, Istituto Nazionale Tumori IRCCS - Fondazione G. Pascale, Naples, Italy

Background: In up to 30% of gastrointestinal (GI) malignancies, fluoropyrimidines (FP) are associated with severe adverse drug reactions (ADRs). Dihydropyrimidine dehydrogenase (DPYD), is a polymorphic gene involved in FP catabolism. The identification of deleterious variants associated with increased toxicity is recommended before treatment initiation [c.1905+1G>A (*2A); c.1679T>G (*13); c.1129-5923C>G (*IVS10); c.2846A>T (*949) or during treatment in case of ADR [c.2194G>A (*6)]. The estimated prevalence of DPYD deficient genotypes in the European population is <8%. This study aimed to determine the prevalence and implication of systematic DPYD testing in an unselected population with GI tumours.

Methods: The germline DPYD test was conducted on a consecutive series of 1000 pts diagnosed with GI malignancies at our Department between June 2020 and December 2022, candidates for FP for colorectal (CRC 69%), gastroesophageal (GEC 15%), biliopancreatic (BPC 12%), other GI tumours (4%) or double GI malignancy (<1%).

Results: Overall, 819 pts (82%) were DPYD wild type (WT) and 181 (18%) had a deleterious DPYD variant. Among DPYD mutated pts, 134 had CRC (74%), 23 GEC (13%), 17 BPC (9%), 5 other GI tumours (2%) and 1 had CRC and GEC (1%). 184 deleterious variants were observed in 181 pts, the most prevalent was DPYD *6 (*N*=146 15%) (Table). In 4 pts *6 coexisted with other variants, requiring dose personalization. Of 133 pts enrolled in interventional trials including FP treatment, 24 (18%) reported a deleterious variant: *2A N=1,* IVS10 *N*=2, *6 *N*=21.

Table: 1753P

DPYD status	N= 1000	%	FP dose[a]
DPYD WT	819	82%	100%
DPYD6_c2194G>A homozygosis heterozygosis	146 * 5 141	15%	70% 85%
IVS10_1129_5923c>G	20	2%	50-70%
DPYD2A_1905+1G>A	12	1%	50%
DPYD949_c2846A>T	5	<1%	50%
DPYD13_c1679T>G	2	<1%	50%

[a] recommended dose based on SIF and CPIC guidelines *4 patients presented a double heterozygosis DPYD6 and *2A (*N*=1), FP dose <50% DPYD6 and c*949 (*N*=1), FP dose <50% DPYD6 and *IVS10 (*N*=2), FP dose 50%
FP= fluoropyrimidines, WT=wild type

Conclusions: Our large cohort of GI pts revealed a higher prevalence of deleterious DPYD variants compared to previous reports. DPYD*6 was the most frequent genotype and, at a low rate, occurred with other variants requiring major dose adjustments. To prevent severe ADR and to adequately report toxicity and changes in pts' quality of life, our data suggest that DPYD assessment should be mandatory and included in all FP-based clinical trials.

1754P Towards a next-generation sequencing/comprehensive genomic profiling value framework: Systematic review for identifying new domains and adapting a diagnostic test value framework in Europe

F. Augustovski[1], C. Colaci[1], M. Mills[2], D. Chavez-Montoya[2], F. Argento[1], V. Alfie[1], A. Pichon Riviere[1], P. Kanavos[2], A. Alcaraz[1]

[1]Health Technology Assessment and Health Economics, Institute for Clinical Effectiveness and Health Policy (IECS)), Ciudad Autonoma De Buenos Aires, Argentina; [2]Medical Technology Research Group, LSE - The London School of Economics and Political Sciences, London, UK

Background: Next Generation Sequencing / Comprehensive Genomic Profiling (NGS/CGP) have recently expanded, mainly in oncology. To guide healthcare decision-making, it is key to have a value framework (VF), which allows a transparent assessment of value criteria. In 2020, IECS published a VF for diagnostic tests in Latin America (Augustovski et al, VIH 2021). This study aims to enrich, update, and adapt the previous VF to develop an NGS/CGP VF targeted to oncology in Europe. The aim of this study is to identify value criteria/sub criteria from published VFs, map them to the current VF, and report an updated and evidence-based list of non-overlapping criteria for subsequent assessment of their relevance for an NGS/CGP VF in Europe.

Methods: A systematic review (SR) of VFs aimed at any type of health technology. A mapping was then performed to determine similarities and differences with the IECS VF criteria.

Results: A total of 43 VFs were identified from 2067 unduplicated records and grey literature. The vast majority (n=38, 88%) were developed in high-income countries, 30% (n=13) were oriented towards genetic testing and only 16% (n=7) targeted oncology. A total of 223 criteria (C) and sub criteria (SC) were retrieved (93% of them fully or partially included in IECS VF). The two most common criteria related to clinical benefit and economic aspects. VFs oriented to oncology had higher overlap with the IECS VF, as well as those VFs oriented to genetic testing. A total of 18 criteria (C) and 35 non-overlapping sub-criteria (SC) were listed (15C and 21SC from IECS VF and 3C and 14SC from the SR). Some examples of new potential criteria included quality assurance/improvement; and public health/population benefit.

Conclusions: Our study provides an evidence-based, user-oriented update of criteria and sub criteria for healthcare decision-making tailored for NGS/CGP genetic testing in oncology, which may be a helpful list of criteria for health technologies in general. This list will serve as the basis to adapt the existing VF with the assistance of key European experts and stakeholders in order to co-create a European NGS/CGP VF in oncology.

1755P Carbohydrate quality index and incidence of obesity-related cancers: The Seguimiento Universidad de Navarra (SUN) project

M. Olmedo López-frías[1], M. Barbería-Latasa[2], M.J. Cobo[2], I. Zazpe[2], J.M. Aramendia[1], M. Bes-Rastrollo[2], M.Á. Martínez-González[2], E. Toledo[2]

[1]Clinical Oncology, Clinica Universidad de Navarra, Pamplona, Spain; [2]Department of Preventive Medicine and Public Health, University of Navarra, Pamplona, Spain

Background: Obesity is a strong risk factor for cancer, with more than 40,000 diagnosed cancers every year attributed to obesity. The role of nutrition in obesity-related cancers (ORC) needs to be better understood to develop tailored prevention strategies. The quality, rather than the quantity, of carbohydrate intake, seems to play a significant role. We investigated the relationship between dietary carbohydrate quality and risk of developing ORC in the "Seguimiento Universidad de Navarra" (SUN) Mediterranean cohort.

Methods: A total of 18,446 Spanish university graduates [mean age 38 years (SD 12), 61% women, mean BMI 23.5 kg/m2 (SD 3.5 kg/m2)], with no personal history of cancer, were followed-up for a median of 13.7 years. Baseline carbohydrate quality index (CQI) was assessed using 4 previously defined criteria: high dietary fibre intake, low glycemic index, high whole-grain: total-grain ratio and high solid carbohydrate: total carbohydrate ratio. Subjects were classified into tertiles according to their CQI score. Obesity-related incident cases were confirmed by an oncologist using medical records and by querying the National Death Index blindly to dietary exposures.

Results: During follow-up, 269 incident cases of obesity-related cancer were confirmed. A higher quality of carbohydrate intake, as measured by the baseline CQI, was associated with a lower risk of ORC with multivariable-adjusted hazard ratio (HR) for the upper (T3) versus the lowest tertile (T1) of 0.68 (95% confidence interval: 0.48, 0.97). Particularly, a higher dietary fibre intake was inversely associated with ORC, HR T3 vs. T1 = 0.58 (0.38, 0.89).

Conclusions: In this Mediterranean cohort, we observed a significant inverse association between a better global quality of carbohydrate intake and the risk of obesity-related cancers. This finding suggests that strategies for cancer prevention should emphasize the quality of carbohydrate intake, and particularly the dietary fibre intake.

1756P Vizcan: A Swedish population-based study to address cancer outcomes using an interactive platform

A. Berglund[1], H. Hållberg[1], E. Fernholm[2], A. Juhlin[3], D. Eek[4]

[1]Research & Development, Epistat AB, Uppsala, Sweden; [2]Medical, AstraZeneca Nordic, Sodertalje, Sweden; [3]Medical, AstraZeneca AB, Stockholm, Sweden; [4]Medical & Regulatory, AstraZeneca Nordic, Sodertalje, Sweden

Background: Cancer is a severe disease, where many of the patients are diagnosed late in their disease course. A detailed understanding of cancer burden at a population level is important to control efforts aimed at reducing the incidence and mortality of cancer. The aim of the present project, which is still in progress, is to build an interactive platform to address and visualize cancer outcomes in Sweden by malignancies, geographical regions, and calendar time for different subgroups such as gender, age groups, level of education and stage at diagnosis.

Methods: In the first step, an interactive visualization platform using the statistical software R and the R Shiny application was developed. In the second step, a registry-based secondary data collection study where subjects will be identified using ICD codes from the Swedish Cancer Registry (SCR) from 2014 and onwards will be conducted. The SCR is held by the National Board of Health and Welfare and is mandatory to report into. Additional information will be retrieved from the Cause of Death Registry, and a social database (LISA) at Statistics Sweden via record-linkage utilizing the Swedish unique personal number. Outcomes will include incidence rates, mortality rates, overall survival and the proportion diagnosed with late-stage disease. Once populated with study data, the interactive platform will be available on a dedicated homepage.

Results: The present study will capture virtually all patients diagnosed with cancer in Sweden from 2014 and onwards. The results from the study will be included in interactive maps, tables and figures so that the user (e.g., health care professionals, patients, and researchers) can explore the outcomes of interest on their own. The data sources together with the interactive tool will increase the understanding of potential socio-economic inequalities and differences in cancer outcomes by geographical regions, gender, and age groups.

Conclusions: The use of population-based information available in the present study in combination with an interactive platform provides a unique opportunity to address a wide range of issues of importance not only for an improved general understanding of cancer, but also for quality assurance and improvement of cancer care.

1757P A real-world evaluation of the effectiveness of thermogram along with clinical breast examination in community-based breast cancer screening program

R. Ravind

Medical Oncology, Renai Medicity, Kochi, India

Background: Breast cancer is a crucially prevailing cancer among women. Early detection and diagnosis of breast cancer are very important for patient survival. This study was conducted to devise a cost-effective and robust community-based breast cancer screening programme for LMIC.

Methods: All enrolled participants will undergo breast thermogram (BT) using an AI-based Thermalytix test along with clinical breast examination (CBE) by trained health workers. Women found suspicious in either CBE/BT or both will undergo confirmatory tests using Sonomammography (US) and/or Mammography; biopsy, where warranted, will be done to confirm the diagnosis. All symptomatic and asymptomatic women aged above 35 years of age, willing to give written informed consent for study participation were included. Those who are pregnant or lactating, treated for any cancers of breast/thorax, active inflammatory disorders on the skin of the breast, breast implants that can hamper testing using a BT or CBE were excluded from this study. The primary study endpoint is to evaluate the effectiveness of combined modality testing for breast cancer detection in healthy women. The benefit of a combined modality of Thermogram and clinical breast examination (CBE) for cancer detection rate were evaluated.

Results: A total of 3030 (both symptomatic and asymptomatic women) were screened for breast cancers over a period of 6months (Oct 2022 to April 2023). Women residing within a 120square kilometre radius were screened. Patients who were detected with screen abnormality on a thermogram B- Score 4 and above were 561 (18.51%). Six hundred and forty-six subjects (21.3%) who had an abnormality on both thermogram and CBE were recalled for further investigations. Out of which 5 subjects were detected with biopsy-proven breast malignancy (3 were early-stage breast cancer and 2 had locally advanced breast cancer).

Conclusions: Dual modality screening tool improves cancer detection rates, and this demonstrates the efficacy of these tools for breast cancer screening. Thermalytix with its artificial intelligence-based scoring system can assist the health care worker in the detection of breast cancer at a community level.

1758P Body composition meets precision medicine: The prognostic value of sarcopenia in patients (pt) treated with Molecularly Targeted Agents (MTA)

C. Hierro[1], L. Notario Rincon[1], A.M. Esteve Gomez[1], A. González[1], A. Llenas[2], J. Horneros[3], C. Ibáñez[4], S. Fontanals[4], A. Clopes[4], R. Mesia Nin[1], L. Arribas[2]

[1]Medical Oncology Department, Catalan Institute of Oncology (ICO)-Badalona, Badalona, Spain; [2]Clinical Nutrition Unit, Catalan Institute of Oncology (ICO)-Hospitalet, Hospitalet De Llobregat, Spain; [3]Radiology Department, Germans Trias i Pujol University Hospital, Badalona, Spain; [4]Pharmacy Department, Catalan Institute of Oncology (ICO)-Hospitalet, Hospitalet De Llobregat, Spain

Background: Sarcopenia is associated with worse prognosis in pt treated with chemo (CT) or immunotherapy, yet there is scarce information with MTA. Some gene mutations (mut) have been involved in muscle wasting pathogenesis but remains unclear which molecular mediators can alter body composition. Our study aimed to analyze the association between sarcopenia and clinical outcomes in MTA-treated pt and to explore the tumor genomic landscape.

Methods: Retrospective analysis of metastatic solid tumors treated with MTA within the spEcial Medication (ME) program at the Catalan Institute of Oncology (off-label or expanded access use) between Jan'11-Dec'19. Skeletal mass index (SMI) was assessed at L3 landmark in computed tomography scans performed one month before first MTA dose. SMI was dichotomized according to the median [high (H) vs low (L) SMI]. Histology-oriented single analysis assays were performed according to the prevalence of actionable findings (IHC, FISH or PCR).

Results: We included 167 cases: 56% female, 86% <75 years, 84% ECOG <2 and 79% received <3 lines of treatment. Locations were thoracic (33%), breast (15%), sarcoma (15%), gastrointestinal (14%), gynae (9%), genitourinary (7%) and others (7%). Oncogenic drivers that guided matched MTA were found in 97 tumors: 75% received MTA monotherapy and 25% combinations (CT or other MTA). Globally there were 28% cases with HER2 overexpression (ove), ALK (23%)/MET (1%)/ROS1 (1%) fusions and EGFR (19%)/BRAF (11%)/BRCA1/2 (7%)/KRAS (4%) mut. Overall survival (OS) was 21.8 months (m) in H-SMI/driver, 13.9 m in H-SMI/no-driver, 10.8 m in L-SMI/driver and 9 m in L-SMI/no-driver groups (p=0.0037). Of note, OS rate at 12 m was 65% (CI 95%; 53-81) in H-SMI/driver group compared to 38% (CI 95%; 24-59) in L-SMI/no-driver group. Interestingly, 81% HER2ove cases had L-SMI (p=0.005).

Conclusions: Our exploratory study shows that pt with H-SMI and presence of an oncogenic driver have better survival outcomes, hence highlights the relevance of guaranteeing early access to MTA through ME programs. L-SMI in HER2ove pt warrants further confirmation and investigation of the underlying mechanism in muscle wasting.

1760P Systematic review of quality of life (QoL) inclusion among endpoints, reporting and impact of QoL results in phase III non-inferiority trials of systemic treatments in oncology

J. Paparo[1], L. Zumstein[1], S. Notarnicola[1], L. Marandino[2], F. Perrone[3], M. Di Maio[1]

[1]Department of Oncology, University of Turin, Mauriziano Hospital, Turin, Italy; [2]Dipartimento di Oncologia Medica, IRCCS Ospedale San Raffaele, Milan,Italy; [3]Clinical Trial Unit, Istituto Nazionale Tumori IRCCS - Fondazione G. Pascale, Naples, Italy

Background: Quality of life (QoL) is an increasingly important endpoint in oncology clinical trials. In the non-inferiority (NI) setting, the experimental treatment should confirm to be preferable, and patient-reported outcomes should have a relevant role. Aim of this study was to assess the inclusion of QoL among endpoints in phase III NI trials, the presence of QoL results in the publications and the impact of QoL results on the interpretation of the study.

Methods: We performed a PubMed search for phase III NI trials published between 2012 and 2021, testing systemic treatments in adult patients with solid tumours. Trials were divided according to 4 NI strategies: (1) different treatments; (2) different route of administration of the same drug; (3) shorter duration of treatment; (4) omission of one or more drugs. Trials were analysed according to three endpoints: (1) proportion of publications including QoL among endpoints; (2) proportion of publications reporting QoL results; (3) proportion of publications with demonstration of NI, in which QoL results actually favour the experimental treatment.

Results: 106 publications were eligible. In 47 studies (44.3%), QoL was not included among endpoints, and QoL results were not available in 66 (62.3%) primary publications. Out of 74 trials with demonstration of NI, QoL was not assessed in 36 (48.64%) and QoL results were not available in 43 primary publications (58.1%); QoL results actually favoured the experimental treatment in 19 trials (25.7%). Considering only the subgroup of 73 trials testing the NI of different treatments, 30 (41.1%) did not include QoL and QoL results were not available in 42 (57.5%) publications; within this subgroup, focusing on 55 trials with demonstration of NI, 25 (45.5%) did not include QoL; QoL results were not available in 29 (52.7%) primary publications; QoL results actually favoured the experimental treatment in 15 trials (27.3%).

Conclusions: Quality of life is not assessed and/or reported in many non-inferiority trials testing cancer treatments. Among trials formally demonstrating the non-inferiority, only a minority can claim quality of life results actually favouring the experimental treatment.

1761P Incidence of herpes zoster in cancer patients in Europe: A systematic review

I. Posiuniene[1], A. Marijam[1], N. Vroom[2], A. Bhavsar[1], N. Lecrenier[1], H. Vroling[2]

[1]Vaccines, GSK, Wavre, Belgium; [2]Epidemiology, Pallas health research and consultancy, P95 company, Rotterdam, Netherlands

Background: Immunocompromised (IC) patients e.g., due to cancer or immunosuppressive therapy, are at increased risk for herpes zoster (HZ) with severe complications, recurrence and mortality. HZ affects up to one in three adults over 50 years, with post-herpetic neuralgia in up to one in ten HZ cases. The objective was to document HZ incidence in a broad range of IC populations, including cancer, in Europe.

Methods: A systematic literature review (2002-2022) identified observational studies reporting HZ incidence in IC populations in the European Union/European Economic Area, Switzerland and the United Kingdom.

Results: 26 studies were included: five in cancer patients reported HZ incidence rates per 1,000 person-years. In mixed hematologic malignancy (HM) patient studies, overall HZ incidence was 12.0-15.2 vs 4.6-6.2 in non-IC controls, increasing with age (Table). Chronic lymphocytic leukemia (CLL) patients had an 11.3 times greater risk of HZ (incidence 2.94 vs controls 0.26). In myelofibrosis (MF) patients, ruxolitinib use increased HZ risk (incidence in long-term, short-term, new and switch users vs non-ruxolitinib users). In mixed solid organ malignancy (SOM) patient studies, overall HZ incidence was 8.8-11.0 vs 4.6-6.2 in non-IC controls, increasing with age (Table), and was higher for women vs men (10.8 vs. 9.0).

Table: 1761P

	Age group	Non-IC	HM	SOM
Spain (2009-2014)	18-29y	2.26 [2.21; 2.31]	4.96 [4.1; 5.94]	3.87 [2.59; 5.56]
	50-59y	5.52 [5.44; 5.61]	13.95 [12.5; 15.52]	10.24 [9.66; 10.85]
	≥80y	9.54 [9.36; 9.71]	18.44 [16.46; 20.6]	12.00 [11.43;12.59]
England (2000-2012)	18-49y	2.12 [2.03; 2.22]	8.46 [7.29; 9.77]	4.32 [3.96; 4.70]
	50-59y	4.90 [4.72; 5.08]	15.41 [13.61; 17.37]	6.79 [6.36; 7.25]
	≥80y	11.02 [10.64; 11.41]	17.53 [15.47; 19.79]	11.63 [11.08; 12.20]

y: year

Conclusions: This systematic review reported a higher HZ risk for HM and SOM patients, varying across countries and cancer type. Stratified data showed risk differed by age, sex and treatment. These real-world studies highlight the increased HZ risk and burden in cancer patients, which may be prevented with the adjuvanted recombinant HZ vaccine approved for multiple IC populations.

1762P Are published data up-to-date? Analysis of time to publication in major oncological journals

P. Sobczuk[1], Z. Kurek[2], K. Marcinkiewicz[2], E. Pelc[2], P. Rutkowski[1]

[1]Department of Soft Tissue/Bone Sarcoma and Melanoma, Maria Sklodowska-Curie National Research Institute of Oncology, Warsaw, Poland; [2]Faculty of Medicine, Medical University of Warsaw, Warsaw, Poland

Background: Dissemination of research results, including data from clinical trials, is one of the essential responsibilities of all scientists. Moreover, whole community of researchers, patients, and general public, should have access to research data at earliest possible moment. However, significant delay between completion of the study and publication of its results has been observed; thus, we aimed to analyze the time from database lockdown to publication and factors that might be associated with it.

Methods: We analyzed all original publications reporting any clinical data published in 2020 and 2021 in 2 leading oncological journal — *Journal of Clinical Oncology* (JCO) and *Annals of Oncology* (AoO). Information of cut-off (database lock) date, publication date, type of the study and its sponsor has been extracted. Descriptive statistics, t-test and chi-square tests were used for statistical analyses.

Results: Overall, 652 articles (482 from JCO, 170 from AoO) has been identified - 63% (411) reported results of clinical trials, 47% (193) of them reporting data from clinical trials. Only 52.3% (341) of trials reported the cut-off date. Reports from clinical trials reported cut-off date more often than other studies (65.5% vs 29.9%, $p<0.001$). Median time from data cut-off to publication (PT) was 15.4 months (range 1.2-130.8), with PT of 12-24 months and >24 months being 45.2% (154) and 22.6% (77), respectively. Reports of studies other than clinical trials had PT>24m more often than clinical trials (36.1% vs 19%; $p=0.003$). Commercially sponsored studies reported cut-off date more often than academic studies (79.2% vs 41.4%; $p<0.001$) but there was no difference in PT depending on type of sponsor ($p=0.170$).

Conclusions: Despite presence of reporting guidelines, significant proportion of scientific publications do not report exact date of data cut-off or last follow-up what make difficult to assess topicality and maturity of data. Moreover, nearly one-quarter of publications report results that are older than 2 years. Causes leading to such disproportion and publication of outdated results may lead on the authors', editors' or publishers' side and need to be studied in more depth to ensure timely publication of relevant research data.

1763P The challenge for Cancer Trials Ireland (CTI) to sponsor NCI and non-EU sponsored trials in the EU

E. Mulroe[1], O. McLoughlin[2], S. O'Reilly[1], M. Morris[3], M. Lawler[4], I.D. Davis[5], D.A. Lacombe[6], T. Goulioti[7]

[1]Cancer Trials Ireland, Dublin, Ireland; [2]Quality & Training, Cancer Trials Ireland, Dublin, Ireland; [3]Northern Ireland Cancer Centre - Belfast Health & Social Care Trust, Belfast, UK; [4]Queen's University Belfast, Belfast, UK; [5]Eastern Health Clinical School, Monash University and Eastern Health, Box Hill, VIC, Australia; [6]DG Office, EORTC AISBL/IVZW - European Organisation for Research and Treatment of Cancer, Brussels, Belgium; [7]Clinical Research Department, Breast International Group (BIG) - AISBL, Brussels, Belgium

Background: The environment for academic clinical trials has become more challenging in the EU and beyond. There are a number of factors contributing, in particular the regulatory challenges. While Ireland and Northern Ireland governments signed an MOU with the US NCI Director in March 2021, solidifying a 25-year arrangement where Ireland and Northern Ireland is considered an NCI site and Irish hospitals are registered and Irish investigators are registered with CTEP, the practicalities of groups like CTI sponsoring NCI trials outside of the US are onerous.

Methods: Gathering experiences from our international partners (EORTC (EU), ANZUP (Australia) and BIG) where significant issues are reported in setting up NCI or other US-sponsored trials. The common thread is the lack of "regulatory harmony" in running international academic clinical trials in the EU with a non-EU sponsor.

Results: Approaches to GDPR in clinical trials are not aligned between the EU and non-EU. The experience of the Groups interviewed is that Standard Contractual Clause with regard to data transfer is a stumbling block. When working with the NCI, the OHRP are also involved and there are clear standards to follow as NCI trials are federally sponsored and funded. The Federalwide Assurance (FWA) is the only type of assurance currently accepted and approved by OHRP. Cancer Trials Ireland and other collaborative groups must have this in place in order to sponsor NCI trials outside of the US.

Conclusions: Public funding is not utilized to its optimal level in multinational academic trials. Propose greater collaboration at government level and mutual recognition agreements with regard to GDPR in clinical trials.

Background: The optimal timing of RT after RP for prostate cancer is uncertain. RADICALS-RT compared the efficacy and safety of adjuvant RT (aRT) versus an observation policy with salvage RT for early PSA failure (Obs+sRT). We previously reported an early outcome measure (OM): bPFS, and now have enough events to report on the primary OM, freedom from distant metastases (FFDM).

Methods: Patients with post-op PSA≤0.2ng/ml and ≥1 risk factor (pT3/4, Gleason 7-10, positive margins, or pre-op PSA≥10ng/ml) were randomised ≤22wk after RP to aRT or Obs+sRT for PSA failure: PSA ≥0.1ng/ml or 3 consecutive rises. Stratification factors were Gleason score, margin status, planned RT volume (prostate bed only, prostate bed + pelvis), RT schedule (52.5Gy/20f, 66Gy/33f) and centre. The primary OM was FFDM with >1200 pts needed for 80% power to detect an improvement from 90% to 95% at 10yr with aRT. Secondary OMs include overall survival, safety & patient reported OMs (1, 5, 10yr). Standard survival analysis methods were used.

Results: 1396 pts were randomised (697 aRT, 699 Obs+sRT) from Oct-2007 to Dec-2016 (82% UK, 13% Denmark, 4% Canada, 1% Ireland). Median age was 65yrs and 37% (517/1396) had a CAPRA-S score of 6+. Data were frozen May 2022 and median follow-up was 8yrs. 93% (650/697) aRT started RT within 5mo; 39% (270/699) Obs+sRT started RT. Median PSA at time of sRT was 0.2ng/ml. 24% (156/650) aRT and 27% (72/270) Obs+sRT reported HT with their RT. With 80 events, FFDM at 10 yrs was 93% for aRT v 90% for Obs+sRT (HR= 0.68 (95%CI 0·43-1·07, p=0·095). Overall survival at 10-yrs was 88% vs 87% (HR=0.98 (95%CI 0.67 to 1.44, p=0.92). Self-reported urinary incontinence and faecal incontinence were worse at 1yr for aRT (p<0.001).

Conclusions: RADICALS-RT is the largest study ever conducted addressing the value of adjuvant RT in prostate cancer. Final results from RADICALS-RT show no evidence of a meaningful benefit for aRT after RP in this patient group. Adjuvant RT increases risk of urinary & bowel morbidity. An observation policy with salvage RT for PSA failure should be the current standard after RP.

Clinical trial identification: NCT00541047.

Background: Xaluritamig is a novel bispecific XmAb® 2+1 T-cell engager with two STEAP1 binding sites designed to facilitate T-cell—mediated lysis of STEAP1-expressing cells. We report results from the dose exploration of xaluritamig monotherapy in a first-in-human study for patients (pts) with mCRPC.

Methods: Eligible pts had mCRPC refractory to prior novel hormonal therapy and 1—2 taxane regimens, ECOG 0—1, and adequate organ function. Xaluritamig was administered as an IV weekly (QW) or Q2W with various dose levels/schedules (DLs). Study objectives were to evaluate safety, tolerability, antitumor activity, PK, and determine the MTD and RP2D.

Results: As of 23 March 2023, 97 pts in 15 DLs received ≥1 dose of xaluritamig. Median (range) age was 67 (40—86) years; 67 pts (69.1%) had received > 3 prior lines of therapy. Treatment emergent adverse events (TEAEs) were reported in 100% of pts (grade ≥3, 74.2%); 95.9% reported treatment-related AEs (TRAEs) (grade ≥3, 52.6%). The most common AEs were cytokine release syndrome (CRS; 72.2%), fatigue (52.6%), anemia (45.4%), pyrexia (40.2%), and myalgia (39.2%). CRS was primarily grade 1 or 2, one event being grade 3 (no grade 4/5 CRS; cycle 1). In the DL15 QW cohort, 3 of 6 DLT evaluable subjects experienced DLTs, defining DL14 QW as the MTD. TRAEs leading to discontinuation occurred in 17.5% of pts. PSA50 (≥ 50% PSA decline) responses occurred in 42 pts (47.2%); PSA90, in 24 pts (27.0%) (Table). PSA responses were more frequent at higher DLs (DL8—15) than in lower DLs (DL1—7). Overall, RECIST responses included 15 (22.7%) confirmed PR and 30 (45.5%) SD. At higher DLs, 14 pts (38.9%) had confirmed PR and 12 (33.3%) SD. Preliminary PK showed dose-proportional increase in exposure with a mean terminal half-life of approximately 3-4 days.

Table: 1765O

	Lower DLs (DL 1−7)	Higher DLs (DL8−15)	Overall
PSA evaluable	N = 43	N = 46	N = 89
PSA ≥ 50%, n (%)	17 (39.5)	25 (54.3)	42 (47.2)
PSA ≥ 90%, n (%)	8 (18.6)	16 (34.8)	24 (27.0)
RECIST evaluable	N = 30	N = 36	N = 66
PR, n (%)	1 (3.3)	14 (38.9)	15 (22.7)
SD, n (%)	18 (60.0)	12 (33.3)	30 (45.5)

Conclusions: Xaluritamig was tolerable with low-grade CRS (occurring primarily cycle 1) with encouraging preliminary efficacy in heavily pretreated pts with mCRPC.

Clinical trial identification: NCT04221542.

Background: RT + ltADT (18-36 months) is a standard-of-care in the treatment of HR/LA-PC. Efforts are ongoing to evaluate intensification of systemic therapy beyond ADT to further improve outcomes. We evaluated 5-year metastasis-free survival (MFS) rates in subgroups of patients (pts) with HR/LA-PC to define patients more likely to benefit from treatment intensification, and guide design and interpretation of adjuvant trials in HR/LA-PC.

Methods: IPD from patients with HR/LA-PC (as defined by any of the following 3 risk factors [RFs]: Gleason ≥8, ≥cT3, PSA >20; or cN1) treated with RT+ltADT in RCTs collated by ICECaP were pooled. 5-year MFS was calculated by Kaplan-Meier method in various risk-groups and by number of RFs. Multivariable Cox regression estimated hazard ratios (HR) for the 3 RFs and cN1 disease, stratified by trials and years of enrolment. MFS was defined as distant metastasis on conventional imaging or death from any cause.

Results: 3604 pts with HR/LA-PC treated with RT+ltADT on 10 randomized trials between 1987-2016 were eligible. Median age was 68 and median PSA was 24 (IQR 12-48). 2602 (72%) were cT3/4, 1942 (54%) had Gleason 8-10 and 422 pts (12%) had cN1 disease. The HR for MFS was 1.5 (95% CI 1.4-1.7) for Gleason ≥8, 1.2 (1.1-1.4) for PSA>20, 1.2 (1.1-1.4) for cT3/T4, and 1.8 (1.5-2.1) for cN1. 5-year MFS (%, 95% CI) rate was 83 (81-85), 78 (75-80) and 77 (73-80) for pts with 1, 2 and 3 RFs respectively, and 68 (63-72) for cN1 disease. Table shows 5-yr MFS rates in various subgroups.

Table: 1770O

5-yr MFS (%, 95% CI)	Gleason 7		Gleason 8-10	
	Tx1-2	T3-4	Tx1-2	Tx3-4
PSA <10	-	87 (82-91)	82 (76-87)	75 (69-80)
PSA 10-20	-	81 (75-85)	84 (77-89)	79 (73-83)
PSA >20	84 (79-87)	80 (76-83)	74 (67-79)	77 (73-80)
cN1	76 (67-82)		64 (58-69)	

Conclusions: Pts with HR/LA-PC treated with RT+ltADT who had ≥2 RFs or cN1 disease had 5-yr MFS rates <80% and are the ones most likely to benefit from treatment intensification. This will guide patient counselling and the design and interpretation of adjuvant trials in HR/LA-PC.

Background: Enzalutamide (ENZ) + leuprolide acetate (L) and ENZ alone delayed metastasis-free survival (MFS) vs placebo (P) + L in high-risk BCR nmHSPC in the phase 3 EMBARK (NCT02319837) trial. Pt-reported outcomes (PROs) provide a pt perspective on disease/treatment (Tx) experience not captured by clinical assessment.

Methods: nmHSPC pts with high-risk BCR (prostate-specific antigen [PSA] doubling time $\leq$9 months, screening PSA $\geq$2 ng/mL above nadir post radiotherapy or $\geq$1 ng/mL post radical prostatectomy) were randomized (1:1:1) to ENZ + L, ENZ alone, and P + L. PROs were assessed at baseline (BL) and every 12 weeks until development of metastasis or death. The main objectives were to assess Tx effects in time to first and confirmed (at next visit) clinically meaningful deterioration (TTFD/TTFCD) as measured with the Brief Pain Inventory Short Form (BPI-SF) worst pain and Functional Assessment of Cancer Therapy-Prostate (FACT-P) total score using predefined thresholds. Other objectives were: Tx effects in TTFD and TTFCD measured by the European Organisation for Research and Tx of Cancer QoL Questionnaire-Prostate 25 (QLQ-PR25) and European QoL 5-Dimensions 5-Levels (EQ-5D-5L) visual analogue scale (VAS). Comparisons were made for ENZ + L vs P + L and ENZ alone vs P + L. Intent-to-treat population was analysed.

Results: At BL, 327—332 pts per group completed the PRO questionnaire; completion rates were 85—95%. No significant differences in TTFD or TTFCD were seen among Tx groups vs P + L in FACT-P total score, BPI-SF worst pain, or EQ-5D-5L VAS. In QLQ-PR25, TTFCD for sexual activity was significantly longer with ENZ alone vs P + L; TTFCD for hormone Tx-related symptoms was significantly shorter with ENZ + L vs P + L (Table).

Table: 1766MO

PRO	Months, median			HR (95% CI)	
	ENZ + L	ENZ	P + L	ENZ + L vs P + L	ENZ vs P + L
BPI-SF					
Worst pain					
TTFD	13.9	16.6	19.4	1.08 (0.89—1.30)	1.09 (0.90—1.31)

*$p<0.05$

Conclusions: ENZ + L or ENZ alone improved MFS without negatively impacting global HRQoL or clinical pain progression, vs P + L in nmHSPC pts. Sexual activity may be better preserved with ENZ alone vs P + L.

Clinical trial identification: NCT02319837.

Background: Effective prognostication will allow better targeting of treatment (Rx) combinations for advanced PCa. A MMAI prognostic test (ArteraAI Prostate) was recently developed in localized PCa. We aimed to validate ArteraAI in advanced PCausing final data from 3 STAMPEDE trials (NCT00268476).

Methods: The MMAI model used digitized whole scan images from new H&E core prostate biopsies (PB), local Gleason score (GS), tumor stage (T), age and pre-ADT serum PSA. Fine-Gray/Cox regression adjusted for Rx allocation and cumulative incidence analyses were performed to evaluate associations with endpoints, as defined in STAMPEDE, for both continuous score (per standard deviation increase) and categorical (quartile,Q). PCa-specific mortality (PCSM) was the endpoint of primary interest. Death not from PCa was treated as a competing risk. HR, 95% CI, and $p<0.001$ (denoted by *) are reported.

Results: Of 3879 patients recruited Oct 2005 — Jan 2014 to ADT +/- radiotherapy (RT) alone or + Doc +/-zoledronic acid or + AAP, 3725 consented to tissue analysis, 2079 had H&E with sufficient tumor of which 1964 had all of GS, T, pre-ADT PSA (918 M0, 1046 M1, median follow-up: 7.8 years, yr). ArteraAI was strongly associated with PCSM (HR 1.67, 1.5-1.84*), overall survival (1.51,1.4-1.63*), failure-free survival (1.48, 1.38-1.59*), and metastatic progression-free survival (1.59, 1.46-1.73*). ArteraAI Q4 v Q1-3 showed similar results for all endpoints, including PCSM (2.27, 1.95-2.65*). Of component clinical variables, p* for PCSM were PSA Q4 v Q1-3 (1.8, 1.54-2.11), Gleason 8-10 v <=7 (1.64, 1.36-1.98), and T4 v T1-2 (1.77, 1.36-2.32). ArteraAI Q4 v Q1-3 had more PCSM events at 5 yr: 16% (11-21) v 6% (4-8) in M0, 58% (52-64) v 40% (36-43) in M1 and notably for M0 treated with ADT +/- RT+ AAP: 18% (9-28) v 2% (0-4%).

Conclusions: ArteraAI successfully validated in STAMPEDE with stronger prognostic associations than individual clinical variables. The MMAI model identified poor prognostic features in PB from high-risk M0 and M1 PCa.

Clinical trial identification: NCT00268476.

1768MO Incidence of fracture related hospitalisations in men with de novo high risk localised and metastatic hormone sensitive prostate cancer: Analysis of routinely collected healthcare data from the STAMPEDE docetaxel and zoledronic acid comparisons

C. Jones[1], P. Dutey-Magni[2], L.R. Murphy[2], M. Murray[2], J.E. Brown[3], E. McCloskey[4], M.K. Parmar[2], N.D. James[5], M.R. Sydes[2], L.C. Brown[2], N.W. Clarke[6], A. Sachdeva[7]

[1]Department of Surgery, The Christie NHS Foundation Trust, Manchester, UK; [2]Clinical Trials, MRC - Medical Research Council Clinical Trials Unit - University College London (UCL), London, UK; [3]Clinical Oncology Department, University of Sheffield Medical School, Sheffield, Yorkshire, UK; [4]Department of Oncology and Metabolism, University of Sheffield Medical School, Sheffield, UK; [5]Prostate and Bladder Cancer Research Department, ICR - Institute of Cancer Research, London, UK; [6]Department of Urology, The Christie and Salford Royal NHS Foundation Trusts, Manchester, UK; [7]Department of Surgery, The Christie NHS Foundation Trust, Manchester, UK

Background: Androgen deprivation therapy (ADT) is the mainstay medical treatment for men with locally advanced (M0) and metastatic hormone sensitive prostate cancer (M1 mHSPC): bone loss and increased fracture risk are recognised complications. The STAMPEDE trial compared patients (pts) treated with ADT ± docetaxel (Doc) ± zoledronic acid (ZA). No survival benefit was demonstrated with the addition of ZA however, long term effects on bone health and fracture risk were not formally collected within the trial. Health systems data through Hospital Episode Statistics (HES) for pts in England provides data with demonstrated integrity and provenance beyond standard trial follow up permitting evaluation of fracture risk.

Methods: HES data were obtained (up to Mar 2021) for pts randomised to ADT (Arm A), ADT+ZA (Arm B), ADT+Doc (Arm C) and ADT+Doc+ZA (Arm E). ZA (4mg) was given as six 3 weekly cycles, then 4 weekly for 2 years. Fracture related hospitalisations (FRH) were identified using a prespecified coding framework of ICD10 diagnosis and OPCS procedure codes. Flexible parametric competing risks models were used to estimate 5- and 10yr cumulative incidence of FRH and subdistribution hazard ratios (SDHR).

Results: Linked data were available for 2,042 (734 M0, 1,308 M1) out of 2,140 eligible pts (95%). The 5-year cumulative incidence of FRH for M1 and M0 pts treated with ADT were 23% (95% CI 19-28%) and 11% (95% CI 8-15%) respectively. The 10-year cumulative incidence with ADT in M0 pts was 26% (95% CI 20-33%). Addition of ZA significantly reduced the incidence of FRH in M1 pts (SDHR 0.73, 95% CI 0.55-0.97; $p=0.015$). Data were inconclusive in M0 pts (SDHR 0.88, 95% CI 0.59-1.32, $p=0.549$). Doc had no significant effect on FRH in both M1 ($p=0.264$) and M0 ($p=0.570$), with no evidence of interaction between ZA and Doc in both M1 ($p=0.526$) and M0 ($p=0.805$).

Conclusions: High incidence of 10yr fracture related hospitalisations was observed in STAMPEDE trial participants with either M0 or M1 prostate cancer. Addition of ZA reduced risk of FRH in people with M1 disease but not with M0 disease. These data support the use of bone protection agents to reduce fracture risk in men with mHSPC.

Clinical trial identification: NCT00268476.

Background: Pts with mCRPC with progressive disease (PD) during 2nd generation hormonal agent therapy typically receive chemo next. Additional therapies are needed in this setting. Pembro + enza had antitumor activity in pretreated mCRPC in early phase studies. KEYNOTE-641 (NCT03834493) evaluated pembro + enza vs placebo (pbo) + enza in pts with chemo-naïve mCRPC with/without prior abiraterone (abi).

Methods: Eligible pts were male, aged ≥18 years, had ECOG PS ≤1, had confirmed mCRPC with no prior chemo except docetaxel in the hormone-sensitive setting, and had intolerance to or PD during prior abi or no prior abi. Pts were randomized 1:1 to pembro 200 mg or pbo IV Q3W for ≤35 cycles + enza 160 mg orally daily. Dual primary endpoints were overall survival (OS) and radiographic progression-free survival (rPFS) per PCWG-modified RECIST 1.1 by blinded independent central review. Time to initiation of first subsequent anticancer therapy (TFST) was a key secondary endpoint. Safety/tolerability was a secondary endpoint.

Results: 1244 pts were enrolled between Aug 21, 2019, and Jun 10, 2022 (n=621 to pembro + enza; n=623 to pbo + enza). As of Dec 12, 2022, the median (range) follow-up time at first prespecified interim analysis was 27.6 mo (6.1−39.8). 60.9% of all pts had prior abi and 29.1% had prior docetaxel, balanced between arms. The dual primary endpoints of rPFS (median 10.4 mo with pembro + enza vs 9.0 mo with pbo + enza; HR 0.98, 95% CI 0.84−1.14; P=0.41) and OS (median 24.7 mo vs 27.3 mo; HR 1.04, 95% CI 0.88−1.22; P=0.66) were not met. The prespecified boundary for futility for OS was crossed and the study was stopped. Median TFST was 13.2 mo vs 12.6 mo, respectively (HR 0.95, 95% CI 0.83−1.09). Any-grade and grade ≥3 treatment-related AEs occurred in 77.9% and 31.2% of 615 pts with ≥1 dose pembro + enza and 61.6% and 10.8% of 620 pts with ≥1 dose pbo + enza. 3 treatment-related deaths occurred with pembro + enza and none with pbo + enza.

Conclusions: Pembro + enza did not significantly improve efficacy outcomes vs pbo + enza in pts with mCRPC with/without prior abi. Pembro + enza was associated with more treatment-related AEs vs pbo + enza; no new safety signals were observed.

Clinical trial identification: NCT03834493.

Background: New therapeutic options are needed to delay disease progression for pts with mHSPC. The combination of pembro + enza has shown antitumor activity in pts with metastatic prostate cancer. The phase 3 KEYNOTE-991 study (NCT04191096) investigated pembro or placebo (pbo) + enza + ADT in pts with next-generation hormonal agent (NHA)-naïve mHSPC.

Methods: Eligible pts (aged ≥18 yrs, ECOG PS ≤1) had confirmed mHSPC (≥2 bone lesions and/or visceral disease, verified centrally), no prior NHA, and had completed any prior docetaxel (≤6 cycles) ≤2 mo from randomization. Pts were randomized 1:1

to receive pembro 200 mg or pbo IV Q3W for ≤35 cycles + enza 160 mg orally daily + continuous ADT (if no history of bilateral orchiectomy). Dual primary endpoints were radiographic progression-free survival (rPFS) per PCWG-modified RECIST 1.1 by blinded independent central review and overall survival (OS). Key secondary endpoints included time to initiation of first subsequent anticancer therapy (TFST) and time to first symptomatic skeletal-related event (TTSSRE). Safety was a secondary endpoint.

Results: Between Mar 2, 2020, and Aug 9, 2021, 626 pts were randomized to pembro + enza and 625 to pbo + enza. As of Oct 31, 2022, the median (range) follow-up time at first prespecified interim analysis was 21.1 mo (14.8−32.0). Baseline characteristics were generally balanced between arms; ∼10% of pts received prior docetaxel in each arm. The primary endpoint of rPFS for pembro + enza vs pbo + enza was not met (median not reached [NR] vs NR, HR 1.20, 95% CI 0.96−1.49, P=0.95). Median OS was NR vs NR (HR 1.16, 95% CI 0.88−1.53). Median TFST was NR in both arms (HR 1.24, 95% CI 1.01−1.54). Median TTSSRE was NR in both arms (HR 0.89, 95% CI 0.61−1.30). Serious AEs occurred in 40.3% vs 23.2% of pts with pembro + enza vs pbo + enza. Any-grade and grade ≥3 treatment-related AEs occurred in 88.0% vs 67.0% and 41.8% vs 13.9% of pts, respectively.

Conclusions: The study was stopped for futility. The addition of pembro to enza plus ADT did not improve rPFS or OS in pts with NHA-naïve mHSPC and was associated with more serious and treatment-related AEs vs enza plus ADT.

Clinical trial identification: NCT04191096.

Background: Prior work from ICECaP (Xie et al, JCO 2017; ICECaP-1) showed that MFS is a valid surrogate for OS for patients (pts) with LPC treated predominantly before 2004, when docetaxel became available for metastatic castrate-resistant prostate cancer (mCRPC). We sought to validate this finding in a more contemporary era (ICECaP-2) with greater availability of docetaxel and AR-pathway inhibitors (ARPIs) for mCRPC.

Methods: Eligible trials for ICECaP-2 were those providing individual patient data (IPD) after publication of ICECaP-1 and evaluating adjuvant/salvage therapy for LPC, and which collected MFS and OS data. MFS was defined as distant metastases or death from any cause, and OS defined as death from any cause. Surrogacy was evaluated using a meta-analytic two-stage validation model, with an R^2 ≥0.7 defined *a priori* as clinically relevant.

Results: 15,164 IPD from 14 trials were included in ICECaP-2. For surrogacy condition 1, Kendall's tau was 0.92 for MFS with OS at the patient-level, and R^2 from weighted linear regression (WLR) of 8-yr OS on 5-yr MFS was 0.73 (95% CI 0.53-0.82) at the trial level. For condition 2, R^2 was 0.83 (0.64-0.89) from WLR of log (HR)-OS on log (HR)-MFS. The surrogate threshold effect on OS was an HR(MFS) of 0.81. Comparisons between ICECaP-1 and ICECaP-2 are shown in the table.

Table: 1773P

	ICECAP-1	ICECAP-2
N	12,712 pts (19 trials)	15,164 pts (14 trials)
Years of enrolment (%)		
1987-2004	11539 (91)	4716 (31)
2005-2009	1111 (9)	6059 (40)
2010-2016	62 (1)	4389 (29)
Median follow-up, yrs	9.9	8.3
Median time from metastasis to death (yrs)	1.9	3.1
No. of OS events (%)	5350 (42)	3168 (21)
No. of MFS events (%)	5733 (45)	3953 (26)
Individual-level surrogacy measures		
Kendall's tau	0.91	0.92
R^2 WLR 8-year-OS on 5-year MFS	0.83	0.73
Trial-level surrogacy measures		
R^2 WLR log(HR)-OS on log(HR)-MFS	0.92	0.83
Surrogate threshold effect	0.88	0.81

Conclusions: MFS remains a valid surrogate for OS in pts with LPC treated in a contemporary era with greater access to docetaxel and ARPIs for mCRPC. Surrogacy

effects were similar to those observed in ICECaP-1. This supports the use of MFS as the primary outcome measure for ongoing trials in LPC.

1774P PC-PEP, a comprehensive daily six-month home-based prostate cancer: Patient empowerment program improves quality of life, physical fitness, and urinary function outcomes among prostate cancer patients with localized disease - Secondary analyses of a randomized clinical trial

G. Ilie[1], R. Rutledge[2]

[1]*Faculty of Medicine, Urology, Dalhousie University, Halifax, NS, Canada;* [2]*Radiation Oncology, Dalhousie University, Halifax, NS, Canada*

Background: In a recently published manuscript we demonstrated significant decreases in mental distress, anxiety and depression compared to standard of care following a 6m daily comprehensive program developed with patient engagement. Here we conduct secondary analyses examining the effects of this Prostate Cancer-Patient Empowerment Program (PC-PEP) on patient-reported urinary, bowel, sexual, hormonal and physical function among men scheduled for curative prostate cancer (PC) treatment.

Methods: This crossover randomized clinical trial evaluated 128 men aged 50−82 yr scheduled for curative prostate cancer surgery or radiotherapy (± hormone), 66 received the 6-mo PC-PEP intervention and 62 were randomized to standard of care for 6m and received PC-PEP to the end of the year. PC-PEP comprises regular physical strength and PFMT training, daily dietary advice, bio-feedback stress reduction, and social networking. Weekly online compliance surveys, the International Prostate Symptom Score (IPSS), Expanded Prostate Cancer Index Composite (EPIC), and SF-12 at baseline, 6 and 12m were completed. MLM analyses were used to evaluate the results.

Results: Baseline patient characteristics and outcomes between the two groups were comparable, and weekly compliance for PC-PEP was high among both groups (early v. late intervention). At six months, the PC-PEP group had improved IPSS bother score, EPIC Urinary Incontinence, EPIC Irritative/Obstructive score, physical fitness (lower weight and BMI), SF-12 physical, and mental health function when compared to the control group ($p=0.004$, $p=0.001$, $p=0.008$, $p=0.001$, $p=0.002$, and $p=0.003$ respectively). Analyses revealed that providing the intervention early or late was equally beneficial to patients. No other significant results emerged.

Conclusions: PC-PEP significantly improves lower urinary tract symptoms, physical function and overall quality of life among men scheduled for curative PC treatment compared to standard of care. The program is being currently tested in an international phase 4 trial.

Clinical trial identification: NCT03660085.

1775P A newly-developed deep-learning algorithm: NAFNet outperforms ResNet50 for predicting adverse pathology events and biochemical recurrence time using MRI from prostate cancer patients

Z. Liu[1], W. Gu[1], F. Wan[1], X. Liu[2], Z. Chen[2], B. Dai[1]

[1]*Department of Urology, Fudan University Shanghai Cancer Center, Shanghai, China;* [2]*Department of Radiology, Fudan University Shanghai Cancer Center, Shanghai, China*

Background: Although deep learning algorithms have shown promising results in medical imaging, their application in predicting adverse pathology events (AP) and biochemical recurrence-free survival (bRFS) in prostate cancer patients is relatively lagging. Here we aimed to evaluate the performance of a novel deep learning network, NAFNet, in predicting AP and bRFS based on pre-treatment multiparametric MRI imaging.

Methods: This multicentre study enrolled 514 prostate cancer patients from six tertiary hospitals throughout China from 2017 and 2021. A total of 367 patients from Fudan University Shanghai Cancer Centre with whole-mount histopathology of radical prostatectomy specimens were assigned to the internal set, and cancer lesions were delineated with whole-mount pathology as the reference. The external test set included 147 patients with BCR data from five other institutes. The prediction model (NAFNet-classifier) and integrated nomogram (DL-nomogram) were constructed based on NAFNet. To evaluate the predictive ability of DL-nomogram for AP, we compared DL-nomogram with radiology score (PI-RADS), and clinical score (Cancer of the Prostate Risk Assessment score (CAPRA)). ROC curves and DCA analyses were performed to assess the AP prediction ability of various models, and survival analyses were also made for bRFS.

Results: After training and validation in the internal set, ROC curves in the external test set showed that NAFNet-classifier alone outperformed ResNet50 in predicting AP (AUC:0.799, 95%CI:0.724-0.873 vs. AUC:0.703, 95%CI:0.618-0.787, $P=0.013$). The DL-nomogram, including the NAFNet-classifier, clinical T stage and biopsy results, showed the highest AUC (0.915, 95% CI: 0.871-0.959) and accuracy (0.850) compared with the

PI-RADS and CAPRA scores. Additionally, the DL-nomogram outperformed the CAPRA score with a higher C-index (0.732, P<0.001) in predicting bRFS.

Conclusions: Our newly-developed deep learning network, NAFNet, combined with clinical factors, accurately predicted AP and poor prognosis in prostate cancer patients from preoperative MRI imaging, providing a potential AI tools in medical imaging risk stratification.

1776P Body composition in adult life and prostate cancer (PCa) incidence and mortality: The PROCA-life study

M. Støyten[1], T. Knutsen[2], E. Stikkbakke[3], I. Agledahl[2], T. Wilsgaard[4], A-E. Eggen[4], E. Richardsen[5], E. Giovannucci[6], I. Thune[7], H. Sagstuen Haugnes[8]

[1]Institute for Clinical Medicine, UiT The Arctic University of Norway, Tromso, Norway; [2]Department of Urology, University Hospital of North Norway, Tromso, Norway; [3]Department of Oncology, UiT The Arctic University of Norway, Tromso, Norway; [4]Institute of Community Medicine, UiT The Arctic University of Norway, Tromso, Norway; [5]Department of Pathology, University Hospital of North Norway, Tromso, Norway; [6]Department of Epidemiology, Harvard T.H. Chan School of Public Health, Boston, MA, USA; [7]Department of Oncology, University of Oslo, Institute of Clinical Medicine, Oslo, Norway; [8]Department of Oncology, University Hospital of North Norway, Tromso, Norway

Background: The global increase in obesity parallels the increase in PCa incidence, but the role of excess weight and weight change throughout adult life and their implications for PCa risk and prognosis are still under debate. We studied whether pre-diagnostic body mass index (BMI) and weight change is linked to PCa risk and prognosis.

Methods: A total of 16 879 healthy men were included to study PCa risk and prognosis in the Prostate Cancer Study throughout life (PROCA-*life),* based on those who participated in the prospective cohort Tromsø Study (1994-2016). Pre-diagnostic BMI and weight change (relative weight change in percent of baseline weight between two waves of the Tromsø study) during follow-up were measured. Detailed information from histopathological and clinical medical records for PCa cases were obtained. Cox proportional hazard and logistic regression models were used to estimate hazard ratios (HRs) and odds ratios (ORs) for the associations between pre-diagnostic measurements of BMI and weight change during follow-up, and PCa risk and overall and PCa specific mortality. Regression models were used to evaluate incidence rate ratios (IRR).

Results: Overall, the participants had a median age at study entry of 44 years, 46.0% were overweight and 13.8% were obese. In total 904 men developed PCa during follow-up, with a median age at diagnosis of 68 years. The incidence rates for PCa increased from 1995 to 2019 (overall IRR 2.27, 95% CI 1.82-2.83). We observed that men with a pre-diagnostic BMI $\geq$ 30kg/m^2 at study entry, and who had a weight gain $\geq$ 5% during follow-up, had a three-fold increased risk for incident PCa (HR 2.94, 95% CI 1.36-6.36). Overweight was associated with lower Gleason grade (OR 0.64, 95% CI 0.43-0.96) and lower Prostate Specific Antigen (OR 0.69, 95% CI 0.48-0.99). Overall, 311 PCa cases died, of whom 154 was PCa related deaths (17%). Pre-diagnostic obesity was associated with PCa-specific death (HR 1.73, 95% CI 1.03-2.91).

Conclusions: Our observation that weight gain in adult pre-diagnostic obese men was associated with increased risk for incident PCa, and that pre-diagnostic obesity increased the risk of PCa-mortality, support the importance to combat excess weight gain in the general population.

Background: The primary analysis of EMBARK demonstrated that after a median follow-up of 60.7 months metastasis-free survival for enza + leuprolide acetate (LA; HR 0.42; 95% CI, 0.30–0.61; p<0.0001) and enza monotherapy (HR 0.63; 95% CI, 0.46–0.87; p=0.0049) was clinically meaningful and statistically superior to placebo + LA. Here, we present other non-key secondary efficacy endpoints for enza monotherapy vs placebo + LA.

Methods: EMBARK (NCT02319837) is a phase 3 study of patients (pts) with high-risk BCR: prostate-specific antigen (PSA) doubling time $\leq$9 months and PSA $\geq$2 ng/mL above nadir post-radiotherapy (RT) or $\geq$1 ng/mL after radical prostatectomy (RP) $\pm$ postoperative RT. Pts were randomized (1:1) to 160 mg/day enza monotherapy (open-label) or placebo + LA (LA alone). LA 22.5 mg was administered every 12 weeks. If the PSA was <0.2 ng/mL at Week 36, tx was suspended at Week 37 and restarted when PSA was $\geq$2 ng/mL for pts with primary RP, and $\geq$5 ng/mL for pts without RP. Secondary endpoints included time to: distant metastasis, symptomatic progression, first symptomatic skeletal event, and resumption of any hormonal therapy following tx suspension.

Results: 713 pts were eligible and randomized (enza monotherapy, n=355; LA alone, n=358). Median (range) tx duration excluding tx suspension was 45.9 (0.4–88.9) months for enza monotherapy and 35.4 (0.7–85.7) months for LA alone. Time to: distant metastasis (HR 0.61; 95% CI, 0.41–0.92; p=0.0171), symptomatic progression (HR 0.62; 95% CI, 0.49–0.79; p<0.0001), and first symptomatic skeletal event (HR 0.42; 95% CI, 0.23–0.79; p=0.0057) all favored enza monotherapy vs. LA alone. Time to resumption of any hormonal therapy after tx suspension favored LA alone vs enza monotherapy (HR 1.66; 95% CI, 1.38–1.98; p<0.0001). All p-values are nominal.

Conclusions: In pts with high-risk BCR, enza monotherapy showed clinically meaningful delays in time to distant metastasis, symptomatic progression, and time to first symptomatic skeletal event vs LA alone. After tx suspension, enza monotherapy shortened time to resumption of any hormonal therapy vs LA alone. Further work is needed to understand the risks and benefits of enza monotherapy vs other options for high-risk BCR.

Clinical trial identification: NCT02319837.

Background: In the phase 3 EMBARK trial, after a median follow-up of 60.7 months, enza + LA (HR 0.42; 95% CI, 0.30–0.61; p<0.0001) and enza monotherapy (HR 0.63; 95% CI, 0.46–0.87; p=0.0049) demonstrated statistically superior and clinically meaningful improvements in metastasis-free survival vs placebo (pbo) + LA. Here, we present other non-key secondary efficacy endpoints for enza + LA vs pbo + LA.

Methods: EMBARK (NCT02319837) is a study of patients (pts) with high-risk biochemical recurrence (BCR): prostate-specific antigen (PSA) doubling time ≤9 months and PSA ≥2 ng/mL above nadir post-radiotherapy (RT) or ≥1 ng/mL after radical prostatectomy ± postoperative RT. Pts were double-blinded and randomized (1:1) to enza 160 mg/day + LA or pbo + LA (LA alone). LA 22.5 mg was administered every 12 weeks. If the PSA at Week 36 was <0.2 ng/mL, tx was suspended at Week 37 and restarted when PSA was ≥2 ng/mL for pts with primary RP, and ≥5 ng/mL for pts without RP. Secondary endpoints included time to: distant metastasis, resumption of any hormonal therapy after tx suspension, castration resistance, symptomatic progression, and first symptomatic skeletal event.

Results: 713 pts were eligible and randomized into the study (enza + LA, n=355; LA alone, n=358). Median (range) tx duration excluding tx suspension was 32.4 (0.1–83.4) months for enza + LA and 35.4 (0.7–85.7) months for LA alone. Time to: distant metastasis (HR 0.44; 95% CI, 0.28–0.69; p=0.0002), resumption of any hormonal therapy after tx suspension (HR 0.69; 95% CI, 0.58–0.83; p<0.0001), castration resistance (HR 0.09; 95% CI, 0.05–0.16; p<0.0001), symptomatic progression (HR 0.55; 95% CI, 0.43–0.70; p<0.0001), and first symptomatic skeletal event (HR 0.26; 95% CI, 0.13–0.55; p=0.0001) favored enza + LA vs LA alone. All p-values are nominal.

Conclusions: In pts with high-risk BCR, enza + LA vs LA alone demonstrated clinically meaningful delays in time to: distant metastasis, resumption of any hormonal therapy after tx suspension, castration resistance, symptomatic progression, and first symptomatic skeletal event. If approved, enza combination may represent a new standard of care for pts with high-risk BCR.

Clinical trial identification: NCT02319837.

Background: Salvage radiotherapy (SRT) is one of the cornerstone for treatment of biochemical relapse (BR) after radical prostatectomy (RP). One randomized controlled trial suggested that next generation imaging (NGI) may have a significant impact on patients management in this scenario. Nonetheless, how to best manage oligometastatic patients identified by PSMA PET imaging requires additional investigation. PSICHE (NCT05022914) is a prospective multicentric trial aimed to test a [68Ga]Ga-PSMA-11 PET/CT imaging tailored strategy.

Methods: Patients affected by biochemical relapse post RP (defined as PSA >0.2 ng/ml, <1 ng/ml) underwent [68Ga]Ga-PSMA-11 PET/CT imaging. After staging, management was performed according to a pre-defined algorithm. Observation and re-staging at further PSA progression were proposed to patients with negative PSMA and previous postoperative RT. Prostate bed SRT was proposed to all patients with a negative staging or positive imaging within prostate bed. Stereotactic body radiotherapy (SBRT) to all sites of disease was used for all patients with pelvic nodal recurrence (nodal disease < 2 cm under aortic bifurcation) or oligometastatic disease. Androgen deprivation therapy +/- androgen receptor targeted agent was provided in case of widespread metastatic disease. In the present analysis, we report early biochemical analysis focusing on complete biochemical response (PSA ≤0.2 ng/ml) and biochemical response (PSA ≤50% if compared to baseline value before treatment). Gastrointestinal (GI) or genitourinary (GU) toxicity was assessed according to CTCAE v 4.0.

Results: Overall, 110 patients were included in the current analysis. At 3 months after treatment, complete biochemical response and biochemical response were detected in 45.4% and 53.6% of patients, respectively. Seven patients had G1 GI toxicity, GU toxicity was reported in 30 patients (only 3 G2 adverse events, overall). No G>2 toxicity was reported.

Conclusions: A PSMA targeted treatment strategy led to promising results and was well tolerated within a prospective multicentric trial.

Clinical trial identification: NCT05022914.

1780P The health inequality impact of darolutamide for non-metastatic castration-resistant prostate cancer: A distributional cost-effectiveness analysis

J. Janssen[1], T. Flottemesch[1], I. Brewer[1], P. Sullivan[1], J. Partridge[2]

[1]HEOR, PRECISIONheor, Bethesda, MD, USA; [2]Global Market Access, Bayer US LLC, Whippany, NJ, USA

Background: In the backdrop of keener scrutiny of health equity issues, the impact of a new intervention on inequality in health outcomes is increasingly viewed as an element in health technology assessment. Non-Hispanic (NH) Black patients are disproportionally affected by non-metastatic castration-resistant prostate cancer (nmCRPC). Darolutamide is an approved treatment for nmCRPC and was shown to be effective and safe among NH-Black patients in the ARAMIS trial. The objective of this study was to quantify the health inequality impact of darolutamide+ androgen-deprivation therapy (ADT) relative to ADT for nmCRPC in the U.S. by means of a distributional cost-effectiveness analysis.

Methods: With a decision model, the quality-adjusted life years (QALYs) and costs were estimated for NH-White, NH-Black, Asian, and Hispanic patients. The degree of differences in QALYs among these subgroups was expressed with Atkinson relative inequality indices (0 = equal outcomes and 1 = maximum inequality between subgroups) for both strategies. Their difference was defined as the inequality impact of darolutamide among treated patients. Subtracting equally distributed health opportunity costs from the QALY gains with darolutamide facilitated calculation of the overall health inequality impact across population subgroups.

Results: Darolutamide+ADT resulted in an additional 1.04 (95% confidence interval 0.57; 1.49) QALYs per treated patient relative to ADT, with the greatest gain observed among NH-Black patients (1.48 QALYs (0.49; 2.72)). The relative inequality in QALYs among patients reduced by 66%, from an inequality score of 0.032 (0.004; 0.080) with ADT to 0.011 (0.000; 0.049) with darolutamide+ADT. Factoring in health opportunity costs, treatment of eligible nmCRPC patients with darolutamide resulted in the largest net gain in QALYs among the NH-Black population, thereby having a favorable impact on inequalities in quality adjusted life expectancy.

Conclusions: Darolutamide+ADT for the treatment of nmCRPC results in greater health outcomes than ADT, and reduces inequality in health outcomes across subgroups according to race and ethnicity in the U.S.

1781P Health-related quality of life (HRQoL) deterioration-free survival (DetFS) by prostate-specific antigen (PSA) decline in darolutamide (DARO)-treated patients with nonmetastatic castration-resistant prostate cancer (nmCRPC) from ARAMIS

A.K. Morgans[1], C. Sweeney[2], C. Wallis[3], S. Halabi[4], A.J. Armstrong[5], A.F. Mohamed[6], P. Adorjan[7], F. Verholen[8], S. Srinivasan[9], M-O. Grimm[10]

[1]Medicine Department, Dana Farber Cancer Institute, Boston, MA, USA; [2]University of Adelaide, South Australian immunoGENomics Cancer Institute, Adelaide, SA, Australia; [3]Division of Urology, Department of Surgery, University of Toronto and Mount Sinai Hospital and University Health Network, Toronto, ON, Canada; [4]Biostatistics and Bioinformatics, Duke University Medical Center, Durham, NC, USA; [5]Medicine, Duke Cancer Center, Durham, NC, USA; [6]Market Access Oncology Department, Bayer HealthCare, Whippany, NJ, USA; [7]Medical Lead Oncology, Bayer Consumer Care AG, Basel, Switzerland; [8]Medical Affairs - GU Franchise, Bayer Consumer Care AG, Basel, Switzerland; [9]Statistics, Bayer HealthCare, Whippany, NJ, USA; [10]Urology Department, Jena University Hospital, Jena, Germany

Background: In ARAMIS (NCT02200614), DARO plus androgen-deprivation therapy (ADT) significantly increased metastasis-free survival by nearly 2 years and reduced the risk of death by 31% in patients (pts) with nmCRPC. DARO also significantly delayed time to deterioration of HRQoL and had a positive impact on local disease recurrence and symptom control. We report the effect of DARO on HRQoL DetFS by PSA decline in ARAMIS.

Methods: Pts with nmCRPC were randomized 2:1 to DARO or placebo, both with ADT. Using the primary analysis data cutoff (Sept 3, 2018), DARO-treated pts were grouped by PSA decline from baseline at wk 16 of ≥90% (PSA90), ≥50% to <90% (PSA50-90), and <50% (PSA50). DetFS was defined as the time from randomization until the earliest event of deterioration in HRQoL (EORTC Quality of Life Questionnaire Prostate Cancer Module urinary and bowel symptoms subscales and Functional Assessment of Cancer Therapy-Prostate [FACT-P] prostate cancer subscale [PCS] and Total), metastasis, death, or treatment discontinuation. Median (95% CIs) DetFS was calculated using Kaplan-Meier estimates.

Results: Of 955 DARO pts, 899 had PSA values at wk 16 and 403 (44.8%) achieved PSA90. Pts achieving PSA90 decline had longer median DetFS of HRQoL for urinary and bowel symptoms and for FACT-P Total and PCS vs those with PSA50-90 and <50% PSA decline (Table). For pts with PSA90, PSA50-90, and <50% PSA decline, 3-year DetFS rates were 38.0%, 31.2%, and 14.6% for urinary symptoms and 33.8%, 17.4%, and 13.3% for bowel symptoms.

Table: 1781P HRQoL DetFS in DARO-treated pts by PSA decline from baseline at wk 16

DetFS, median (95% CI), months	PSA ≥90% decline (n=403)	PSA ≥50% to <90% decline (n=379)	PSA <50% decline (n=117)
EORTC urinary symptoms subscale	22.3 (18.6–30.8)	18.5 (14.8–22.2)	11.6 (7.6–15.0)
EORTC bowel symptoms subscale	25.6 (18.4–26.0)	14.7 (11.2–15.0)	11.5 (7.6–15.0)
FACT-P PCS	22.3 (18.4–NR)	15.0 (11.1–18.5)	11.1 (7.6–18.3)
FACT-P Total	NR (NR–NR)	32.9 (26.0–40.5)	16.1 (11.1–25.8)

NR, not reached.

Conclusions: In ARAMIS, a high proportion of DARO pts achieved PSA90. DARO demonstrated local symptom control for urinary and bowel measures and better HRQoL in pts who achieved PSA90. These findings confirm the cancer control and HRQoL benefits of early DARO treatment for pts with nmCRPC.

Clinical trial identification: NCT02200614.

1782P Prostate radiotherapy reduces long-term risk of obstructive uropathy in metastatic hormone sensitive prostate cancer (mHSPC): Results from the STAMPEDE M1|RT comparison

C. Jones[1,2], P. Dutey-Magn[3], L. Murphy[3], M. Murray[3], L. Brown[3], M. Parmar[3], N. James[4], C. Parker[4], M. Sydes[3], N. Clarke[1,2], A. Sachdeva[1,2]

[1]Urology, The Christie NHS Foundation Trust, Manchester, United Kingdom; [2]Genito Urinary Cancer Research Group, Division of Cancer Sciences, University of Manchester, Manchester, UK; [3]Medical Research, MRC - Medical Research Council Clinical Trials Unit - University College London (UCL), London, United Kingdom; [4]Prostate and Bladder Cancer Research Department, ICR - Institute of Cancer Research, London, United Kingdom

Background: Men with advanced prostate cancer are at risk of upper urinary tract obstruction (UUTO) due to local progression leading to increased morbidity. Primary site radiotherapy (RT) improves overall survival in patients with low volume metastatic hormone sensitive prostate cancer (mHSPC), with limited data available to demonstrate its impact on local progression. Accessible, high quality healthcare systems data (HSD) provides accurate event data beyond standard trial follow up, permitting evaluation of the impact of primary RT on need for UUTO interventions.

Methods: Linked HSD from Hospital Episode Statistics (HES) with follow-up to March 2021 were available for patients randomised 1:1 in England between arms A (standard of care [SOC]) and H (SOC+RT). Radiotherapy was delivered either daily: 55 Gy in 20 fractions over 4 weeks or weekly: 36 Gy in six fractions over 6 weeks. Interventions for UUTO (including percutaneous nephrostomy and or ureteric stent insertion) were identified using a comprehensive coding framework using International Classification of Diseases (ICD 10) diagnosis and Classification of Interventions and Procedures (OPCS 4) codes Multivariate flexible parametric survival models adjusted for randomisation stratification factors were used to estimate the treatment effect of primary RT on the cumulative incidence of UUTO and sub distribution hazard ratios (SDHR).

Results: 1791/2061 (88%) were followed up by English hospitals; connected HSD were available for 1724/1791 (96%). After excluding 19 patients who had a UUTO intervention in the 90 days leading to randomisation, model-based 5-year incidence of UUTO requiring intervention was 5% [4; 7%] in patients randomised to SOC, and 3% [2; 4%] in patients randomised to SOC + RT (SDHR 0.568, 95% CI 0.353-0.912; p=0.017). Treatment effects were comparable in high- and low-volume metastasis subgroups.

Conclusions: UUTO interventions are performed in a modest proportion of mHSPC patients. Prostate radiotherapy significantly reduced the use of UUTO interventions. These data support the use of prostate radiotherapy in men with mHSPC at risk of UUTO.

Background: ADT+ dct has been a standard of care first-line for hvHSPC patients (pt). We hypothesized that early addition of ipi and/or nivo could improve outcomes.

Methods: PROSTRATEGY was designed as a seamless randomized (2/1/1) multi-arm multi-stage trial, to compare ADT+dct (75 mg/m^2 x6 cycles) vs ADT+dct→nivo (3 mg/Kg/2w x 12 mo), or ADT+ipi+dct→nivo (ADT + ipi 1 mg/Kg/3w x 2 cycles → dct x3 cycles → ipi 3mg/Kg/3w x2 cycles → dct x3 cycles → nivo x 12 mo) in hvHSPCa pt in 30 academic centers in Spain. The aims of the pilot phase were to check ffeasibility, safety and efficacy outcomes in terms of radiographic and PSA response, radiographic and clinical progression-free survival or death (rPFS, cPFS), time to castration-resistant prostate cancer or death (TCRPC), time to symptomatic skeletal-related event (TSSRE) and overall survival (OS) from the first dose of ADT, based on both RECIST1.1 + PCWG3 and iRECIST (Seymour, Lancet Oncol 2017) + PCWG3 criteria.

Results: 150 pt were randomized to dct (75 pt), dct-nivo (37 pt) or dct+ipi-nivo (38 pt). Mean age was 66.4 y (39% >70 y), 98% were Caucasian, 99.3% had ECOG 0-1, 88% were metastatic at diagnosis, mean PSA was 157 ng/ml, 88% had Gleason ≥ 8, 31% visceral involvement, and 17% received local therapy to the prostate, with no differences among arms. With a median follow-up of 32.5 mo from ADT, 60% of pt have progressed and 41.3% have died. Safety is described separately. Efficacy results are summarized in the table.

Conclusions: The addition of ipi and/or nivo to ADT + Dct in pt with hvHSPCa is feasible. So far, we have found no statistical or clinically meaningful differences between arms that justify the continuation of the study. Results seem to be similar regardless of using PCWG3 plus either RECIST or iRECIST criteria although some differences between both methods may appear with longer follow-up.

Clinical trial identification: EudraCT 2017-004377-13.

Background: In ARASENS (NCT02799602), DARO + ADT + DOC significantly reduced risk of death by 32.5% (HR 0.68; 95% CI 0.57—0.80; $P<0.0001$) vs ADT + DOC in pts with mHSPC. In post hoc analyses, HRs for overall survival (OS) were similar for pts with high-volume (HV HR 0.69; 95%CI 0.57—0.82) and low-volume (LV HR 0.68; 95% CI 0.41—1.13) disease. We report PSA outcomes in these pt subgroups.

Methods: Pts with mHSPC were randomized to DARO 600 mg twice daily or placebo (PBO), both with ADT + DOC. PSA was measured at screening and every 12 weeks. Analyses included the proportion of patients achieving undetectable PSA (<0.2 ng/mL) and time to PSA progression. The association between undetectable PSA at any time with time to PSA progression and OS was evaluated using Kaplan-Meier estimates with HRs (95% CI) based on a stratified Cox regression model.

Results: Of 1305 pts, 1005 (77%) had HV disease and 300 (23%) had LV disease. Rapid undetectable PSA response as early as 12 weeks was achieved in nearly twice as many patients receiving DARO vs PBO and continued to increase for both HV and LV subgroups over time (at 24 weeks: HV 43.1% vs 21.7%, LV 66.9% vs 31.5%; at 52 weeks, HV 54.7% vs 23.6%, LV 77.9% vs 34.9%; and at any time, HV 62.2% vs 25.8%, LV 83.8% vs 38.4%). Time to PSA progression was prolonged in pts receiving DARO vs PBO in HV (HR 0.30; 95% CI 0.24—0.37) and LV (HR 0.09; 95% CI 0.05—0.18) pts (4-yr PSA progression-free rates: HV 65.8% vs 27.0%; LV 91.7% vs 36.3%). Pts receiving DARO who achieved undetectable PSA had improved time to PSA progression (HV HR 0.11, 95% CI 0.07—0.16; LV HR 0.02, 95% CI 0.004—0.10) and improved OS (HV HR 0.20; 95% CI 0.15—0.27; LV HR 0.34; 95% CI 0.14—0.79) vs those who did not.

Conclusions: Early treatment intensification with DARO + ADT + DOC allows pts with HV and LV mHSPC to achieve rapid, deep, and durable PSA responses that are associated with improved time to PSA progression and OS.

Background: Androgen deprivation therapy (ADT) is associated with increased fracture risk, due to bone loss and bone quality impairment, as well as with profound alterations in body composition favoring the transition to sarcopenic obesity. Additional metabolic effects of next generation hormonal agents (NGHA) in combination with ADT have been poorly studied.

Methods: BonEnza (NCT03336983) is a prospective phase II trial in which mHSPC patients were randomized to receive either ADT plus enzalutamide (E arm) or the same combination with the addition of zoledronic acid (EZ arm). Bone mineral density (BMD), trabecular bone score (TBS), fat body mass (FBM) and lean body mass (LBM) were assessed at baseline and after 18 months using dual energy x-ray absorptiometry (DEXA) scan.

Results: From February 2018 to December 2022, a total of 89 patients (46 from EZ arm and 43 from E arm), had paired DEXA evaluation at both timepoints. Femoral BMD and TBS significantly reduced in E arm (-9.1%, $p<0.001$; -3.1%, $p=0.001$, respectively), while they increased in EZ arm (5.3%, $p<0.001$; 2.8%, $p=0.008$, respectively). FBM increased by 22.7% ($p<0.001$) and LBM decreased by 6.3% ($p<0.001$) after 18 months of therapy, irrespective of study arm.

Conclusions: The addition of enzalutamide to ADT is associated with a marked reduction in BMD and impaired bone quality as measured by TBS. Both effects are prevented by zoledronic acid administration. The reduction in LBM and increase in FBM were doubled compared to previous observations with ADT alone, putting patients at an elevated risk of sarcopenic obesity.

Background: In TITAN mCSPC pts, 3 mos' APA + ADT produced rapid and deep $\leq$0.2 ng/mL PSA decline that was associated with improved overall survival (OS) (Chowdhury et al, Ann Oncol. 2023). Here we evaluate the effect of UL PSA on outcomes.

Methods: 525 and 527 pts receiving 240 mg/d APA or placebo (PBO) + ADT were analyzed. Two groups of UL PSA, >0.02 to $\leq$0.2 ng/mL (UL1) and $\leq$0.02 ng/mL (UL2), were assessed for association with OS, radiographic progression-free survival, time to castration resistance, and time to PSA progression using landmark analysis, Kaplan-Meier method, and Cox proportional hazards model.

Results: Of 515 APA and 520 PBO pts with evaluable UL PSA values, 49% and 17%, respectively, achieved UL2 PSA during the study. By 3 mos, UL1 and UL2 were achieved in 38% and 23% of APA and 15% and 5% of PBO pts. By 6 mos, these values were 29% and 36% (APA), and 17% and 6% (PBO). APA pts with UL1/UL2 at 3 mos had lower baseline PSA and higher % of low-volume disease vs PSA>0.2 ng/mL. Pts with UL1/UL2 at 3 or 6 mos had improved long-term outcomes irrespective of volume. Volume-adjusted outcomes were significantly improved in pts with UL1/UL2 achieved at 3 mos (Table) or at 6 mos. At 42 mos' follow-up post landmark, survival rate (% [95% CI]) was 89 (81-94), 81 (75-85), and 34 (26-43) when UL2 was achieved at 3 mos, after 3 mos, or never after 3 mos and was 89 (83-93), 77 (70-83), and 34 (26-43) when UL2 was achieved at 6 mos, after 6 mos, or never after 6 mos. Survival rate at 42 mos with UL1, UL2, or none achieved at any time was 59 (48-68), 92 (88-95), and 33 (26-41). APA safety profile across subgroups was consistent with previous reports.

Table: 1786P

HR (95% CI)	PSA values achieved at landmark 3 mos vs PSA >0.2 ng/mL (ref) in APA group[a]	
	UL1 (>0.02 to $\leq$0.2 ng/mL)	UL2 ($\leq$0.02 ng/mL)
OS[b]	0.46 (0.31-0.67)	0.24 (0.13-0.43)
Radiographic progression-free survival[c]	0.54 (0.35-0.83)	0.28 (0.14-0.54)
Time to castration resistance[b]	0.56 (0.39-0.8)	0.2 (0.11-0.38)
Time to PSA progression[b]	0.51 (0.34-0.76)	0.11 (0.04-0.27)

[a]Stratified by disease volume at baseline. [b]44.0 mos follow-up. [c]22.7 mos follow-up.

Conclusions: More TITAN mCSPC pts achieved UL PSA with APA vs PBO. Rapid and deep UL PSA was associated with significantly improved survival outcomes regardless of disease volume, most notably UL2. Data may guide design of future treatment escalation/de-escalation trials in mCSPC.

Clinical trial identification: 56021927PCR3002.

1787P Prostate specific membrane antigen positron emission tomography (PSMA PET)-directed clinical outcomes in metastatic hormone-sensitive prostate cancer (mHSPC): Implications for the STAMPEDE2 trial design

H. Abdel-Aty[1], N. Hujairi[2], I. Murray[2], Y. Yogeswaran[3], L.R. Murphy[4], N. van As[1], L.C. Brown[4], N.D. James[1]

[1]Radiotherapy and Imaging, Institute of Cancer Research and Royal Marsden Hospital, London, UK; [2]Radiology and Nuclear Medicine, Royal Marsden Hospital, London, UK; [3]Institute of Clinical Trials & Methodology, Medical Research Council, Clinical Trials Unit, University College London, London, UK; [4]MRC Clinical Trials Unit, MRC - Medical Research Council Clinical Trials Unit - University College London (UCL), London, UK

Background: The potential for PSMA PET-directed treatment decisions to improve outcomes in mHSPC remains unknown. We explored first response and progression/relapse patterns in newly diagnosed PSMA PET-detected mHSPC and correlated PET-directed staging with clinical outcomes.

Methods: 184 patients with baseline PSMA PET were retrospectively reviewed. Patients were sub-grouped into oligometastatic disease (OMD) and polymetastatic disease (PMD) utilising the STAMPEDE2 trial definition. Data on patient demographics, treatment, and imaging findings were collected. Treatment response was assessed using PSA nadir and radiological imaging at six months from PSA nadir. Disease progression/relapse was assessed using PCWG3, RECIST 1.1 and PERCIST 1.0 criteria. Kaplan Meier method estimated median time to radiographic progression-free survival (rPFS).

Results: Median age was 69 years. All patients had androgen deprivation therapy. 161/184 (88%) had additional systemic therapies. 99/184 (54%) had OMD and 85/184 (46%) had PMD. Prostate radiotherapy was given in 76/99 (77%) OMD patients and 47/85 (55%) PMD patients. Median time to PSA nadir in OMD and PMD was 10 months (range 1 to 29) and 8 months (range 1 to 36), respectively. Response images were available in 35/99 (35%) OMD patients and 39/85 (46%) PMD patients. Median time to radiological response in OMD and PMD was 10 months (range 2 to 58) and 9 months (range 2 to 36), respectively. Radiological progression in OMD most frequently occurred with new sites of disease (73%). Median rPFS was 53 months (95% CI 40, undefined) in OMD patients and 35 months (95% CI 22, 43) in PMD patients.

Table: 1787P Radiological response and progression/relapse in OMD and PMD

	OMD (N= 99)	PMD (N= 85)
Radiological response	**n= 35 (35%)**	**n= 39 (46%)**
Complete Response	12 (34%)	7 (18%)
Partial Response	21 (60%)	29 (74%)
Stable Disease	1 (3%)	2 (5%)
Not evaluable	1 (3%)	1 (3%)
Site of Radiological progression/relapse compared with baseline disease	**n= 22 (22%)**	**n= 37 (43%)**
Same sites	5 (23%)	18 (49%)
Different sites	10 (45%)	9 (24%)
Mixed sites	6 (27%)	10 (27%)
Not evaluable	1 (5%)	0 (0%)

Conclusions: PSMA PET-guided outcomes were similar to series with conventional staging, suggesting PET-directed therapy choices might not significantly influence time to progression. This will be further investigated in the forthcoming STAMPEDE2 trial.

Background: CHART trial has demonstrated the survival benefit of rezvilutamide plus androgen deprivation therapy (ADT) over bicalutamide plus ADT in treating patients with high-volume, metastatic hormone-sensitive prostate cancer (mHSPC). This post-hoc analysis aimed to evaluate the association between achievement of deep PSA decline with survival outcomes in patients with high-volume mHSPC in the CHART trial.

Methods: Patients with high-volume mHSPC were randomly assigned (1:1) to receive ADT plus either rezvilutamide or bicalutamide. PSA kinetics and the association between deep PSA decline ($\leq$0.2 ng/ml) and radiographic progression-free survival (rPFS) and overall survival (OS) in two groups were evaluated.

Results: A total of 654 patients were included in the analysis, with 326 patients in the rezvilutamide plus ADT group, and 328 patients in the bicalutamide plus ADT group. The median PSA nadir levels were 0.02 ng/ml, and 0.68 ng/ml in two groups, respectively. At 6-month, 170 (52.15%) and 90 (27.44%) patients achieved a deep PSA decline, respectively. With a median follow-up of 29.3 months, patients who achieved a deep PSA decline at 6-month had longer rPFS (HR=0.359, 95%CI 0.238, 0.543, P<0.001) and OS (HR=0.339, 95%CI 0.212, 0.540, P<0.001) than those who did not achieve it in the rezvilutamide plus ADT group. Significantly, rezvilutamide plus ADT was found to significantly prolong rPFS compared to bicalutamide plus ADT, regardless of whether patients achieved deep PSA decline at 6-month (HR=0.462, 95%CI 0.283, 0.754, P=0.002) or not (HR=0.587, 95%CI 0.428, 0.804, P<0.001).

Table: 1788P PSA kinetics in CHART trial

Variables	Rezvilutamide plus ADT (n=326)	Bicalutamide plus ADT (n=328)
PSA baseline (ng/ml), median (Q1, Q3)	78.79 (12.82, 314.80)	51.32 (8.08, 236.63)
PSA nadir (ng/ml), median (Q1, Q3)	0.02 (0.00, 0.41)	0.68 (0.08, 3.16)
Time to PSA nadir, day, median (Q1, Q3)	308.0 (169.0, 634.8)	167.0 (85.0, 281.0)
PSA nadir $\leq$0.2 ng/ml, n (%)	224 (68.7)	109 (33.2)
Time to PSA $\leq$0.2 ng/ml, day, median (Q1, Q3)	392.0 (222.3, 671.0)	238.0 (141.0, 393.0)
PSA $\leq$0.2 ng/ml at 3-month, n (%)	125 (38.34)	58 (17.68)
PSA $\leq$0.2 ng/ml at 6-month, n (%)	170 (52.15)	90 (27.44)
PSA $\leq$0.2 ng/ml at 12-month, n (%)	201 (61.66)	108 (32.93)

Conclusions: Rezvilutamide plus ADT resulted in a deep PSA decline, which was associated with improved long-term survival in patients with high-volume mHSPC.

Clinical trial identification: NCT03520478.

1789P Low- and high-volume disease in mHSPC: From CHAARTED to PSMA PET

L.M. Unterrainer[1], T. Hope[2], W. Fendler[3], H. Ndlovu[4], F. Barbato[3], M. Sathekge[4], K. Herrmann[3], J. Czernin[1], J. Calais[1]

[1]Nuclear Medicine, UCLA, Los Angeles, CA, USA; [2]Department of Radiology and Biomedical Imaging, UCSF - University of California San Francisco, San Francisco, CA, USA; [3]Nuclear Medicine and German Cancer Consortium (DKTK), University of Duisburg-Essen, Essen, Germany; [4]Nuclear Medicine, University of Pretoria, Pretoria, South Africa

Background: The volume of disease (high-volume disease (HVD) / low-volume disease (LVD)) as defined by the CHAARTED criteria based on conventional imaging, is associated with overall survival and used for treatment decisions in mHSPC patients. It remains unknown how the definition of HVD and LVD can be transferred to PSMA-PET imaging.

Methods: In this retrospective study that included 4 international sites, mHSPC patients who underwent a ^{68}Ga-PSMA-11 PET/CT or PET/MRI and a BS (CI) (within a maximum time interval of 100 days) were included. Treatment in between both scans was excluded. HVD and LVD was determined on the BS and on the CT or MRI component. CHAARTED stratification into HVD and LVD was also applied to PSMA-PET. HVD was defined by the presence of visceral metastases and / or > 4 bone metastases (with > 1 beyond spine and pelvis). EXINIbone™ 3.4 (EXINI Diagnostics) was used for the number / localization of bone metastases on BS. The whole-body (WB) PSMA-PET positive tumor volume (PSMA-TV) was obtained using a semi-automatic thresholding method on Affinity 3.0.2 (Hermes Medical Solutions).

Results: Paired PSMA-PET+BS of 50 mHSPC patients were included (median PSA 43.8 (0.2 — 2840.0) ng/ml). 13/50 patients had disease detected in the prostate fossa, 25/50 in lymph nodes, 34/50 in bones and 2/50 in visceral organs by CI and 31/50, 28/50, 29/50 and 2/50 by PSMA-PET, respectively. Based on CI, 14/50 patients had CI-HVD (28%) and 36/50 CI-LVD (72%). Based on PSMA-PET, 21/50 patients had PSMA-HVD (42%) and 22/50 PSMA-LVD (44%). 7/50 (14%) patients had no PSMA-positive lesion or only in the prostate fossa while CI was at least CI-LVD. Overall, mean WB-PSMA-TV was 248.1 ml (0 — 3734.0 ml). In CI-HVD, mean WB PSMA-TV was 713.7 (0.3 — 3734.0) ml, in CI-LVD, 46.4 (0-228.0) ml. In PSMA-HVD, 518.1 (0 — 3734.0) ml and in PSMA-LVD, 59.7 (0 — 228.0) ml. Downstaging from CI to PSMA-PET occurred in in 7/50 patients (14.0%), upstaging (LVD to HVD) in 8/50 patients (16.0%).

Conclusions: Stage migration between LVD and HVD from CI to PSMA PET occurs both by up- and downstaging. Correlation with outcome will lead to new definitions of HVD/LVD based on PSMA PET/CT.

1790P Utilisation rates of treatment intensification for metastatic hormone sensitive prostate cancer (mHSPC) in England, UK

J. Dodkins[1], A. Cook[1], J. Nossiter[1], H.A. Payne[2], N.W. Clarke[3], J. van der Meulen[4], A. Aggarwal[4]

[1]Clinical Effectiveness Unit, Royal College of Surgeons of England, London, UK; [2]Department of Oncology, University College London Hospitals NHS Foundation Trust, London, UK; [3]Department of Urology, The Christie and Salford Royal NHS Foundation Trusts, Manchester, UK; [4]Department of Health Services Research and Policy, London School of Hygiene and Tropical Medicine, London, UK

Background: Following several practice changing clinical trials regarding management of mHSPC, international guidelines now recommend 'treatment intensification' of ADT in combination with either docetaxel and/or novel hormonal therapy (NHT). The national utilisation of these treatments in England, UK and the determinants of variation are yet to be explored.

Methods: This national population based study using data from the National Prostate Cancer Audit (NPCA) identified all patients newly diagnosed with mHSPC in the English National Health Service (NHS) between 2018 and 2021. Patients receiving docetaxel, enzalutamide, abiraterone or apalutamide within 6 months of diagnosis were identified in the Systemic Anti-Cancer Dataset (SACT). Treatment patterns were studied in the overall population and also by age, ethnicity, deprivation and co-morbidity.

Results: Of the 13,820 men diagnosed with mHSPC in England between 2018 and 2021, 5,346 (38.7%) received 'treatment intensification' with either docetaxel, enzalutamide, abiraterone or apalutamide. Of these, 3,386 (24.5%) received docetaxel, 1,736 (12.6%) enzalutamide, 167 (1.2%) Abiraterone and 57 (0.4%) apalutamide. Utilisation of docetaxel peaked in 2018 and utilisation of enzalutamide has steadily increased (0.2% 2018 to 28.3% 2020). Abiraterone and Apalutamide utilisation have also increased during the study period (Table). Patients who were younger or who lived in least deprived areas or who had fewer co-morbidities were more likely to receive treatment intensification. There was no evidence of variation in utilisation according to patient ethnicity.

Table: 1790P Percentage utilisation of treatment intensification for mHSPC over time

	2018	2019	2020	2021
Any treatment intensification	38.1%	38.3%	42.0%	36.7%
Docetaxel	37.6%	37.3%	11.6%	11.2%
Enzalutamide	0.2%	0.7%	28.3%	21.8%
Abiraterone	0.3%	0.3%	2.1%	2.1%
Apalutamide	0%	0%	0%	1.6%

Conclusions: This study identifies the underutilisation of treatment intensification for mHSPC in England, particularly amongst certain patient groups. Further studies are needed to understand the reasons for underutilisation of intensified treatments in this setting.

Background: Alterations in *PTEN* are associated with aggressive behavior and treatment resistance in patients (pts) with castration-resistant prostate cancer (PC). The aim of this study is to characterize the molecular alterations related to *PTEN* low mRNA expression and its prognostic value in metastatic hormone-sensitive PC (mHSPC) pts.

Methods: This is a multicenter retrospective study enrolling mHSPC pts. Alterations in *PTEN* were assessed by mRNA expression by nCounter platform, targeted sequencing, and protein by IHC in FFPE tumor samples. RNA-seq analysis was performed to assess differences in gene expression between low vs. high/medium *PTEN* expression tumors. *PTEN* expression was correlated with castration resistance-free survival (CRPC-FS) and overall survival (OS) by Kaplan Meier and multivariate Cox analysis.

Results: 218 pts were included: 125 treated with ADT + docetaxel (D) and 93 with ADT, with a median follow-up of 46 months (7-223). Median age was 66 years, 76% of pts presented *de novo* stage IV and 68% had high-volume disease. 54 pts were tested for *PTEN* expression and targeted sequencing. Pts with low *PTEN* expression (*PTEN*-low) had higher frequency of *PTEN* mutations ($p<0.02$) and lower IHC expression ($p<0.01$). RNAseq (n=66) differential expression analysis found 13 genes differentially expressed (padj<0.05) in *PTEN*-low vs the rest. In the functional analysis *PTEN*-low tumors had overexpression of several pathways including cell cycle, DNA repair, metabolism and immune reponse, and infraexpression of the androgen-response hallmark. In the whole cohort, *PTEN*-low (31%) was independently associated with lower CRPC-FS (13 vs. 20.5 m, HR 1.8 (95% CI, 1.3 − 2.5), $p<0.001$) and OS (40.1 vs 57.9 m, HR 1.7 (95% CI, 1.2 − 2.3) p=0.003). Moreover, *PTEN*-low pts treated with ADT+D or ADT presented similar CRPC-FS (12.1 and 14.6 m, respectively) or OS (38.8 and 41 m), while *PTEN*-high/mid treated with ADT+D had the largest CRPC-FS (21.9 m, p=0.01) and OS (60.1 m, p=0.032), suggesting that *PTEN*-low pts may not benefit from chemotherapy.

Conclusions: Lower expression of *PTEN* correlates with a distinct molecular profile and a more aggressive disease in pts with mHSPC, supporting the development of new therapeutic strategies for these pts.

Background: Enzalutamide (ENZA) and abiraterone are standard of care for people with metastatic hormone-sensitive prostate cancer (mHSPC). It is important to understand the benefits of these agents in older patients, who may be more frail and have more co-morbidities. In this post-hoc analysis, we assessed the efficacy of ENZA in patients with mHSPC ≥70yrs vs <70yrs of age.

Methods: ENZAMET randomly assigned participants (pts) with mHSPC to treatment with testosterone suppression (TS) plus either a non-steroidal anti-androgen (NSAA) or enzalutamide (ENZA). Stratification factors included age, volume of disease (high vs low), and planned use of concurrent docetaxel (DTX) as agreed by the participant and the treating physician. The same methods were used for overall survival (OS) analysis as in the full trial. Quality of Life (QoL) and safety analyses by age ≥70yrs vs <70yrs are ongoing.

Results: Of 1125 pts randomised, 514/1125 (46%) were aged ≥70yrs. The rate of DTX usage was lower in pts aged ≥70yrs (35% vs 52%). The beneficial effects of ENZA on OS seen in the whole cohort are maintained in pts aged ≥70yrs, regardless of planned use of early DTX (Table). Pts aged ≥70yrs treated with ENZA had a significant improvement in OS (Table) in line with younger pts.

Table: 1792P Hazard ratios (HR) and confidence intervals (CI) for effects of ENZA vs NSAA on OS in subgroups according to age and planned DTX

Characteristic	N	Deaths	HR	95% CI
Full cohort	1125	476	0.70	0.58-0.84
Age alone				
<70yrs All	611	239	0.75	0.58-0.97
≥70yrs All	514	237	0.64	0.50-0.83
Age and DTX				
<70yrs and DTX	322	147	0.87	0.63-1.20
≥70yrs and DTX	181	84	0.73	0.47-1.12
<70yrs and No DTX	289	92	0.62	0.41-0.94
≥70 and No DTX	333	153	0.60	0.44-0.83

Conclusions: This post-hoc analysis demonstrates that pts aged ≥70 yrs treated with ENZA/TS +/- DTX have similar benefical treatment effects to the overall cohort. These data suggest ENZA is a suitable option for older men with mHSPC fit for enzalutamide.

Clinical trial identification: NCT02446405.

Background: ADT+ dct has been a standard of care first-line for hvHSPC patients (pt). We hypothesized that early addition of ipi and/or nivo could improve outcomes.

Methods: PROSTRATEGY was designed as a seamless randomized (2/1/1) multi-arm multi-stage trial, to compare ADT+dct (75 mg/m^2 x6 cycles) vs ADT+dct→nivo (3 mg/Kg/2w x 12 mo), or ADT+ipi+dct→nivo (ADT + ipi 1 mg/Kg/3w x 2 cycles → dct x3 cycles → ipi 3mg/Kg/3w x2 cycles → dct x3 cycles → nivo x 12 mo) in hvHSPCa pt in 30 academic centers in Spain. The aims of the pilot phase were to check feasibility and safety (presented in this abstract) as well as to estimate efficacy outcomes. Dose reductions were only planned for dct. Primary prophylaxis with GCSF during dct was recommended, and secondary prophylaxis was mandatory.

Results: 150 pt were randomized to dct (75 pt), dct-nivo (37 pt) or dct+ipi-nivo (38 pt). Mean age was 66.4 y (39% >70 y), 98% were Caucasian, 99.3% had ECOG 0-1, 88% were metastatic at diagnosis, mean PSA was 157 ng/ml, 88% had Gleason ≥ 8, 31% visceral involvement, and 17% received local therapy to the prostate, with no differences among arms. With a median follow-up of 32.5 mo from ADT, 60% of pt have progressed and 41.3% have died. Efficacy is described separately. Main adverse events (AEs) are summarized in the table. Two pt in the Dx+Ipi-Nivo arm died due to toxicity (1 pt febrile neutropenia and sepsis, 1 pt immune-related encephalitis).

Table: 1793P

	Dct	Dct → Nivo	Dct +Ipi → Nivo
Any AE Any serious AE	97.3% 18.7%	97.3% 62.2%	100% 39.5%
Treatment-related G3-4 AEs Any Infusional reactions Anemia Neutropenia Febrile neutropenia Thrombocytopenia ALT/AST Diarrhea/colitis Mucositis Rash/dermatitis Arthomialgias Peripheral neuropathy Myasthenic sd Hypophysitis Myocarditis Nephritis Encephalitis	34.7% 0% 0% 4.0% 6.7% 0% 0% 1.3% 0% 0% 0% 2.7% 0% 0% 0% 0% 0%	67.6% 0% 2.7% 8.1% 5.4% 0% 2.7% 5.4% 2.7% 0% 0% 2.7% 0% 0% 0% 0%	60.5% 2.6% 2.6% 2.6% 2.6% 0% 2.6% 5.3% 0% 2.6% 2.6% 0% 0% 2.6% 2.6% 2.6% 2.6%
Dct dose reduction	22.7% 2.6% - -	27% 2.7% 5.4% -	7.9% 7.9% 5.4% 2.7%
Discontinuation due to AEs docetaxel nivolumab ipilimumab			
Treatment-related dead	0%	0%	5.4%

Conclusions: The addition of ipi and/or nivo to ADT + Dct in pt with hvHSPCa is feasible. No unexpected or more frequent toxicities were observed in this trial with the addition of checkpoint inhibitors to ADT+ Dx. As expected, the addition of ipi + nivo to ADT+dct is associated with a slightly increase of immune-related AEs.

1794P Prognostic role of metastatic site in patients with de novo metastatic prostate cancer: A population-based analysis in new hormonal agents era

E. Yekeduz[1], M. Eid[2], E. Saad[2], R.M. Saliby[2], K. Semaan[2], S. Gillessen[3], T.K. Choueiri[2], Y. Urun[4]

[1]Medical Oncology Clinic, Ankara Etlik City Hospital, Ankara, Turkey; [2]Medical Oncology Department, Dana Farber Cancer Institute-Lank Center for Genitourinary Oncology, Boston, MA, USA; [3]Medical Oncology Department, Oncology Institute of Southern Switzerland, Bellinzona, Switzerland; [4]Medical Oncology Department, Ankara University Medical School, Ankara, Turkey

Background: Recently, triplet therapies have improved outcomes in patients with metastatic castration-sensitive prostate cancer (mCSPC). Triplet therapies might be reasonable, especially in de novo metastatic disease. Bones are the most common site of distant metastases, but visceral metastasis also occurs in about 10%. It is still largely unknown how the site of de novo metastasis impacts survival in patients treated with new hormonal agents.

Methods: We identified patients from the Surveillance, Epidemiology, and End Results (SEER) database (17 reg, Nov 2022). We used the following criteria for inclusion: microscopically confirmed de novo metastatic, prostate adenocarcinoma, diagnosed between 2016 and 2020; and exclusion: unknown metastatic site and metastasis only to distant lymph nodes. The primary endpoint was overall survival (OS). We used Cox's proportional hazards regression models for multivariable analysis.

Results: We included 20,100 patients. Metastatic sites were classified as bone only, bone + distant lymph node metastasis, lung without liver metastasis, liver metastasis, and other sites (i.e., except for bone, lung, liver, and distant lymph node). Bone was the most common metastatic site (95.4%), followed by lung (10%), other sites (6.3%), and liver (4.7%). The median OS was 33.0 (95% Confidence Interval (CI): 31.9-34.1), 29.0 (95% CI: 21.1-30.8), 28.0 (95% CI: 25.1-30.8), 23.0 (95% CI: 20.5-25.4), and 12.0 (95% CI: 10.5-13.4) months in bone only, bone + distant lymph node, lung without liver, other sites, and liver metastatic groups. Liver metastasis was an independent prognostic factor for worse OS (Hazard Ratio: 8.14, 95% CI:3.06-21.62, $p<0.001$) after adjusting for confounding factors, such as age, race, PSA, and Gleason. However, bone + distant lymph node metastasis, lung metastasis, and metastasis to other sites were not associated with significantly increased mortality compared to bone only metastasis.

Conclusions: Distinguishing by the site of visceral metastasis could add more granularity to the classification of metastatic hormone-sensitive disease and thus may help to select those who would benefit most from the triplet therapies.

Legal entity responsible for the study: The authors.

1795P China ARCHES: A multicenter phase III randomized double-blind placebo (PBO)-controlled efficacy and safety trial of enzalutamide (ENZA) + androgen deprivation therapy (ADT) vs PBO + ADT in Chinese patients (pts) with metastatic hormone-sensitive prostate cancer (mHSPC)

F. Zhou[1], Z. Gongqian[2], H. Guo[3], Z. Hu[4], X. Zhang[5], D. He[6], Z. He[7], D. Zhang[8], Y. Li[1], H. Kadeerbai[9], Y. Liu[10], D. Ye[11]

[1]Department of Urology, Sun Yat-sen University — Cancer Center, Guangzhou, China; [2]Department of Urology, Hunan Cancer Hospital, Changsha, China; [3]Department of Urology, Nanjing Drum Tower Hospital, Nanjing, China; [4]Department of Urology, Tongji Hospital, Tongji Medical College of HUST, Wuhan, China; [5]Department of Urology, Wuhan Union Hospital, Wuhan, China; [6]Department of Urology, First Affiliated of Xi'an Communication University, Xi'an Shaanxi, China; [7]Department of Urology, Peking University First Hospital, Beijing, China; [8]Department of Urology, Zhejiang Provincial People's Hospital, Hangzhou, China; [9]Department of Data Science, Astellas Pharma China, Beijing, China; [10]Medical Development Department, Astellas Pharma China, Beijing, China; [11]Department of Urology, Fudan University — Shanghai Cancer Center (FUSCC), Shanghai, China

Background: In the global ARCHES trial (NCT02677896), ENZA + ADT improved overall survival and radiographic progression-free survival (rPFS) vs PBO + ADT in pts with mHSPC. The China ARCHES trial evaluated the efficacy and safety of ENZA + ADT vs PBO + ADT in Chinese pts with mHSPC.

Methods: Chinese men with mHSPC (positive bone scan or CT scan) were randomized 2:1 to ENZA (160 mg/day) + ADT or PBO + ADT, stratified by disease volume and prior docetaxel therapy. Treatment continued until intolerability or confirmed radiographic progression. The primary endpoint was time to prostate-specific antigen (PSA) progression (TTPP; PSA progression defined as ≥25% increase and absolute increase of ≥2 ng/mL above the nadir, confirmed after ≥3 weeks), based on central laboratory test. Selected secondary endpoints included rPFS, time to castration resistance (TTCR), PSA undetectable (<0.2 ng/mL) rate in patients with detectable PSA at baseline, and safety. We report the results of a prespecified interim analysis (63 TTPP events accrued).

Results: At data cut-off (November 18, 2022), 180 pts (ENZA + ADT, n=120; PBO + ADT, n=60) had been randomized from 27 centers in China (median age, 68.5 years). Baseline characteristics were balanced between treatment arms. Median treatment duration with ENZA + ADT vs PBO + ADT was 25.66 vs 15.11 months. Based on 63 centrally confirmed PSA progressions (ENZA + ADT, 23; PBO + ADT, 40), ENZA + ADT significantly reduced the risk of PSA progression by 87% vs PBO + ADT (Table). rPFS, TTCR, and PSA undetectable rate were among the secondary endpoints improved with ENZA + ADT vs PBO + ADT. Safety outcomes in pts from China were consistent with those in the global ARCHES population.

Table: 1795P

Endpoint	ENZA + ADT N=120	PBO + ADT N=60	Hazard ratio[a] (95% CI)	p value
TTPP[b] (95% CI)[c]	NR (NR, NR)	9.2 (6.54, 17.48)	0.13 (0.076, 0.222)	<0.0001[d]
rPFS[b] (95% CI)[c]	NR (28.25, NR)	19.4 (13.63, NR)	0.33 (0.196, 0.556)	<0.0001[d,e]
TTCR[b] (95% CI)[c]	NR (31.18, NR)	8.3 (6.41, 14.69)	0.172 (0.107, 0.276)	<0.0001[d,e]
PSA undetectable, % (95% CI)[f]	76.3 (67.4, 83.8)	22.8 (12.7, 35.8)		<0.0001[e,g]

[a]Cox proportional hazards model[h] [b]Median months: Kaplan-Meier method [c]Brookmeyer and Crowley method [d]Log-rank test[h] [e]Nominal p value [f]Clopper-Pearson method based on exact binomial distribution [g]Cochran-Mantel-Haenszel score test[h] [h]Stratified model/test CI=confidence interval; N=no. of randomized pts; NR=not reached.

Conclusions: Efficacy and safety results in China ARCHES were generally consistent with those in the global ARCHES trial.

Background: Androgen deprivation therapy (ADT) was the standard of care (SOC) for patients with metastatic Hormone Sensitive Prostate Cancer (mHSPC); recently, emerging therapies associated with ADT have proven to be more effective than ADT alone, however there is an unmet need of standardization of randomized control trials (RCTs) comparing the various combinations of available drugs. Real Word Data (RWD) may be used to identify relevant outcomes with unmet clinical needs with a greater likelihood of benefiting from new therapies. We aim to describe demographics, clinical characteristics, treatment patterns and clinical outcomes of a large multicenter cohort of patients with mHSPC in RWD under the PIONEER project.

Methods: Data of patients with mHSPC across a distributed network of observational databases were collected. Male patients without prior orchiectomy with mHSPC were enrolled in Cohort 1, while Cohort 2 was defined as the start of ADT as a surrogate definition of mHSPC disease, both in metachronous and synchronous disease settings.

Results: Overall, 94,261 mHSPC patients were included among which 77,123 patients received treatment. 28% of mHSPC diagnosed were not on ADT monotherapy. More than half of the patients were over 70 years old (54%), older than the average age on the available RCT. In cohort 2, 2,819 patients were metachronous and 55,502 patients were synchronous. Most of the patients are treated with ADT only; after a Median follow-up (ranged from 398-699 days) in the metachronous setting 22% of them discontinued the treatment. Regarding the clinical outcomes, time to admission to hospital or emergency Department, adverse events and death increase with time, but noticeably events are more common in synchronous disease.

Conclusions: This is the largest study in Europe with RWD in the mHSPC setting. Landscape of prostate cancer treatment is constantly evolving, so it is important to understand the behavior of the disease in real-world setting, so we are able to fill gaps or create new questions to create evidence. In RWD that patients are older, with more co-mobilities and 1/3 of them do not undergo a SCO treatment when compared to RCT.

1797P Application of novel machine learning model in [68Ga] Ga-PSMA-11 PET/CT: Predicting survival in oligometastatic prostate cancer patients

M. Dell'Oro[1], M.A. Ebert[2], J. Ong[3], M. McCarthy[3], C. Tang[2], R.J. Francis[4]

[1]Australian Centre for Quantitative Imaging, School of Medicine, University of Western Australia, Perth, WA, Australia; [2]Department of Radiation Oncology, Sir Charles Gairdner Hospital, Nedlands, WA, Australia; [3]Department of Nuclear Medicine, Fiona Stanley Hospital, Perth, WA, Australia; [4]Department of Nuclear Medicine, Sir Charles Gairdner Hospital, Nedlands, WA, Australia

Background: Biochemical recurrence is estimated to occur in $\geq$ 25% of patients with prostate cancer (PC) following primary curative therapy. Machine learning models are being developed for lesion detection and tracking to provide a comprehensive view of disease burden, allowing clinicians to quantify and predict effectiveness of treatment for individual lesions. This study applied novel AI-assisted technology to automatically extract features from [^{68}Ga] Ga-PSMA-11 (PSMA) PET/CT images that correlate with treatment intervention and survival data to create a scoring system.

Methods: Between 2015 and 2016, 185 men with oligometastatic PC had a baseline and follow-up PSMA PET/CT scan (at ~6-months) whilst treated per standard clinical care. Lesions were quantified and matched between timepoints using AIQ Solutions technology. Imaging features were extracted from each patient, including change in basic features (SUV_{max}, SUV_{mean}, and number of lesions at baseline), and heterogeneity features (intrapatient heterogeneity of disease and response). Univariate predictive power of overall survival (OS) prediction of each measure was determined using Cox regression models. An AI approach was evaluated to predict OS using 5-fold cross-validation of a random survival forest. Model performance was evaluated using the c-index.

Results: The top univariate predictors of survival were all heterogeneity features, proportion of lesions increasing (c-index=0.62), number of stable lesions (0.62), number of decreasing lesions (0.60), and number of new lesions (0.59). In an individual scan, the proportion of increasing lesions >29% correlated with poorer progression. The AI model was able to predict responders vs suboptimal responders based on whether they had a treatment intervention or observation alone (35%) (c-index=0.83 in both cases).

Conclusions: This study demonstrates that an AI-assisted lesional response analysis can help predict response and prognosis of oligometastatic PC patients. These results support further studies to validate these findings in a prospective cohort.

Background: Metastatic castration resistant prostate cancer (mCRPC) patients (pts) with HRR alterations (HRR^+) benefit from PARPi. We aimed to elucidate the RW outcomes and impact of streamlined access to a biomarker driven tx approach.

Methods: In a multicentre prospective mPCa cohort study, cell free DNA next generation sequencing (cfDNA NGS) was performed using accredited assays (BC Cancer, Foundation Medicine, Alberta panel). Time to CRPC was compared between HRR^+ and negative/unknown status (HRR^0) using log rank test. In olaparib tx pts, $\geq$50% PSA decline, radiographic progression free survival (rPFS), serious adverse events (SAE), and overall survival (OS) were examined.

Results: Of 119 pts, 41 (35%) were HRR^+ (23 *BRCA2*, 14 *ATM*, 5 *CDK12*, 3 *CHEK2*, 2 *PPP2R2A*, 1 *BRCA1*, 1 *PALB2*). Median age at diagnosis was 64 yrs, 45% had Gleason $\geq$ 8, and 13% were non-caucasian. HRR^+ pts had a shorter time to CRPC than HRR^0 pts (13.7 vs 31.3 months; HR: 2.2; p=0.001). 28 HRR^+ pts (19 BRCA2, 8 ATM, 1 BRCA1) received olaparib, demonstrating a trend towards improved OS from mCRPC compared to HRR^+ pts without PARPi (38.1 vs 17.4 mo, p=0.20). In 9 HRR^+ pts without PARPi, 7 had androgen receptor pathway inhibitor (ARPi) tx and taxane, 1 had ARPi, and 1 had docetaxel. 50% of pts received olaparib after $\geq$2 systemic tx lines. A longer OS trend was observed in pts receiving 1st line mCRPC olaparib tx than pts receiving olaparib in later tx lines (17.2 vs 11.1 mo, p=0.07). OS from mCRPC was similar in HRR^0 and olaparib tx HRR^+ pts (37.4 vs 38.1 mo, p=0.70). In olaparib tx pts, median OS post initiation was 11.7 mo, rPFS was 5.4 mo, 36% had $\geq$50% PSA decline, and 29% had $\geq$30 days tx beyond PSA progression (PCWG3 criteria). SAE occurred in 39%; 4 pts required transfusion for anemia. Of 8 pts receiving additional systemic tx, 6 had taxane- and 2 had platinum-based chemotherapy.

Conclusions: In this study of heavily pre-treated mPCa pts, RW rPFS and OS on olaparib were reduced compared to clinical trials. Similar OS was seen in olaparib tx HRR^+ and HRR^0 pts, despite historically poorer prognosis in HRR^+ pts. These results demonstrate that a biomarker driven tx approach and earlier access to PARPi may improve outcomes in HRR^+ pts.

1800P Differential tumor gene-expression profiling of patients (pts) with de-novo metastatic castration-sensitive prostate cancer (dn-mCSPC) versus (vs.) mCSPC relapsing after prior localized therapy (PLT-mCSPC)

V. Mathew Thomas, B. Chigarira, G. Gebrael, N. Sayegh, N. Tripathi, R. Nussenzveig, G. Galarza Fortuna, K. Sahu, H. Li, A. Srivastava, B. Nordblad, E. Dal, J. Brundage, B.L. Maughan, U. Swami, N. Agarwal

Division of Medical Oncology, Department of Internal Medicine, University of Utah Health - Huntsman Cancer Institute, Salt Lake City, UT, USA

Background: Dn-mCSPC is markedly aggressive, with shorter time to castration resistance and poorer overall survival than PLT-mCSPC (PMID: 28899723). We interrogate and validate differences in tumor gene expression profiles of dn-mCSPC vs. PLT-mCSPC.

Methods: In this IRB-approved retrospective study, eligibility criteria included histologically confirmed prostate adenocarcinoma (PC) and available RNA sequencing results from treatment naïve primary prostate tissue from a CLIA-certified lab [either Tempus (T) or Caris (C)]. T cohort was used for interrogation and C for validation. Pts in each cohort were categorized into two groups: dn-mCSPC vs. PLT-mCSPC. The DEseq2 pipeline was used to analyze differentially expressed genes between the groups. The data included the Log2 fold change, Wald-Test p-values, and Benjamini-Hochberg adjusted p-values for each differentially expressed gene. Results were subjected to Gene Set Enrichment Analysis (GSEA) to identify pathways enriched in each cohort. Bioinformatic analysis was performed using R v4.2.

Results: 128 pts were eligible. T cohort: n=78 (dn-mCSPC=37, PLT-mCSPC=41); C cohort: n=50 (dn-mCSPC=30, PLT-mCSPC=20). Both T and C showed that dn-mCSPC had an increased expression of the TNFα signaling, hypoxia signaling, and inflammatory response pathway (PTW). PLT-mCSPC had higher expression of E2F target,

G2M checkpoint, and MYC target PTW. Normalized enrichment scores (NES) are reported in the table.

Table: 1800P Differential GSEA in dn-mCSPC vs. PLT-mCSPC (q value for each pathway <0.01)

T		C	
PTW	NES	PTW	NES
TNFα signaling	3.1	TNFα signaling	3.0
Hypoxia	2.3	Hypoxia	2.3
Inflammatory response	2.2	Inflammatory response	2.3
MYC target	-1.9	MYC target	-1.5
G2M checkpoint	-2.0	G2M checkpoint	-1.3
E2F target	-2.3	E2F target	-1.5

Positive NES = upregulation in dn-mCSPC, negative NES = downregulation in dn-mCSPC

Conclusions: Pts with dn-mCSPC had PTW associated with tumor aggressiveness such as TNFα signaling, hypoxia, and inflammatory response. After external validation, these hypothesis-generating data may provide rationale for personalized therapy in men with PC.

1801P Impact of intensified androgen deprivation therapy (ADTi) in the metastatic castration-sensitive prostate cancer (mCSPC) setting on metastatic castration-resistant prostate cancer (mCRPC) disease characteristics and survival outcomes

N. Tripathi, G. Gebrael, N. Sayegh, D. Goel, J. Brundage, B. Nordblad, A. Srivastava, E. Dal, C. Hage Chehade, B. Chigarira, V. Mathew Thomas, K. Sahu, B.L. Maughan, N. Agarwal, U. Swami

Medical Oncology/Internal Medicine, University of Utah Health - Huntsman Cancer Institute, Salt Lake City, UT, USA

Background: ADTi is the standard of care treatment (Rx) for mCSPC. We hypothesized that pts who received ADTi in mCSPC and progressed to mCRPC would have different disease characteristics and survival than those treated with ADT monotherapy (ADTm) in the mCSPC setting.

Methods: After IRB approval, patient (pt)-level data were collected retrospectively. Eligibility: confirmed diagnosis of mCRPC, treated with 1L approved Rx with follow up data available. Pts were stratified based on whether they received ADTi (docetaxel or novel hormonal therapies) or ADTm in the mCSPC setting. Study endpoints: Progression-free survival (PFS) as and overall survival (OS) from time of mCRPC diagnosis. A multivariate analysis using the Cox proportional hazards model was used adjusting for potential confounders.

Results: 519 consecutive pts (368 ADTm and 151 ADTi) seen at our institution between 2009 to 2022 were eligible. mCRPC pts who received ADTi compared to ADTm had lower PSA (10.3 vs. 21.5 ng/ml, $P = 0.002$), more visceral metastases (20.5 vs. 11.1%, $P = 0.005$), higher alkaline phosphatase (110.5 vs. 96 U/L, $P = 0.034$); and had worse median PFS (5.3 vs. 8.6 months, $P < 0.001$) and OS (21.2 vs. 31.7 months, $P < 0.001$) compared to those with ADTm in both univariate and multivariate analysis (Table).

Table: 1801P

	PFS HR (95% CI, *P*-value)	OS HR (95% CI, *P*-value)
ADT vs. ADTi (univariate)	0.7 (0.57-0.86, $P < 0.001$)	0.63 (0.49-0.8, $P < 0.001$)
ADT vs. ADTi (multivariate)	0.7 (0.53 − 0.91, $P = 0.009$)	0.69 (0.50 − 0.97, $P = 0.03$)
Visceral Metastasis	0.73 (0.52 − 1.02, $P = 0.062$)	0.62 (0.43 − 0.90, $P = 0.012$)
Log PSA	1.12 (1.06 − 1.18, $P < 0.001$)	1.13 (1.06 − 1.21, $P < 0.001$)
Hemoglobin	0.86 (0.80 − 0.92, $P < 0.001$)	0.87 (0.81 − 0.94, $P < 0.001$)
Alkaline Phosphatase	1.00 (1.00 − 1.00, $P = 0.081$)	1 (1.00 − 1.00, $P = 0.086$)
Gleason Score > 8	0.77 (0.58 − 1.01, $P = 0.062$)	0.79 (0.57 − 1.09, $P = 0.14$)

Conclusions: In the era of ADTi for mCSPC, the survival outcomes in the mCRPC is poorer compared to those in the era of ADTm for mCSPC. These hypothesis-generating data may aid patient counseling, prognostication, and clinical trial design in mCRPC in the current era.

Background: Pts with mCRPC and mutations in *AR* LBD (amino acids 671-920) have poor prognosis. The oral PROteolysis TArgeting Chimera (PROTAC) AR degrader bavdegalutamide (bavdeg; ARV-110) showed clinical activity in previously treated pts with mCRPC in a phase 1/2 study (NCT03888612), with enhanced activity seen in pts with the *AR* LBD mutations T878 and/or H875.

Methods: In phase 1, pts with mCRPC and ≥2 prior therapies (including a novel hormonal agent [NHA]) received bavdeg 35–700 mg once daily (QD) or 210–420 mg twice daily. In phase 2, pts with mCRPC and 1–2 prior NHAs ± prior chemotherapy were assigned to biomarker-defined subgroups; pts who had 1 prior NHA and no prior chemotherapy were enrolled in a clinically defined subgroup. All phase 2 pts received 420 mg bavdeg QD. In exploratory analyses across the phase 1/2 population treated with 420 mg bavdeg QD, efficacy was assessed in pts with *AR* 878/875 mutation(s) without an *AR* L702 mutation (*AR* 878/875 pts) and in those with any *AR* LBD missense mutation except *AR* L702H alone (*AR* LBD pts).

Results: As of Dec 20, 2022, median rPFS (95% CI) per PCWG3 was 11.1 months (7.10–not reached) in 25 *AR* 878/875 pts (10 events; 4 pts still on treatment) and 8.1 months (3.81–10.97) in 44 *AR* LBD pts (20 events; 5 pts still on treatment). Best prostate-specific antigen (PSA) declines of ≥50% after ≥1 month of PSA follow-up were seen in 56.0% of *AR* 878/875 pts (n=25) and 37.2% of *AR* LBD pts (n=43). In response-evaluable pts with measurable disease at baseline, overall response rate was 9.1% in *AR* 878/875 pts (n=11) and 10.0% in *AR* LBD (n=20) pts; 55% and 50%, respectively, had stable disease. There were no grade ≥4 treatment-related adverse events (TRAEs) with 420 mg bavdeg (n=158 across phase 1/2); any grade TRAEs reported in ≥20% of pts were nausea (54%; 1% grade 3), fatigue (35%; 1% grade 3), vomiting (31%; 1% grade 3), diarrhea (25%; 2% grade 3) and decreased appetite (23%; 0 grade 3).

Conclusions: Bavdeg had encouraging efficacy in post-NHA pts with mCRPC and *AR* 878/875 or any *AR* missense LBD mutation (excluding *AR* L702H alone) and was tolerable; these pt populations will be analyzed in a phase 3 study of bavdeg.

Clinical trial identification: NCT03888612.

Background: ARX517 is a novel ADC composed of a fully humanized anti-PSMA mAb conjugated to amberstatin-269, a potent tubulin inhibitor. ARX517 was designed to reduce off-target ADC instability-related toxicity issues observed in earlier anti-PSMA ADCs by using site-specific synthetic amino acids and stable oxime conjugation chemistry to minimize premature payload release in the human circulation.

Methods: An i3+3 dose escalation design was used. Eligible pts had ≥ 2 FDA-approved treatments for mCRPC with progression by Prostate Cancer Working Group criteria. Key objectives include safety, PK and clinical efficacy. Baseline PSMA PET expression was not required for eligibility but was evaluated as a biomarker.

Results: 24 pts received ARX517 q3w at escalating doses (Table). Pts had a median of 4 prior lines of therapy; 100% received ≥ 1 androgen pathway inhibitor, 50% received taxane, and 12.5% received PSMA-targeted radionuclide. Grade (Gr) 1/2 treatment-related adverse events (TRAEs) were dry mouth (41.7%), fatigue (33.3%), diarrhea and platelet count decrease (20.8% each). Four Gr3 TRAEs were reported at 1.7, 2.4, and 2.88 mg/kg (two lymphopenia, two platelet count decrease). No DLTs, treatment-related serious AEs (SAEs), or ≥ Gr 4 AEs were reported. At higher doses (Cohorts 4-8), median duration on-treatment was 6.3 months (range 0.7+, 11.8+). Additionally, > 50% PSA and ctDNA decline were observed (Table); 2/7 pts had confirmed RECIST v1.1 responses. PK profiles for total antibody and ADC were similar, suggesting strong stability of ARX517 with minimal premature payload release.

Table: 1804P PSA and ctDNA decline, confirmed responses, DLTs, and Grade 3/4/5 TRAEs by dose level

	Cohort 1 0.32 mg/kg	Cohort 2 0.64 mg/kg	Cohort 3 1.07 mg/kg	Cohort 4 1.4 mg/kg	Cohort 5 1.7 mg/kg	Cohort 6 2.0 mg/kg	Cohort 7 2.4 mg/kg	Cohort 8 2.88 mg/kg
Best % change from baseline*								
PSA > 30%	0/1	1/3	1/3	2/3	2/5	3/3	2/3	2/3
PSA > 50%	0/1	0/3	0/3	1/3	0/5	3/3	2/3	2/3
PSA > 90%	0/1	0/3	0/3	0/3	0/5	2/3	0/3	0/3
ctDNA > 50%	0/1	1/2	2/3	1/3	3/5	3/3	2/2	n/d
Confirmed RECIST v1.1 response	0/1	0/1	0/0	1/2	0/3	1/1	0/1	n/d
DLT	0/3	0/3	0/3	0/3	0/5	0/3	0/3	0/3
Gr3 TRAE	0/3	0/3	0/3	0/3	1/5	0/3	1/3	2/3
Gr4/5 TRAE	0/3	0/3	0/3	0/3	0/5	0/3	0/3	0/3

*Data cut-off 03May23; n/d = no data available

Conclusions: ARX517 treatment resulted in PSA declines and RECIST v1.1 responses without treatment-related SAEs. Dose expansion has begun, additional safety, PD, efficacy, and PSMA PET data will be presented.

Clinical trial identification: NCT04662580.

Background: PROpel (NCT03732820) met its primary endpoint with a significant investigator-assessed radiographic progression-free survival (IA rPFS) benefit with ola + abi vs pbo + abi in the intention-to-treat (ITT) population in first-line mCRPC (hazard ratio [HR] 0.66, 95% confidence interval [CI] 0.54–0.81; $P<0.001$). At final prespecified analysis there was a trend to improved overall survival (OS) with ola + abi vs pbo + abi (median 42.1 vs 34.7 months [m]; HR 0.81, 95% CI 0.67–1.00; $P=0.0544$). The greatest magnitude of benefits was seen in the BRCAm subgroup. *Post hoc* exploratory analyses were conducted to further investigate outcomes in non-BRCAm pts.

Methods: PROpel was a phase 3 double-blind trial. Pts were enrolled irrespective of biomarker status and randomized 1:1 to receive ola (300 mg twice daily [bid]) or pbo, and abi (1000 mg once daily) + prednisone/prednisolone (5 mg bid). Treatment continued until radiographic disease progression, unacceptable toxicity or withdrawal of consent. Aggregated tumour tissue (FoundationOne®CDx) and ctDNA (FoundationOne®Liquid CDx) test results, performed after randomization and before primary analysis, were used to classify pt mutation status. Non-BRCAm pts had no positive BRCAm test result and at least 1 negative BRCAm tissue or ctDNA result.

Results: In the non-BRCAm subgroup (n=693), there was a meaningful clinical benefit across endpoints for pts treated with ola + abi (Table). Safety profile of the combination was consistent with the ITT population. Within the non-BRCAm subgroup, analyses by baseline clinical characteristics showed consistent effect and will be presented.

Table: 1805P

Background: The randomized, double-blind, phase 3 MAGNITUDE study evaluated NIRA+AAP vs placebo and AAP (PBO+AAP) as 1st line therapy for mCRPC that was HRR+ based on targeted next-generation sequencing of tumor tissue and/or plasma-based assays.[1] Here we aimed to assess treatment efficacy by assay.

Methods: Tumor tissue and/or plasma was collected from mCRPC patients (pts) who consented to the pre-screening protocol and tested using local tissue assays or centrally using the Foundation Medicine FoundationOne®CDx (F1CDX®) tissue assay or Agilent-Resolution Bioscience Resolution HRD™ Plasma assay. Pts HRR+ (BRCA1, BRCA2, FANCA, PALB2, CHEK2, BRIP1, HDAC2, ATM, CDK12) were randomized 1:1 to receive NIRA+AAP or PBO+AAP (NCT03748641). Primary (radiographic progression-free survival, rPFS) and secondary end-points (time to cytotoxic chemotherapy, TCC; time to symptomatic progression, TSP; and overall survival, OS) are reported for interim analysis 2 for each subgroup (events [NIRA+AAP/PBO+AAP], Hazard ratio and 95% CI).

Results: Overall, 423 pts were HRR+ with 225 BRCA+. Pts, 159 (96), were HRR+ (BRCA+) with both assays, the remaining pts were positive with either tissue/plasma (Table). Pts, 124 (62) HRR+ (BRCA+), were tissue positive but plasma negative, and 38 (17) HRR+ (BRCA+) pts were positive with plasma, but tissue negative. Hazard ratios for end-points, except OS, had $p<0.05$ for pts BRCA positive by either assay, with similar results for HRR+ pts.

Table: 1806P

	Population, n (NIRA+APP / PBO+APP)	rPFS	TCC	TSP	OS
BRCA+	**Overall** 113/112	57/78 0.55 (0.39-0.78)	28/44 0.56 (0.35-0.90)	31/51 0.54 (0.35-0.85)	43/49 0.88 (0.58-1.34)
	Plasma 71/79	0.63 (0.42-0.96)	0.49 (0.28-0.87)	0.51 (0.30-0.89)	0.88 (0.53-1.46)
	Tissue 76/86	0.51 (0.33-0.77)	0.44 (0.24-0.82)	0.50 (0.28-0.89)	0.83 (0.49-1.40)
All HRR	**Overall** 212/211	124/140 0.76 (0.60-0.97)	57/77 0.67 (0.47-0.94)	54/83 0.60 (0.42, 0.84)	90/89 1.01 (0.75-1.36)
	Plasma 129/148	0.77 (0.57-1.04)	0.60 (0.39-0.92)	0.58 (0.38-0.88)	1.04 (0.73-1.49)
	Tissue 144/147	0.80 (0.59-1.08)	0.62 (0.40-0.96)	0.56 (0.36-0.86)	0.97 (0.67-1.42)

Conclusions: Clinically meaningful benefit from NIRA+AAP are similar for BRCA+ pts detected by either tissue or plasma-based assays. Positivity by either test is sufficient to guide treatment decisions. 1. Efstathiou E, et al. *J Clin Oncol*. 2023;41(suppl 6):170.

Background: The randomized, Phase 3, placebo (PBO)-controlled TALAPRO-2 study demonstrated statistically significant improvements in radiographic progression-free survival (rPFS) for 1st-line TALA + ENZA vs PBO + ENZA in patients (pts) with mCRPC in all-comers and in HRR subgroups (HRR-deficient [HRR+] and HRR-non-deficient [HRR-] or unknown). Here, we report baseline characteristics and secondary efficacy and safety endpoints for all-comers by HRR status.

Methods: Pts randomized 1:1 to TALA 0.5 mg or PBO, + ENZA 160 mg/day, were stratified by prior abiraterone or docetaxel for castration-sensitive PC (yes vs no) and by HRR status (HRR+ vs HRR-/unknown). The primary endpoint was rPFS by BICR per RECIST 1.1/PCWG3. Secondary endpoints included overall survival (OS), objective response rate (ORR), time to PSA progression, time to initiation of cytotoxic chemotherapy, time to progression on first subsequent antineoplastic therapy or death (PFS2), and safety.

Results: Of 805 enrolled pts, all had prospective tumor tissue HRR test results. Overall, baseline characteristics were relatively well-balanced between treatment groups and by HRR status; however, in the younger group (age <65 y), there were more HRR+ (29.6%) than HRR-/unknown (19.3%) pts, and HRR+ pts had evidence of more aggressive disease (Table). Treatment with TALA + ENZA improved ORR, and

Table: 1807P

		HRR+	HRR+	HRR-/unknown	HRR-/unknown

	P	0.0059		0.33	

P values 2-sided

prolonged time to PSA progression; time to initiation of cytotoxic chemotherapy; and PFS2 vs PBO + ENZA, with benefit seen in both HRR+ and HRR-/unknown subgroups (Table). OS remains immature. Further data will be presented on baseline characteristics, efficacy, and TEAEs by treatment group for HRR+ and HRR-/unknown subgroups.

Conclusions: TALA + ENZA demonstrated improvements in secondary efficacy endpoints over PBO + ENZA as 1st-line treatment in pts with mCRPC in both HRR+ and HRR-/unknown subgroups.

Clinical trial identification: NCT03395197.

Background: In CABASTY trial (NCT02961257), CBZ 16 mg/m^2 q2w + G-CSF significantly reduced grade $\geq$3 neutropenia and/or neutropenic complications vs CBZ 25 mg/m^2 q3w + G-CSF with comparable overall survival (OS) benefit in older and heavily pretreated patients (pts) with mCRPC *(Oudard et al. ESMO 2022)*. Here, we report changes in HRQL in both arms during therapy.

Methods: The Functional Assessment Cancer Therapy-Prostate (FACT-P) questionnaire was collected at each visit and analyzed in all pts exposed to CBZ with evaluable HRQL at baseline and post-baseline. Higher values indicated better HRQL. Changes of $\geq$10 points in FACT-P total score and $\geq$2 points in Prostate Cancer Subscale (PCS)-pain score, confirmed by 2 consecutive evaluations were judged clinically meaningful.

Results: 196 pts (median age, 74.6 yrs; $\geq$75 yrs, 49%; G8 $<$14, 20%; vulnerable or frail per SIOG guidelines, 30.1%; moderate to severe pain, 18%) previously treated with docetaxel and novel hormonal therapies (median 3 lines) were randomized to CBZ q3w (n=97) or q2w (n=99) + G-CSF. Median treatment duration was 19.0 and 20.1 weeks with CBZ q3w and q2w, respectively. HRQL was evaluable in 88 (90.7%) and 96 (97.0%) pts with CBZ q3w and q2w. PCS-pain improved in 35.2% vs 38.5% (CBZ q3w vs q2w). The probability of not having PCS-pain deterioration during treatment was 81.8% vs 75.0% with CBZ q3w vs q2w (HR=1.5 [95% CI, 0.80-2.9], p=0.2). Total FACT-P score improved from baseline in 17.0% vs 13.5% of pts with CBZ q3w vs q2w, respectively. FACT-P score was either stable or improved from baseline in 75.0% vs 74.0% of pts with CBZ q3w vs q2w. At 75% percentile, time to deterioration was 4.9 vs 3.3 months (HR: 1.2; p =0.57) with CBZ q3w vs q2w.

Conclusions: In this older and heavily pretreated mCRPC pts population, CBZ q3w and q2w + G-CSF similarly relieved pain and maintained or improved HRQL in 3 out of 4 pts with a comparable OS benefit. Since bi-weekly dosing induces less grade $\geq$3 neutropenia and/or neutropenic complications, it should be offered to pts unfit to receive the standard CBZ regimen.

Clinical trial identification: NCT02961257.

Background: Liquid biopsies enable non-invasive detection of circulating biomarkers for disease monitoring and treatment resistance interrogation. We aimed to study circulating tumour DNA (ctDNA) to identify biomarkers of response from cabazitaxel in mCRPC patients (pts).

Methods: mCRPC pts (N=104) candidate for cabazitaxel treatment were enrolled in a prospective biomarker multi-centre trial (NCT03381326). Plasma was collected at baseline (BL), prior to cycle 3/4 (C3) and at progression (PD) and analyzed using a bespoke prostate cancer capture panel (PCF_SELECT, Orlando et al, NAR Cancer 2022). ctDNA fraction was calculated using allelic imbalance-based quantitation of the most abundant hemi-deletions. Primary outcome measures were overall survival (OS) and progression-free survival (PFS). Medians and [IQR] or 95% CI are reported.

Results: 97 pts were evaluable. ctDNA fraction was significantly lower at C3 (0.05 [0.04-0.38]) versus (vs) BL (0.40 [0.25-0.51]) and PD (0.41 [0.27-0.59] p=0.003). ctDNA dynamics strongly associated with outcome: pts with any increase in ctDNA fraction at C3 vs BL (N=20/65) had the worst outcome (PFS 2.6 months (mo), 95% CI 2.2-3.1; OS 7.5 mo, 95% CI 5.2-9.9) whilst pts who had a decrease at C3 (N=27/65) had a similar PFS (6.7 mo, 95% CI (5.1-8.2) but worse OS (15.7 mo, 95% CI 11.4-21.4) compared to undetectable ctDNA at both BL and C3 (N=18/65; PFS 8.2 mo, 95% CI 4.9-11.2; OS 29.9 mo, 95% CI 22.5-39.6). Median ctDNA fraction was significantly higher (0.50 [0.38-0.64]) in early progressors (at or before C3) vs late (after 4 cycles; 0.32 [0.17-0.55] p=0.03). In samples with detectable ctDNA, there was overall a consistent prevalence of gene copy number alterations at BL and PD; however, a significantly higher prevalence of gains of *PIK3CB* (chr3q22; 55 vs 29%, p=0.01) and *AKT1* (chr14q32; 31 vs 14%, p=0.048) was observed in PD samples compared to BL.

Conclusions: ctDNA dynamics associated with cabazitaxel outcomes and identified pts progressing early. An enrichment in *PIK3CB* and *AKT1* gains was observed upon cabazitaxel progression.

Clinical trial identification: NCT03381326.

Background: This *post hoc* analysis of the phase 3 VISION study of [^{177}Lu]Lu-PSMA-617 (^{177}Lu-PSMA-617) plus standard of care (SoC) vs SoC alone in adults with progressive, prostate-specific membrane antigen (PSMA)-positive metastatic castration-resistant prostate cancer (mCRPC), assessed associations of PSA decline, radiographic progression-free survival (rPFS) and overall survival (OS) with time to worsening (TTW) of health-related quality of life (HRQoL).

Methods: Associations of PSA decline with TTW of HRQoL ($n = 385$) were assessed in the ^{177}Lu-PSMA-617 arm. Patients were grouped by PSA decline (unconfirmed) overall or up to 12 weeks of treatment: no decline, $\leq 50\%$, > 50 to $\leq 90\%$ and $> 90\%$. Worsening of HRQoL was defined as a decrease of ≥ 10 (total) or ≥ 3 (subdomain) points in FACT-P, an increase of ≥ 2 points in BPI-SF or any decrease in EQ-5D-5L. Associations of rPFS or OS with TTW of HRQoL were carried out in the full analysis set (FAS; $N = 831$) using three Spearman's rank methods (restricted, highest rank, iterative multiple imputation), with and without imputation for missing OS and rPFS data.

Results: In the ^{177}Lu-PSMA-617 arm, greater PSA decline overall and up to 12 weeks of treatment was associated with longer median TTW in FACT-P total and subdomain scores (Table). Correlations of rPFS and OS with and without imputation with TTW of HRQoL were positive and significantly different to zero in both arms, but mainly weak/moderate. In the total FAS without imputation, rPFS correlations were 0.27—0.51 (FACT-P total), 0.19—0.34 (EQ-5D-5L) and 0.26—0.47 (BPI-SF severity); OS correlations were 0.41—0.55 (FACT-P total), 0.13—0.31 (EQ-5D-5L) and 0.20—0.55 (BPI-SF severity).

Table: 1810P HRQoL outcomes by magnitude of PSA decline

	Median[a] TTW in FACT-P score, months (95% CI)				
	Total	Physical wellbeing	Emotional wellbeing	Social/family wellbeing	Functional wellbeing
PSA decline up to week 12[b], %					
0 (n = 104)	3.3 (2.5, 3.9)	2.3 (2.0, 3.3)	3.3 (3.0, 4.5)	3.5 (3.2, 4.4)	3.2 (2.3, 3.9)
≤ 50 (n = 62)	6.2 (4.6, 7.9)	4.7 (3.3, 7.8)	7.1 (4.6, 9.1)	6.7 (5.1, 9.1)	4.6 (1.9, 5.7)
> 50 to ≤ 90 (n = 113)	8.0 (6.4, 10.7)	8.8 (6.2, 10.6)	8.4 (6.7, 10.7)	8.0 (6.3, 10.6)	7.0 (4.6, 8.6)
> 90 (n = 61)	11.3 (6.9, 15.6)	10.2 (4.6, 14.6)	15.6 (9.3, 18.4)	8.8 (5.3, 15.1)	7.8 (2.6, 11.5)

[a]Kaplan–Meier estimates; [b]^{177}Lu-PSMA-617 + SoC group.

Conclusions: Greater PSA decline and increased rPFS and OS were associated with longer TTW of HRQoL. Ongoing analyses will assess associations of other HRQoL measures with PSA decline and overall response rate.

Background: TALAPRO-2 (NCT03395197) showed statistically significant improvement in imaging-based progression-free survival with TALA + ENZA (n=200) vs PBO + ENZA (n=199) (HR=0.45; 95% CI 0.33–0.61; P<0.0001) in men with HRR mutations receiving first-line treatment for mCRPC. Here we report PRO data for this HRR mutation cohort.

Methods: PROs were assessed at day 1 and scheduled visits (every 4 weeks until week 53, then every 8 weeks) until radiographic progression using the EORTC QLQ-C30 and its prostate cancer module, QLQ-PR25. Prespecified PRO endpoints included

overall mean change from baseline (per longitudinal repeated measures mixed-effects model) and time to definitive deterioration (TTD) with a clinically meaningful change of ≥10-points. Stratified log-rank test and Cox proportional hazards model were used to make TTD between-arm comparisons.

Results: Of the 399 men in the HRR mutation cohort, 394 (n=197 both arms) had at least a baseline plus 1 post-baseline PRO score. No statistically significant difference in treatment effect on the global health status (GHS)/quality of life (QoL) scale was observed between arms. The treatment effect on the physical, emotional, and cognitive functioning scales favored TALA + ENZA, but did not meet the clinical meaningful threshold (Table). A longer TTD for TALA + ENZA vs PBO + ENZA was observed in GHS/QoL (HR=0.69; 95% CI 0.49–0.97; *P*=0.032; median 27.1 vs 19.3 months) and urinary symptoms (HR=0.56; 95% CI 0.34–0.93; *P*=0.022; median not reached vs 30.2 months).

Table: 1811P Overall change from baseline in PROs

Scale	TALA + ENZA estimated mean (95% CI)	PBO + ENZA estimated mean (95% CI)	Estimated mean difference (95% CI)	P value
GHS/QoL	−3.6 (−5.9, −1.4)	−4.9 (−7.3, −2.6)	1.3 (−2.0, 4.5)	0.447
Physical	−3.5 (−5.5, −1.5)	−7.3 (−9.4, −-5.2)	3.8 (0.9, 6.7)	0.010*
Role	−4.5 (−7.1, −1.9)	−6.6 (−9.3, −3.9)	2.1 (−1.7, 5.8)	0.276
Emotional	−0.3 (−2.4, 1.8)	−3.5 (−5.7, −1.3)	3.2 (0.2, 6.2)	0.038*
Cognitive	−5.6 (−7.9, −3.4)	−9.1 (−11.5, −6.8)	3.5 (0.3, 6.7)	0.034*
Social	−5.6 (−7.9, −3.4)	−6.2 (−8.6, −3.8)	0.6 (−2.7, 3.9)	0.730

Positive scores indicate better GHS/QoL and functioning
*Did not meet the predefined threshold of clinical meaningfulness

Conclusions: TTD in GHS/QoL and urinary symptoms were significantly longer with TALA + ENZA vs PBO + ENZA. Modest treatment differences favoring TALA + ENZA vs PBO + ENZA were observed for some functioning scales. These data complement the benefit–risk assessment of TALAPRO-2 for men with mCRPC who have HRR mutations.

Clinical trial identification: NCT03395197.

Background: TALAPRO-2 evaluated the PARP inhibitor talazoparib (TALA) combined with the androgen receptor pathway inhibitor enzalutamide (ENZA) as 1st-line treatment in patients (pts) with metastatic castration-resistant prostate cancer (mCRPC). The primary endpoint was radiographic PFS (rPFS) assessed centrally. Exploratory biomarker analyses assessed g vs s origin of HRR gene alterations and potential associations with efficacy in the HRR-deficient population from TALAPRO-2.

Methods: Alterations were defined as known/likely pathogenic variants. The frequency of gHRR alterations (gHRRm) was assessed in pts evaluable for saliva sequencing using the Ambry CustomNext-Cancer panel (sequenced 9/12 genes from

the HRR12 tumor panel). Association of g vs s tumor HRRm and efficacy was assessed in the ITT population using saliva data (or solid tumor s-g-zygosity prediction when adequate saliva results unavailable) to annotate tumor alteration origin (limited to short variants). Associations with rPFS were evaluated using a stratified log-rank test. Data cutoff: October 3, 2022.

Results: 91/302 pts (30.1%) evaluable for gHRR exhibited $\geq$1 HRR alteration in their saliva: *BRCA2* (14.9%); *CHEK2* (7.3%); *ATM* (4.0%); *PALB2* (2.3%); *BRCA1* (1.0%); *NBN* (1.0%); *MRE11A* (0.7%); *MLH1* (0.3%). Where evaluable, solid tumor and prospectively tested baseline ctDNA HRR alterations were typically of s origin (eg *BRCA2* [44 g vs 50 s], *CDK12* [1 g vs 27 s], *ATM* [14 g vs 49 s]) with some exceptions (eg *BRCA1* [7 g vs 4 s], *CHEK2* [24 g vs 2 s], *NBN* [5 g vs 2 s]). rPFS was comparable for pts with g and s alterations in the TALA + ENZA arm (HR 0.74, 95% CI, 0.35−1.58; 2-sided *P* value = 0.44), but relatively shorter for gHRRm pts in the placebo (PBO) + ENZA arm (HR 1.87, 95% CI, 1.06−3.30; $P = 0.03$).

Conclusions: GHRRm incidence in mCRPC pts with tumor HRRm was 30.1%. No association with differential antitumor activity for TALA + ENZA was observed in tumors bearing HRRm of g vs s origin. Though the analyses were exploratory, a shorter rPFS in PBO + ENZA-treated gHRRm pts may reflect an intrinsically poor prognosis subgroup that could be prioritized for TALA + ENZA treatment. Further study is warranted.

Lee Moffitt Cancer Center & Research Institute - Magnolia Campus, Tampa, FL, USA; [10]Urology Department, Hospital St. Luc du CHUM, Montreal, QC, Canada; [11]Clinical Dpt, ESSA Pharmaceuticals Corp., South San Francisco, CA, USA

Background: EPI-7386 is a next generation aniten designed to inhibit androgen receptor (AR) activity by binding the N-terminal domain and blocking transcription despite resistance driven by point mutations and splice variants in the ligand-binding domain. In preclinical models, the combination of EPI-7386 with Enz results in a deeper blockade of the AR pathway and greater antitumor activity, prompting this trial.

Methods: This phase I/II multicenter, open-label clinical trial (NCT05075577) is enrolling mCRPC patients on androgen deprivation therapy and naïve to second-generation antiandrogens (1 line of prior chemotherapy in the metastatic hormone sensitive setting allowed). PI examines escalating doses of EPI-7386 with Enz. Primary and secondary endpoints of PI evaluate the safety and pharmacokinetics (PK) of EPI-7386 and Enz when co-administered to establish recommended phase II combination doses (RP2CDs) and address possible drug-drug interactions (DDIs). Once RP2CDs are established, phase II (PII) will commence as a two arm, 2:1 randomized trial evaluating antitumor activity of EPI-7386 in combination with Enz versus Enz alone.

Results: To date, 11 patients have been enrolled in cohorts 1-3 (cohort 4 is currently enrolling). Safety is consistent with second-generation antiandrogens (e.g., Grade 1 or 2 AEs of fatigue and hot flashes). PK results demonstrate Enz exposure is minimally impacted by EPI-7386, allowing testing of the full dose of Enz (160 mg) in the current cohort 4. EPI-7386 exposure is strongly reduced by Enz (CYP3A4 inducer that metabolizes EPI-7386) but remains in the clinically relevant range seen in xenograft studies. EPI-7386 BID dosing shows an increase in EPI-7386 exposure and mitigates DDI caused by Enz. Data from the first 10 evaluable patients show 9/10 achieve a PSA90, and 7/10 patients reach PSA $<$0.2 ng/mL.

Conclusions: With no safety concerns from cohorts 1-3, cohort 4 is currently enrolling at EPI-7386 BID + 160 mg QD Enz to evaluate optimal RP2Ds before the P2 component of the trial. Updated results, including cohort 4, will be presented.

Clinical trial identification: NCT05075577.

Background: VISION study showed that [^{177}Lu]Lu-PSMA-617 added to BSoC prolonged imaging based progression-free survival and overall survival in patients (pts) with PSMA-positive mCRPC. French Health Authorities has granted a "cohort" early access for [^{177}Lu]Lu-PSMA-617 in this indication.

Methods: PSMA positive pts with mCRPC pretreated with 1-2 taxane chemotherapy and $\geq$1 androgen receptor pathway inhibitor (ARPI) were included. Treatment administration planned 6 IV of [^{177}Lu]Lu-PSMA-617 (7.4 GBQ) every 6 weeks. Pts' characteristics, efficacy and safety data were collected during the 6 follow-up visits (average: 17,1 $\pm$ 11,2 weeks). AE grading was not evaluated.

Results: From 12/1/2021 to 1/31/2023, 664 pts were exposed to treatment. At data closure, 428 were still under treatment, and 236 stopped treatment due to disease progression (50.2%), adverse events (AE) (14.0%) or death (11.0%; 1 death suspected to be due to the treatment). 42 pts (17.6%) completed all 6 injections. Pts baseline characteristics: median age 72.9 years; ECOG status 0-1: 85.4%; median PSA level 81.94 ng/ml; metastases: bone 94.1%, lymph node 63.0%, liver 11.3%; prior taxane regimen: 97.4% of which 65.5% received 2 taxane; prior ARPI treatment: 100% of which 67.9% received 2-5 previous ARPI treatments. For pts who received all injections, disease control was estimated by radiological (2.7% CR, 40.5% PR, 27.0% SD), clinical (11.9% clinical improvement and 78.9% stabilization), and PSA evaluation (34.2% decreased PSA level and 34.2% stabilization). 11.9% of pts experienced $>$1 treatment-related AE, including 63 pts with $\geq$1 serious AE. 3 fatal cases and 3 life-threatening cases related to treatment have been reported. The most reported AEs were thrombocytopenia (5.7% of pts) and anemia (4.5% of pts).

Conclusions: We observed a higher incidence of prior 2 taxane regimen and lymph nodes metastases at baseline compared to VISION study but the safety profile of [^{177}Lu]Lu-PSMA-617 remains safe and well tolerated. Since the study is still ongoing, updated efficacy results will be further analyzed and presented at ESMO congress, including longer follow-up period and higher number of pts who completed treatment.

Background: TALAPRO-1 evaluated talazoparib in patients (pts) with mCRPC and homologous recombination repair (HRR) alterations (11-gene panel, including *BRCA1/2, PALB2,* and *ATM*), who had received at least a taxane-based chemotherapy regimen and progressed on $\geq$1 novel hormonal therapy. Primary endpoint was objective response rate (RECIST 1.1) by blinded independent central review. Exploratory biomarker analyses assessed ctDNA and its associations with antitumor activity.

Methods: Serial ctDNA samples from Weeks (Wks) 1, 9, and 25, and Safety follow-up visit (SFUV) were assessed using FoundationOne Liquid CDx. Plasma tumor fraction (TF) was calculated based on tumor aneuploidy as described by Husain et al (JCO Precis Oncol 2022; 6:e2200261). Data cut-off was September 4, 2020 (primary completion date).

Results: *BRCA2* mutational complexity (variants/*BRCA2*m pts) was 18/16 (1.1), 12/10 (1.2), 62/11 (5.6), and 57/14 (4.1) at Wks 1, 9, and 25, and SFUV, respectively. At Wk 25, the median number of *BRCA2* variants was 2 (range 1−18; 3 pts had $\geq$15 variants). Mutational complexity increased for *BRCA1* and *PALB2* by Wk 25 but remained unchanged for *ATM*. Of 26 evaluable pts, 7 cases of emergent variants in PARP1, PARP2, or PARP3 at Wk 25 and/or SFUV were detected. These included 5 cases of PARP1 variants predicted to truncate PARP1 and/or inhibit talazoparib binding, including 3 cases of A898T. 15/27 pts had TF quantifiable at Wk 1 (range 10−68%). Of these 15 pts, 10 had TF below limit of quantitation (BLQ; 10%), 1 had TF reduction $\geq$50%, and 4 had TF unchanged (change $<$50%) at Wk 9. Reductions to BLQ were seen in 4/4 with partial response, 2/2 with non-complete response/non-progressive disease, 3/5 with stable disease (an additional patient reduced $\geq$50%), and 1/4 with progressive disease.

Conclusions: Increased mutational complexity of genes in the *BRCA1-PALB2-BRCA2* axis and emergent PARP variants likely reflects selective pressure to escape talazoparib-mediated synthetic lethality and/or PARP trapping. Early reductions in TF were evident and numerically more common in pts with antitumor responses. Further exploration of emergent variants in HRR and PARP genes and of ctDNA burden are warranted.

Clinical trial identification: NCT03148795.

1816P Combination treatment with radium-223 (223Ra) and enzalutamide (enza) in patients (pts) with metastatic castration-resistant prostate cancer (mCRPC) in the REASSURE study

B. Tombal[1], P.J. Goebell[2], N.D. Shore[3], D.J. George[4], A. Pinto[5], O. Sartor[6], J. Meltzer[7], F. Verholen[8], A. Schmall[8], F. Saad[9]

[1]Division of Urology, Cliniques Universitaires St. Luc, Brussels, Belgium; [2]Department of Urology, Friedrich-Alexander University, Erlangen, Germany; [3]Uro-Oncology Department, Carolina Urologic Research Center, Myrtle Beach, SC, USA; [4]Medical Oncology Department, Duke University School of Medicine, Durham, NC, USA; [5]Medical Oncology Department, La Paz University Hospital, Madrid, Spain; [6]Tulane Cancer Center, Tulane University School of Medicine, New Orleans, LA, USA; [7]Medical statistics, Bayer HealthCare Pharmaceuticals Inc., Whippany, NJ, USA; [8]Global Medical Affairs, Oncology, Bayer Consumer Care AG, Basel, Switzerland; [9]Cancer Prognostics and Health Outcomes Unit, Division of Urology, University of Montréal Health Center, Montreal, QB, Canada

Background: ^{223}Ra and enza both prolong overall survival (OS) in pts with mCRPC. Their different mechanisms of action and non-overlapping safety profiles make them attractive combination partners. Here, we present clinical outcomes of pts who received combined or layered treatment with ^{223}Ra and enza in REASSURE (NCT02141438), a global, prospective, observational study of ^{223}Ra use in pts with mCRPC.

Methods: Data from 1,465 pts (All pts) were analysed. Pt subgroups included "combined" (pts started ^{223}Ra and enza within 30 days of each other, n=46) and "layered" (pts started ^{223}Ra >30 days after starting enza or vice versa, n=205). Statistics were descriptive in nature.

Results: The proportions of pts who had completed ≥1 life-prolonging therapy for mCRPC prior to ^{223}Ra were 43%, 52% and 61% in the combined, layered and All pts groups, respectively (30%, 27% and 33% had received prior abiraterone and 17%, 29% and 36% had received prior docetaxel, respectively). More pts in the combined group (74%) completed 6 cycles of ^{223}Ra than in the layered (61%) or All pts (59%). Median duration of observation from start of ^{223}Ra for combined, layered and All pts was 17.3, 11.1 and 11.5 months (mo), respectively. The proportions of pts with a ≥30% decline in alkaline phosphatase at week-12 were 58%, 41% and 47% in the combined, layered and All pts groups, respectively; corresponding values for a ≥30% decline in prostate specific antigen were 54%, 17% and 20%. Median OS was 22.2 mo (95% CI 13.7—26.8) in the combined group, 16.5 mo (95% CI 13.9—19.5) in the layered group and 15.6 mo (95% CI 14.6—16.5) in All pts.

Table: 1816P Summary of safety

	Combined group n=46	Layered group n=205	All Pts n=1,465
Drug-related any-grade TEAE, n (%)	17 (37)	58 (28)	510 (35)
Drug-related grade ≥3 TEAE, n (%)	6 (13)	17 (8)	155 (11)
Drug-related serious adverse events, n (%)	5 (11)	15 (7)	80 (5)
Concomitant bone health agent (BHA), n (%)	25 (54)	95 (46)	566 (39)
Fractures in pts with concomitant BHA, n (%)	2 (8)	2 (2)	19 (3)
Without concomitant BHA, n (%)	21 (46)	110 (54)	899 (61)
Fractures in pts without concomitant BHA, n (%)	1 (5)	4 (4)	51 (6)

Conclusions: When combined or layered with enzalutamide, treatment with ^{223}Ra was not associated with new safety signals and did not appear to increase fracture risk. Median OS was numerically longer in the combined vs the layered group or All pts. A phase 3 trial (PEACE III, NCT02194842) investigating the combination of enza with ^{223}Ra is ongoing.

Clinical trial identification: NCT02141438.

Background: New therapy for mCRPC patients refractory to the second-generation anti-androgen or androgen receptor hormonal therapy and/or chemotherapy is a definite unmet medical need. The ORR and median rPFS of refractory mCRPC patients are 7% to 17% and 2 to 4 months in second to fourth line settings, respectively. Studies have reported that AKT inhibitor plus an anti-androgen inhibitor is a potential treatment for refractory mCRPC with a longer rPFS and a better ORR compared to standard of care (SOC).

Methods: This is a multicenter, open-label, global phase I/II study to assess the efficacy and safety of combination therapy of LAE001 (a dual inhibitor of CYP17A1 and CYP11B2)/prednisone plus afuresertib (an AKT inhibitor) in refractory mCRPC patients who failed 1-3 lines of SOC. The patients in phase I and phase II received the combination therapy of LAE001 75 mg BID/prednisone 5 mg BID plus afuresertib 125 mg QD were included in analysis.

Results: The study enrollment was completed on 01Mar2023. At the data cut-off date on 25Apr2023, 40 patients (6 from phase I and 34 from phase II) were treated and followed-up between 1.8 to 31.3 months. The median prior lines of therapy were 2 and median Gleason score was 9. Seven rPFS events were observed and 26 patients are still in the study without radiographic tumor progression. The rPFS data is expected to be mature and will be reported at the meeting. Partial response per RECIST 1.1 were observed in 3 of 10 patients who had measurable lesions at baseline and at least one post-baseline tumor assessment. The most commonly reported AEs ($\geq$ Grade 3) were thrombocytopenia (7.5%), anaemia (5.0%), hyperglycaemia (5.0%), hyponatraemia (5.0%), and hypertension (5.0%). SAEs were reported in 9 patients (22.5%), 5 (12.5%) were assessed as related to study treatment. No related G5 AE occured.

Conclusions: The combination therapy demonstrated clinical benefit and a tolerable safety profile in mCRPC patients who failed multiple lines of SOC. The preliminary results warrant further evaluation in a phase III pivotal trial.

Clinical trial identification: NCT04060394.

Background: In the multicenter, phase IIb OSTRICH trial, poor-prognosis mCRPC patients were randomized between CBZ and ARTA, directly following progression on docetaxel (DOC) treatment.

Methods: mCRPC patients with poor-prognosis ($\geq$1 factor: visceral metastases, CRPC within 1 year, progression $\leq$6 months after DOC completion) were randomized 1:1 between CBZ and ARTA (Abiraterone OR Enzalutamide). Primary endpoint was to establish the Clinical Benefit Rate (no radiotherapy, no ECOG PS increase $\geq$2, no therapy switch and no radiological progression) at 12 weeks (CBR) in both study arms, while comparison of the CBR was a secondary endpoint. A Fisher Exact test was used to assess differences in rates and a log rank test to assess differences in time to event endpoints.

Results: A total of 106 patients were randomized, 53 in each arm. Baseline median age was 70 and PSA 76 ng/ml. DOC was received in the HSPC stage in 36 patients (34%), while 40 patients (38%) received ARTA prior to DOC. CBR was 60.8% (95% CI: 46.1 − 74.2%) in the CBZ arm and 67.3% (95% CI: 52.9 − 79.7%) in ARTA arm (p=0.54)). At 12 weeks, PSA responses were 17% (95% CI: 8.1−29.8%) and 5.3% (95% CI:31.6−59.6%) in the CBZ and ARTA arms, respectively (p = 0.003). After a median follow-up of 30.9 (95% CI: 25 − NA) months, median Time to Symptomatic Progression was 4.2 (95% CI: 3.7 − 5.9) vs 5.8 (95% CI: 4.6 − 6.5) months in the CBZ vs ARTA arm (p=0.07). Time to Radiological progression was 7.1 (95% CI: 5.3 − 13.8) and 5.8 (95% CI: 5.4 − 11.4) months in CBZ and ARTA (p=0.77), Time to PSA progression was 3.6 (95% CI: 2.6 − 7.8) and 4.1 (95% CI: 3.3 − 8.9) months in the CBZ and ARTA arm (p=0.95), respectively. Progression free survival 2.5 (95% CI: 2.2 − 3.4) in the CBZ arm and 3 (95% CI: 2.6 − 3.6) months ARTA arm (p=0.24). Overall Survival was 14.9 (95% CI: 9.7 − 19.5) months in CBZ and 13.9 (95% CI: 11.7 − 16.5) months in the ARTA arm (p=0.53). Grade $\geq$3 adverse events (AEs) occurred in 62% and 26% patients in CBZ and ARTA arm.

Conclusions: No significant difference in CBR and time to event endpoints was established between CBZ and ARTA treated patients. Further studies will concentrate on prespecified subgroups.

1819P PSMA-BAT: Prospective biomarker trial of patients (pts) with metastatic castration-resistant prostate cancer (mCRPC) undergoing bipolar androgen therapy (BAT)

A.B. Lara Gongora[1], P. Isaacsson Velho[2], J.F. Gomes Marin[3], D.L.F. Jardim[4], L.T. Inoue[5], E.M. Coser[5], C.A. Buchpiguel[3], F. Galiza[3], M. Queiroz[3], A. Schuch[6], G.B. Grossman[6], F. Bettoni[5], A.A. Camargo[7], D.A. Bastos[1]

[1]Medical Oncology, Hospital Sírio-Libanês, São Paulo, Brazil; [2]Oncology Department, Hospital Moinhos de Vento, Porto Alegre, PA, Brazil; [3]Nuclear Medicine, Hospital Sírio-Libanês, São Paulo, Brazil; [4]Clinical Oncology Department, Hospital Sirio Libanes - Complexo Hospitalar Bela Vista, São Paulo, Brazil; [5]Molecular Oncology Center, Instituto Sirio-Libanes de Ensino e Pesquisa, São Paulo, Brazil; [6]Nuclear Medicine Department, Hospital Moinhos de Vento, Porto Alegre, Brazil; [7]Molecular Oncology Center, Hospital Sirio Libanes - Complexo Hospitalar Bela Vista, São Paulo, Brazil

Background: BAT has shown clinical activity and capacity of tumor resensitization to androgen receptor targeted therapy in mCRPC. We aimed to explore imaging and genomic biomarkers of response to BAT.

Methods: This is a single-arm study of pts with mCRPC and progressive disease on at least one novel AR-targeted therapy. Pts were treated with BAT (testosterone cypionate 400 mg intramuscular) every 4 weeks. All pts underwent PSMA-PET/CT (PSMA-PET) and FDG-PET/CT (FDG-PET) at baseline and week 12. Molecular tumor volume (mTV), total lesion expression (TL), standardized uptake value (SUV) max and mean were evaluated in PSMA-PET scans; total lesion glycolisys (TLG), metabolic tumor volume (MTV), SUVmax and SUVmean in FDG-PET scans. AR-V7 expression in circulating tumors cells (CTCs) was analyzed in each cycle and at week 12. Variables were correlated with PSA response, 6-month progression-free survival (PFS) and overall survival (OS).

Results: A total of 20 pts were included from Oct 2020 to Mar, 2022. Median age was 66y, and median number of prior systemic therapies was 3.5 (2-5). Any PSA and PSA50 responses were achieved in 45% and 30% of pts. Median PFS was 5.6 months (mos) (95% CI 3.4 - 7.8 mos), and 40% reached a PFS >6 mos. PFS or OS were not associated with baseline PSA or demographic characteristics. Higher interim PSMA mTV, variation (Δ) mTV week 12-baseline mTV > -17%, Δ TL-PSMA week 12-baseline >39% and higher week 12 PSA/PSMA SUVmax were associated with PFS < 6 mos (p=0.01; p=0.009; p=0.009, p=0.01). Median OS was 23.1 mos. Higher baseline PSMA mTV, TL-PSMA, FDG MTV and TLG were associated with worse OS (p=0.009; p=0.02; p=0.006; p=0.02). At baseline, 14/20 pts were positive (+) for CTCs. Of those, 8 were AR-V7+. At week 12, 6 pts became negative (-) for CTCs and 6 became - for AR-V7; only 2 pts became + for CTCs and none became + for AR-V7. The difference between baseline and week 12 AR-V7 + pts was statistically significant (p=0.03). Positive AR-V7 was associated with worse OS (p<0.05).

Conclusions: Higher PSMA-PET mTV and TL-PSMA may predict worse PFS in pts treated with BAT. Positive AR-V7 was associated with worse OS. Responses to BAT can influence AR-V7 dynamics. Larger trials are necessary to confirm our findings.

Clinical trial identification: NCT04424654.

1820P Cardiovascular effects of androgen receptor signalling inhibitors in the treatment of advanced and metastatic prostate cancer: A systematic review and meta-analysis of randomised controlled trials

O. El-Taji[1], C. Jones[1], M.D. Brown[2], N.W. Clarke[1], A. Sachdeva[1]

[1]Genitourinary Cancer Research Group, University of Manchester, The Christie & Salford NHS Foundation Trust, Manchester, UK; [2]Genito Urinary Cancer Research Group, The University of Manchester, Manchester, UK

Background: Cardiovascular (CV) events remain a significant cause of mortality amongst men with advanced and metastatic prostate cancer (PCa). The introduction of novel androgen receptor signalling inhibitors (ARSI) has transformed the treatment landscape of PCa in recent years, however their impact on CV toxicity remains unclear. We aimed to assess the CV effects of ARSI treatment in combination with standard of care (SOC) in advanced and metastatic PCa.

Methods: Systematic search of PubMed, SCOPUS, Web of Science, EMBASE and Clinicaltrials.gov were performed to identify randomized controlled trials (RCTs) comparing the addition of ARSI agents (Enzalutamide, Abiraterone, Apalutamide and Darolutamide) with SOC in treatment of non-metastatic and metastatic PCa, across both hormone-sensitive and castrate resistant settings. Outcomes of interest included: CV events defined by CV event grade (primary outcome), hypertension, acute coronary syndrome (ACS), cardiac dysrhythmia, CV death, cerebrovascular event, and venous thromboembolism (secondary outcomes).

Results: A total of 22 studies (n=22,967) were eligible for inclusion. ARSI therapy increased risk of any grade CV event (RR 1.72, 1.49-2.00, p<0.0001) and grade $\geq$ 3 CV events (RR 1.98 [1.58-2.48] p<0.0001). ARSI therapy also resulted in an increase in grade $\geq$ 3 hypertension (RR 2.02 [1.62-2.53] p<0.0001), ACS (RR 2.00 [1.46-2.74] p<0.0001), grade $\geq$3 cardiac dysrhythmia (RR 1.64 [1.23-2.19] p=0.0007), CV related death (RR 1.88 [1.22-2.89] p=0.004) and cerebrovascular events (RR 1.76[1.33-2.34] p<0.0001) across all PCa settings. Subgroup analysis demonstrated increased risk of all CV events and grade $\geq$3 across the disease spectrum (RR for all CV events: non-metastatic hormone sensitive PCa 2.20 [1.4-3.47], p<0.0007; metastatic hormone sensitive PCa 1.69 [1.39-2.06], p<0.0001; metastatic castrate resistant PCa 1.53 [1.36-1.71], p<0.0001).

Conclusions: There is compelling evidence indicating a significantly increased risk of all and high-grade CV events in men treated with ARSIs.

1821P High serum FSH/T ratio as a marker for the development of cardiovascular disease in ADT recipients

J.H. Pinthus[1], D. Margel[2], V. Subramony Gayathri[1], E. Duceppe[3], S. Yousef[4], M. Naeim[4], M. Khajehei[4], S. Hopmans[4], S. Popovic[5], Y. Ber[6], D. Heels-Ansdell[7], P.J. Devereaux[7], W.C.M. Duivenvoorden[1]

[1]Surgery, McMaster University, Hamilton, ON, Canada; [2]Urology Department, Rabin Medical Center, Petah Tikva, Israel; [3]Medicine, Université de Montreal - Faculté de Médecine, Montreal, QC, Canada; [4]Surgery, McMaster Institute of Urology - St. Joseph's Healthcare Hamilton, Hamilton, ON, Canada; [5]Department of Pathology and Molecular Medicine, McMaster University, Hamilton, ON, Canada; [6]Urology, Rabin Medical Center, Petah Tikva, Israel; [7]Population Health Research Institute, McMaster University, Hamilton, ON, Canada

Background: Cardiovascular disease (CVD) is a leading cause of death in men with prostate cancer (PC). Androgen deprivation therapy (ADT) may increase this risk. GnRH agonists or antagonists induce equivalent castration but have a distinctive effect on follicle-stimulating hormone (FSH). We hypothesize that FSH mediates the atherogenic and cardiovascular effects associated with testosterone (T) deficiency.

Methods: We investigated mouse models of atherosclerosis using gain and loss of FSH and two clinical studies with primary CVD endpoints. Low-density lipoprotein receptor-deficient (LDLR-/-) and FSHβ-/-;LDLR-/- mice were treated with different modes of ADT for 14 weeks and aortic atherosclerotic plaque, its necrotic and inflammatory content and serum hormones were determined. In a prospective cohort of PC patients commencing on ADT, serum FSH and T were determined after three and six months and related to the development of cardiovascular events. In a prospective nested case-control study of 848 men undergoing surgery, serum FSH and T were related to the development of cardiovascular event.

Results: Compared to LDLR-/- mice, FSHβ-/-;LDLR-/- mice, untreated or castrated, demonstrated significantly less atherosclerosis, but not following delivery of FSH. The significant differences in necrotic core and total atherosclerotic plaque in mice treated with GnRH-agonists vs. antagonists were nullified by loss of FSH in the FSHβ-/-;LDLR-/- mice. Atherosclerotic plaque, its necrotic and inflammatory content, correlated significantly with the serum FSH/T ratio. In PC patients commencing on ADT, serum FSH/T after three and six months significantly predicted the development of cardiovascular event. In men undergoing surgery, high FSH/T ratio increased odds of a postoperative cardiovascular event by 39% (95% CI 3-87%).

Conclusions: FSH facilitates CVD in men with low or castrated T. Serum FSH/T ratio associates with the risk of developing a cardiovascular event following a stressful cardiovascular trigger such as ADT or surgery. Accordingly, GnRH-antagonists associated with lower necrotic and atherosclerotic plaque burden in mice and clinically, with significantly lower serum FSH/T levels and fewer cardiovascular events compared to GnRH-agonists.

1822P PSMA-alpha targeted radionuclide therapy (TRT) with or without prior PSMA-beta TRT

M. Sun[1], C. Thomas[2], J. Stangl-Kremser[3], A. Fajardo[4], J. Palmer[1], J. Thomas[5], S. Huicochea Castellanos[4], J. Osborne[6], J. Nauseef[7], A.M. Molina[1], C.N. Sternberg[1], D.M. Nanus[8], N.H. Bander[9], S.T. Tagawa[10]

[1]Hematology and Medical Oncology, NewYork-Presbyterian Hospital/ Weill Cornell Medical Center, New York, NY, USA; [2]Biostatistics, Weill Cornell Medicine, New York, NY, USA; [3]Urology, New York Presbyterian/Weill Cornell Medical Center, New York, NY, USA; [4]Nuclear Medicine, NewYork-Presbyterian Hospital/ Weill Cornell Medical Center, New York, NY, USA; [5]Hematology and Oncology, NewYork-Presbyterian Hospital/Weill Cornell Medical Center, New York, NY, USA; [6]Nuclear Medicine, Weill Cornell Medicine, New York, NY, USA; [7]Division of Hematology and Oncology, Weill Cornell Medicine - Belfer Research Building, New York, NY, USA; [8]Medicine, Weill Cornell Medical College, New York, NY, USA; [9]Urology, Weill Cornell Medicine, New York, NY, USA; [10]Urology, Hematology and Medical Oncology Department, NewYork-Presbyterian Hospital/Weill Cornell Medical Center, New York, NY, USA

Background: PSMA-TRT has included either beta-emitters (Lutetium-177) or alpha-emitters (Actinium-225). Responses have been observed in patients treated with 225Ac after 177Lu, supporting sequential administration. There are no known data-driven normal organ dose limits for radionuclide therapy, with putative limits extrapolated from EBRT. Here, we evaluate baseline demographics and prior exposures for association with outcome following treatment with 225Ac-J591.

Methods: Patients treated on prospective clinical trials of 225Ac-J591 were retrospectively analyzed with focus on efficacy and adverse events (AEs) with prior therapies (Table). Kaplan-Meier method was used for time to event endpoints (overall survival/OS, progression-free survival/PFS). Fisher's exact test for analysis of associations between categorical variables.

Results: No significant difference in efficacy of 225Ac-J591 with/without prior 177Lu-PSMA: PSA50 (52 vs 58%), PFS (4.03 vs 5.07 mo), or OS (16.4 vs 17.3 mo); no efficacy differences based upon prior Ra223. Gr 4 myelosuppression may be more common in those with prior 177Lu, though numbers are small (n=1 for ANC and Hb; 14 vs 7.8% Gr 4 plts, p=0.4). No differences in frequency of nausea, xerostomia, or pain were seen with/without prior 177Lu, but Gr 2 fatigue was more common in those with prior 177Lu (48 vs 17%, p=0.023). No treatment-related renal failure observed with short-term follow up +/- prior 177Lu. Similar AE trends were seen for Gr 4 heme AE with prior Ra223 exposure, but no trend for non-heme AEs. Those with ≥2 lines chemo may be more likely to have Gr 4 heme AE. Within limits of small sample size, higher exposure of sequential 177Lu, Ra223, EBRT, and 225Ac-J591 associated with higher rate of Gr 4 plts (p=0.031).

Table: 1822P

225Ac-J591 n=86	
Median PSA	50.9 (range 2.43-9614)
Median age	71.5 (range 51-91)
Bone metastases	74 (86%)
Nodal metastases	49 (57%)
Lung metastases	10 (12%)
Liver metastases	10 (12%)
CALGB high risk	47 (55%)
CALGB intermediate risk	29 (34%)
CALGB low risk	10 (12%)
Prior 177Lu-PSMA TRT	22 (26%)
Prior Radium-223 (Ra223)	15 (17%)
>1 androgen-receptor pathway inhibitor	51 (59%)
Taxane chemotherapy	50 (58%)
Median # External Beam Radiation Therapy (EBRT)	1 (range 0-6)

Conclusions: Alpha-TRT with 225Ac-J591 retains efficacy following beta-TRT and Ra223. Risk of Gr 4 plts appears highest in those with prior 177Lu and Ra223 and EBRT, but high-grade events are rare. New examination of organ dose-limits with TRT is warranted.

Background: Imaging prior to Radium-223 therapy (Ra-223) is crucial for selecting metastatic castration-resistant prostate cancer (mCRPC) patients with bone-only disease. The purpose of this study was to evaluate if baseline PSMA PET/CT versus CT is associated with biochemical response during Ra-223.

Methods: A secondary analysis of the data of a prospective observational study (NCT04995614) was performed. Patients received a maximum of six cycles of Ra-223 and were retrospectively divided into the PSMA PET/CT (bPSMA) or CT (bCT) group based on baseline imaging technique. All patients received baseline bone scintigraphy. Primary endpoints were alkaline phosphatase (ALP) and prostate specific antigen (PSA) response, defined as ≥ 30% decline from baseline. Secondary endpoints were overall survival (OS) and radiological response.

Results: Between 2017 and 2020, 122 mCRPC patients were included: 18 (14.8%) in the bPSMA and 104 (85.2%) in the bCT group. All baseline characteristics were comparable. No significant differences in ALP or PSA response were found between the groups. The bCT group showed a significant shorter OS compared to the bPSMA group (12.4 vs.19.9 months, $p < 0.01$, table). Post-therapy soft tissue involvement (STI) was detected in 29/76 patients (38.2%) that received bCT and post-therapy CT (bCT/pCT), compared to 0/18 bPSMA patients. No significant difference in OS was found between bCT/pCT patients without STI and bPSMA patients.

Table: 1823P OS (months) among subgroups

Baseline imaging	Post-therapy imaging	N	Median OS (IQR)	P-value
PSMA	Total PSMA A. STI B. W/o STI CT C. STI D. W/o STI No imaging	18 11/18 0/11 11/ 11 4/18 0/4 4/4 3/18	19.9 (12.7 — 29.0) - - 21.2 (14.7 — 40.8) - - 20.3 (15.2 — 36.8) 4.9 (3.1 - NR)	**0.038** vs. bCT - - - - - - -
CT	Total PSMA A. STI B. W/o STI CT C. STI D. W/o STI E. Unknown STI No imaging	104 7/104 6/7 1/7 76/104 29/76 44/76 3/76 21/104	12.4 (7.9 — 18.2) - 14.6 (11.5 — 24.9) 21.5 (NR) - 10.6 (6.0 — 14.2) 14.8 (9.3 — 26.0) - 9.2 (4.0 — 12.9)	**0.038** vs. bPSMA - - - - **<0.01** vs. bCT/pCT w/o STI 0.457 vs. bPSMA - -

Abbreviations: W/o, without; NR, not reached.

Conclusions: bPSMA versus bCT does not seem to predict biochemical response during Ra-223. Nevertheless, patients in the bCT group had a significantly shorter OS, most likely due to underdetection of STI in this group. Therefore, replacing baseline CT with PSMA PET/CT appears to be a valuable screening method to ensure in-label use of Ra-223.

1824P Treatment patterns among novel hormonal therapy-experienced patients with metastatic castration-resistant prostate cancer

V. Narayan[1], M. Patel[2], S. Teitsson[3], L. Rosenblatt[2], X. Yin[2], K.A. Betts[4], I. Pivneva[5], S. Gao[4], M. Sundar[4]

[1]Division of Hematology and Medical Oncology, University of Pennsylvania, Philadelphia, PA, United States of America; [2]Worldwide Health Economics & Outcome Research, Bristol Myers Squibb, Lawrenceville, NJ, United States of America; [3]Worldwide Health Economics & Outcome Research, Bristol Myers Squibb, Uxbridge, United Kingdom; [4]Health Economics & Outcome Research, Analysis Group Inc., Los Angeles, CA, United States of America; [5]Health Economics & Outcome Research, Analysis Group Inc., Montreal, QC, Canada

Background: Patients with advanced prostate cancer are commonly treated with novel hormonal therapy (NHT). However, treatment patterns following NHT remained unclear. This study evaluated treatment patterns among metastatic castration-resistant prostate cancer (mCRPC) patients with prior NHT.

Methods: This study used the Flatiron Health electronic health records data between 1/1/2013-7/31/2022. NHT-experienced mCRPC patients with $\geq$ 1 line of therapy (LOT) in the mCRPC setting and without chemotherapy in the last 365 days were included. The first LOT in the post-NHT mCRPC setting was defined as index line. Treatment patterns in the post-NHT mCRPC setting were summarized.

Results: A total of 804 patients (median follow-up: 10.6 months) were included. Of these, 239 (30%) patients used enzalutamide as index LOT, 191 (24%) patients used abiraterone, 171 (21%) used docetaxel, and 203 (25%) used other treatment (Table). Patients receiving prior NHT in the non-metastatic castration-resistant or metastatic castration-sensitive settings were more likely to cycle to NHTs than those receiving prior NHT in the mCRPC setting. The median time on treatment for index LOT was 4.1 months. A total of 126 (16%) patients died within 90 days after index LOT while 494 (61%) patients received a 2nd post-NHT LOT. Subsequently, 104 (13%) patients died within 90 days after the 2nd post-NHT LOT while 265 (33%) patients received a 3rd post-NHT LOT. Most patients received chemotherapy while fewer patients received NHTs in the 2nd and 3rd post-NHT LOTs. Commonly observed treatment sequences included index enzalutamide followed by docetaxel (N=62, 8%), index docetaxel followed by other chemotherapy (N=54, 7%), and index abiraterone followed by docetaxel (N=48, 6%).

Table: 1824P Treatment patterns in the post-NHT mCRPC setting

	NHT-experienced patients with mCRPC (N = 804)
Index line (the 1st post-NHT LOT)	804 (100%)
Enzalutamide	239 (30%)
Abiraterone	191 (24%)
Docetaxel	171 (21%)
Other NHTs	29 (4%)
Radium-223	22 (3%)
Other chemotherapy	21 (3%)
Poly adenosine diphosphate ribose polymerase inhibitors (PARPi)	8 (1%)
Other	123 (15%)
The 2nd post-NHT LOT	494 (61%)
Docetaxel	145 (18%)
Other chemotherapy	90 (11%)
Enzalutamide	58 (7%)
Abiraterone	39 (5%)
Radium-223	29 (4%)
Other NHTs	21 (3%)
PARPi	15 (2%)
Other	97 (12%)
The 3rd post-NHT LOT	265 (33%)
Other chemotherapy	96 (12%)
Docetaxel	58 (7%)
Enzalutamide	17 (2%)
Radium-223	16 (2%)
PARPi	10 (1%)
Other NHTs	9 (1%)
Abiraterone	7 (1%)
Other	52 (6%)

Conclusions: The real-world treatment patterns in the post-NHT mCRPC setting are heterogeneous, but the majority of patients attempted additional NHT followed by chemotherapy.

St Vincent's Medical School, The University of Melbourne, Parkville, VIC, Australia; [10]Molecular Imaging and Therapeutic Nuclear Medicine, The University of Melbourne, Parkville, VIC, Australia; [11]Medical Oncology Department, Peter MacCallum Cancer Centre, Melbourne, VIC, Australia; [12]Division of Cancer Medicine, Peter MacCallum Cancer Centre, Melbourne, VIC, Australia

Background: The phase I PRINCE trial (NCT03658447) is evaluating efficacy of ^{177}Lu-PSMA-617 plus pembrolizumab for mCRPC. Genomic and clinical features at baseline of patients who respond best to this combination are not yet known.

Objective: Evaluate associations of PET imaging and CTC features at baseline with Department of prostate specific antigen (PSA) response.

Methods: A total of 37 patients were enrolled. PSA levels were assessed 3 weekly. CTCs (CK+, CD45-, and DAPI+) were enumerated from 3ml of blood, immunoassayed for Prostate Specific Membrane Antigen (PSMA) expression, and single CTCs profiled with low-pass whole-genome sequencing (Epic Sciences). Baseline PSMA-PET metabolic tumour volume (MTV) and PSMA expression (SUV) were measured. Patients were split into response groups based on the best percentage change in PSA from baseline: Good (drop in PSA >90%, n=17), Intermediate (drop in PSA <90%, n=16) and Poor (no decrease in PSA, n=4). Wilcoxon and Kruskal-Wallis tests were used for pairwise and multi-group comparisons, respectively.

Results: MTV (mls) was lower in the Good (median: 218) than in both Intermediate (median: 328) and Poor (median: 538) response groups, but pairwise comparison of Good versus Intermediate-Poor responders combined was not significant (Wilcoxon p=0.286). The strongest image-based association was mean PSMA-PET SUV, which increased from Poor (median: 7.8), to Intermediate (median: 8.5) and Good (median: 11) responders, achieving a Wilcoxon p-value of 0.079 for the Good versus the Intermediate-Poor groups. In contrast, stronger associations with PSA response were based on features of baseline CTCs. Baseline PSMA+ CTC counts were higher in Good (mean: 23.7) than Intermediate (mean: 4.3) and Poor (mean: 6) responders (p=0.022). Number of Large-scale State Transitions, a measure of genome instability was lowest for CTCs in Good (mean: 10.2), higher in Intermediate (mean: 15.1), and highest in Poor responders group (mean: 24.4), a highly significant trend (Kruskal-Wallis p=0.0004).

Conclusions: In the PRINCE cohort, CTCs data were more strongly associated with extent of drop in PSA than PET metrics.

Clinical trial identification: NCT03658447.

Background: Lutetium-177(177Lu)-PSMA-617 prolonged progression-free survival (PFS) and overall survival (OS) versus standard of care in metastatic castration-resistant prostate cancer (mCRPC) patients, as shown in the phase III VISION trial; in this trial, patients already received taxane-based chemotherapy. Here we report the analysis from a phase II trial of 177Lu-PSMA617 administered in pre- and post-taxane mCRPC settings.

Methods: In the IRST-185.03 study, which is an open-label, single-center, phase 2 prospective trial, 145 mCRPC patients were enrolled between April 2017 and October 2022. 142 patients received up to 6 cycles of 177Lu-PSMA617 - radiolabelled by IRST Radiopharmacy - every 6 weeks, with a mean dose of 17.5 GBq (up to 33 GBq of total dose). Best biochemical response (BBR), defined as ≥50% PSA reduction from baseline, is the main clinical endpoint of the trial, whilst PFS, OS, and safety are the main secondary endpoints.

Results: Among 142 evaluable patients, 100 patients received at least one cycle of taxane-based chemotherapy for castration-sensitive and castration-resistant disease (post-taxane group), whilst 42 were taxane-naïve (pre-taxane group). Baseline clinical characteristics of the two groups were balanced in terms of age, Gleason score, and previous ARSI, except for a higher proportion of ECOG PS 1-2 patients in the post- versus pre-taxane group (42 and 16.7%, respectively). At the first interim analysis, after a median follow-up of 28.8 months, BBR was obtained in 23 (54.8%) and 35 (35%) patients in the pre- and post-taxane groups, respectively. Median PFS was 8.5 and 6.0 months while median OS was 35.1 and 12.6 months in the pre- and post-taxane groups, respectively. Concerning safety, anemia was the most common adverse event (G1: 71.4 and 69%, G2: 9.6 and 11%. G3: 0 and 5%, in the pre- and post-taxane groups, respectively). No G3 adverse events were recorded in the pre-taxane group.

Conclusions: 177Lu-PSMA617 could be a valid therapeutic choice in taxane-naïve mCRPC patients, especially in those who are deemed frail and unfit for chemotherapy.

Clinical trial identification: EudraCT/RSO 2016-002732-32, Start date: 2017-02-15.

1827P Real-world (RW) overall survival (OS) with enzalutamide (ENZ) and abiraterone acetate (ABI) in patients (pts) with chemotherapy (cx)-naïve metastatic castration-resistant prostate cancer (mCRPC)

D.J. George[1], K. Ramaswamy[2], H. Yang[3], Q. Liu[3], A. Zhang[3], A. Greatsinger[3], J. Ivanova[2], B. Thompson[4], B. Emir[2], A. Hong[2], S.J. Freedland[5]

[1]Department of Medicine, Duke Cancer Institute, Durham, NC, USA; [2]Value and Evidence, Pfizer Inc., New York, NY, USA; [3]Value and Evidence, Analysis Group, Inc., Boston, MA, USA; [4]Oncology, Pfizer Inc., New York, NY, USA; [5]Department of Urology, Cedars-Sinai Medical Center, Los Angeles, CA, USA

Background: There are no head-to-head phase 3 clinical trials comparing OS between ENZ and ABI. A French National Database (SNDS) study reported improved RW OS with ENZ vs ABI.[1] We compared OS in US Medicare pts with cx-naïve mCRPC who initiated ENZ or ABI.

Methods: This retrospective analysis of Medicare fee-for-service claims data (2009—2020) included adult men with ≥1 claim for prostate cancer and a metastatic diagnosis who were cx-naïve and initiated ENZ or ABI (index date) between September 10, 2014, and May 31, 2017. OS overall and by subgroups defined by baseline characteristics was evaluated using Kaplan—Meier analysis with inverse probability treatment weighting (IPTW) to adjust for potential baseline confounders.

Results: Overall, 2911 pts who initiated ABI and 2595 pts who initiated ENZ were included. Baseline characteristics were generally comparable between cohorts. Median follow-up was 19.1 months for ABI and 20.3 months for ENZ. The IPTW-adjusted median OS (95% CI) was 20.6 months (19.7, 21.4) for ABI and 22.5 months (21.2, 23.8) for ENZ, with an IPTW-adjusted hazard ratio (HR) of 1.10 (95% CI 1.04, 1.16; P<0.001). Median OS was significantly shorter for ABI vs ENZ in subgroups of pts who were ≥75 years old, White, low or middle/high (not shown) socioeconomic status (SES), and with baseline comorbidities (cardiovascular disease [CVD], diabetes, and renal disease; table).

Table: 1827P IPTW-adjusted OS

	n	Median OS (IPTW-adjusted), months (95% CI)			P-value
		ABI	ENZA	HR	
Age, years					
≥75	3609	17.4 (16.5, 18.4)	19.5 (18.7, 20.5)	1.16	<0.001
<75	1897	28.0 (26.0, 30.1)	27.9 (26.2, 29.5)	1.00	0.928

White	4285	20.0 (19.1, 21.0)	22.0 (20.6, 23.7)	1.11	0.002
Low SES	1240	17.6 (16.3, 20.1)	21.7 (19.4, 23.8)	1.14	0.040
With baseline					
CVD	4155	18.0 (17.2, 19.2)	20.6 (19.5, 22.0)	1.15	<0.001
Diabetes	1873	18.9 (17.2, 20.7)	21.8 (20.3, 23.8)	1.14	0.009
CVD or diabetes	4432	19.0 (17.9, 20.0)	21.6 (20.1, 23.0)	1.15	<0.001
CVD and diabetes	1556	16.6 (15.2, 18.0)	20.2 (18.3, 21.8)	1.15	0.008
Renal disease	1332	14.5 (13.1, 15.9)	16.8 (15.6, 17.8)	1.15	0.018

Conclusions: In the large, representative US Medicare dataset, pts with cx-naïve mCRPC treated with ABI had significantly shorter OS than those treated with ENZ. This study with >5500 pts validates previous RW studies reporting improved OS with ENZ vs ABI, including a prior French SNDS study with >10000 pts,[1] and shows that results are robust across different health systems. These findings may be particularly important in older pts and those with comorbidities. 1. Scailteux, et al. *Am J Epidemiol*. 2021;190:413—22.

1828P ARX517: A next generation anti-PSMA antibody drug conjugate (ADC) demonstrates notable stability and pharmacokinetic (PK) profile in the ARX517 phase I clinical trial (APEX-01)

S.T. Tagawa[1], J. Shen[2], L. Skidmore[3], J. Nelson[3], R. Pachynski[4], S. Zhang[3]

[1]Urology, Hematology and Medical Oncology Department, NewYork-Presbyterian Hospital/ Weill Cornell Medical Center, New York, NY, USA; [2]Medical Oncology Department, Jonsson Comprehensive Cancer Center at UCLA, Los Angeles, CA, USA; [3]Ambrx, Inc., La Jolla, CA, USA; [4]Oncology Department, Washington University School of Medicine in St. Louis, St. Louis, MO, USA

Background: ARX517 is a next-generation, anti-PSMA, ADC conjugated to AS269 (pAF-269; a potent tubulin inhibitor), at a drug-to-antibody ratio (DAR) of two. ARX517 was designed to address the instability issues encountered by previous PSMA-targeted ADCs with three key components: a non-cleavable PEG linker, a non-cell permeable payload, and stable oxime conjugation chemistry. The site-specific conjugation of AS269 to the mAb is enabled using proprietary synthetic amino acid incorporation. This ADC design minimizes premature payload release and off-target toxicity.

Methods: 21 patients received ARX517 at doses ranging from 0.32 to 2.4 mg/kg across 7 cohorts. ARX517 was administered by intravenous infusion q3w. Patient serum samples were collected at fixed time points and evaluated in validated Total Antibody (TA; sum of deconjugated antibody and conjugated antibody), ADC (conjugated antibody with a DAR of 1 or 2), and payload pAF-AS269 assays. The lower limit of quantitation for the TA, ADC, and pAF-AS269 assays were 62.5 ng/mL, 7.8 ng/mL, and 0.02 ng/mL, respectively. PK parameters were determined using non-compartmental analysis based on serum concentrations of TA, ADC, and pAF-AS269.

Results: ARX517 exhibited virtually overlapping TA and ADC PK concentration-time curves at all dose levels tested, indicating strong stability of the ADC with minimal premature payload release. A long ADC terminal half-life of ~6—10 days was observed at doses $\geq$ 1.4 mg/kg, thereby maximizing drug exposure over a dosing cycle of 3 weeks. Low concentrations of pAF-AS269 (approximately 0.02—0.2 ng/mL) were observed at all dose levels and appeared slowly in the circulation, with Cmax observed approximately 7 days after administration. This is in contrast to other ADCs that typically exhibit payload Cmax hours to days after dosing.

Conclusions: ARX517 is the first anti-PSMA ADC tested in the clinic to demonstrate notable stability and a long terminal half-life. These attributes enable continuous drug delivery throughout the dosing cycle to potentially improve efficacy and minimize toxicity due to premature payload release, indicating a clear and favorable therapeutic index.

Clinical trial identification: NCT04662580.

1829P Exposure-safety analyses of talazoparib in combination of enzalutamide in patients with metastatic castration-resistant prostate cancer (mCRPC) in TALAPRO-2 trial

A.A. Azad[1], Y. Wang[2], M. Hadigol[2], J. Hoffman[2], N. Agarwal[3], N. Matsubara[4], V.R. Lincha[2], F. Zohren[5], L. DeAnnuntis[6], D. Wang[7]

[1]Oncology Department, Peter MacCallum Cancer Centre, Melbourne, VIC, Australia; [2]Clinical Pharmacology - Oncology, Pfizer Inc, San Diego, CA, USA; [3]Oncology/Internal Medicine Department, University of Utah Health - Huntsman Cancer Institute, Salt Lake City, UT, USA; [4]Medical Oncology Department, National Cancer Center Hospital East, Kashiwa, Chiba, Japan; [5]Global Product Development - Oncology, Pfizer, Cambridge, MA, USA; [6]Oncology, Pfizer Inc, San Diego, CA, USA; [7]Clinical Pharmacology - Oncology, Pfizer Inc, San Diego, CA, USA

Background: The TALAPRO-2 trial (NCT03395197) showed that the addition of talazoparib (tala), a potent PARP inhibitor, to enzalutamide (enza) significantly improved radiographic progression-free survival in patients with mCRPC. Approximately 75% and 56% of patients (pts) in TALAPRO-2 experienced dose interruption and dose reduction of tala, respectively, due to an adverse event (AE). We investigated the relationship between tala exposure as well as other factors and Grade 3 or higher Anemia, Thrombocytopenia, and Neutropenia, the most common AEs leading to dose interruptions or reductions.

Methods: Safety and PK data from 412 pts in the tala (starting dose of 0.5 mg QD) + enza (160 mg QD) arm were available. To account for the changes in tala exposure over time due to dose modifications and effect of enza and its n-desmethyl metabolite on tala exposure, time-varying average tala concentrations ($C_{avg,t}$) were used in the analysis. $C_{avg,t}$ was calculated as posthoc estimated AUC_t/t based on population PK model. The relationship between $C_{avg,t}$/potential predictive factors and the selected safety events was evaluated using Cox proportional hazard (PH) univariate and multivariate models with p value cutoff of 0.05.

Results: Visual examination suggested a higher $C_{avg,t}$ in pts with Anemia, Thrombocytopenia, and Neutropenia events versus pts without events. Cox PH models indicated that a higher $C_{avg,t}$ was associated with a higher risk of Grade 3 or higher Anemia, Thrombocytopenia, and Neutropenia. The HR (95% CI) for $C_{avg,t}$ was 1.433 (1.32, 1.555) for Anemia, 1.609 (1.35, 1.917) for Thrombocytopenia, and 6.942 (3.337, 14.44) for Neutropenia. Higher risk of all tested safety endpoints was associated with lower baseline hemoglobin. Higher risk of Anemia was associated with lower baseline body weight (BWT) and higher baseline lactate dehydrogenase. Higher risk of Neutropenia was associated with lower absolute neutrophil count and lower BWT.

Conclusions: A higher risk of Anemia, Thrombocytopenia, and Neutropenia was associated with higher tala exposure. These findings support the proposed dose modification algorithm as an effective approach for management of AEs.

1830P CBP-1018, a bi-ligand-drug conjugate treated in patients with advanced solid tumors: A phase I, multi-center, open-label, dose-escalation and dose expansion study

K. Li[1], J. Wu[1], S. Ye[1], Y. liu[1], H. Huang[1], F. fan[1], Y. lai[1], S. Zhuang[1], L. Zhou[2], R. Huang[3], Y. Teng[3], X. Chai[3], J. Zhang[3], Y. Shi[2], H. Huang[1]

[1]Department of Urology, Sun Yat-Sen Memorial Hospital, Guangzhou, China; [2]Phase I Clinical Trial Ward, TMUCIH - Tianjin Medical University Cancer Institute and Hospital, Tianjin, China; [3]Clinical Development, Coherent Biopharma (Suzhou) Co., Ltd. Suzhou, Jiangsu, China, Suzhou, China

Background: Prostate-specific membrane antigen (PSMA) is highly expressed on prostate cancer and folate receptor α (FRα) overexpressed in various malignant tissues which both related to tumor invasiveness. CBP-1018 is a first-in-class bi-ligand-drug conjugate targeting both PSMA and FRα with monomethyl auristatin E (MMAE) as payload.

Methods: This phase 1 study included both a dose-escalation and expansion stage. In the dose-escalation stage, an accelerated titration was conducted in single patient at 0.03mg/kg followed by an i3+3 design for dose levels (DLs) $\geq$ 0.06 mg/kg, Q2W (IV.) in a 4-week cycle. This stage mainly enrolled patients (pts) with metastatic castration resistant prostate cancer (mCRPC) which had experienced standard treatment failure or intolerance before. The primary objectives were to evaluate the safety and tolerability, determine dose limiting toxicity (DLT) and maximum tolerated dose (MTD). Additionally, pharmacokinetics (PK) and preliminary efficacy will also be evaluated.

Results: As of 27 April 2023, 20 pts (18 mCRPC, 1 bladder cancer and 1 ureteral carcinoma) were enrolled at 6 dose levels (DLs). No DLTs or drug-related deaths were observed. For 15 pts (75%) experienced treatment-related adverse events (TRAEs) $\geq$ grade 3, most common were neutrophil decrease (50%), WBC decrease (40%), hypokalemia (10%) and hypertriglyceridaemia (10%). Among 17 evaluable mCRPC pts, 5 SD and 7 Non-PD were observed with 9 pts delayed administration and 6 pts dropped for COVID-19. Prostate-specific antigen (PSA) 50% decrease was detected in 2 pts. The median PFS was 9.2 months (95%CI, 1.7-9.2) in mCRPC pts. For PK profile of CBP-1018 and free MMAE, $t_{1/2z}$ was ranged 0.54-1.15 h and 38.27-57.27 h, respectively, no accumulation of both substances after multiple doses.

Conclusions: CBP-1018 was well-tolerated at DLs of 0.03-0.14 mg/kg Q2W. Multiple SD and PSA decrease were observed at DLs of 0.08-0.14 mg/kg, conferred a promising preliminary antitumor activity in pts with mCRPC despite of COVID-19's impacts. MTD was not reached and dose-escalation to establish the RP2D is continuing.

Clinical trial identification: NCT04928612.

1831P Dissecting the meaning of obesity in metastatic castration resistant prostate cancer: Size or metabolism?

L.G. Horvath[1], C. Kench[2], R. Mellor[1], H-M. Lin[3], B. Mak[1], T. Scheinberg[1], K. Mahon[1], L. Graham[4], A.A. Azad[5], A.M. Joshua[6], M.R. Stockler[7], G.M. Marx[8], K. Briscoe[9], K. Samaras[10]

[1]Medical Oncology, Chris O'Brien Lifehouse, Camperdown, NSW, Australia; [2]Medicine, Royal Prince Alfred Hospital, Camperdown, NSW, Australia; [3]Cancer, Garvan Institute of Medical Research, Darlinghurst, NSW, Australia; [4]Clinical Trials Unit, Chris O'Brien Lifehouse, Camperdown, NSW, Australia; [5]Oncology Department, Peter MacCallum Cancer Centre, Melbourne, VIC, Australia; [6]Medical Oncology, The Kinghorn Cancer Centre, Sydney, ON, Australia; [7]NHMRC Clinical Trials Centre, NHMRC Clinical Trials Centre, Camperdown, NSW, Australia; [8]Medical Oncology, Sydney Adventist Hospital, Wahroonga, NSW, Australia; [9]Medical Oncology, Coffs Harbour Health Campus, Coffs Harbour, NSW, Australia; [10]Endocrinology, Garvan Institute of Medical Research, Darlinghurst, NSW, Australia

Background: Obesity is associated with longer survival in patients with metastatic castration resistant prostate cancer (mCRPC). Our group has also established that elevated circulating sphingolipids are associated with a poorer prognosis in patients with mCRPC. Additionally, we have validated a CLIA-compliant circulating lipid biomarker, PCPro, which identifies patients with the poor prognostic lipid profile. This study aimed to define the metabolic characteristics underlying the obesity phenotype in mCRPC.

Methods: Six Australian Centres enrolled 72 patients with mCRPC (45% taxanes, 55% abiraterone or enzalutamide). DEXA scans assessed the distribution of lean muscle, fat, water and bone in the body. The PCPro biomarker status at baseline was assessed by mass spectrometry. Cox proportional hazards modelling assessed the association between DEXA parameters, PCPro and overall survival (OS).

Results: According to standard Body Mass Index (BMI) criteria, 32% of patients were obese, 38% overweight and 30% healthy weight range. Increasing BMI was associated with longer OS (HR=0.92, 95% CI=0.85-0.99, p=0.027). Increasing total weight (p=0.019), fat weight (p=0.014) and fat mass index (p=0.021) were all associated with improved OS. Changes in lean weight, android/gynoid weight patterns and visceral fat distribution were unrelated to OS (p>0.1). PCPro positive patients (21%, 14/66) had a shorter OS (HR=3.17, 95% CI=1.50-6.70, p=0.001). PCPro expression was an independent prognostic variable when modelled against BMI, fat weight or fat mass index.

Conclusions: Obesity and a higher amount of body fat are associated with longer OS in mCRPC. However, a PCPro positive plasma lipid profile is associated with shorter OS after adjusting for these variables. This supports the concept that clinical outcomes are driven by metabolic aspects, rather than BMI or measures of body fat alone. Future therapeutic interventions should target lipid metabolic aberrations.

1832P Centralized screening for homologous recombination repair (HRR) genes in metastatic castration-resistant prostate cancer (mCRPC): A feasibility study from a multicenter Spanish cohort

J. Freire[1], B. Caramelo[2], I. Duran Martinez[3], S. del Carmen[1], A. Azueta[1], P. García-Berbel[2], P.D. Diaz[1], D. Cacho Lavin[3], M. Orellana[4], M. Lencina[4], C. Mordillo[4], J. Gómez[1]

[1]Department of Pathology, HUMV - Hospital Universitario Marques de Valdecilla, Santander, Spain; [2]Department of Pathology, IDIVAL - Instituto de Investigacion Sanitaria Valdecilla, Santander, Spain; [3]Department of Medical Oncology, HUMV - Hospital Universitario Marques de Valdecilla, Santander, Spain; [4]AstraZeneca, AstraZeneca Farmaceutica Spain S A, Madrid, Spain

Background: The presence of pathogenic variants (PV) in BRCA1-2 in mCRPC patients has been associated with improved response to PARP inhibitors (PARPi) and better survival outcomes. Thus, tumor testing for somatic alterations in HRR genes in mCRPC patients has been recently incorporated to the main clinical guidelines. However, its implementation in daily practice could represent a challenge due to lack of access to testing. Moreover, there is scarce data about PV prevalence and distribution in Spain.

This study aims to characterize the feasibility of centralized genetic testing for HRR mutations in mCRPC samples and to describe the PV prevalence and distribution from a large multicenter Spanish cohort.

Methods: From January-22 to April-23, formalin-fixed paraffin-embedded (FFPE) samples from patients with mCRPC pre-treated with ≥1 novel hormonal agent and who were eligible for a successive line of treatment (ECOG 0-1 and hemoglobin >10 mg/dl) were collected. Samples older than 5 years were excluded in order to guarantee the quality of the genetic material. The molecular analysis and the interpretation of the results were centralized at Hospital Marqués de Valdecilla, where an HRR panel which included BRCA1, BRCA2, CHEK2, ATM, and CDK12 genes was used. Bioinformatics analysis was performed on DataGenomics platform.

Results: 633 samples from 70 centers from 14 Spanish regions were analyzed. 49 (8%) samples were rejected, 67% due to poor DNA quality and 33% due to insufficient material. In total, 74 variants of uncertain significance and 111 PV were detected. The global prevalence of HRR PV was 19%. The PV detected in order of frequency were: BRCA2 (39%), ATM (28%), CDK12 (17%), BRCA1 (10%), and CHEK2 (6%).

Conclusions: Centralization of HRR genetic screening in reference centers is a feasible option to provide HRR mutation to practice physicians. Aspects such as FFPE conservation and processing are vital for the success of the technique and one of the points that could potentially be improved. A better understanding of the distribution of PV can help to detect those patients that could benefit from PARPi treatment, as well as guide the indication of family genetic studies.

Background: Integrative medicine practitioners offer high-dose IVC for cancer treatment, but its incorporation into clinical practice has sparked controversy and remains an active area of investigation. While preclinical studies have shown that IVC may have anti-cancer effects in prostate cancer models, evidence from clinical research is limited. While several clinical trials showed that IVC is well tolerated, can reduce toxicities, and may improve quality of life (QoL), uncertainties remain. Here we investigated if combining IVC with docetaxel could improve the prostate-specific antigen (PSA) response rate in patients with mCRPC and could mitigate docetaxel toxicities.

Methods: We randomized (2:1) patients with mCRPC who progressed despite androgen receptor-targeted therapy to receive docetaxel (75mg/m^2 IV every 3 weeks) with IVC (1g/kg) (n=32) or placebo twice/week (n=15). Primary endpoints were PSA50 response by 24 weeks and adverse events (AEs) of fatigue, nausea, bone pain, and anorexia. Secondary endpoints included overall survival (OS), progression-free survival (PFS), and QoL measured by the Functional Assessment of Cancer Therapy-Prostate (FACT-P).

Results: PSA response rate was 41% in the vitamin C and 33% in the placebo group, with no statistically significant difference (p=0.44). Grade 1-2 and grade 3-4 AEs occurred in 69% and 6% vs 60% and 0% of patients, respectively (one-sided Cochran Armitage test, p=0.90). FACT-P was not significantly different at any timepoints. Median rPFS was 10.1 months (95% CI, 5.85, 14.7) vs 10.0 months (95% CI: 5.32, NA), HR 1.35 (95% CI, 0.66-2.75, p=0.40). Median OS was 15.2 months (95% CI, 13.2-25.3) vs 29.5 months (95% CI, 18.1-NA; HR 1.98 [95% CI 0.85-4.58], p=0.11). The median PFS (modified PCWG2 definition) was 5.5 months vs 8.4 months (HR 1.19 [95% CI 0.60-2.38], p=0.62).

Conclusions: Concurrent high-dose IV vitamin C did not improve PSA response, toxicity, or clinical outcomes in mCRPC patients receiving docetaxel.

Clinical trial identification: NCT02516670.

1834P Exposure-efficacy analyses of talazoparib in combination with enzalutamide in patients with metastatic castration-resistant prostate cancer (mCRPC) in the TALAPRO-2 trial

A.A. Azad[1], V.R. Lincha[2], M. Hadigol[2], J. Hoffman[2], N. Agarwal[3], N. Matsubara[4], Y. Wang[2], L. DeAnnuntis[5], F. Zohren[6], D. Wang[2]

[1]Oncology Department, Peter MacCallum Cancer Centre, Melbourne, VIC, Australia; [2]Clinical Pharmacology - Oncology, Pfizer Inc, San Diego, CA, USA; [3]Oncology/Internal Medicine Department, University of Utah Health - Huntsman Cancer Institute, Salt Lake City, UT, USA; [4]Medical Oncology Department, National Cancer Center Hospital East, Kashiwa, Japan; [5]Global Product Development - Oncology, Pfizer Inc, Collegeville, PA, USA; [6]Global Product Development - Oncology, Pfizer, Cambridge, MA, USA

Background: The TALAPRO-2 trial (NCT03395197) showed that the addition of talazoparib (TALA), a potent PARP inhibitor, to enzalutamide (ENZA) significantly improved radiographic progression-free survival (rPFS) in mCRPC unselected for DNA damage repair deficiencies. The objective of the analysis was to evaluate the relationship between TALA exposure and rPFS to support the recommended TALA dosing regimen in combination with ENZA and identify potential prognostic factors for rPFS

Methods: Efficacy and pharmacokinetics (PK) data from 391 patients in Part 2 Cohort 1 (All-comers group) who received TALA starting dose of 0.5 mg QD plus 160 mg QD ENZA were included in the analyses. To account for the changes in TALA exposure over time due to dose modifications and effect of ENZA and its n-desmethyl metabolite on TALA exposure over time, time-varying average TALA concentrations ($C_{avg,t}$) were used in the analysis. $C_{avg,t}$ was calculated as post-hoc estimate AUC_t/t based on population PK model. The relationship between $C_{avg,t}$ as well as potential prognostic factors and rPFS was evaluated using Cox proportional hazard univariate and multivariate models with p value cutoff of 0.05.

Results: Visual examination suggested higher $C_{avg,t}$ in patients with longer rPFS than in those with shorter rPFS. Multivariate analysis showed that higher exposure was associated with longer rPFS. Lower baseline lactate dehydrogenase, lower baseline alkaline phosphatase, absence of measurable disease and bone only metastatic disease were associated with longer rPFS, while lower baseline lymphocyte was associated with shorter rPFS.

Conclusions: Longer rPFS was found to be associated with higher $C_{avg,t}$, This supports using 0.5 mg QD (in combination with ENZA) which provides similar exposure as 1 mg QD, the maximum tolerable dose of TALA monotherapy, for the treatment of mCRPC. These data also support treating grade 1-2 AEs with symptomatic management without TALA dose reduction to maximize efficacy.

Clinical trial identification: NCT03395197.

Background: Up to 30% of pts with advanced PC have homologous recombination repair (HRR) gene alterations. Pts with HRR gene alterations (HRR+), particularly those with BRCA gene alterations, have poor outcomes with standard of care therapies and may benefit from PARP inhibitor treatment. PREVALENCE (NCT03871816) prospectively evaluated the frequency of HRR+ in metastatic castration sensitive and castration resistant prostate cancer (mCSPC/mCRPC) pts.

Methods: In this multicenter, international study across 319 sites in 25 countries, mCSPC and mCRPC pts aged ≥18 consented to specimen collection (eg, saliva, blood, archival tumor) for germline, tumor tissue, and/or ctDNA testing. HRR genes of interest included ATM, BRCA1, BRCA2, CHEK2, CDK12, BRIP1, FANCA, HDAC2, PALB2, RAD51B, and RAD54L. PREVALENCE test results were also used to assess biomarker eligibility for niraparib interventional studies: MAGNITUDE (NCT03748641) and AMPLITUDE (NCT04497844).

Results: 14598 pts enrolled between April 2019 and October 2022. Of 14073 pts who had at least one result by any assay, 1972 (14.0%) pts had at least 1 mutation in the HRR genes of interest; BRCA gene alterations were the most common, occurring in 756 pts (5.4%). 7%, 22%, and 11.5% of pts who had a test result by germline, tumor tissue and ctDNA, respectively, had at least 1 HRR gene alteration. The frequency of HRR+ was similar in mCSPC and mCRPC. Of the pts who did not have at least one result by any assay, 143 pts (1%) had no specimens submitted and 382 pts (2.6%) failed testing by all assays. Test failure rate was highest in tumor tissue (24.1%), followed by germline (3.2%) and ctDNA (2.4%).

Conclusions: In a study of over 14000 pts with advanced PC, 14% had at least 1 HRR gene alteration; BRCA gene alteration was most common. The frequency of HRR+ was highest in pts tested by tumor tissue. PREVALENCE demonstrates the feasibility of prospective genetic testing to identify PC pts who benefit most from a precision oncology approach.

Background: PRESIDE (NCT02288247) was a randomised, international trial that met its primary endpoint of prolonged progression-free survival (PFS) with continued ENZ beyond progression in patients (pt) starting Doc. A pre-specified aim of PRESIDE was to test for androgen receptor (AR) blood-based biomarkers to test for differential benefit.

Methods: Pt who participated in PRESIDE, consented to the biomarker sub-study and donated blood at randomization (Period 2 baseline, P2BL) were included. Blood was also collected on treatment (P2 Week [W] 4 and 13), progression and follow up. Pre-specified primary objectives were to evaluate PFS for 1) ENZ versus (v) Placebo (P) in pt split by +/- plasma *AR* gain or AR-V7 in circulating tumor cells (CTC) at P2BL and 2) PFS for all pt split by +/- tumor in plasma DNA (ptDNA) at P2W4. Custom targeted next-generation sequencing on plasma DNA was performed using a bespoke panel (PCF SELECT). Identification of CTC +/- AR-V7 in whole blood samples was performed by Epic Sciences (San Diego, California).

Results: Of 271 pt randomised to ENZ / P, 157 (57.9%, 79 on ENZ + Doc, 78 on P + Doc) donated blood. 100 (64%) were plasma *AR* wild type (wt), 56 (36%) had *AR* gain. 126 (80%) were AR-V7 negative (-), 17 (11%) AR-V7 positive (+). AR status not available for plasma DNA (1 pt) and CTC (14 pt, 9%). Pt who were AR wt and AR-V7- (N=87, 55%) had significantly prolonged PFS from continuing ENZ (11.2 months (m) v 8.7 m P, HR: 0.49; 95% CI: 0.29-0.82, p=0.006), whilst pt with *AR* gain or AR-V7+ (N=62) did not (6.2 m ENZ v 7.9 m P; HR: 1.29; p=0.44). Restricted mean survival times at 18 m for *AR* wt and AR-V7- was 11.5 m ENZ v 8.9 m P, p=0.0046, for *AR* gain or AR-V7 + was 7.9 m ENZ vs 7.1 m P, p=0.5023. Compared with negative ptDNA at P2W4 (99, 74% of 134 pt included), pt with positive ptDNA (35, 26%) had significantly shorter PFS (5.4 m vs 10.8 m, HR: 1.92; 95% CI: 1.14-3.23, p=0.0145).

Conclusions: The benefit of continuing ENZ beyond progression with Doc vs Doc alone is greatest in patient with no evidence of plasma *AR* gain or AR-V7+ CTC. Plasma tumor DNA detection after 3 weeks Doc +/- ENZ identifies patients with shorter PFS.

Clinical trial identification: NCT02288247.

Background: Prior data have shown that prostate specific antigen (PSA) $\leq$ 0.2 ng/dL with androgen deprivation therapy (ADT) is prognostic for OS. We explored whether PSA $\leq$ 0.2 ng/dL at 4-7 months post randomization is a valid surrogate for OS in men with mHSPC. If so, it could be used to expedite phase 3 clinical trials. This hypothesis was investigated by the STOPCAP M1 Collaboration.

Methods: Individual patient data (IPD) from 13 eligible randomized trials comparing treatment regimens (ADT or docetaxel in the control or research arms in mHSPC) were utilized. We considered PSA measurements collected post randomization and evaluated the surrogacy of PSA $\leq$ 0.2 ng/dL at 4-7 months at the patient and trial levels. We utilized the proportional hazards model and estimated the hazard ratios (HR) for PSA $\leq$ 0.2 ng/dL predicting OS. We also fitted weighted linear regression, stratified by trial and treatment arm, and computed R^2 to quantify the proportion of variance that was explained by the regressions. We defined *a priori* clinically relevant surrogacy of R^2 value greater than 0.75. Lastly, we computed the surrogate threshold effect (STE), which is the minimum PSA treatment effect necessary to estimate a non-zero effect on OS.

Results: IPD from 5513 pts randomized from 1994-2012 from 13 trials were pooled for a stratified analysis. There were 3324 deaths, of which 70.5% were due to prostate cancer. The median follow-up was 74 months. At 4-7 months, the proportion of patients who had PSA $\leq$0.2 was 25.8%. At the individual level, PSA $\leq$0.2 ng/dL was a strong predictor of OS. Median OS in patients who experienced PSA$\leq$0.2 and the results for the surrogacy analysis are presented in the table.

Table: 1837P

	PSA<=0.2 ng/dL (n=1425)	PSA>0.2 ng/dL (n=4088)
Median OS months (95%CI)	91.6 (85.1-98.2)	40.9 (39.3-42.7)
Hazard Ratio (95% CI)	2.5 (2.3-2.7)	
Condition 2	0.93 (0.78-0.99)	
STE	0.75	

Conclusions: PSA$\leq$0.2 ng/dL at 4-7 months met the surrogacy criteria and appears to be a valid surrogate endpoint for OS in men with mHSPC treated with ADT as backbone hormonal therapy. Validation of this endpoint in trials with drugs having other mechanisms of action is planned.

Background: The prognostic value of neutrophil-to-lymphocyte ratio (NLR) and absolute lymphocyte count (ALC) in patients with mCRPC treated with prostate-specific membrane antigen (PSMA)-targeted radioligand therapy has not been studied. Here, we assessed the association of NLR and ALC with [^{177}Lu]Lu-PSMA-617 (^{177}Lu-PSMA-617) treatment outcomes in patients from the VISION study.

Methods: Adults with PSMA-positive mCRPC received ^{177}Lu-PSMA-617 (7.4 GBq every 6 weeks, $\leq$ 6 cycles) + standard of care (SoC), or SoC alone. In this *post hoc* analysis, patients were categorized by NLR $<$ 3 vs $\geq$ 3 and ALC $<$ 1.0 $\times$ 10^3/μl vs $\geq$ 1.0 $\times$ 10^3/μl at baseline. Associations with overall survival (OS) and radiographic progression-free survival (rPFS) were assessed using the Kaplan−Meier method. Hazard ratios (HR) were estimated using Cox proportional hazards models.

Results: NLR and ALC data were available for a subset of patients (Table). Baseline characteristics were well balanced across subgroups. At baseline, median NLR was 3.8 vs 4.0 and median ALC was 1.06 $\times$ 10^3/μl and 1.0 $\times$ 10^3/μl, for ^{177}Lu-PSMA-617 + SoC vs SoC alone, respectively. Shorter OS and rPFS were observed with higher NLR and lower ALC in each treatment arm (Table). ^{177}Lu-PSMA-617 + SoC prolonged OS and rPFS vs SoC alone in all subgroups (Table). More patients with baseline NLR $\geq$ 3 reported serious adverse events (^{177}Lu-PSMA-617 + SoC, 41.0%; SoC, 28.7%) than those with NLR $<$ 3 (30.7%; 24.1%).

Conclusions: NLR $\geq$ 3 and ALC $<$ 1.0 $\times$ 10^3/μl at baseline are prognostic for poor efficacy outcomes in patients with mCRPC in VISION. Treatment with ^{177}Lu-PSMA-617 improved OS and rPFS vs SoC alone regardless of baseline NLR/ALC. Additional analyses including change in NLR and ALC during treatment, associations with prostate-specific antigen and biochemical and objective response rates will be presented.

Background: Taxanes are a standard of care for mCRPC and no clinically qualified biomarker has as yet been identified for these. lpWGS of ctDNA identifies copy-number alterations (CNAs) common in advanced PC and may identify mCRPC subtypes most responsive to taxane therapy. ctDNA lpWGS identified genomic aberrations associating with treatment outcomes for participants of three prospective Phase III taxane trials (CARD, FIRSTANA and PROSELICA).

Methods: Genomic alterations in ctDNA were assessed for correlations with overall survival (OS), radiologic progression-free survival (rPFS), and PSA or radiological response rate (RR) using univariable and multivariable mixed-effect regression models to study CNAs significantly associated with differential outcomes of prognostic and predictive significance.

Results: Genome-wide analysis identified several genomic alterations that were significantly associated with worse OS in these taxane-treated individuals including chromosome 2p, 9p and 13 deletions. Several CNAs remained independently significant (Chr2p HR 2.89, $p<0.01$; Chr9p HR 2.9, $p<0.01$, Chr12q HR 2.06, $p<0.01$) following multivariable analyses incorporating PSA, LDH, haemoglobin, the presence of visceral metastases and tumour fraction estimate. Conversely, several loci including 20q and X gain, and 15q loss associated with worse rPFS and OS on the CARD control arm (abiraterone post enzalutamide or vice versa) but exhibited no difference in rPFS and OS on the cabazitaxel-treated arm. To confirm these results, we explored the association of CNAs with response rate in the FIRSTANA and PROSELICA study cohorts and found that several loci were associated with higher taxane-response rates in biomarker-positive individuals.

Conclusions: These ctDNA lpWGS studies in mCRPC patients have identified genomic alterations in ctDNA of prognostic and predictive significance in men suffering from mCRPC receiving taxane treatment. Prospective validation will facilitate treatment selection and identify potential clinical biomarkers associated with outcome.

1840P RNASEH2B loss and PARP inhibition (parpi) in metastatic castration resistant prostate cancer (mCRPC)

J. Carmichael[1], I. Figueiredo[2], B. Gurel[2], W. Yuan[2], J. Rekowski[3], G. Seed[2], S. Carreira[2], C. Bertan[2], N. Beije[1], D. Westaby[1], C. Guo[1], A. Neeb[2], J. Welti[2], L. Gallagher[2], D. Bogdan[2], M. Crespo[2], R. Riiisneas[2], C. Lord[4], A. Sharp[5], J.S. de Bono[1]

Background: mCRPC is molecularly heterogenous and PARPi is the only precision medicine for these diseases. PARPi improves outcomes in DNA repair defective (DRD; 20-30%) mCRPC but may also impact other mCRPC molecular subsets not currently encompassed in the FDA approved companion biomarker suite for PARPi. The *RNASEH2B* gene is located on chromosome 13, flanking *RB1*, with this locus being commonly lost in mCRPC at treatment resistance, associating with lineage plasticity and genomic instability. *RNASEH2B* may be co-deleted with *RB1*, with loss of the former but not the latter sensitising to PARPi. We have hypothesised that *RNASEH2B* loss in mCRPC is subclonal and that PARPi can clear these *RNASEH2B* deleted subclones.

Methods: Immunohistochemistry (IHC) for RNASEH2B and RB1, utilising validated assays, was performed on matched (same patient) hormone-sensitive (HSPC) and mCRPC patient biopsies, together with whole-exome sequencing (WES), targeted next-generation sequencing (NGS), and RNA sequencing. Low-pass whole genome sequencing (LP-WGS) was performed on a distinct mCRPC cohort for copy number analysis. RNASEH2B expression was correlated with clinical outcome, DRD and DNA damage signatures.

Results: Subclonal deletions on chromosome 13 encompassing *RB1* and *RNASEH2B* are frequent in HSPC and mCRPC biopsies, although deep deletions are rare, and co-loss of RB1 and RNASEH2B protein is surprisingly uncommon. Heterogeneous and subclonal RNASEH2B protein loss was detected by IHC in mCRPC biopsies, with 54/124 (44%) samples having RNASEH2B loss in 50% cells, although complete RNASEH2B loss is uncommon (8.8%). Interestingly, RNASEH2B loss is not an independent prognostic variable, perhaps related to increasing PARPi and platinum use (50/125 (40%) patients in this study), but did not associate with established DRD or DDR signatures. Studies of the impact of PARPi on RNASEH2B subclone clearance in human mCRPC are ongoing.

Conclusions: RNASEH2B protein is frequently lost in mCRPC subclones, with RB1 loss being less common, and may be of critical importance as this discordant loss is most likely to sensitise to PARPi. This needs further exploration in clinical trials of PARPi.

Background: Patients (pts) with prostate cancer treated with radiotherapy (RT) or radical prostatectomy (RP) as primary therapy may develop BCR, defined as a prostate-specific antigen (PSA) increase without evidence of metastases on conventional imaging. Prostate-specific membrane antigen (PSMA) positron emission tomography/computed tomography (PET/CT), a more effective and precise imaging method, may detect small lesions in patients with BCR. Patients with BCR at high risk of metastatic progression and who have lesions identified by PSMA PET/CT need effective treatment to delay this progression. Darolutamide (DARO) is a structurally distinct and highly potent androgen receptor inhibitor, which significantly improved metastasis-free survival (MFS) and overall survival (OS) in pts with nonmetastatic castration-resistant prostate cancer (CRPC). The ARASTEP study (NCT05794906) is designed to evaluate whether DARO plus ADT improves radiological progression-free survival (rPFS) by PSMA PET/CT vs placebo (PBO) plus ADT in pts with BCR following primary therapy and PSMA PET/CT-positive lesions.

Trial design: Eligible pts have prostate cancer treated by primary RT or RP followed by adjuvant RT (ART) or salvage RT (SRT), or RP alone if ART/SRT was not appropriate, with BCR (defined as PSA doubling time [PSADT] <12 months and PSA ≥0.2 ng/mL after primary RP [± ART/SRT] or PSA ≥2 ng/mL above nadir after primary RT only), ≥1 PSMA PET/CT-positive lesion without visible lesions on conventional imaging, and serum testosterone >150 ng/dL. Approximately 750 pts from 184 sites worldwide will be randomized to oral DARO 600 mg twice daily or PBO, both with ADT, for 24 months. Image-guided radiotherapy or surgery is allowed within 12 weeks from randomization. Randomization is stratified by PSADT <6 vs ≥6–<12 months, prior RP vs primary RT, and distant ± locoregional vs locoregional-only metastases. The primary endpoint is rPFS by PSMA PET/CT, assessed by blinded independent central review (BICR). Secondary endpoints include MFS by BICR, time to CRPC, OS, quality of life, and safety. Enrollment began in April 2023.

Clinical trial identification: NCT05794906.

1842TiP Phase II randomized trial of two dose levels of vobramitamab duocarmazine in participants with metastatic castration resistant prostate cancer (mCRPC; TAMARACK)

J.S. de Bono[1], S.K. Sandhu[2], K. Fizazi[3], J. Sun[4], A. Ward[5], E.S. Antonarakis[6]

[1]Division of Clinical Studies, Royal Marsden Hospital Institute of Cancer Research, Sutton, UK; [2]Division of Cancer Medicine, Peter MacCallum Cancer Centre, Melbourne, VIC, Australia; [3]Cancer Medicine Department, Institut Gustave Roussy, Villejuif, France; [4]Biostatistics, MacroGenics, Inc., Rockville, MD, USA; [5]Clinical Development, MacroGenics, Inc., Rockville, MD, USA; [6]Hematology, Oncology and Transplantation, Masonic Cancer Center - University of Minnesota, Minneapolis, MN, USA

Background:: B7-homolog 3 (B7-H3) is highly expressed in multiple solid tumors including mCRPC (Guo, PMID 36114082) with limited expression in normal tissue, may play an immune suppressive role, and favors cancer growth. Vobramitamab duocarmazine (vobra duo, or MGC018) is an investigational anti–B7-H3 IgG1 antibody-drug conjugate with a duocarmycin-based DNA-alkylating payload that can damage DNA in both dividing and nondividing cells, causing cell death (Scribner, PMID 32967924). Phase 1 testing of vobra duo (NCT03729596) demonstrated acceptable safety at doses up to 4.0 mg/kg IV every 3 weeks (Q3W) in patients with solid tumors (Jang, ASCO 2021, Abstract 2631). In an mCRPC cohort, 4/16 (25%) evaluable patients had an objective response and 21/39 (53.8%) had reduction in PSA from baseline of > 50% (PSA50) (Shenderov, ESMO 2021, Abstract 620P). In this cohort, which received vobra duo at 3.0 mg/kg Q3W, adverse events resulted in discontinuation, dose reduction, or interruption of drug in 10%, 30%, and 55% of participants respectively, and the median number of doses received was 3.5 (range 1.0-8.0) (Shenderov, ESMO 2021, Abstract 620P). Lowering the starting dose may improve tolerability, extend treatment duration, and enhance effectiveness.

Trial design: TAMARACK is a randomized, open-label, Phase 2 dose selection (Simon, PMID 4075313) study assessing the efficacy, safety, and tolerability of two dose levels of vobra duo (2.0 mg/kg and 2.7 mg/kg IV Q4W). The study will enroll participants with mCRPC previously treated with one prior ARAT (abiraterone, enzalutamide, or apalutamide) for prostate cancer. Approximately 100 participants will be randomized 1:1 between the two study treatment arms. The primary endpoint of the study is radiographic progression-free survival by investigator assessment using Prostate Cancer Working Group 3 criteria. Secondary endpoints include frequency and severity of adverse events, PSA50 response rate, objective response rate, and occurrence of symptomatic skeletal events. One futility analysis based on PSA50 response rate will be performed for each arm after 20 evaluable patients are enrolled. Enrollment is ongoing.

Clinical trial identification: NCT05551117.

Background: Immune checkpoint inhibitors (ICIs) achieved breakthroughs in advanced non-small cell lung cancer (NSCLC). Chronic psychosocial stress manifests as depression and anxiety symptoms and is common among NSCLC patients. It activates the HPA axis and sympathetic nervous system, which impairs organic immunity and induces an immunosuppressive tumor microenvironment. We aim to investigate the role of chronic psychosocial stress on the efficacy of ICIs.

Methods: The STRESS-LUNG-1 study is a multicenter prospective observational trial (NCT05477979). Stage IIIB-IV NSCLC treated with first-line therapy of ICIs were enrolled. The patients' stress status was assessed using PHQ-9 and GAD-7 scales. The last follow-up date was March 1, 2023. Prediction models integrating psycho-biological factors to predict efficacy was established.

Results: A total of 166 NSCLC patients were enrolled with 53.6% of patients classified as stressed. The baseline characteristics between stressed and non-stressed groups were well-balanced. With the median follow-up of 11.5 months, the stressed group had a lower ORR (38.8% vs 68.4%, $p<0.001$) and a worse median PFS (7.9 vs 15.5 months; $p=0.028$). The stress group had a lower 1-year (69.0% vs 91.9%; p=0.001) and 2-year survival rate (50.6% vs 71.8%; $p=0.092$). Patients in the stress group demonstrated multidimensional detriments of quality of life (QoL). Chronic psychological stress was the independent prognostic factor for ORR (HR=3.93; $p<0.001$), PFS (HR=1.59; $p=0.038$), and OS (HR=3.16; $p=0.005$). A negative correlation was observed between the degree of stress and the efficacy. The stressed group had higher plasma epinephrine (160.97 vs 122.94 pg/ml, $p=0.029$) and serum cortisol levels (445.05 vs 382.10 nmol/L, $p=0.037$). Notably, an integrated model including stress status, stage, and PD-L1 expression demonstrated superior efficiency in predicting PFS (AUC=0.810) and OS (AUC=0.865) than using psychological and biological factors alone.

Conclusions: Chronic psychological stress was associated with poor efficacy of ICIs and QoL in advanced NSCLC. Combining psychological with biological factors may represent a useful psycho-biomarker able to predict the clinical response to ICIs.

Clinical trial identification: NCT05477979.

1844MO Association of peripheral blood leukocyte DNA methylation profiles with the development of depressive symptoms in lung cancer patients undergoing systemic therapy

A.M. Starzer[1], J.H. Fuerst[1], E. Tomasich[1], L. Gottmann[1], J.M. Berger[1], M. Korpan[1], C. Englisch[2], M. Kleinberger[1], F. Moik[2], G. Heller[1], L. Carlberg[3], M. Preusser[1], A.S. Berghoff[1]

[1]Division of Oncology, Department of Medicine I, Medical University of Vienna, Vienna, Austria; [2]Haematology/Haemostaseology Department, Medical University of Vienna, Vienna, Austria; [3]Clinical Division of General Psychiatry, Department of Psychiatry and Psychotherapy, Medical University of Vienna, Vienna, Austria

Background: Depression is a serious comorbidity in cancer patients and is associated with increased morbidity and mortality. We investigated blood DNA methylation profiling as a potential biomarker for monitoring the likelihood of developing depressive symptoms during systemic anticancer treatment in order to early detect vulnerable patient populations.

Methods: Lung cancer patients receiving systemic anticancer therapy at the Medical University of Vienna were included in this analysis. Leukocyte DNA methylation profiling from whole blood samples at timepoint of inclusion was performed with Infinium Methylation EPIC microarrays. Patients completed the EORTC QLQ-C30 questionnaire at inclusion and at every re-staging. The development of clinically relevant depressive symptoms was defined by an emotional functioning (EF) subscore below 80. The lowest EF score during the observation period per patient was used for the analyses.

Results: Seventy-three lung cancer patients (29/73 female, 39.7%; 44/73 male, 60.3%; median age 65 years, range 36-83 years) were included in this analysis. Six of 73 patients received chemotherapy, 34/73 immunotherapy and 33/73 chemo-immunotherapy. At least one EF score was available from each patient (median of 3 available scores, range 1-12 available scores). Fifty-seven of 73 (78.1%) patients developed relevant depressive symptoms during anticancer treatment while 16/73 (21.9%) patients maintained EF scores $\geq$80. DNA methylation differences defined by statistical tests as well as effect size were calculated between patients with EF scores $<$80 and patients with EF scores $\geq$80. Both patient groups formed well-separated clusters based on the methylation patterns of the top 500 differentially methylated CpG sites, independent of gender, the type of received systemic therapy or histologic subtype.

Conclusions: DNA methylation profiling from peripheral blood leukocytes may identify lung cancer patients at risk for the development of depressive symptoms during systemic cancer therapy. Larger studies and biological interrogations are needed to substantiate our finding.

1845P Exclusion of patients with psychiatric disorders from early phase oncology trials: A limited access to innovation?

P. Matte[1], M. Delaye[1], A. Mc Govern[2], K. Ouali[3], F-X. Danlos[3], C. Henon[1], V. Goldschmidt[3], L. Mahjoubi[1], A. Hollebecque[3], J-M. Michot[3], A. Gazzah[3], R. Bahleda[3], C. Smolenschi[3], A. Marabelle[3], S. Champiat[3], Y. Loriot[3], S. Ponce Aix[3], P. Rouby[4], C. Lemogne[5], C. Baldini[1]

[1]Drug Development Department, Institut Gustave Roussy, Villejuif, France; [2]Psychiatrie de l'enfant et de l'adolescent, AP-HP Hôpital Robert Debré, Paris, France; [3]Drug Development Department (DITEP), Gustave Roussy - Cancer Campus, Villejuif, France; [4]Psychiatry, Gustave Roussy, Villejuif, France; [5]Psychiatry, Groupe Hospitalier Hôtel Dieu (AP-HP), Paris, France

Background: Psychiatric disorders (PD) are highly prevalent in patients with cancer and associated with poorer outcomes. This may be partly explained by a limited access to innovation since patients with PD are often underrepresented in oncology

clinical trials. This study examines the frequency and the nature of exclusion criteria for patients with PD in a large sample of early phase oncology clinical trials (EPCT).

Methods: All protocols of EPCT opened to inclusion at the Drug Development Department at Gustave Roussy Cancer Centre in November 2022 were independently reviewed by 2 authors to identify exclusion criteria related to PD and classify them according to a 4-cluster classification (A: any PD, not specified; B: specific PD; C: pharmacology criteria and D: exclusion based on the clinician's judgment). The type of investigational drug, the route of administration and the type of cancer included in each trial were also collected.

Results: We analyzed a total of 117 protocols. The drugs most commonly studied included immune checkpoint blockers (44%), tyrosine kinase inhibitors (30%) and bispecific antibodies (15%). The most frequent route of administration was the intravenous route. A vast majority of ongoing studies (n=114, 97.4%) featured at least one criterion that could exclude patients with PD. Cluster D was the most prevalent (96.6%), followed by cluster C (14.5%), A (12.0%) and B (4.3%). Within cluster B, substance use disorder was the most frequently mentioned PD. In cluster C, all criteria concerned QT-prolonging drugs.

Conclusions: Nearly all the examined EPCT contained at least one criterion that could potentially result in the exclusion of patients with PD, most commonly based on subjective clinical judgment. Enhancing subjective clinical judgement with validated tools for evaluating consent capacity and future compliance may help in making more informed decisions and in reducing the impact of personal biases on the decision to exclude a patient with PD. Additionally, improved communication between psychiatry and oncology units engaged in clinical trials is also warranted.

1846P The impact of newly diagnosed early breast cancer on distress, perception of health and psychologic resilience

A. Budisavljevic[1], N. Dedic Plavetic[2], K. Klarić[3], R. Kelemenic-Drazin[4], M. Letica Crepulja[5]

[1]Oncology Department, General Hospital Pula, Pula, Croatia; [2]Department of Medical Oncology, KBC - University Hospital Centre Zagreb, Zagreb, Croatia; [3]Department of Radiology, General Hospital Pula, Pula, Croatia; [4]Department for Hematology, Oncology and Clinical immunology, General Hospital Varazdin, Varazdin, Croatia; [5]Department of Psychiatry and Psychological Medicine, University of Rijeka - Faculty of Medicine, Rijeka, Croatia

Background: Confronting breast cancer diagnosis, alongside with complex and challenging treatment procedures comprise an extremely stressful experience. Psychological resilience (PR) is the ability to maintain or restore normal functioning while facing the adversity, leading to better quality of life and preventing stress-related health conditions in cancer patients. We aimed to investigate the impact of early breast cancer (EBC) diagnosis on PR, distress and perception of health.

Methods: Case-controlled study included 50 newly diagnosed EBC patients and 67 women without breast cancer whose screening mammography was graded by Breast imaging-reporting and data system 1 and 2. The level of distress, perception of health and PR were assessed using the Depression Anxiety and Stress Scale 21, SF 36-Item Health Survey 1.0 and Connor-Davidson RISC-25 scale. EBC patients were questioned after confronting EBC diagnosis and before starting the treatment.

Results: The EBC patients reported deterioration of health, compared to previous year (t *(df)* 3,835, $p<0.01$), while there were no differences between groups related to general and emotional health. There was no significant statistical difference between groups regarding the levels of depression, anxiety and stress. Majority of the EBC patients and controls, 66% and 82%, had no symptoms of depression, while severe depression was noted in 10% and 3%, respectively. Around 78% EBC patients and 89% controls didn't show any anxiety. Still, 8% EBC patients and 4.5% controls were severely anxious, and 10% EBC and 4% controls were severely stressed. And finally, regarding resilience, EBC patients showed significantly higher levels of PR than healthy control (t*(df)* 2,530, $p<0.05$).

Conclusions: Confronting EBC diagnosis, possibly leads to activation of intra-individual coping mechanisms and dynamic processes of effective adaptation leading to higher PR levels of EBC patients compared with healthy controls. Further research of PR should be encouraged, by investigating the mechanisms that protect individuals and prevent stress-related health conditions, resilience research shifts a paradigm from a disease-oriented to health-oriented and focuses on mechanisms that prevent stress-related disorders.

1847P Monitoring of psychological state and quality of life during Simonton-training for oncologic patients

P. Harasztosi[1], J. Lovey[1], A.C. Nagy[2], M. Mailáth[3]

[1]Department of Radiotherapy, National Institute of Oncology, Budapest, Hungary; [2]Department of Health Informatics, University of Debrecen, Debrecen, Hungary; [3]Oncology Clinic, University of Debrecen, Debrecen, Hungary

Background: With the increasing number of oncologic patients, consultation time per patient shortens, which negatively affects the doctor — patient relationship. Participation in psychotherapeutic groups can help patients gain trust in their treatment. The aim of this study is to quantify the effects of Simonton-training on the psychological state, quality of life and compliance in oncologic patients.

Methods: This survey was carried out at the University of Debrecen in the course of a 12-occasion-long Simonton training. A total of 27 patients in the psychotherapeutic

group, and 63 patients in the control group were included in this study. Patients filled out an online questionnaire three times, before the training (t0), right after the training (t1), and again 3 months later (t2). The online questionnaire contained: The Hospital Anxiety and Depression Scale (HADS), WHO Quality of Life 5-item questionnaire (WHO QOL5), Morisky Medication Adherence Scale (MMAS-8) and five questions (5Q) about the general attitude towards their treatment and the trust in their oncologist. The distribution of continuous variables was statistically analysed with the Shapiro-Wilk test, and Wilcoxon test was used for comparisons between the case and control groups due to the non-normal distribution of the majority of variables.

Results: From t0 to t1, the Simonton group's quality of life significantly increased (p=0,016), meanwhile the control group's QoL didn't change significantly (p=0,575). According to HADS scale, the Simonton group's anxiety significantly decreased from t0 to t1 (p=0,0005), and the change of the control wasn't significant (p=0,247). Depression values also showed a significant decrease for the Simonton group from t0 to t1 (p=0,003), whereas the control's depression values didn't change significantly (p=0,122). After psychotherapy, the Simonton group evaluated their therapy-related attitude better with the 5Q, than at t0 (p=0,026). During this time, the control's value didn't change significantly (p=0,532).

Conclusions: On the basis of this study the Simonton training had a positive impact on the patients' psychological state and their quality of life increased.

Clinical trial identification: DE RKEB/IKEB 5773-2021.

1849P Use of antipsychotic drugs during radiotherapy in adult cancer patients in Korea: The nationwide retrospective cohort study based on the health insurance review and assessment service database

J.H. Choi[1], I.G. Hwang[2], S.M. Kim[3], S.H. Hong[4], T.H. Go[4]

[1]Radiation Oncology, Chung-Ang University Hospital, Seoul, Republic of Korea; [2]Hematology-oncology, Chung-Ang University Hospital, Seoul, Republic of Korea; [3]Psychology, Chung-Ang University Hospital, Seoul, Republic of Korea; [4]Medical statistics, Yonsei University Wonju College of Medicine, Wonju-si, Republic of Korea

Background: Antipsychotic drugs (APDs) are used in cancer patients for mental illness. There have been attempts to repurpose APD for cancer treatment based on suggestions that APD may have anti-cancer effects. However, reports on the use of APDs in cancer patients have been absent in Korea. Therefore, we conducted a nationwide study to assess the use of APDs during radiotherapy (RT) in adult cancer patients in South Korea.

Methods: We utilized the Health Insurance Review and Assessment Service database of all Koreans. We conducted an analysis on cancer patients identified by the International Classification of Diseases, aged ≥18, from 2010 to 2020, who underwent RT or chemotherapy (cisplatin or 5-Fluorouracil). Data including sex, age, diagnosis code, and prescription details of APDs were collected. The APDs included in the analysis were aripiprazole, quetiapine, olanzapine, risperidone, haloperidol, and chlorpromazine.

Results: A total of 558,318 patients received RT, and 100,810 patients received concomitant chemo-radiotherapy (CCRT). Among the patients who received RT, 78,785 were prescribed APD, and 19,689 (4%) took APD during RT. Among the patients who received CCRT, 21,689 were prescribed APD, and 4,612 (4.7%) took APD during CCRT. The number of patients who took ADP during RT was 3.598 (78.01%) in men. The age distribution was as follows: 0.67%, 2.23%, 8.54%, 23.87%, 34.35%, 26.24%, and 4.10% were in <30s, 40s, 50s, 60s, 70s, and ≥80, respectively. When classifying patients who took ADP during RT by diagnosis, lung cancer accounted for 18.53% (12,355 out of 66,669), and breast cancer accounted for 2.21% (2,896 out of 130,700). The most frequently used ADPs during RT were quetiapine (62.11%), chlorpromazine (14.21%), risperidone (12.64%), olanzapine (11.03%), aripiprazole (0.01%), and haloperidol (0.002%). Survival of patients prescribed APD during RT was worse compared to those without APD (HR 2.84).

Conclusions: Only 4% of patients who received RT took ADP simultaneously during RT and took quetiapine the most. The survival rate of patients who took ADP during RT was worse than those who did not. Further studies are needed on the effects of ADP in cancer patients.

1850P The effectiveness of a CBT-based mobile application for the mental state of women with breast cancer

M. Haneczok[1], E. Wojtyna[1], M. Jarzab[2], R. Matkowski[3], A. Syska-Bielak[2], A. Kołodziejczyk[3], M. Pawełczak-Szastok[4], Z. Kurasz[1], M. Krzyżowski[5], M. Ostrowski[6]

[1]Institute of Psychology, University of Silesia in Katowice, Katowice, Poland; [2]Breast Cancer Unit, National Oncology Institute Maria Sklodowskiej-Curie National Research Institute, Gliwice Branch, Gliwice, Poland; [3]Breast Cancer Unit, Lower Silesian Oncology Center, Wroclaw, Poland; [4]Department of Transplantation and Oncohematology, National Oncology Institute Maria Sklodowskiej-Curie National Research Institute, Gliwice Branch, Gliwice, Poland; [5]Department of Biology, University of Silesia in Katowice, Katowice, Poland; [6]Clinical Trial, Prosoma Sp. z o.o., Szczecin, Poland

Background: Anxiety and depression are the most common psychopathological problems encountered in psycho-oncological care. It is estimated that among cancer patients, the prevalence rates of these disorders range between 17% and 49% in the case of anxiety disorders and between 4% and 60% in the case of depression. Access to psycho-oncological assistance is still significantly difficult, and many cancer patients do not receive adequate help. The digital form of psychological intervention can be the answer to these problems. The study's objective was to investigate the effect of mobile application-based cognitive-behavioural therapy (LivingWell app) in addition to usual psycho-oncological care on the anxiety and depression in women with breast cancer undergoing primary oncological treatment, compared with the usual psycho-oncological standard of care alone.

Methods: The participants (n=78) were recruited via two cancer breast units up to two weeks after breast cancer diagnosis. The mobile-app intervention group consists of 44 women (app group). The control group with a standard of care included 34 women (SoC group). The app group was asked to use the mobile application at least three times a week. There were 4 measurements conducted at baseline and 6th, 12th and 18th week to assess levels of experienced depression and anxiety (Hospital Anxiety and Depression Scale).

Results: Within all measurements, only in the app group was observed a significant anxiety decrease. Additionally, the app group had an overall level of anxiety in the norm since the sixth week, while the level of this emotion in the SoC group stayed high. Within all measurements, was observed a significant decrease in depression in both groups, although average values in the app group remained constantly lower.

Conclusions: Mobile application-based CBT is an effective digital intervention for improving the mental state and functioning of women with cancer during oncological treatment. Mobile application-based CBT can be a valuable psycho-oncological support tool.

1851P Psychological well-being of patients with colorectal cancer during the third wave of the COVID-19 pandemic: Results from cohort II of the PICO-SM study

K.V. Kamposioras[1], K. Dadouli[2], P. Ntellas[3], K.H.J. Lim[1], M. Adamou[4], D. Anderson[5], L. Simpson[1], A. Shanthappa[1], M. Braun[1], J. Barriuso[1], J. Connell[1], J. Williams[1], D. Lehwald[1], J. Hasan[1], S. Mullamitha[1], K. Marti[1], M.P. Saunders[6]

[1]Medical Oncology Department, The Christie NHS Foundation Trust, Manchester, UK; [2]Medical Oncology Department, University of Thessaly, Larissa, Greece; [3]Medical Oncology, University Hospital of Ioannina, Ioannina, Greece; [4]Health Sciences, University of Huddersfield, Huddersfield, UK; [5]Psycho-Oncology, The Christie NHS Foundation Trust, Manchester, UK; [6]Clinical Oncology Department, The Christie NHS Foundation Trust, Manchester, UK

Background: We have previously reported on the initial results of the prospective longitudinal PICO-SM study (Lim *et al.* 2023), highlighting the impact of the COVID-19 pandemic on the lives of patients with colorectal cancer. Herein, we present the psychological impact of the third wave of the pandemic to patients, when the Omicron variant became prevalent (December 2021 to early 2022).

Methods: Patients were invited to participate in cohort II of the PICO-SM study by completing a questionnaire, including screening psychometric tools. Multivariate analysis was performed using logistic regression for binary outcomes: anxiety (GAD-7 score ≥ 5), depression (PHQ-9 score ≥ 10), and poor well-being (WHO-5 < 50); and odds ratios (OR) with 95% confidence interval (CI) were calculated.

Results: In total, 96 participants were included: mean age 64 years, 64% (n = 61) males. 33% (n = 32/96) reported poor well-being (WHO-5 < 50), 27% (n = 26/96) anxiety (GAD-7 ≥ 5), 11% (n = 11/96) depressive symptoms (PHQ-9 ≥ 10) and 3% (n = 3/96) probable post-traumatic stress disorder (PC-PTSD-5 ≥ 4). The results compare

with distress levels in the second pandemic wave: 31%, 24%, 15% and 3%, respectively. Multivariate analysis showed that patients who had investigations cancelled (OR 9.22, 95% CI 1.09-77.85; p = 0.041) or felt that the pandemic would affect their mental health (OR 3.82, 95% CI 1.96-7.44; p < 0.001) had increased risk of anxiety. Similarly, concern that the pandemic would affect their cancer treatment (OR 4.59, 95% CI 1.03-20.56; p = 0.046) or would affect their mental health (OR 3.90, 95% CI 1.38-11.03; p = 0.010) were found independent predictors of poor wellbeing.

Conclusions: The psychological distress experienced by patients, particularly anxiety, remained persistently high during the third wave of the COVID-19 pandemic. These updated results align with our initial findings, emphasizing the critical importance of continuing cancer treatment amidst the ongoing humanitarian emergency. It is crucial for healthcare services to prioritize ongoing psychological support for cancer patients, with a particular focus on those who are more vulnerable.

1852P Mental health among Tunisian oncologists

N. Issaad, Y. Zenzri, I. lasmer, H. Ben Mansour, K. Meddeb, N. Chraiet, F. Letaief-Ksontini, H. Rais, A. Mokrani, M. Ayadi, A. Mezlini

Medical Oncology Department, ISA - Institut Salah Azaiez, Tunis, Tunisia

Background: Oncology is a satisfying career. Helping patients through their cancer diagnosis and treatment can offer a sense of self fulfilment. But on the other hand, it can take its emotional toll on doctors. Long hours, dealing with life and death can affect oncologist's mental health. It can cause depression, anxiety and PTSD. Our aim is to identify individuals who are at risk for burnout and facilitate interventions to prevent it.

Methods: This study used a descriptive design to identify individuals at risk for burnout among oncologists. It included 100 clinicians, working in various hospitals in Tunisia, recruited via email invitations. Inclusion criteria included being a practicing oncologist with at least one year of experience. Participants anonymously completed the Maslach Burnout Inventory (MBI) questionnaire, a tool used to detect burnout. The MBI consists of 22 items that assess emotional exhaustion, depersonalization, and personal accomplishment.

Results: The population is made of 77% females and 23% males. With an average age of 33 years, medical oncologists represented 80%, radiotherapists 12% and surgical oncologists 8%. The majority had professional experience ranging from 1 to 5 years. Gender difference was seen on the emotional exhaustion subscale where women scored higher. No significant differences were observed in the scores based on professional experience or field of practice. Emotional Exhaustion: Participants had a mean score of 29. Meaning the participants experienced high levels of emotional exhaustion. Only 20% of the population had low score, 20% scored moderately and 60% had high scores. Depersonalization: Results showed a mean score of 10. Participants are experiencing moderate levels of depersonalization, with 28% scoring low, 32% scoring moderate and 40% scoring high. Personal Accomplishment: the average score was 35. Participants are experiencing moderate levels of personal accomplishment, with 32% at low risk of burnout, 20% at moderate risk and 48% at high risk of burnout.

Conclusions: Our study provides valuable information about the levels of burnout experienced by oncologists. It should inform interventions and strategies to mitigate burnout and promote wellbeing in this population. It should also ring alarm bells to oncologists' suffering mental health.

1853P Effect of logotherapy on anxiety in patients with cancer: A systematic review and meta-analysis

D.C. Barroso[1], T.M. Madeira[2], A.D. Marinho[3], A.V. Teixeira Filho[4], M.A.A. Freitas[5], J. Pirez[6]

[1]Medicine, State University of Santa Cruz, Ilhéus, Brazil; [2]Internal Medicine, UFMG - Universidade Federal de Minas Gerais, Belo Horizonte, Brazil; [3]Medicine, Universidade Federal do Estado do Rio de Janeiro, Rio de Janeiro, Brazil; [4]Department of Psychiatry and Behavioral Sciences, University of Miami/Jackson Memorial Hospital, Miami, FL, USA; [5]Medicine, State University of Região Tocantina do Maranhão, Imperatriz, Brazil; [6]Medicine, Universidade Cesumar, Maringá, Brazil

Background: Frankl's Logotherapy is a psychotherapeutic approach aimed at finding meaning in life. Although the incidence of death anxiety, existential loneliness, and depression in cancer patients is high, the efficacy of Logotherapy in this population is not well established.

Methods: Two independent investigators searched PubMed, Embase, and Cochrane Library databases up to March 2023. We systematically reviewed, according to PRISMA guidelines, controlled clinical trials evaluating the use of Logotherapy in cancer anxiety symptoms. We performed a pooled analysis on anxiety scores of patients that underwent group Logotherapy sessions vs. non-exposed control groups.

Results: We included seven studies, four randomized controlled trials (RCTs), and three quasi-experimental, comprising 280 patients, published between 1977 and 2023. A total of 139 patients (49.6%) had sessions of Logotherapy, and ages ranged from 18 to more than 68 years. Total treatment duration ranged between 360 and 1200 minutes. The Standard Mean Difference (SMD) for anxiety symptoms was -1.63 (95% CI = [-2.65, -0.61]; z = 3.12; P = 0.002; I^2 = 92%) in patients who underwent Logotherapy compared to non-exposed control groups. In a subgroup analysis including only RCTs, a similar effect was observed with an SMD of -0.64 (95% CI = [-1.72, 0.44]; z = 1.16; P = 0.25; I^2 = 91%).

Conclusions: Despite limited evidence, Logotherapy group sessions were associated with a reduction in anxiety scores of adult patients with cancer when compared to inactive control groups.

1854P The role of "1 minute" time perception in evaluating depression and anxiety in cancer patients receiving chemotherapy

S. Kitaplı[1], A. Alkan[2], O. Tanriverdi[2]

[1]Oncology Department, Mugla Sitki Kocman University - Faculty of Medicine, Mugla, Turkey; [2]Medical Oncology Department, Mugla Sitki Kocman University - Faculty of Medicine, Mugla, Turkey

Background: Impaired perception of time has been associated with many psychiatric and neurological diseases. Time perception has been studied with different validated scales in the literature. However, the length of these scales limits its feasibility. The aim of our study was to evaluate the relationship of "1 minute" time perception with depression and anxiety in cancer patients receiving chemotherapy.

Methods: The cancer patients receiving active systemic therapy were included in the study. Time perception assessment was performed by testing how they perceived the 1-minute period. The patients were asked to guess the length of 1 minute by using a chronometer. Time perception duration (TPD) were recorded. The median 39 seconds was used to categorize patients as fast and slow time perception. Depression and anxiety were evaluated using the Hospital Anxiety and Depression Scale (HADS).

Results: In the study; 242 patients with a median age of 61 (33-88 years) were evaluated. In the TPD evaluation, the median estimation time was 39s (7-135sec) and 50.4% was found to be rapid time perception (<39sec). Anxiety and depression scores were recorded as high in 12% of the patients. There was no significant correlation between TPD and anxiety (r=0.027, p=0.68) and depression scores (r= 0.017, p= 0.79). TPD was similar between the groups with high and normal anxiety scores (39 vs 39 sec, p= 0.90) and those with short perception patients were similar in both groups (51.7% vs 50.2%, p=0.51). TPD was shorter in those with high depression scores (34 vs 40s, p= 0.37). Those with rapid TDP were more common in these patients, but this did not reach statistical significance (58.6% vs 49.3%, p= 0.22). In the multivariate analysis. Female gender and low income were found to be risk factors for high anxiety scores.

Conclusions: The 1-minute time perception assessment could not be shown to be effective in predicting depression and anxiety scores. In our study, in which the group with high depression/anxiety scores was low, the small sample size may be the reason for the insignificant result. Testing the efficacy of 1 minute time perception in larger groups can provide important data to the literature.

1855P Assessment of depression and anxiety among adult patients with solid tumours admitted in national institute of cancer research & hospital

S.B. Al Ayub[1], M.H. Rahman[2], M.R. Islam[1], A. Hossain[1], A.T.M.K. Hasan[1], N. Khatun[1], M.R. Islam[1]

[1]Medical Oncology Department, NICRH - National Institute of Cancer Research & Hospital, Dhaka, Bangladesh; [2]Medical Oncology, Ahsania Mission Cancer & General Hospital, Dhaka, Bangladesh

Background: Cancer is one of the most common causes of mortality & morbidity globally, and the diagnosis of cancer is a stressful event causing significant psychological distresses, most commonly depression and anxiety, directly interfering with disease outcome and quality of life.

Methods: This cross-sectional type of descriptive study was conducted at the National Institute of Cancer Research & Hospital (NICRH), Dhaka for a period of 12 months. Sample size was 405 using purposive sampling. Data were collected from the patients through face-to-face interviews using a semi-structured questionnaire and Bangla version of the DASS-21 scale.

Results: In this study, the mean age of the respondents was 47.4 ± 16.5 years, predominantly male. Gastrointestinal cancers (27.4%) were most prevalent, followed by lung cancer (19.5%). The prevalence of depressive and anxious symptomatology was 38.02% and 42.96%, respectively. More than half (53.3%) of the patients were suffering from either of depression and/or anxiety.

Table: 1855P

Severity	Depression	Anxiety
Mild	19.7%	17.3%
Moderate	13.6%	11.6%
Severe	3.7%	9.4%
Extremely Severe	1%	4.7%

In inpatient setting, depressive disorders were significantly higher in females than males ($p<0.01$) and among the lung cancer patients; in contrast, gastrointestinal cancer and the presence of co-morbidities predisposed more to anxiety ($p<0.05$). Although mode of treatment and severity of disease showed no significant relationship with the prevalence of depression or anxiety, ECOG performance status was found to have significant impact on both of the disorders. On analysis of the socio-demographic variables, illiterate and low-income people were seen to suffer more with a severe and extremely severe level of depression, on the other hand, homemakers and lower socio-economic class had higher levels of anxiety.

Conclusions: The study findings showed a higher prevalence of depression and anxiety in the inpatient setting; therefore, counseling, screening, and timely evaluation of mental health should be a part of the standard protocol of oncology care.

1857P Psychological distress in Georgian cancer patients undergoing chemotherapy: Before and after the COVID-19 pandemic

M. Abuladze[1], K. Saganelidze[2], T. Melkadze[3], E. Mariamidze[3], N. Otkhozoria[3], S. Tsitsilashvili[3], M. Katcharava[1], E. Kekelia[3], B. Tchatchiashvili[4], I. Kipiani[5], T. Esakia[3]

[1]Department of Oncology and Hepatology, Todua Clinic, Tbilisi, Georgia; [2]Dean of Medical School, New Vision University, Tbilisi, Georgia; [3]Oncology and Hematology Department, Todua Clinic, Tbilisi, Georgia; [4]Radiation Oncology, Todua Clinic, Tbilisi, Georgia; [5]Medical School, New Vision University, Tbilisi, Georgia

Background: The COVID-19 pandemic has been closely associated with a decline in mental health. The goal of this study was to identify the degree of distress of cancer patients before and after the pandemic and to find out if COVID-19 worsened the mental health of cancer patients.

Methods: A self-rated survey was conducted for 2 groups of patients at The Todua Clinic, Tbilisi, Georgia twice: at the peak of pandemic and again 6 months after the pandemic. Study included adult cancer patients, with solid tumors, over 18 years of age, receiving chemotherapy, being able to understand and answer the questions in written English. Event Scale-Revised (IES-R) test was implemented to measure Post-Traumatic Stress Disorder (PTSD). Total IES-R score of 33 or over signifies the likely presence of PTSD.

Results: Study enrolled total of 195 patients, 103 patients - during and 92 - after the pandemic. 3 independent and 5 dependent variables were created. Independent variables were: 1. IES-R score ≥24 (y=1 if score ≥ 24, y=0 if score ≤ 24); 2. IES-R score≥ 33 (y=1 if score ≥ 33, y=0 if score ≤ 33); 3. IES-R score 37 (y= 1 if score ≤ 37, y=0 f score ≤ 37). Five dependent variables were: time, type of disease, stage, sex, and marital status. We created 3 regression models with independent and dependent variables (model 1: independent variable was IES-R score ≥24, model 2 independent variable was - IES-R score ≥ 33, model 3 IES-R score ≥ 33). We observed improvement in IES-R scores in the post-pandemic period: In model 1 - results improved by 20%, In model 2 - 16%, and in model 3 — 14%. Female and married individuals had better results in both periods. We calculated the data and observed that all dependent variables other than the disease type and the disease stage had a significant impact on IES-R scores.

Conclusions: Our findings showed a significant difference in IES-R scores in patients before and after the COVID-19 pandemic, with notable improvement in the post-COVID period. We also observed that sex, disease stage, marital status, and disease stage affected IES-R scores. We conclude that COVID-19 worsened the mental health of cancer patients. Our study highlighted the need for efforts to better integrate psychosocial support into cancer treatment.

Background: Identifying the patient's discomfort and unmet needs is crucial for providing effective care. However, accurately understanding the patient's discomfort can be challenging due to various limitations in the medical field, and in some cases, their discomfort may be underestimated. To better understand the difficulties faced by cancer patients, we implemented Social Listening to identify areas where improved treatment may be provided.

Methods: From October 1, 2021 to September 30, 2022, we gathered online data related to cancer and anti-cancer treatments. Using NetBase as our social listening platform, we filtered out irrelevant and commercial content from the collected data.

Results: A total of 169,575 social mentions related to cancer and anticancer treatment were collected. Among them, 12% (n=20,899) addressed the challenges experienced by patients following a cancer diagnosis. These challenges were further categorized based on the content of social media posts, with 52% focusing on physical difficulties, 42% on emotional challenges, and 6% on difficulties related to daily life. Emotional difficulties such as worry, denial, depression, fear, and anxiety were prevalent among cancer patients, with variations in priority depending on the time of diagnosis, treatment, and post-treatment stages. Of the 16,743 social media discussions related to cancer care, only 9% were related to managing emotional stress. A majority (84%) of discussions related to mental health management involved receiving psychiatric treatment, with the remaining 16% focusing on self-help groups, communication with others, meditation, hobbies, and religious practices.

Conclusions: Emotional burdens, along with physical difficulties, were frequently discussed on social media. However, there appeared to be a relative lack of focus on the management of emotional burdens. Considering the known association between emotional management and cancer treatment outcomes, it is imperative for physicians to prioritize their patients' emotional well-being and offer appropriate support.

1859P Digital goal management training as treatment for cognitive impairment in cervical cancer survivors: A feasibility study

E.W. Areklett[1], B.I. Hagen[2], S. Andersson[3], K. Bruheim[1], E. Fagereng[4], J. Stubberud[3], K. lindemann[5]

[1]Department of Oncology, Oslo University Hospital - The Norwegian Radium Hospital, Oslo, Norway; [2]Department of Social Education, UiT The Arctic University of Norway, Harstad, Norway; [3]Department of Psychology, University of Oslo, Oslo, Norway; [4]TRS National Resource Centre for Rare Disorders, Sunnaas Rehabilitation hospital, Bjørnemyr, Norway; [5]Department of Gynecological Cancer, Oslo University Hospital - The Norwegian Radium Hospital, Oslo, Norway

Background: Cognitive impairment (CI) is a common late effect after cancer treatment, for which effective treatment is lacking. Goal Management Training (GMT) is a validated cognitive remediation protocol reported to improve cognition including perceived daily life executive functioning, in neurological conditions. However, GMT has never been examined in cancer survivors, nor been presented in a digital format. This study examined the feasibility and acceptability of digital GMT in cervical cancer survivors (CCS) with subjective and/or objective CI.

Methods: We invited 65 CCS with CI to participate. Participants were randomized in a 1:1 ratio between digital GMT and a computerized cognitive training (CCT) program (BrainHQ). GMT consists of six weekly group-based modules encompassing discussion of participants' real-life cognitive deficits, practice on tasks of attention and self-monitoring, as well as homework assignments. BrainHQ is a web-based training platform with exercises targeting several cognitive domains. For six weeks, participants joined digital training sessions of one hour twice a week. The primary endpoint was attendance, and participants attending $\geq$80% of the sessions were categorized as completers. Acceptability was evaluated 1 week post-intervention using the Client Satisfaction Questionnaire-8 (CSQ-8). A total CSQ-8 score $\geq$ 26 was defined as "very satisfied", scores 20-25 as "satisfied", and scores $<$20 as "not satisfied".

Results: 33 CCS with a median age of 50.0 years (range 35-67) were randomized to either GMT ($N = 16$) or CCT ($N = 17$). In the GMT group, all participants completed the intervention (100%), compared to 15 (88%) in the CCT group. Median CSQ-8 in the GMT and CCT group was 25 (*SD* 3.7, range 18-31) and 24 (*SD* 3.1, range 19-30) respectively. Participants in both groups reported a high level of satisfaction as 40% reported being "very satisfied" and 53% "satisfied".

Conclusions: A digital cognitive training program such as GMT is feasible with a high level of compliance and satisfaction in CCS and is suitable to be tested in a larger study. Exploratory analyses of neuropsychological assessments in our study will provide important preliminary data on the efficacy of improving cognitive function in CCS.

1860P Objective and subjective neurocognitive functioning (NCF) in advanced cancer survivors treated with immune checkpoint blockade (ICB)

N. Vanlaer[1], I. Dirven[1], M. Vounckx[1], J. Tijtgat[1], M. Verhaert[1], S. Aspeslagh[1], L. Decoster[1], A. Rogiers[2], B. Neyns[1]

[1]Department of Medical Oncology, Vrije Universiteit Brussel (VUB), Universitair Ziekenhuis Brussel (UZ Brussel), Jette, Belgium; [2]Department of Psychiatry, Centre Hospitalier Universitaire Brugmann, Brussels, Belgium

Background: Limited knowledge currently exists on NCF in advanced cancer survivors treated with ICB. Here, we present the baseline data of an ongoing prospective trial regarding objective and subjective NCF.

Methods: Patients (pts) followed-up at a single center, diagnosed with stage III/IV cancer of any type, who initiated ICB at least one year prior to and were in complete remission (CR) at time of inclusion, were invited to participate. Objective NCF was assessed using the test battery COGBAT®. Neurocognitive impairment (NCI) was defined by the International Cancer and Cognition Taskforce guidelines and deficits per subtest as 1.5 standard deviation below the normative mean. Subjective NCF, anxiety, depression and fatigue were assessed respectively through the Cognitive Failures Questionnaire, Hospital Anxiety and Depression Scale, and Fatigue Severity Scale.

Results: From July 2022 to April 2023, 58 pts were enrolled (48 melanoma, 6 non-small cell lung carcinoma, 2 colon cancer, 1 renal cell carcinoma, 1 bladder cancer), median age was 64 y [34-92]); 34 male; 55 pts (95%) had stage IV disease; 12 pts (21%) had a history of brain metastasis. Median time since CR was 3.0 y [0.1-14.1]; median time since last ICB administration was 3.6 y [0.0-11.4]. We found objective NCI in 34 pts (59%), with deficits predominantly in memory (33%) and attention (31%) and in a lesser amount in executive functioning (16%). Moderate to severe subjective cognitive complaints were found in 12 pts (21%). Objective NCF only correlated significantly with age (r = -.782, $p < .001$) but not with subjective NCF, fatigue, anxiety, depression or a history of brain metastasis. Subjective NCF correlated significantly with anxiety, depression and fatigue (respectively $r = .694$, $r = .454$, $r = .447$, all p-values $< .001$).

Conclusions: A majority of the advanced cancer survivors treated with ICB had objective NCI. A noteworthy lesser proportion had subjective cognitive complaints, indicating the need of neuropsychological assessment. Moderate to strong associations exist between subjective NCF and psychological distress, indicating the value of an integrative approach, including NCF remediation and psychosocial support when treating cognitive complaints.

1861P A randomized controlled trial on the efficacy and safety of the Untire app for moderate-to-severe cancer-related fatigue in German patients

S. Spahrkäs[1], K. Abraham[2], F. Akbari[3], H-P. Zenner[4], H. Reitsma[2], B. Kuiper[5], E. Schuit[2]

[1]Head of Research, Tired of Cancer, Utrecht, Netherlands; [2]THINC. The Healthcare Innovation Center, UMC - University Medical Center Utrecht, Utrecht, Netherlands; [3]Research, Tired of Cancer, Utrecht, Netherlands; [4]Director, CRO Zenner, Tübingen, Germany; [5]Reserach & Development, Tired of Cancer, Utrecht, Netherlands

Background: This RCT examined the clinical efficacy and safety of the German version of the self-management Untire app for reducing fatigue and improving quality of life in cancer patients and survivors, with the hypothesis that app access as an add-on to care as usual will lead to superior clinical outcomes in patients with moderate-to-severe fatigue as compared to care as usual only, over 12-weeks.

Methods: Patients with cancer-related fatigue (CRF) were recruited from across Germany through newspaper advertisements, and randomized (1:1) to receive either care-as-usual alone (control; n=111) or care-as-usual plus access to the Untire app (intervention; n=104). The primary outcome measure was fatigue, and secondary outcomes included quality of life, stress, depression, and anxiety, all assessed at baseline, 4, 8, and 12 weeks. Linear mixed models, ANCOVAs were employed for all outcomes to evaluate the treatment effects over 12 weeks while adjusting for baseline values and adhering to the intention-to-treat principle.

Results: The intervention group experienced a significantly larger improvement at week 12, with an average fatigue score of 4.8 (SE=0.18) compared to 5.6 (SE=0.17) in the control group (p=0.0016, 95% CI: -1.29 to -0.30). This difference of -0.79 is statistically significant and also clinically relevant as it is larger than the MCID of -0.57, with 58.7% of patients in the intervention group experiencing an improvement of more than 0.57 points compared to 43.2% in the control group. For the secondary outcomes, disease-related quality-of-life scores were also significantly higher in the intervention group at week 12 (p=0.0178, 95% CI: 0.16 to 1.64), and improved to a clinically relevant degree. No significant interactions were found between the treatment groups and the subgroup variables. Sensitivity analyses (per-protocol and reference-based) indicated the robustness of the findings. The degree of app usage did not affect the treatment effect over 12 weeks. Adverse events occurred with no discernible patterns between groups, and no deaths occurred during the trial.

Conclusions: The German version of Untire can be an effective and safe digital health application for patients with moderate to severe CRF.

Clinical trial identification: DRKS00027477.

1862P Measuring the prevalence of fatigue in children with cancer: Evidence from Egypt

N.K. Abdalkader

Clinical Pharmacy, NGU - New Giza University, Giza, Egypt

Background: Cancer related fatigue (CRF) is a common side effect of cancer and cancer treatment that impacts every aspect of quality of life. To our knowledge, the statistics for prevalence in pediatrics are lacking in Egypt. The aim of this study is to record the prevalence of fatigue and its significant predicting factors in pediatric oncology patients.

Methods: We interviewed children aged 8-18 years with cancer, prescribed chemotherapy and not in severe distress. After the consent of the guardian is taken, the children personally filled 2 fatigue-related questionnaires (PROMIS Pediatric Short Forms of Fatigue (PROMIS fatigue), pedsQL multidimensional fatigue (PedsQL fatigue)) and 3 symptoms related questionnaires.

Results: 42 children (47.6% female) (mean age 12.1 years (SD 3.3 years)) participated. Half of the children were in primary school (n=21, 50%) and most of them had their parents accompanying them (n=35, 83.3%). Most children suffered from a hematological tumor (n=35, 83.3%) and didn't suffer from other chronic health conditions (n=39, 92.8%). Reported moderate to severe fatigue in children is between half to third of the children depending on the measurement tool used. The mean T-score for PROMIS fatigue was 53.76 (SD 12.5), the mean score for PedsQL fatigue was 74.27 (SD 21.79). Stepwise standardized multivariant linear regression showed that fatigue following PROMIS fatigue could be predicted by depressive symptoms.

Conclusions: CRF is multifactorial and prevalent among children and adolescents with cancer. Moreover, predicting factors differed between different tools as they measure fatigue from different dimensions. PedsQL fatigue was predicted by more factors. There is a need to include fatigue screening for pediatric oncology patients and incorporate its management in the medical care plan.

1863P Compassion fatigue among the staff involved in medical carcinology services

N.A. Abidi

Medecine, University of Sfax - Faculty of Medicine, Sfax, Tunisia

Background: A descriptive, cross-sectional, multicenter study was carried out among the nursing staff working in several departments caring for cancer patients (Carcinology Sousse, Monastir, Sfax, Institut Salah Azaiez and Ariana).

Methods: The instrument used to measure CE was the "Professional quality of life" (PRO-QOL version5), which is composed of 3 subscales: 10 items to measure compassion satisfaction (SC), 10 items to measure professional exhaustion (PE) and 10 items to measure secondary traumatic stress (STS).

Results: A total of 120 health personnel responded to the questionnaire. The average age of the participants was 36.13±8.06 with a clear female predominance (sex ratio=0.29). Most respondents were physicians (55.9%). The mean CS score was 33.57±6.24, which is consistent with an average level of CS. However, 13.3% of the staff had a high SC score. The mean PE score was 29.88±5.12, which corresponds to an average level of PE. Only 10.9% had a low PE score. The mean STS score was 33.16±7.56, which corresponds to an average level of STS. However, 17.5% had a high STS score.

Conclusions: Compassion fatigue can lead to real burnout. Its prevention, detection and implementation of solutions to stem the process is essential.

1864P To what extent do nulliparous, female adolescents and young adults diagnosed with cancer have children after cancer treatment?

L. Bentsen[1], L.B. Colmorn[2], H. Pappot[1], K.L.T. Macklon[2], D. Vassard[2]

[1]Department of Oncology, Copenhagen University Hospital, Rigshospitalet, Copenhagen, Denmark; [2]Department of Fertility, Copenhagen University Hospital, Rigshospitalet, Copenhagen, Denmark

Background: Globally, more than 1.3 mio adolescents and young adults (AYAs) are diagnosed with cancer each year. Long-term survival has increased due to improved cancer therapy; however, a potential side effect is reduced fertility. Despite development in fertility preservation uncertainty regarding future fertility is still of major concern to the AYAs. The aim of this study was to identify to what extent nulliparous, female AYAs with cancer have children after cancer treatment compared to nulliparous female AYAs without cancer.

Methods: This is a national register study based on the Danish National Assisted Reproductive Technology-Couple cohort including female AYAs diagnosed with cancer when aged 18-39 from 1978—2016. According to diagnosis onset, the female AYAs with cancer were randomly age-matched with 60 female AYAs without cancer (comparison group: CG). Study participants were followed until end of study, death, or migration (31/12-2017). Death was incorporated as a competing risk in all analyses. Hazard Ratio (HR) were calculated, comparing the female AYAs with cancer with the CG. HR was adjusted for time of diagnosis, immigration status, marital status, and educational level.

Results: 33.3% of AYAs with cancer had at least one child after cancer treatment vs. 40% in the CG. Female AYAs with malignant melanoma had solely a higher HR of having children after cancer treatment compared to the CG. Female AYAs with leukaemia, breast and CNS cancer had the lowest HR of having children after cancer treatment, especially in the age interval 32-39 years.

Table: 1864P

	N (%)	≥ 1 child after cancer N (%)	Adjusted HR (95% CI)*		
			18-25 y	26-31 y	32-39 y
All	7519 (100)	2505 (33.3)	0.77 (0.72-0.82)	0.65 (0.61-0.69)	0.59 (0.52-0.67)
Gyn cancer	1773 (23.6)	435 (24.5)	0.49 (0.42-0.58)	0.44 (0.38-0.50)	0.39 (0.29-0.52)
Breast cancer	1115 (14.8)	179 (16.1)	0.63 (0.42-0.95)	0.46 (0.37-0.56)	0.35 (0.26-0.48)
Mal melanoma	1960 (26.1)	1071 (54.6)	1.02 (0.93-1.12)	1.03 (0.93-1.13)	1.13 (0.92-1.39)
CNS cancer	303 (4.0)	65 (21.5)	0.70 (0.51-0.97)	0.40 (0.26-0.61)	0.25 (0.06-0.97)
Leukaemia	258 (3.4)	37 (14.3)	0.39 (0.26-0.57)	0.25 (0.09-0.65)	0.41 (0.13-1.26)
Lymphoma	278 (3.7)	78 (28.1)	0.63 (0.47-0.85)	0.48 (0.30-0.75)	0.76 (0.32-1.84)
CG	499,616	199,861 (40.0)	1	1	1

*Adjusted analysis is based on complete case sample, N=6275. Approximately 16% (6275/7519) is excluded in the adjusted analysis due to missing data.

Conclusions: A third of nulliparous, female AYAs with cancer had at least one child after cancer which is lower than for female AYAs without cancer. The HR for having children after cancer decrease with increased age being lowest in female AYAs with leukaemia, breast- and CNS cancer.

1865P Women with elderly early-stage breast cancer with type A personality may have decreased self-esteem after chemotherapy: A pilot study (POSEIDON Study)

O. Tanriverdi

Medical Oncology, Mugla Sitki Kocman University - Faculty of Medicine, Mugla, Turkey

Background: This study aimed to determine how the chemotherapy process can lead to a change in self-esteem in elderly patients with early-stage breast cancer according to personality type.

Methods: The research was completed as a pilot study between 2019-2022. Female patients aged 65 and over who were planned for adjuvant treatment were included in

the study. Personality type and self-esteem were determined in all patients before and after adjuvant chemotherapy. Bortner Rating Scale was used to determine personality type, and Rosenberg Self-Esteem Scale was used to determine self-confidence. Paired t-test was performed for recurrent variables in pre-treatment and post-treatment measures. Multivariate logistic (binary) regression analysis was performed to determine the independent factors affecting low self-esteem from the study variables with the model created as a result of correlation and univariate analysis. Statistical analysis was performed using the SPSS v19 program and a p value of <0.05 was considered statistically significant.

Results: A total of 69 Her2-negative elderly female patients were included in this pilot study. The mean age of the patients was 68 years (65-72). 54% had radical mastectomy. 69% received paclitaxel for 12 weeks, 21% received 6x DC, and 10% received 3x CEF followed by 3x docetaxel for adjuvant setting. 56% of them had personality type A. Before treatment, 62% had high self-esteem and this was significantly higher in type A personality than in type B (84% vs 48%, respectively; p=0.037). While the rate of high self-esteem decreased in type A personality after treatment (p=0.009), there was no change in type B personality (p=0.379). It was determined that type A personality structure was independent affecting low self-esteem after treatment (OR 5.37 95%CI 1.489-9.396; p=0.006).

Conclusions: In this study, it was concluded that elderly women with type A personality structure may be more sensitive and may have low self-esteem after the treatment is completed. It was concluded that the personality type should be guided by the patient's treatment compliance, need for psychosocial support, and coping methods after the completion of the treatment, supported by the physician.

Legal entity responsible for the study: Ethics committee approval could not be obtained because it was a pilot study. In the follow-up research, the results of the pilot study will be declared and consent will be obtained.

Funding: Has not received any funding.

1866P Unmasking the extent of hidden sexual distress in young breast cancer survivors

Z. Naimi, M. El Bessi, M. Bohli, R. Ben Amor, A. Hamdoun, R. Haddad, G. Bouguerra, L. Kochbati

Department of Radiation Oncology, Abderrahmen Mami Hospital, Ariana, Tunisia

Background: The aim of this study was to compare sexual health between young breast cancer survivors and healthy young women without history of cancer, to better analyse the impact of breast cancer diagnosis and treatment on sexual health.

Methods: We conducted a cross-sectional study including all young breast cancer patients ($\leq$40 year-old) referred for radiotherapy between 2017 and 2021. Patients were asked to fill in the Female Sexual Function Index (FSFI) in its validated Arabic translated version. A comparable cohort of young healthy women was recruited to fill in the same questionnaire. Sexual scores were calculated for both groups and statistically compared.

Results: A total of 102 young breast cancer patients (BC group) and 53 young healthy women (control group) were included in this study. Only 39.2% of breast cancer patients answered the questionnaire. Ninety-seven percent of patients underwent chemotherapy. Adjuvant endocrine therapy was prescribed for 77% of patients, of whom 97% underwent ovarian function suppression. All patients received adjuvant hypofractionated radiotherapy. Mean FSFI score was 24.01 (2.4-33) in the BC group versus 28.88 (23.8-34.4) in the control group (p=0.000). Two patients declared having unpleasurable sexual activities before their diagnosis. Sexual dysfunction (FSFI score $<$ 26,55) was reported in 55% and 20%, respectively in the BC and control group (p=0.001). Mean desire score was 3.58 vs 4.08 (p=0.016), respectively in the BC group and the control group. Ninety-two percent of breast cancer patients suffered from hypoactive sexual desire disorder (desire score $<$5), versus 87% in the control group (p=0.35).

Table: 1866P Female Sexual Function Index questionnaire scores

Domain	Breast cancer group	Control group	P value
Desire	3.58	4.08	0.016
Arousal	3.71	4.56	0.001
Lubrification	4.15	5.16	0.00
Orgasm	4.23	4.97	0.007
Satisfaction	4.44	5.49	0.00
Pain	3.85	4.62	0.008

Conclusions: This study showed a significant alteration of sexual function in young breast cancer survivors when compared with a control group. Assessment and management of sexual dysfunction should become a standard practice, in order to improve quality of life and sexual health in young breast cancer survivors.

1867P A cross-sectional examination of information disclosure and health literacy amongst patients with lymphoma

S.E. Kalloger[1], A. Watson[1], S. Sajkowski[2], L. Warwick[3]

[1]Research and Information, Lymphoma Coalition - Head Office, Mississauga, QC, Canada; [2]Research, Lymphoma Coalition, Mississauga, QC, Canada; [3]Lymphoma Coalition, Mississauga, QC, Canada

Background: Health literacy of patients is a requirement for shared decision making. However, little is known about the experiences of patients with lymphoma with regard to health literacy and information disclosure from their treating physicians. We sought to explore health literacy through a survey deployed across a large and diverse group of patients with lymphoma.

Methods: The 2022 Lymphoma Coalition (LC) Global Patient Survey (GPS) was completed by 7113 patients from 84 countries. We sought to understand how patients initially understood their disease. Responses to the question: "To what extent, if at all, were diagnostic tests and results explained to you?" were stratified across core demographics and tabulated. Tests for significant differences across strata were computed with JMP Pro v17.

Results: Of the 6684 respondents who indicated a level of satisfaction or dissatisfaction with regard to the comprehension of diagnostic and laboratory tests, 58% and 42% were males and females respectively with a median age of 60 and range of 18 - 97 years. Overall, 36% of respondents reported poor comprehension. Increasing age was a significant positive predictor of health literacy with a Range OR = 6.9 [5.4 - 8.9]. Likewise, male biological sex was a significant predictor of improved comprehension OR = 1.5 [1.3 - 1.6]. Regional disparities were identified that indicated North America and Europe had the highest rates of satisfactory comprehension with 72% and 68% respectively. This was contrasted with the Asia-Pacific region at 53% ($p<0.0001$).

Conclusions: One of the goals of precision medicine is to deliver the right therapeutics to the right patient at the right time. [LW1] Shared decision making has the ability for patients to provide valuable feedback to their treating physicians. However, a lack of health literacy essentially excludes patients from participating in the decision making process. All three demographics examined above indicated highly significant disparities that can have adverse ramifications on healthcare equity. We feel that patients should understand their disease and the available treatment options which will yield increased participation in their care.

1868P Challenges for shared decision making in incurable cancer, with a focus on health literacy

C.E. Holden[1], R. Wagland[1], S. Wheelwright[2], A. Harle[3]

[1]Health Sciences, University of Southampton, Southampton, UK; [2]Sussex Health Outcomes Research & Education in Cancer (SHORE-C), Brighton and Sussex Medical School - University of Sussex, Brighton, UK; [3]Dorset Cancer Centre, University Hospitals Dorset NHS Foundation Trust, Poole, UK

Background: Patients with incurable cancer often face difficult decisions about their care. Shared decision making (SDM) can help people make the decisions that are right for them, by supporting understanding and ensuring their priorities are considered. Essential for this is health literacy (HL) - the personal competencies and situational resources needed for people to process information to make decisions. This study sought to understand the barriers to SDM in the context of HL from the perspective of patients and clinicians, and consider how they may be overcome.

Methods: This mixed methods study comprised: 1) semi-structured interviews with patients with incurable cancer and suspected HL difficulties, identified by clinicians from 2 district hospitals; and 2) an online survey of NHS healthcare professionals caring for patients with incurable cancer. Interview data were analysed using the Framework Approach to identify important and recurrent themes. For the survey, a descriptive analysis was carried out for the quantitative data, and thematic analysis for the qualitative data.

Results: Twenty-one interviews were conducted. Patients had a range of diagnoses and had received various treatments. Themes related to experiences (supportive staff in an imperfect system, additional pressure from COVID-19, in the expert's hands, treatment not so bad) and barriers to SDM (emotional hurdles, accessing and understanding information, wanting to be a good patient). Survey participants (N=70)

included doctors, nurses, and a pharmacist. Views towards SDM ranged from those who aim to 'always' use it, to those who feel its use should be limited. Patient, clinician, and situational barriers were identified. Key challenges for SDM include the persistence of paternalistic clinician-patient roles, dealing with emotional hurdles, and practical issues.

Conclusions: There are socio-cultural, emotional and system barriers to SDM in incurable cancer for those with HL difficulties. Addressing this combination of issues will be important to fully embed its use in practice. Recommendations to improve SDM range from large scale policy changes to provision of easily accessible and understandable patient information and decision aids in a variety of formats.

1869P First impressions: A prospective evaluation of patient comprehension and satisfaction in the communication of diagnosis, treatment, and prognosis following the initial medical oncology consultation

Y. Bach[1], E.D. Panov[2], O. Espin-Garcia[3], E. Chen[4], M.K. Krzyzanowska[5], G.M. O'Kane[1], M. Moore[1], R. Prince[1], J. Knox[1], R. Grant[6], L. Ma[1], M. Allen[6], L. Eng[5], T. Megid[6], R.W-J. Jang[1], E. Elimova[1]

[1]Medical Oncology, UHN - University Health Network - Princess Margaret Cancer Center, Toronto, ON, Canada; [2]Medical Oncology Department, Trillium Health Partners, Mississauga, QC, Canada; [3]Biostatistics, Princess Margaret Cancer Centre, Toronto, ON, Canada; [4]UHN - University Health Network - Princess Margaret Cancer Center, Toronto, ON, Canada; [5]Department of Medical Oncology & Hematology, UHN - University Health Network - Princess Margaret Cancer Center, Toronto, ON, Canada; [6]Medical Oncology, Princess Margaret Cancer Centre, Toronto, ON, Canada

Background: Despite the plethora of patient (pt) communication studies in the past decade, many of them include a diverse and heterogeneous pt and physician cohort. Thus, this single-centre prospective study aimed to measure gastrointestinal (GI) cancer pts' understanding of the information discussed during their *first* medical oncology visit and their satisfaction with the communication from subspecialized GI medical oncologists.

Methods: Between January and August 2021, chemotherapy-naïve pts in the gastrointestinal clinic at the Princess Margaret Cancer Centre (PMCC), Toronto, Canada, were consecutively approached within 24 hours of their initial consultation to complete a paper-based questionnaire about their understanding of their cancer (diagnosis, treatment plan/intent, prognosis) and satisfaction with the communication. GI medical oncologists concurrently completed a similar questionnaire. Pt and physician responses were compared to assess the degree of concordance. Uni/multivariable analyses were performed to identify pt/physician-based factors associated with concordance levels and pt satisfaction.

Results: A total of 184 matched pt-physician surveys were completed. The concordance rates for understanding of diagnosis, treatment plan, treatment intent, and prognosis were 92.9%, 59.2%, 66.8%, and 59.8%, respectively. Pts who reported treatment intent to be unclear at the time of the consultation were independently associated with lower satisfaction scores compared to those who reported their treatment intent to be curative (p=0.014). There was no statistical significance between patient satisfaction and whether prognosis was disclosed (p=0.08).

Table: 1869P

N=184	Fully concordant, n (%)	Partially concordant, n (%)	Fully discordant, n (%)	Missing, n (%)
Diagnosis	171 (92.9)	N/A	10 (5.4)	3 (1.6)
Treatment Plan	109 (59.2)	75 (40.8)	0 (0.0)	0 (0.0)
Treatment Intent	123 (66.8)	N/A	55 (29.9)	6 (3.3)
Prognosis	110 (59.8)	N/A	65 (35.3)	9 (4.9)

Conclusions: Pt understanding of treatment intent and prognosis after the first medical oncology consultation remain low. Further studies on the effectiveness of consultation aids in this setting are needed.

1871P The PainRELife ecosystem: A new aid for improving clinical care and shared decision-making in breast cancer patients with chronic pain

M. Masiero[1], C. Filipponi[1], C. Marzorati[2], E. Munzone[3], L. guido[4], V. Guardamagna[4], S. Marceglia[5], A.M. Caruso[6], V. Manzelli[6], C. Savino[6], C. Conti[7], F. Rizzi[8], G. Candiani[9], F. Memini[9], L. Chiveri[10], M. Corbo[10], A. Milani[11], E. Fragale[2], F. Didier[2], G. Pravettoni[2]

[1]Department of Oncology and Hemato-Oncology, University of Milan, Milan, Italy; [2]Applied Research Division for Cognitive and Psychological Science, IEO - Istituto Europeo di Oncologia IRCCS, Milan, Italy; [3]Medical Senology Department, IEO - Istituto Europeo di Oncologia, Milan, Italy; [4]Division of Palliative Care and Pain Therapy, IEO - Istituto Europeo di Oncologia IRCCS, Milan, Italy; [5]Dipartimento di Ingegneria e Architettura, Università degli Studi di Trieste, Trieste, Italy; [6]Technology Officier, Nuvyta SRL, Cologno Monzese, Italy; [7]Consulting and Services, IMS — Istituto di Management Sanitario, Milan, Italy; [8]Clinical Study Manager and Grants Development Specialist, IMS - Istituto di Management Sanitario, Bresso, Italy; [9]Agenzia di comunicazione scientifica Zadig srl Società benefit, Agenzia di comunicazione scientifica Zadig srl Società benefit, Milan, Italy; [10]Dipartimento di Scienze Neuroriabilitative, Casa di Cura Policlinico (CCP), Milan, Italy; [11]Nursing School, Associazione Infermieri di Assistenza Oncologica, Milan, Italy

Background: Evidence suggests that introducing *e*Health ecosystems improves the clinical management of chronic pain (CP) in breast cancer patients (BCPs). These tools contribute to overcoming established contextual, social, and individual barriers by monitoring patients' physical health and psychological well-being and early recognizing high-risk patients. Moreover, *e*Health ecosystems increase patient participation in treatment decisions through specific *decision aids* modules, thus enabling shared decisions.

Methods: This pilot study is nested in *PainRELife Project* (ID:1173269). The primary endpoint was investigating patients' usability experience using an *e*Health ecosystem constituted by *Nu Platform* joined with the *PainRELife mobile application*. Twenty-five female BCPs (M_{age}=47, SD=8.41) were enrolled and utilized the mobile application for three months. A set of self-report measures were administered at scheduled time points evaluating the following constructs: physical and mental characteristics; pain experience and intensity; pain self-efficacy; and patients' preferences for participating in clinical decision-making and shared decision-making. The usability was evaluated by means of the Mobile Application Rating Scale (MARS).

Results: A reduction in pain intensity was observed from baseline (M=5) to 3 months (M=3.72), p<.04. The BCPs reported high values in all subscales of the MARS: *engagement* (M=3.31); *functionality* (M=4.14); *aesthetics* (M= 3.98); *quality of the information* (M=4.18); *subjective quality* (M=3.5); *influence to change patient behaviors* (M=4.05). A positive correlation was found between shared decision-making and engagement (r=.445*), quality of the information (r=.427*), and subjective quality attributed to the mobile application (r=.548**).

Conclusions: The *e*Health ecosystems could be valuable *aids* in supporting clinicians and patients to accomplish the physical, social, and psychological challenges associated with the *disease's trajectory*, also improving patients' participation in treatment decisions allowing the implementation into clinical practice of shared decision-making models.

Legal entity responsible for the study: Applied Research Division for Cognitive and Psychological Science, European Institute of Oncology, IRCCS.

1872P Financial distress of a cancer disease in Germany: A new patient reported outcome measure (PROM) and first results from a bi-centered cross-sectional analysis

S. Pauge[1], L. Richter[2], A. Züger[3], K. Mehlis[3], V. Mathies[4], T. Ernst[4], W. Greiner[1], N. Menold[2], E.C. Winkler[5]

[1]School of Public Health, Bielefeld University, Bielefeld, Germany; [2]Institute of Sociology, Dresden University, Dresden, Germany; [3]Section Translational Medical Ethics, NCT - National Center for Tumor Diseases Heidelberg, Heidelberg, Germany; [4]University TumorCentrum Jena, Jena University Hospital, Jena, Germany; [5]Medical Oncology Department, NCT - National Center for Tumor Diseases Heidelberg, Heidelberg, Germany

Background: Individual financial distress (FD) of a cancer disease impacts patient's health-related quality of life. FD also occurs in countries with universal healthcare coverage, but comprehensive data about the extent is lacking. We have developed a new standardized PROM for FD in Germany based on qualitative pre-studies (patients/social services representatives) and a literature review. The validity of the

PROM is tested in two survey waves including at least n=400 cancer patients. This study aims to determine the degree of FD in cancer patients using the PROM.

Methods: A bi-centered cross-sectional study was performed including n=112 cancer patients; the PROM was administered between June/ July 2022 in outpatient units, ambulances or oncological wards of two university hospitals in Germany. Patients were eligible if they had confirmed solid cancer (ECOG-Status <2) and had undergone >2 months of therapy. A MANOVA was performed to analyze the dimensions of FD.

Results: 88.3 percent of patients reported higher (non-)medical costs due to cancer disease in the last six month, spending on average 400€ per month. 65.1 percent of patients experienced a loss of income (p<.001), so that the average monthly income changed from 2000-2499€ (M: 4.39; SD: 2.82) to 1500-1999€ (M: 3.17; SD: 2.19). Most patients cope with changes by gaining an overview of their financial situation, being frugal or adopting a relaxed attitude to their financial situation. Perceived FD is mainly attributed to difficulties in maintaining a healthy lifestyle and housing. Female gender, living alone and a low income are significantly associated with higher FD. There are no significant differences in age, education level, occupational status, type of insurance and time since cancer diagnosis.

Conclusions: FD is a common phenomenon that also occurs in countries like Germany. It is driven by rising direct (non-) medical costs and income losses due to diagnosis and treatment. In the next step, we validate the PROM in a second larger sample with n=400 participants and verify our initial findings of FD. There is a need to comprehensively measure FD using a validated PROM to determine the effects on health outcomes and to derive targeted support.

Clinical trial identification: NCT05319925.

1873P Patients with myeloproliferative neoplasms and self-care behaviours: Preliminary data of a cross-sectional study

V. Biagioli[1], A. Barone[1], A. Inzoli[2], V. Rosti[3], G. Barosi[3], S-C. Research Study Group[1]

[1]AIPAMM, Italian Association of MPN Patients, Pavia, Italy; [2]Hematology, Ospedale Maggiore Ospedale Maggiore ASST di Crema, Crema, Italy; [3]Center for the Study of Myelofibrosis, General Medicine 2, Fondazione IRCCS Policlinico San Matteo, Pavia, Italy

Background: Patients living with myeloproliferative neoplasms (MPN), including myelofibrosis (MF), polycythaemia vera (PV) and essential thrombocythemia (ET), should engage in self-care behaviours to improve their health. This study aims to preliminary assess self-care behaviours in MPN patients.

Methods: A descriptive cross-sectional study has been conducted in 9 haematology centres in Italy since November 2021. The Italian Association of MPN Patients (AIPAMM) promoted this study. The Self-Care in MyeloProliferative Neoplasms Inventory (SC-MPNI), a 31-item questionnaire measuring self-care behaviours according to the Middle-Range Theory of Self-Care of Chronic Illness, was developed and tested for its content validity. MPN patients were asked to complete a paper-and-pencil questionnaire during their outpatient visit or at home.

Results: Preliminary data from 171 patients (54% male; mean age=58, SD=19) and 5 centres were analysed (45.6% of the expected sample). Participants were living with overt MF (n=51), prefibrotic MF (n=24), PV (n=48) or ET (n=44). Concerning self-care maintenance, the most frequent behaviour was attending all scheduled clinical appointments (M=5.9, SD=0.6), and the least used one was performing activities that improve mental and physical well-being (M=3.1, SD=1.7). Concerning self-care monitoring, the most frequent behaviour was getting blood tests as prescribed by the haematologist (M=5.9, SD=0.5), and the least used one was checking any measurement the healthcare providers recommend (M=4.7, SD=1.4). Concerning self-care management, the most frequent behaviour was accurately reporting symptoms to the healthcare providers during visits to get a comprehensive response (M=5.5, SD=0.9), and the least used one was asking for psychological support to overcome emotional problems (M=2.6, SD=1.5).

Conclusions: This study will contribute to assessing self-care behaviours in patients with MPN. Health professionals should support innovative interventions to promote self-care, which is crucial for MPN patients to reduce cardiovascular events and be medically fit to undergo hematopoietic stem cell transplantation.

1874P Beliefs about chemotherapy in Tunisian patients newly diagnosed with cancer

H. Ayadi, M. Nesrine, H. Rachdi, M. Saadi, Y. Berazaga, H. Boussen

Medical Oncology Department, Hopital Abderrahmen Mami de Pneumo-Phistiologie, Ariana, Tunisia

Background: Patients may hold opinions about chemotherapy and cancer that may influence their decisions. We aimed to examine beliefs regarding chemotherapy (CT) and explore associated factors.

Methods: This is a cross-sectional study, conducted between January –April 2023 including 156 patients receiving chemotherapy in a day hospital. A questionnaire adapted from the BMQ (beliefs about medicines questionnaires) was delivered to patients regardless of gender, cancer site or stage, and how are under ongoing CT. We reported demographic and clinical features and beliefs about CT and evaluated correlated factors.

Results: The mean age was 53 years, 79% were female and 60% were treated for breast cancer. Forty-three per cent of patients believed that CT leads automatically to weight loss and 34% to cognitive impairment. The 3 main symptoms that patients feared were alopecia (65%), vomiting (50%) and asthenia (48%) and 40% associated the intensity of side effects to higher levels of efficacy. Patients considered that their life depended on CT in 89%, that without it they will be very sick in 53%, and that it protected their health in 55%. However, 35% were uncertain if CT was addictive, 20% thought there is no drug for CT-induced vomiting, 7% thought it is contagious and 28% believed that some plants may be more effective on cancer. After receiving CT, 60% changed their negative beliefs about it and 89% endorsed the necessity of chemotherapy. Women who were satisfied with the information given by their physicians and those who had a close relative treated with CT had stronger beliefs about the necessity of chemotherapy (p=0,01). However, the advanced-stage, questionnaire before chemotherapy initiation, gender and socioeconomic level did not impact patients' beliefs about CT.

Conclusions: Providing better interpersonal communication with patients may increase patients' belief in chemotherapy. Oncology nurses could help advocate for tailored educational programs to support informed decision-making regarding chemotherapy acceptance.

1875P Behind the use of ChatGPT for oncological purposes: Fears and challenges

I. Durosini[1], M. Strika[1], G. Pravettoni[2]

[1]Department of Oncology and Hemato-Oncology, University of Milan, Milan, Italy; [2]Applied Research Division for Cognitive and Psychological Science, IEO, European Institute of Oncology IRCCS, Milan, Italy

Background: Technological innovations made rapid progress in the last years and are expected to play a growing role in the decision-making process. ChatGPT, a new chatbot that uses deep learning to mimic human language processing, has increased. In the health domain, ChatGPT could support healthcare delivery thanks to its language models and ability to simulate human conversational manner. Even if the advantages are multiple, there are some psycho-social and ethical aspects related to the implementation of these technologies that remain open.

Methods: This study examines psychological challenges associated with using ChatGPT to clarify its role in screening decisions. Forty-one participants (aged M=29.8) were provided with a scenario describing a hypothetical conversation between ChatGPT and a user who has received an oncological breast or prostate diagnosis report. Successively, each participant answered questions about concerns related to the chatbot, intention to use, decision-making process, and emotional activation.

Results: Descriptive analysis highlighted that 58.5% (n= 24) of participants have already used ChatGPT, but only 0.05% (n= 2) use the chatbot for healthcare purposes. 31.7% (n= 13) of participants reported the absence of fears about using the chatbot for oncological purposes, whereas the remaining 68.3% (n= 28) confirmed the presence of several concerns. Specifically, participants reported concerns about the risks related to data privacy and possible conflict of interest related to developers (n= 2). Other participants described the ChatGPT elaboration processes as a "black box" and highlighted doubts about the correct use of the results (n= 13). Additionally, some participants (n= 8) highlighted the risk that ChatGPT could generate hypochondriacal symptoms and inappropriate healthcare practices. Lastly, participants showed a fear that ChatGPT could replace human doctors in healthcare practice (n=6).

Conclusions: Current results will contribute to understanding the general population's attitude towards ChatGPT and its possible uses in the health domain.

1876P Cancer stigma: How Tunisian patients perceive their cancer

S. Fendri, Y. Berrazaga, S. Haddaoui, H. Rachdi, M. Saadi, N. Daoud, N. Mejri, H. Boussen

Medical Oncology Department, Hopital Abderrahmane Mami de Pneumophistiologie, Ariana, Tunisia

Background: Societal beliefs about cancer can impact how patients perceive their disease generating cancer stigma (CS) with risk of emotional distress especially in Arab countries where cancer remains a taboo. This study aimed to evaluate aspects of CS according to Tunisian cancer patients, explore risk factors and describe the impact on mental health.

Methods: The study was a cross-sectional questionnaire-based study, conducted between February and April 2023, including 100 patients treated for cancer regardless of gender, type or stage. We developed the questionnaire by adapting items from the "Cancer stigma scale" using questions grouped in three domains: impossibility of recovery, stereotypes of cancer patients and experience of social discrimination. Depression and anxiety were evaluated by using the "Hospital Anxiety and Depression Scale".

Results: Median age was 50 years old, 75% of patients were women. On average, patients were surveyed 20.48 months after diagnosis. Patients reported at least one form of CS in 57% of cases. They believed in the impossibility of recovery after cancer experience in 47% of cases. Forty percent of patients held stereotypical views of themselves: 48% endorsed that cancer patients would have a difficult time having sexual intimacy which was the item with the highest mean (2.45) among all questions. Thirty four percent of patients reported social discrimination on grounds of cancer: by family/spouse in 31%, at the workplace in 15% and by friends/neighbors in 13% of cases. Cancer stigma was significantly more perceived by patients with low socio-economic status (OR= 3.74 [1.42-9.82]), living in rural areas (OR=26 [3.38-205] and with advanced stage disease (OR=4.2 [1.67-10.5]). Forty percent of patients reported significant depressive symptoms and 47% significant anxiety symptoms. Patients who experienced CS were 4.27 times more likely to have depression ($p < 0.001$) and 3.57 times more probably to be anxious ($p < 0.001$) than patients with positive attitudes.

Conclusions: Despite increased awareness, cancer patients had high levels of CS with negative impact on mental health. These results ring the alarm bell to change societal beliefs and to help patients perceive "better" their disease.

1877P Meaning-making in the re-entry phase: A qualitative focus group study with patients with breast cancer and melanoma

A. Visser[1], L. Post[2], J. Dekker[3], C. van Zuijlen[1], I.R. Konings[1]

[1]Medical Oncology Department, Amsterdam UMC - Vrije University Medical Centre (VUmc), Amsterdam, Netherlands; [2]Spiritual Care Department, Amsterdam UMC - Vrije University Medical Centre (VUmc), Amsterdam, Netherlands; [3]Psychiatry Department and Rehabilitation Department, Amsterdam UMC - Vrije University Medical Centre (VUmc), Amsterdam, Netherlands

Background: After completion of curative cancer treatment patients enter the re-entry phase, which is characterized by the difficult task to pick up life again. In the re-entry patients face existential concerns, besides physical and psychosocial concerns. Finding meaning and purpose in this new situation may help in dealing with existential concerns. More insight is needed in the existential concerns and the meaning-making process in order to support patients in the re-entry phase.

Methods: We conducted 6 focus groups with 16 patients (5 patients with melanoma and 11 with breast cancer) during the re-entry phase, defined as the point from completion of treatment (after surgical treatment and adjuvant systemic treatment, except for hormonal therapy) up to 18 months in remission. A thematic content analysis was performed by two researchers.

Results: In general, patients experienced existential concerns regarding their world-view, inner posture, values and the future. In addition, patients with melanoma struggled with trust and responsibility for their health; patients with breast cancer struggled with relationships and identity. Outcomes of the meaning-making process identified were: meaning is affected and gives distress, existing sources of meaning are helpful, search for meaning or new meaning has been found. These outcomes were found at the beginning as well as further into the re-entry, however during the re-entry the focus of the meaning-making process shifted from the disease to (picking up) life.

Conclusions: The transition from being a patient to picking up daily life in the re-entry phase involves dealing with existential concerns causing distress. Patients use existing sources of meaning, search for new meaning or have found new meaning in order to deal with these existential concerns and distress. A meaning-centered intervention increasing patients awareness of their personal sources of meaning might strengthen their meaning-making process and can help in dealing with existential concerns.

1878P Prevalence of burnout in GU oncologists in central Asia: BUCARE survey

O. Shatkovskaya[1], D. Kaidarova[2], B. Ongarbayev[2], T. Mitin[3], I. Tsimafeyeu[4]

[1]KazIOR, Almaty, Kazakhstan; [2]Kazakh Research Institute of Oncology & Radiology-KazIOR, Almaty, Kazakhstan; [3]Radiation Oncology, OHSU - Oregon Health Science University, Portland, OR, USA; [4]NYC, Bureau for Cancer Research, New York, NY, USA

Background: The growing number of patients with genitourinary cancers (GU) could create an increasing burden on GU oncologists. Bureau for Cancer Research (BUCARE) describes the prevalence of burnout in GU oncologists in Central Asia region.

Methods: This is a cross-sectional survey study conducted among practicing cancer care physicians (surgical, medical, radiation) at the ASCO / Asian American GU Symposium (Almaty, April 2023). The primary outcome was burnout experience assessed through the Maslach Burnout Inventory.

Results: A total of 101 oncologists completed the questionnaire. Table summarizes physician's characteristics. Despite the fact that 100% of responders are interested in their work, 66% (67 of 101) had symptoms of burnout (high emotional exhaustion and/or depersonalization scores). Fifty percent of oncologists are ready to turn to a psychologist for help. Significant drivers of burnout identified in multivariable regression modeling included $^{3}20$ patients per day (odds ratio [OR] = 14.8; $P<0.001$) and $^{3}10$ working hours per day (OR=8.6; $P<0.001$). Male gender (OR=0.14; $P<0.001$) and specialization in radiation therapy (OR=0.20; $P<0.01$) were associated with lower odds of burnout.

Conclusions: More than half of participants met predefined standardized criteria for burnout. Expanding the staff of GU oncologists and reducing the daily workload may improve the emotional state of physicians.

Table: 1878P

Characteristics	N=101
Gender, N (%)	
Female	68 (67.3)
Male	33 (37.7)
Region, N (%)	
Kazakhstan	85 (84.2)
Other countries	17 (16.8)
Specialty, N (%)	
Surgery	39 (38.6)
Medical Oncology	44 (43.6)
Radiation Oncology	18 (17.8)
Department, N (%)	
In-patient	79 (78.2)
Out-patient	22 (21.8)

1879P Investigating the effect of family support on the mental health of patients with breast cancer

M. Garousi, P. Fadavi, A. Foroughi, S. Soltani

Radiation Oncology Department, Iran University of Medical Sciences, Tehran, Iran

Background: Cancer affects many aspects of life and can have negative consequences such as reduced: health and quality of life and mental disorders. Cancer patients face most of the stressors associated with diagnosis and treatment. The aim of this study is

investigating the effect of family support on the mental health of patients with breast Cancer.

Methods: This cross-sectional study examined 70 breast cancer patients who were referred within 6 months to Imam Khomeini and Shohadah Ha* Tir Hospitals for radiotherapy, chemotherapy or follow- up treatment. In terms of mental health, these patients were assessed using the criteria of hospital anxiety and depression and distress thermometer, and the level of family support using the McMaster Family Assessment Device and attachment style criteria. The psychiatric interview with the patients was conducted by the psychiatric resident and all questionnaires were completed by her in face-to-face interviews or video calls with the patient. Before the start of the study, all patients gave written informed consent. The Family Support Questionnaire contains 60 questions that identify the structural, professional, and interactive characteristics of the family. This questionnaire has 7 subscales.

Results: The mean (standard deviation) of the total score on the Family Support Questionnaire for the subjects studied was 15.7 (2.96) with a range of 9.87 to 21.06. the mean (standard deviation) of anxiety and depression scores were 9.68 (5.34) and 8.34 (4.41), respectively. the results show that increasing the score on anxiety and depression significantly increases family support and its sub-comparisons.

Conclusions: The study revealed that the mean scores of the depression and anxiety in breast cancer patients is more than normal limitation. The results showed that decreasing family support and its sub- comparisons (an increase in the score indicates an unhealthy situation) significantly increases anxiety and depression in these individuals.

1880P Cancer care: Psychoeducational intervention for first-year residents of a general hospital in northeastern Mexico

C.B. Gonzalez-Alcorta[1], J.A.M. Moyano[2], P.A. Lopez Sierra[2], J.F. Gonzalez Guerrero[2], A.G. Alcorta Garza[2], O. Vidal-Gutierre[3], A. Alcorta-Garza[4]

[1]Radiation Oncology, UANL - University Autonomous of Nuevo Leon, Monterrey, Mexico; [2]Oncología médica, CUCC - Centro Universitario Contra el Cáncer - Universidad Autónoma de Nuevo León (UANL), Monterrey, Mexico; [3]Oncología médica, UANL - Universidad Autonoma de Nuevo Leon, San Nicolas De Los Garza, Mexico; [4]NL, UANL - University Autonomous of Nuevo Leon, Monterrey, Mexico

Background: Physicians must help patients to maintain motivation and resolve barriers to adherence to treatment, but this does not happen in many cases. The impact of cancer in the coming years will have devastating consequences for the health system since it is the third cause of mortality in the country. Therefore, a substantial change in medical education, health policies is imperative. They are future specialists, the attitudinal barriers could limit their skills and abilities in the task for general surgeons, gynecologists, otolaryngologists, and anesthetists. To detect and change barriers, implement a strategy of 180 minutes in a reflexive focus group.

Methods: Descriptive, non-blind study approved by the Research Ethics Committee (ON23-00003), informed consent was requested from 51 medical residents of the surgical areas of a general hospital who attended a psychoeducational focus group in 2 frequencies, they answered the survey about their beliefs and attitudes regarding the care of cancer patients. 3 key questions were analyzed to ensure knowledge together with reflection, reinforcing empathic attitudes and team collaboration of the participants.

Results: The subjects correctly considered the definition of oncology pre and post-intervention (84 vs 91%), that the treating physician had to give the diagnosis (55 vs 92%) that there is no correct answer for how long a patient would live (89 vs 96%), The term used by the patient to name the cancer doesn't matter as long as they understand the disease (32 vs 42%), That they should not join the conspiracy of silence proposed by the patient or family (77 vs 91%) If they believed that there is treatment in any stage of cancer (55 vs 87%), if they should care for patients with cancer with a CPR indication vs other chronic patients with hypertensive crisis and DM (64 vs 81%), if they considered palliative care and psycho-oncology for diagnostic phases (63 vs 85%). In the qualitative aspect they left satisfied and mostly looking forward to new sessions that would allow them to carry out their work and education.

Conclusions: There was a percentage impact in generating substantive changes in the opinion of the subjects; this first step should be followed up with more studies and is of relevance to medical educators.

Background: In the phase 1 LITESPARK-001 study of the HIF-2α inhibitor belzutifan for ccRCC, the MTD was not reached for dosages up to 240 mg per day, and the RP2D was 120 mg QD based on PD, PK, and safety. The phase 2 LITESPARK-013 study (NCT04489771) examined if a higher belzutifan dose could improve efficacy while maintaining an acceptable safety profile.

Methods: Pts with advanced ccRCC, measurable disease per RECIST v1.1, ≤3 prior systemic regimens for advanced ccRCC including an anti—PD-1/L1 agent, and disease progression during or after an anti—PD-1/L1 agent were randomly assigned 1:1 to belzutifan 120 mg or 200 mg QD. Pts were stratified by IMDC risk score (0 vs 1-2 vs 3-6) and number of prior TKI therapies for advanced ccRCC (0 vs 1 vs 2-3). Primary end point was ORR per RECIST v1.1 by blinded independent central review. Secondary end points included DOR, PFS, OS, safety, and PK. Database cutoff was February 10, 2023.

Results: 154 pts were enrolled (120 mg: n=76; 200 mg: n=78). Baseline characteristics were well balanced between arms. Median follow-up was 20.1 months (range 14.8-28.4). ORR was 23.7% (18 PR) vs 23.1% (4 CR; 14 PR) for the 120 mg and 200 mg arms, respectively (P=0.5312; −0.5% [95% CI, −14.0 to 12.9] using the Miettinen-Nurminen method stratified by IMDC risk). PFS (median 7.3 vs 9.1 months; HR 0.94 [95% CI 0.63-1.40]) and OS (medians not reached; HR 1.11 [95% CI, 0.65-1.90]) did not differ between arms. Median DOR was not reached for the 120 mg arm (range 2.6+ to 16.1+) and was 16.1 mo (2.1+ to 23.5+) for the 200 mg arm; 64.7% and 51.3% of pts had ongoing responses ≥15 mo, respectively. 142 pts had a treatment-related AE (TRAE; 70 [92.1%] with 120 mg; 72 [92.3%] with 200 mg]. 2 pts (2.6%) in the 120 mg arm and 7 (9.0%) in the 200 mg arm discontinued treatment due to a TRAE. Treatment-related anemia (81.6% with 120 mg and 83.3% with 200 mg) and hypoxia (23.7% with 120 mg and 26.9% with 200 mg) was similar between arms.

Conclusions: The efficacy of belzutifan was similar between the RP2D of 120-mg dose and the 200-mg dose and was consistent with prior reports of antitumor activity in ccRCC. Safety at both doses was consistent with the known safety profile of belzutifan. These results further support 120 mg QD as the preferred dose for belzutifan.

Clinical trial identification: NCT04489771.

Background: Anti-PD-1 antibody plus antiangiogenic therapy can play a synergistic antitumor role in the treatment of advanced renal cancer. Toripalimab is a humanized monoclonal antibody against PD-1. Here, we report the results of a randomized, open label, phase 3 trial (NCT04394975) comparing toripalimab plus axitinib with sunitinib as first-line treatment for advanced RCC patients (pts).

Methods: Eligible pts had untreated unresectable or metastatic clear cell RCC and were intermediate or poor risk per International Metastatic Renal Cell Carcinoma Database Consortium criteria. Pts were randomized in a 1:1 ratio to receive toripalimab (240mg) intravenously once every 3 weeks plus axitinib (5mg) orally twice daily or sunitinib (50mg) orally once daily for 4 weeks (6-week cycle) or 2 weeks (3-week cycle). The primary endpoint was progression-free survival (PFS) assessed by the blinded independent central review per RECIST version 1.1.

Results: A total of 421 pts were randomized: 210 to the toripalimab plus axitinib arm and 211 to the sunitinib arm. After a median follow-up of 14.6 months, a significant

improvement in median PFS was detected for the toripalimab plus axitinib arm compared to the sunitinib arm (18.0 vs. 9.8 months, HR = 0.66 [95% CI: 0.49-0.87], P = 0.0034). The 1-year PFS rates were 62.5% and 45.4%, respectively. The objective response rate (ORR) was 56.7% (95% CI: 49.7-63.5) for the toripalimab plus axitinib arm versus 30.8% (95% CI: 24.6-37.5) for the sunitinib arm (P < 0.0001). The median overall survival was not reached in the toripalimab plus axitinib arm and 26.8 months in the sunitinib arm (HR = 0.61 [95% CI: 0.40-0.92], P = 0.0186). The incidence of Grade ≥ 3 adverse events (AEs) (71.2% vs 67.1%), AEs leading to discontinuation of treatment (14.4% vs 8.1%), and fatal AEs (1.0% vs 1.0%) were similar between two arms.

Conclusions: Among patients with previously untreated advanced RCC, treatment with toripalimab plus axitinib resulted in significantly longer PFS, as well as a higher ORR, than treatment with sunitinib. These results support the use of toripalimab with axitinib as a first-line treatment for advanced RCC.

Clinical trial identification: NCT04394975.

1883MO MEDI5752 (volrustomig), a novel PD-1/CTLA-4 bispecific antibody, in the first-line (1L) treatment of 65 patients (pts) with advanced clear cell renal cell carcinoma (aRCC)

Background: PD-1/CTLA-4 inhibition has improved survival in aRCC but maximizing the potential benefit of CTLA-4 inhibition is limited by toxicity. MEDI5752 (volrustomig) is designed to fully inhibit PD-1 while preferentially inhibiting CTLA-4 on activated PD-1+ T cells. This first-time-in-human trial showed encouraging activity with volrustomig 1500 mg in 1L aRCC. We present data from the 750 mg and 500 mg cohorts (M750 and M500).

Methods: Treatment-naïve pts with aRCC received M750 mg or M500 mg every 3 weeks until disease progression or unacceptable toxicity. The primary objective was objective response rate (ORR).

Results: In M750 (n=32)/M500 (n=33), 75.0/63.6% had IMDC I/P risk. Median duration of follow-up in M750/M500 was 15.9 (range, 2.2-20.4)/8.6 (1.6-14.7) months. ORR was similar in M750/M500 (46.9%/45.5%), with higher CR rate/DCR and longer mPFS in M750 (Table). The median duration of response (DOR) was 13.2/8.4 months; mDOR in pts who discontinued due to AE was not reached in M750. Grade 3-4 immune-related adverse events (irAEs) were higher at M750 (46.9% vs 24.2%), although nearly half of events did not require steroids and nearly all non-endocrine irAEs resolved. There was increased T cell proliferation at both doses and greater T cell activation in M750 vs M500.

Conclusions: Volrustomig is a novel bispecific antibody with high degree of efficacy in 1L aRCC and across IMDC risk groups, with a low rate of upfront treatment failure. The safety profile is consistent with dual checkpoint inhibition. Volrustomig with lenvatinib is also being evaluated in 1L aRCC (NCT04522323).

Clinical trial identification: NCT03530397.

Background: Combinations (combos) of VEGFR-TKI plus anti-PD1/L1 immunotherapy (IO) are the standard of care for first-line therapy of mRCC pts due to increased response rate, prolonged progression-free (PFS) and overall (OS) survivals compared to TKI alone. It is well recognized that the majority of toxicities of the combos are due to the TKI.

Methods: mRCC pts with prior nephrectomy, and with no symptomatic/bulky disease nor liver mets, were treated with Ave 800 mg flat dose IV Q2W + Axi 5 mg PO BID for 36 weeks (W). At W36, pts who achieved RECIST partial response (PR) discontinued Axi and continued Ave until disease progression (PD) or unacceptable toxicity. In case of PD, they re-started Axi for 24W and discontinued it again in case of new PR while continuing Ave. Pts with stable disease at 36W continued the combo until PD or unacceptable toxicity. Primary endpoint: rate of pts free of progression (FoP) after 8W from Axi discontinuation ($\geq$48%). Secondary endpoints: median PFS, objective response rate (ORR) and safety. 75 pts have been planned to be enrolled.

Results: 79 pts were enrolled and 75 evaluated for efficacy (IMDC risk: 40.0% favorable, 57.3% intermediate, 2.7% poor). A total of 29 (38.2%) pts discontinued Axi at 36W; the rate of pts FoP after 8W was 72.4%. With a median follow-up of 19.3 mos, the mPFS was 23.8 mos (95%CI, NR-NR) with 70% of pts FoP at 18 mos; mOS was not reached. The ORR was 76.0% (12.0% CR, 64.0% PR); 18.7% had SD and 4.0% had PD. The median duration of first Axi discontinuation was 16.0 weeks (95%CI, 10.9 − 21.1). Among the 29 pts who discontinued Axi, 9 were still ongoing, 20 had PD and 19 restarted Axi (9 ongoing, 6 had further PD, 4 discontinued Axi again). Safety: 96.2% of pts had at least one adverse event (AE) and 40.5% had G3-G4 AEs with no treatment-related death. All-grades and G3-G4 axitinib-related AEs were reported in 34.2% and 11.4% of overall pts, respectively, and in 10.3% and 0% of those who discontinued Axi.

Conclusions: The TIDE-A study shows that TKI discontinuation is safe for selected mRCC pts with evidence of response to TKI+IO combos in first line. Axi discontinuation allows decreasing of toxicity, while maintaining the possibility of Axi benefit in case of its reintroduction.

Background: Pexa-vec (PV) is an oncolytic and immunotherapeutic vaccinia virus engineered to express GM-CSF. The REN026 study assessed the antitumor activity and safety of intravenous (IV) or intratumoral(IT) PV in combination with cemiplimab (REGN2810, anti-PD-1 inhibitor) in patients with metastatic or unresectable renal cell carcinoma (RCC).

Methods: The study enrolled 89 patients with measurable histologically or cytologically confirmed metastatic or unresectable RCC, randomly assigned to one of four study arms. Patients who were treatment-naive to immune check point inhibitors (ICIs) with accessible tumors were randomized into Arm A (IT PV and cemiplimab) or Arm B (cemiplimab monotherapy, upon disease progression PV (IT) was added. Patients who were treatment-naïve to ICIs with non-accessible tumors were assigned to Arm C with IV PV, and those with prior treatment with ICIs were assigned to Arm D with IV PV. PV was given IT (Arms A and B) administered every 2 weeks or IV (Arms C and D) weekly for 3 or 4 treatments as 1×10^9 pfu. Cemiplimab IV infusion (all arms) was administered every 3 weeks, at a dose of 350 mg.

Results: Between June 2018 and October 2022, 89 patients were assigned to the study arms as follows: 15 in Arm A, 16 in Arm B, 30 in Arm C, and 28 in Arm D. The median number of prior systemic regimens in the metastatic setting was 1 (0-4) in Arms A, B, and C and 3 (1-5) in Arm D. With the median follow-up of 22.2 months, efficacy outcomes are shown in table. The most common treatment-related adverse event was pyrexia, with a Grade $\geq$ 3 of 13.3% in Arm A, 0% in Arm B,0% in Arm C, and 3.6% in Arm D. No Grade 5 events occurred in any of the study arms.

Table: 1885P Summary of efficacy results

	A (n=15)	B (n=16)	C (n=30)	D (n=28)
	IT		IV	
ORR (95% CI)-%	13.3 (1.7-40.5)	12.5 (1.6-38.4)	23.3 (9.9-42.3)	17.9 (6.1-36.9)
DCR (95% CI)-%	60.0 (32.3-83.7)	56.2 (29.9-80.3)	60.0 (40.6-77.3)	67.9 (47.7-84.1)
PFS median (mo) (80% CI)	4.3 (3.3-6.3)	5.6 (2.1-NA)	4.8 (4.4-8.3)	6.4 (3.6-12.3)
OS median (mo) (80% CI)	22.0 (22.0-NE)	20.8 (19.5-NE)	25.1 (22.7-NE)	18.5 (14.8-NE)
Median duration of response (range,months)	6.1 (3.7-8.5)	7.7 (4.1-11.3)	10.4 (5.5-24.1)	8.5 (1.1-11.3)

Conclusions: The combination immunotherapy of IV PV and cemiplimab demonstrated an acceptable safety profile and encouraging efficacy of ORR and survival with durable responses in patients with metastatic or unresectable RCC, regardless of previous ICI treatment.

Clinical trial identification: NCT03294083.

Background: Anti-PD1 immune checkpoint inhibitors (ICI) are effective in some people with ccRCC. Preliminary data suggest inhibition of Receptor Activator of Nuclear Factor κB Ligand (RANKL) signaling may potentiate ICI. We evaluated the activity and safety of the RANKL-inhibitor denosumab (D) with pembrolizumab (P) in people with pretreated advanced ccRCC.

Methods: This single arm, multi-centre, phase 2 trial recruited participants (pts) with metastatic or unresectable ccRCC, progressing on or after vascular endothelial growth factor receptor inhibitors (VEGFi), and no prior treatment with an ICI or D. Study treatment was P 200mg IV q3w plus D 120mg SC on days 1, 8 and 22, then q3w until disease progression, unacceptable toxicity, or a maximum of 24 months. The primary endpoint was objective tumour response (OTR) per RECIST 1.1. Secondary objectives included median progression free survival (PFS), PFS at 6 months (PFS6), duration of response (DOR), and adverse events (AE). Biospecimens were collected for future correlative studies of immune and RANKL signaling.

Results: We recruited 59 of a planned 70 pts from Dec 2017 — Jul 2022; accrual was impacted by COVID-19. Pts were typical of this population; mostly male (81%), 48% International Metastatic Database Consortium favorable risk, one prior VEGFI in all pts, two or more prior agents in 16%. With median follow-up of 40 months in 58 evaluable pts, an OTR was documented in 31% (all partial; 95%CI 20-45%). Median DOR was 17 months. 53% of pts experienced PFS6 (95%CI, 39-65%), with mPFS 7.5 months. Immune related grade 3+ AE were reported in 20% of pts; study treatment discontinued for toxicity in 22%. One pt suffered G3 osteonecrosis of the jaw, one G3 hypocalcaemia. One pt died of myositis attributed to study treatment.

Conclusions: Compared to studies of anti-PD1 ICI in ccRCC progressing after VEGFi (Table), KeyPAD shows encouraging activity without overlapping toxicity, warranting further studies combining RANKL inhibitors like D with ICI like P.

Table: 1886P

Background: EVEREST is a ph3 trial of pts with either clear or non-clear cell RCC at intermediate-high or very-high risk for recurrence after nephrectomy, randomized to receive adjuvant EVE 10 mg QD or placebo x 54 wks. Longer recurrence free survival (RFS) for EVE [HR 0.85; 95%CI, 0.72-1.0; P= 0.051] was seen but the nominal significance level (p=0.044) was narrowly missed (Ryan, ASCO22). Placebo-controlled ph3 trials of sunitinib (STRAC) & pembrolizumab (KN546) limited entry to clear cell subtype and reported modest benefits in disease-free survival (DFS) despite other trials of in-class agents reporting no such benefit. Differences in pt recurrence risk have been suggested as a possible factor for the conflicting results. Here we report the results of an analysis of a very high-risk cohort of pts with clear cell in EVEREST.

Methods: Post-nephrectomy RCC pts w/ any clear cell component & very high-risk disease, defined as pT3a (gr 3-4), or pT3b-c (any gr), or T4 (any gr), or node-positive (N+), were identified. Pt characteristics, treatment, and adverse event (AE) data were summarized. A Cox regression model stratified by performance status was used to evaluate RFS & OS.

Results: Of 1,499 pts, 717 had both clear cell & very high-risk disease. 699 were eligible: 348 EVE; 351 placebo. Only 163/348 (47%) of EVE pts completed all treatment as planned while more pts completed planned treatment with placebo [225/351 (64%)]. Grade 3+ AEs were more frequent with EVE (42%) vs placebo (8%). Adjuvant EVE resulted in significant RFS improvement in ITT and per-protocol cohorts.

Table: 1887P

Outcome	Hazard Ratio for EVE vs Placebo (95% CI)	5-year Kaplan-Meier estimates: EVE vs Placebo	2-sided p-value
RFS, Intent to Treat (n=699)	0.80 (0.65, 0.99)	57 vs. 50%	0.040
RPS, Per Protocol* (n=685)	0.80 (0.65, 0.99)	57 vs. 50%	0.040
OS, Intent to Treat (n=699)	0.85 (0.64, 1.14)	85 vs. 81%	0.28

*per-protocol: all pts who received any of their protocol-assigned treatment

Conclusions: EVEREST remains the only phase III adjuvant RCC trial of an mTOR inhibitor. In pts with clear cell RCC at very high-risk for recurrence, adjuvant EVE was associated with significantly improved RFS vs. placebo in a subset of pts comparable to those in STRAC and KN546. These results can inform the design & development of future adjuvant trials in high-risk RCC.

Clinical trial identification: NCT01120249.

1888P 24-month follow up of durvalumab and savolitinib combination in MET-driven clear cell and non-clear cell renal cancer

F. Jackson-Spence[1], C. Suarez Rodriguez[2], J. Larkin[3], P. Patel[4], B. Perez Valderrama[5], A. Rodriguez-Vida[6], M.J. Mendez Vidal[7], A. Markovets[8], R.J. Hartmaier[9], B.E. Szabados[1], F. Jamal[1], C. Ackerman[1], T.B. Powles[1]

[1]Centre for Experimental Cancer Medicine, Barts Cancer Institute, London, UK; [2]Oncology Department, Vall d'Hebron University Hospital, Barcelona, Spain; [3]Medicine Department, The Royal Marsden Hospital - NHS Foundation Trust, London, UK; [4]Medical Oncology Department, City Hospital Campus - Nottingham University Hospitals NHS Trust, Nottingham, UK; [5]Medical Oncology Department, Hospital Universitario Virgen del Rocio, Seville, Spain; [6]Medical Oncology Department, Hospital del Mar IMIM Research Institute, Barcelona, Spain; [7]Medical Oncology, Hospital Universitario Reina Sofia, Córdoba, Spain; [8]Oncology Data Science, AstraZeneca Oncology R&D, AstraZeneca, Boston, MA, USA; [9]Translational Medicine, Oncology R&D, AstraZeneca, Boston, MA, USA

Background: The CALYPSO trial (NCT02819596) showed promising response rates (RR) for the combination of durvalumab (D) (PD-L1 inhibitor) and savolitinib (S) (MET inhibitor) in MET-driven tumours in papillary renal cancer (PRC). Response data for the combination in other settings such as clear cell (ccRCC) and non-MET driven tumours was less impressive (Suárez et al, JCO, 2023). Here we give the updated 24-month efficacy analysis.

Methods: This study included a ccRCC and PRC cohort, both of which have been presented previously with shorter follow up. The ccRCC cohort was a randomised phase II study comparing DS combination with D alone, in previously treated ccRCC. The PRC cohort was a single arm study of DS in treatment naïve or pre-treated patients. RR (confirmed, RECIST 1.1), progression-free survival (PFS) and overall survival (OS) were the efficacy endpoints. DNA alterations were measured using Foundation One analysis.

Results: At 24 months follow-up, the RR in the ITT PRC population (n=41) was 29% (95% CI, 16-46) and 53% (95% CI, 28-77) in MET-driven patients (n=17). The median PFS was 5.8 months (95% CI, 2.9 -12.3) in the ITT population and 15.7 months (95% CI, 3.0 - 27.4) in MET-driven patients. The median OS was 14.1 months (95% CI, 7.3 - 30.7) in the ITT population and 27.4 months (95% CI, 9.3 — 34.7) in MET-driven patients. The hazard ratio (HR) for PFS in MET-driven vs non MET-driven in PRC cohort is 0.43 (95% CI, 0.20-0.93, p=0.03). In the ccRCC cohort, 39 patients received DS combination and 39 D alone. RR for DS was 13% vs 10% for D alone. The HR for PFS was 1.38 (95% CI, 0.5-1.2, p= 0.2) and HR for OS was 1.5 (95% CI, 0.9-2.6, p= 0.1). Median OS was 21.9 months (95% CI, 18.0-26.7) for all ccRCC patients and 8.2 months (3.7- 26.7) for MET-driven patients (n=17). No new safety signals were seen.

Conclusions: Durvalumab and savolitinib combination has activity in MET-driven PRC, supporting the ongoing SAMETA trial (NCT05043090). Savolitinib does not appear to improve efficacy of durvalumab in clear cell tumours.

Clinical trial identification: NCT02819596.

Background: BT is a recombinant fusion protein containing an extracellular region of AXL combined with human immunoglobulin G1 heavy chain (Fc), demonstrating potent and specific AXL inhibition through competitive binding of its ligand GAS6. In a prior phase (P)1 study, BT RP2D was identified as 15 mg/kg IV every 2 weeks (q2w) in combination with cabo 60 mg oral daily (QD).

Methods: P1b and P2 data was analyzed for BT 15 mg/kg (n=41), 20 mg/kg (n=10), q2w + cabo 60 mg QD in advanced ccRCC pts who received at least 1 prior systemic therapy. Primary endpoint was investigator-assessed objective response rate (ORR) by RECIST v1.1; key secondary endpoints were safety, progression free survival (PFS), and overall survival.

Results: As of April 21, 2023, 51 pts received at least one dose of BT with cabo with median (m) follow-up of 11.4 months (mo) (range 3.7-23.7). All pts had received prior immune-oncology therapy (IO). 51% of pts had prior VEGF-tyrosine kinase inhibitor (TKI). The ORR for the entire cohort and prior-VEGF-TKI pts was 43.1% and 53.8%, receptively. The mPFS for the entire cohort and prior-VEFG-TKI pts was 9.2 and 11.4 mo, respectively. Table presents results.

Table: 1889P

	Batiraxcept + Cabo N=51 (%)	Prior VEGF-TKI	
		Yes N=26 (%)	No N=25 (%)
Median age (range)	62 (40-81)	61 (40-76)	62 (42-81)

Background: In mRCC patients combinations of tyrosine kinase inhibitors (TKI) and checkpoint inhibitors (CPI) are standards of care. We previously reported on our switch-maintenance approach (CPI after TKI) in mRCC. Today, we report on exploratory analyses that investigated predictive value of the PD-L1 status.

Methods: Pts. with measurable clear cell mRCC, ECOG 0-2, adequate organ function and partial remission or stable disease to TKI therapy were eligible. 49 patients were randomized to early study termination between 12/2016 and 08/2018. After 12 weeks, 1:1 randomization to TKI continuation (24 pts.) or nivolumab (NIVO; 25 pts.; 240 or 480 mg IV q2-4wk) was performed. PD-L1 expression was determined by immunohistochemistry using the SP163 antibody clone and defined as combined positivity score (CPS) with setting 1 as cut-point for positivity (n=41). Objective response rate (ORR) was assessed according to RECIST 1.1. KM and log-Rank analyses were used for survival analyses.

Results: Median age was 65 years (range 35 - 79), 82% were male and 4% had ECOG PS 2. With metastases predominantly in lung (47%), lymph nodes (27%) and liver (24%). 55% received sunitinib. ORR for NIVO vs. TKI differed when assessed from randomization (16 vs. 48%; P=0.03). Accordingly, progression free survival (PFS) from randomization was 3.0 vs. 11.9 mo. (HR = 2.57 [95% CI: 1.36 − 4.89]) in favor for TKI continuation. With a 2-year OS of 64% for NIVO vs. 66% for TKI (HR = 1.12 [95% CI: 0.43 − 2.89]; P=0.82). ORR in CPS<1 vs >1 RCC was 13.3% and 40.0% for NIVO and 37.5% and 75.0% in TKI cases. Tumors with a CPS<1 most frequently showed PD as the best response in both arms. However, a greater proportion of patients reported PD for NIVO (n=9, 60.0%) compared to TKI (n=1, 12.5%).

Conclusions: Continuation of TKI is more efficacious than early switch to NIVO, despite PD-L1 positivity. The major limitation of our trial is the premature closure and its limited sample size. Background: In a subset of patients (pts), immune checkpoint inhibitors (ICIs) hold the potential to achieve lasting and sustainable responses, or even complete recoveries in pts with clear cell renal cell carcinoma (ccRCC). We sought to understand the immunogenomic determinants of these exceptional responses to ICIs.

Methods: We analyzed pre-therapy genomic and transcriptomic data in treatment-naive metastatic ccRCC pts treated with standard-of-care immunotherapies: (1) combination of PD-1/PDL1 and CTLA-4 (IO/IO), or (2) PD-1/PD-L1 inhibitor and VEGF-receptor (IO/VEGF) combination. We also compared baseline characteristics and outcomes between these cohorts and the International Metastatic RCC Database Consortium (IMDC) dataset. We defined 3 groups of pts in each cohort: (a) extreme responders (ER): pts with complete response (CR) and progression free survival (PFS) $\geq$ 12 months or partial response (PR) with tumor shrinkage 50% and PFS $\geq$ 24 months or PR with PFS $\geq$ 36 months; (b) intermediate responders, pts with CR and PR who were not exceptional responders (IR); (c) pts with progressive disease (PD).

Results: 550 pts on IO/IO had available whole exome sequencing (WES) data while 434 pts in the IO/VEGF cohort had available WES and RNA-sequencing data. A greater proportion of pts from clinical trials had ER (25%) when compared to real-world data (6%) in the IO/IO cohort. Neither tumor mutation burden, mean HLA-I evolutionary divergence, whole genome integrity index, tumor purity nor tumor ploidy were associated with ER in the trial cohorts. In the IO/IO cohort, clonal neoantigen load (CNL) was significantly higher in ER pts (vs. IR: p=0.043; vs. PD: p=0.017). In a multivariate Cox regression, only CNL remained associated with improved PFS (p = 0.007). In the IO/VEGF cohort, ER pts had high expression of signatures for plasma cells, memory B-cell inside, and tertiary lymphoid structures (TLS). Pts with ER had higher TLS signature score compared to IR and PD using 3 different gene expression signatures.

Conclusions: Our results suggest that ER is partly mediated by clonal neoantigen-driven cytotoxic T-cell responses and TLS formation in the tumor microenvironment.

1892P A pooled meta-analysis of salvage nivolumab/ipilimumab (N+I) after nivolumab (N) in patients with advanced renal cell carcinoma (RCC)

R.R. McKay[1], W. Xie[2], K. Leucht[3], O. Jegede[4], D.A. Braun[5], M.B. Atkins[6], M-O. Grimm[7], T.K. Choueiri[8]

[1]Medicine, University of California San Diego - UCSD, La Jolla, CA, USA; [2]Medicine, Dana Farber Cancer Institute, Boston, MA, USA; [3]Urology, Universitätsklinikum Jena, Jena, Germany; [4]Data Science, Dana Farber Cancer Institute, Boston, MA, USA; [5]Center of Molecular and Cellular Oncology, Yale University School of Medicine - Yale Cancer Center, New Haven, CT, USA; [6]Oncology Department, Lombardi Cancer Center Georgetown University, Washington, DC, USA; [7]Urology Department, Universitaetsklinikum Jena - Klinik für Innere Medizin II, Jena, Germany; [8]Medical Oncology Department, Dana Farber Cancer Institute, Boston, MA, USA

Background: N+I has demonstrated improved survival for patients with treatment-naïve advanced clear cell RCC. A series of phase 2 trials (OMNIVORE NCT03203473; HCRN GU16-260 NCT03117309; TITAN-RCC NCT02917772) evaluated N+I in patients lacking an objective response to N. We performed a pooled meta-analysis of these studies to better inform the activity of N+I after N.

Methods: Key baseline characteristics and outcomes were collected and analyzed centrally. The primary endpoint was confirmed objective response rate (ORR) to N+I as defined by investigator assessed RECIST v.1. Secondary endpoints included ORR to N, progression-free survival (PFS) rate from N+I start (only for OMNIVORE and HCRN GU-16-260), and overall survival (OS) rate from N start.

Results: The analysis included 448 patients of whom 410 (91.5%) had clear cell RCC, 369 (82.3%) had IMDC intermediate/poor risk disease, and 139 (31.0%) had prior treatment. The 16-18-week ORR to N prior to N+I was 21.9% (n=98) and best ORR to N was 24.1% (n=108). 249 (55.6%) patients treated with N received N+I at a median of 16 weeks (9-21 IQR) after initiation of N [26.1% (n=65) with stable disease (SD) to N and 73.9% (n=184) with progressive disease (PD) to N]. The ORR to N+I was 12.9% (n=32) (Table). Median follow-up was 34.2 months. 6-month PFS on N+I was 39% (95% CI 30-49). 3-year OS was 57% (95% CI 52-62) from N start.

Table: 1892P ORR to N+I

Subgroup	N	ORR (%)
Overall	249	12.9
Treatment naïve	145	12.4
Prior therapy	104	13.5
IMDC Favorable	39	15.4
IMDC Intermediate	169	14.2
IMDC Poor	41	4.9
Clear cell RCC	230	12.6
Non-clear cell RCC	19	15.8
Response to N at N+I Start — SD	65	9.2
Response to N at N+I Start — PD	184	14.1
Best response to N — CR/PR	24	25.0
Best response to N — Non-response	225	11.6

Conclusions: A small subset of patients lacking a response to N monotherapy derive benefit from salvage N+I. Additional correlative studies are warranted to investigate markers associated with benefit to N+I post N.

Clinical trial identification: NCT03203473, NCT03117309, NCT02917772.

Background: A favourable relationship between immune related adverse events (irAEs) and survival has been established across tumours. However, for patients with metastatic renal cell carcinoma (mRCC) treated with Immuno-oncology (IO) based combination first-line therapies, the prognostic impact of irAEs remains uncertain.

Methods: To examine the association between irAEs and survival among first-line ipilimumab-nivolumab (IOIO) or anti-PD-1/PD-L1 + vascular endothelial growth factor receptor inhibitors (IOVE), we used an IMDC dataset, a large multicenter international cohort study. Only clinically impactful irAEs (requiring systemic steroids or IO treatment delay), were included. To minimize immortal time bias, only patients surviving longer than 3 months were included in the survival analysis.

Results: 328/1448 (22.7%) patients developed an irAE. As per table, patients that developed an irAE had a similar median age and BMI, were more likely to have pre-existing auto-immune co-morbidities, improved IMDC risk and clear cell histology. Frequency of irAEs were similar in patients treated with IOIO and IOVE (23.2% vs 21.2% respectively p=0.40). Cytoreductive nephrectomy (OR 1.69 95% CI 1.16 — 2.47 p=0.006) and non-sarcomatoid histology (OR 1.98 95% CI 1.26 — 3.12 p=0.003) were more likely to be associated with an increased odds of developing irAEs. Development of an irAE was associated with a longer overall survival, median not estimable [95% CI 44.5 — not estimable] vs 47.2 months [95% CI 40.7 — 53.4] logrank p = 0.005). A favourable independent association of irAEs with overall survival was found in multivariable analysis, after IMDC risk factor adjustment (HR 0.68 [95% CI 0.52 — 0.89] p=0.006).

Table: 1893P

Characteristic	IRAE		*P*
	No	Yes	
Median Age (IQR)	63.0 (55.8 - 70.0)	64.4 (58.6 - 69.8)	
Median BMI (IQR)	27.1 (23.8 - 31.0)	28.1 (24.3 - 31.5)	
ECOG			*0.002*
0	553/748 (73.9%)	195/748 (26.1%)	
1	405/494 (82.0%)	89/494 (18.0%)	
2	51/75 (68%)	24/75 (32%)	
3	13/16 (81.3%)	3/16 (18.8%)	
Autoimmune Condition			*0.01*
Yes	14/25 (56%)	11/25 (44%)	
No	1106/1423 (77.7%)	317/1423 (22.3%)	
IMDC			*0.03*
Fav	152/200 (76%)	48/200 (24.0%)	
Int	493/671 (73.5%)	178/671 (26.5%)	
Poor	295/365 (80.8%)	70/365 (19.2%)	
Sarcomatoid			0.004
Yes	156/192 (81.3%)	36/192 (18.9%)	
No	534/572 (71.0%)	218/572 (29.0%)	
1L IO Combination			0.4
IOIO	786/1024 (76.8%)	238/1024 (23.2%)	
IOVE	334/424 (77.8%)	90/424 (21.2%)	

Conclusions: Development of an irAE is a potential treatment biomarker of improved outcome for patients treated with first-line IO combination therapy in mRCC. Patients with pre-existing auto-immune co-morbidities at baseline have a high incidence of irAEs.

Background: Immunotherapy is associated with different response patterns compared with chemotherapy and targeted therapy, including delayed response and stabilization after disease progression. In clinical practice, immunotherapy can be continued after radiological progression when clinical benefit is observed. Therefore, progression-free survival (PFS), calculated with the first disease progression, may not express the real benefit derived from immunotherapy.

Methods: The Meet-URO 15 study was a multicentric retrospective analysis on 571 pretreated mRCC pts receiving nivolumab. TTF was defined as the time from start of therapy to the definitive disease progression which changed the therapeutic line or death. The comparison between TTF and PFS and the prognostic performance of the Meet-URO score versus (vs) the IMDC score according to TTF and PFS were assessed. Moreover, response and survival outcomes between TBP pts and non-TBP pts were evaluated.

Results: 571 pts were included in the analyses (PMID: 34046089). Median TTF was 8.9 months (range: 7.2-10.2) and mPFS was 7.2 months (range: 5.8-8.6). The Meet-URO score performed better than the IMDC score in both TTF (c index: 0.63 vs 0.59) and PFS (0.62 vs 0.59). TBP pts were associated with higher overall response rate (34.4% vs 23.6%; $p = 0.035$) and disease control rate (61.3% vs 54.8%; $p = 0.30$). Moreover, TBP pts interestingly correlated with longer TTF (25.0 vs 10.7 months; $p<0.001$) and OS (42.5 vs 26.7 months; $p<0.001$), but had similar PFS compared with non-TBP pts. In TBP pts, a mean delay of 13.2 months (range: 6-20.4) from first to definitive disease progression was observed (25 vs 11.8 months), while non-TBP pts had overlapped TTF and PFS (10.8 months).

Conclusions: In pretreated mRCC pts receiving nivolumab, a small difference between mTTF and mPFS (∼2 months) was observed in the overall population. However, TBP pts were associated with significantly better ORR (+10%), TTF (+13 months) and OS (+ 15.8 months). Moreover, the Meet-URO score prognostically performed better with TTF than with PFS and compared with the IMDC score in both survival outcomes.

1896P Clinical management and outcomes of patients with advanced renal cell carcinoma (aRCC) treated with nivolumab+ipilimumab (N+I): A real-world study

T.R. Geldart[1], L.M. Pickering[2], A. Sharma[3], D. Scott[4], O.A. Parikh[5], S. coleman[6], P. Dhokia[6], M. Hale[7], L. Vaz[8]

[1]Medical Oncology, Poole Hospital - University Hospitals Dorset NHS Foundation Trust, Poole, UK; [2]Medical Oncology, The Royal Marsden Hospital (Chelsea) - NHS Foundation Trust, London, UK; [3]Medical Oncology, Mount Vernon Cancer Centre, Northwood, UK; [4]Medical Oncology, University Hospital Southampton NHS Foundation Trust, Southampton, UK; [5]Oncology, Royal Preston Hospital - Lancashire Teaching Hospitals NHS Foundation Trust, Preston, Lancashire, UK; [6]Medical, BMS Pharmaceuticals Limited - Uxbridge, Uxbridge, UK; [7]Data Science and Analytics, HEOR - Health Economics and Outcomes Research Ltd, Cardiff, UK; [8]Medical Affairs - Oncology, BMS Pharmaceuticals Limited - Uxbridge, Uxbridge, UK

Background: N+I is approved for the first-line (1L) treatment of adult patients with intermediate/poor-risk aRCC, with efficacy demonstrated in CheckMate 214. Real-world effectiveness (RWE) data are limited; we assessed clinical characteristics and outcomes for aRCC patients who received N+I in England.

Methods: This retrospective, observational chart review examined patient demographics, clinical characteristics, treatment patterns, safety and outcomes (objective response [OR], progression-free survival [PFS], overall survival [OS]) of patients with aRCC treated with N+I at five sites in England. Eligible patients-initiated N+I at any line of therapy from 5-Apr-19 to 1-Apr-22 (including during COVID lockdown periods) and were followed until death or study end.

Results: 128 patients met eligibility criteria (mean age 60.7 yr, 71.1% male); 85.2% had clear cell histology; most had intermediate or poor IMDC classification at index (49.2% and 39.1%, respectively). Median follow-up (min-max) was 13.6 (0.8-37.9) mo. 95.3% (n=122) received 1L N+I. Median time on treatment from 1L initiation was 2.8 (0.03-34.4) mo and 54.1% (n=66) advanced to 2L therapy, mostly (n=56, 77.8%) to cabozantinib. Overall, 82% discontinued 1L therapy; most frequently for disease progression (n=23; 50.5%) or AEs (n=40; 38.1%). In patients receiving 1L N+I, OR was 29.7%, with a complete response rate of 1.1%; median PFS from 1L initiation was 7.6 mo; 1-yr PFS was 40.3% and 1-yr OS was 71.4%.

Conclusions: This study provided RWE on the characteristics and outcomes of patients with aRCC who received N+I. OR, PFS and OS were slightly inferior to those observed in CheckMate 214 but comprised a real-world population with a higher proportion of poor risk patients, those with CNS metastases, non-clear cell histology and treatment during the COVID pandemic.

Background: The upfront treatment of metastatic renal cell carcinoma (mRCC) has been revolutionized by the introduction of immune-based combinations. The role of cytoreductive nephrectomy (CN) in these patients is still debated. The ARON-1 study (NCT05287464) was designed to globally analyze real-world data of mRCC patients receiving first-line immuno-oncology combinations. This sub-analysis is focused on the role of upfront or delayed partial or radical CN in three geographical areas (Western Europe, Eastern Europe, America/Asia).

Methods: We conducted a multicenter retrospective observational study in mRCC patients treated with first-line immune combinations from 55 centers in 19 countries. From 1152 patients in the ARON-1 dataset, we selected 651 patients with *de novo* mRCC. 255 patients (39%) had undergone CN, partial in 14% and radical in 86% of cases; 396 patients (61%) received first-line immune-combinations without previous nephrectomy. Primary endpoint was overall survival (OS) while progression-free survival (PFS) and tumor response rate were secondary endpoints.

Results: Median OS from the diagnosis of *de novo* mRCC was 41.6 months and not reached (NR) in the CN subgroup and 24.0 months in the no CN subgroup, respectively ($p<0.001$). Median OS from the start of first-line therapy was NR in patients who underwent CN and 22.4 months in the no CN subgroup ($p<0.001$). Patients who underwent CN reported longer OS compared to no CN in all the three geographical areas (Western Europe: NR vs 23.7 months, $p<0.001$; Eastern Europe: NR vs 29.8 months, $p=0.005$; America/Asia: 57.3 months vs 25.5 months, $p<0.001$).

Conclusions: No significant differences in terms of patients' outcome seem to clearly emerge in our analysis, even if the rate CN and the choice of the type of first-line immune-based combination varies across the different Cancer Centers participating in the ARON-1 project.

Clinical trial identification: NCT05287464.

1898P Comparative real-world effectiveness of PD-1/L1 inhibitor (PD-1i) plus cabozantinib (cabo) vs cabo after progression with prior immune checkpoint inhibitor (ICI) treatment (Rx) in metastatic clear cell renal cell carcinoma (mccRCC)

U. Swami, Y. Jung Jo, V. Mathew Thomas, G. Gebrael, H. Li, N. Sayegh, N. Tripathi, A. Srivastava, B. Nordblad, E. Dal, J. Brundage, P. Campbell, G. Galarza Fortuna, C. Hage Chehade, B.L. Maughan, N. Agarwal

Medical Oncology/Internal Medicine Department, University of Utah Health - Huntsman Cancer Institute, Salt Lake City, UT, USA

Background: ICI rechallenge in solid tumors (including in mccRCC) after discontinuation or disease progression following a prior ICI is often practiced in the clinic and is an area of active investigation. Two ph 3 trials (NCT04338269/Contact-3 and NCT04987203/*TiNivo*-2) are evaluating this Rx paradigm in mccRCC. Cabo is the most common 2L Rx in mccRCC.

Methods: This study used the de-identified nationwide (US based) Flatiron Health EHR-derived database. Inclusion: diagnosis of mccRCC, receipt of 1L Rx with any ICI based Rx (between 3/2016 to 7/2022) followed by receipt of 2L Rx with cabo or cabo + PD-1i (between 6/2018 to 9/2022). Exclusion: 1L Rx with cabo, or pts with no evidence of contact for 90 days from diagnosis of mccRCC at treating institution to ensure pts were actively engaged in care. TTNT (time to next therapy; measured from 2L to 3L) and overall survival (OS; measured from 2L) were summarized via Kaplan-Meier survival estimates with 95% confidence interval (CI) and compared in the context of propensity score (PS) matching weighted analysis and Cox proportional hazard model (PSM- CoxHzM). PS model included 1L baseline covariates: age, race, smoking status, practice type, insurance, year of 1L, six IMDC risk factors, and missingness of covariates. Missing data were multiply imputed using predictive mean matching on 50 chained equations. All analysis done using R version 4.2.3.

Results: Of 12,285 mccRCC pts in the dataset, 314 pts met eligibilty. Results summarized in table.

Table: 1898P 2L cabo vs cabo-PD-1i in pts with PD-1i based therapy in 1L

	Median TTNT (95% CI) mos	Median OS (95% CI) mos
Cabo (n=251)	7.6 (6.9 — 8.9)	29 (25 - 33)
Cabo + PD-1i (n=63)	15 (10, not reached)	31 (25- not reached)
PSM- CoxHzM Hazard ratio (95% CI, p-value)	0.69 (0.45 - 1.06, 0.087)	1.08 (0.69 - 1.68, 0.74)

Conclusions: No benefit of adding PD-1i therapy to cabo vs cabo alone in 2 L was observed on PSM — CoxHzM. These results from a real world mccRCC pts are similar to those in a recent press-release on CONTACT-03 trial and question the practice of ICI rechallenge in mccRCC and other solid tumors.

1899P Comparative effectiveness of second-line (2L) treatment (Rx) with cabozantinib (cabo) in patients (pts) with metastatic clear cell renal cell carcinoma (mccRCC) after first-line (1L) Rx with ipilimumab + nivolumab (ipi+nivo) vs. PD-1/L1 inhibitor (PDI) + tyrosine kinase inhibitor (TKI)

G. Gebrael, Y. Jung Jo, V. Mathew Thomas, H. Li, G. Galarza Fortuna, K. Sahu, N. Sayegh, N. Tripathi, B. Chigarira, A. Srivastava, C. Hage Chehade, B. Nordblad, E. Dal, J. Brundage, B.L. Maughan, N. Agarwal, U. Swami

Medical Oncology/Internal Medicine, University of Utah Health - Huntsman Cancer Institute, Salt Lake City, UT, USA

Background: The preferred 1L Rx for pts with mccRCC is either ipi+nivo or PDi + TKI (NCCN Guidelines V4.2023). Cabo was approved based on Ph3 METEOR trial results from pts after prior mccRCC progression on 1-2 TKIs but not PDi Rx. In real world, cabo is the most used 2L therapy but its effectiveness after prior PDi based combination is unknown.

Methods: De-identified nationwide (US based) Flatiron Health EHR-derived database was used. Inclusion: diagnosis of mccRCC, 1L Rx with ipi+nivo or PDi+TKI (from 10/2017 to 7/2022) followed by 2L Rx with single-agent cabo. Exclusion: 1L Rx with cabo, pts with no documentation of 1L Rx or pts with no evidence of contact for 90 days from diagnosis of mccRCC at treating institution to ensure pts were actively engaged in care at the data providing institution. TTNT (time to next therapy; measured from 2L to 3L) and overall survival (OS; measured from 2L) were summarized via Kaplan-Meier survival estimates with 95% confidence interval (CI) and compared in the context of propensity score (PS) matching weighted analysis and Cox proportional hazard model (PSM- CoxHzM). PS model included baseline covariates: age, race, smoking status, practice type, insurance, year of 1L, IMDC risk factors (all six), and missingness of covariates. Missing data were multiply imputed using predictive mean matching on 50 chained equations. All analysis done using R version 4.2.3.

Results: Of 12,285 mccRCC pts in the dataset, 237 pts met eligibility, and all received ipi+nivo or PDi+TKI followed by cabo. Results summarized in table.

Table: 1899P

	Median TTNT (95% CI) mos	Median OS (95% CI) mos
Ipi+nivo (n=145)	8.0 (6.9 - 11)	26 (21 - 32)
PDi+TKI (n=92)	7.5 (6.3 - 16)	34 (27- NR)
PSM-CoxHzM Hazard ratio (95% CI, p-value)	1.43 (0.98 - 2.11, 0.07)	1.16 (0.73 - 1.83, 0.88)

Conclusions: Cabo retained similar effectiveness in 2L regardless of prior ipi+nivo or PDi+TKI. These results may aid with counseling of pts, prognostication, treatment decision in clinic and design of future clinical trials.

1900P Role of cytoreductive nephrectomy (CN) in metastatic clear cell renal cell carcinoma (mccRCC) in the era of immunotherapy (IO): An analysis of the national cancer database (2004-2020)

A. Basnet[1], M. Bou Zerdan[2], R. Wong[3], H. Goldberg[1]

[1]Heamtology Oncology, SUNY Upstate Medical University, Syracuse, NY, USA; [2]Internal Medicine, SUNY Upstate Medical University, Syracuse, NY, USA; [3]Department of Public Health and Preventive Medicine, Norton College of Medicine, SUNY Upstate Medical University, Syracuse, New York, SUNY Upstate Medical University, Syracuse, NY, USA

Background: The effectiveness of CN is still uncertain despite two significant trials, SURTIME and CARMENA, which aimed to demonstrate its benefits for mccRCC. These trials, conducted with Sunitinib as the standard treatment, did not provide evidence supporting the use of CN.

Methods: We identified stage IV mccRCC only patients (pts) who received IO with or without surgery in the NCDB 2004-2020. Overall survival (OS) was calculated among three groups of IO alone (group (gr)1), IO followed by CN (gr2), CN followed by IO (gr3). Cox models compared OS by treatment group after adjusting for sociodemographic, health, and facility variables.

Results: From 1,549,101 renal cancer cases, 7,367 met our criteria. 2.8% of ccRCC had sarcomatoid histology. Pts in the gr 2 and gr 3 had 63%, 95% CI [0.304 - 0.460] and 47%, 95% CI [0.492-0.571] (P= 0.001) risk reduction in mortality compared to gr 1.Black race compared to white race, Medicare pts compared to privately insured, and pts treated at a comprehensive community cancer center compared to academic center had an increased mortality risk by 15%, 95% CI [1.025-1.290] (P= 0.017), 12%, 95% CI [1.017-1.242] (P= 0.021), 17%, 95% CI [1.092-1.260] (P= 0.001) respectively. Median income quartiles ranging > 63k, had 22% reduction in mortality over income quartiles < 40k, 95% CI [0.696-0.888] (P= 0.044). Regardless of the sequence of CN, partial nephrectomy was minimally used. Pts in gr 3 had a 40% increased mortality risk compared to pts in gr 3, 95% CI [1.126-1.735] (P= 0.002).

Conclusions: Pts receiving CN regardless of sequence with IO did better than IO alone in this national registry-based adjusted analysis for mccRCC. Over the past few decades, the understanding of the role of CN has undergone changes, and while we await additional trial outcomes, the current evidence supports the notion that select mRCC patients can benefit from CN.

Table: 1900P

1901P Specific dynamic changes of peripheral blood immune profile (PBIP) associate with clinical response to nivolumab (NIVO) in patients (pts) with metastatic renal cell carcinoma (mRCC): The I-RENE trial (meet-URO 8)

Background: Here, we describe the potential of measuring dynamic changes occurring in peripheral blood as indicators of response to NIVO in mRCC pts.

Methods: After failure to antiangiogenics, mRCC pts (n=60) received NIVO within the I-RENE trial (NCT04891055). Blood samples were collected during NIVO at baseline, 2, 4, 12 weeks (wks) and at PD. Therapy induced dynamic changes were evaluated in PBMCs and plasma, by high resolution flow cytometry (n=144 lymphoid and myeloid

cell subsets) and multiplex analysis, respectively. A panel of very good (n=17, R) and very poor (n=16, NR) responders were selected for correlations. Tumor transcriptomics and immune infiltrate assessment were performed on baseline biopsy to gain insight into the immunomodulation occurring at tumor site.

Results: Dynamic changes were detected in multiple PBMC subsets and plasma cyto/chemokines since 2 wks from NIVO and at subsequent time points in all pts. However, R pts showed at 2 wks a statistically significant decrease of monocytic MDSCs (M-MDSC, $CD14^{+}HLA\text{-}DR^{neg}$) cells, followed at 4 wks by a boost of $CD8^{+}$ and central memory T cells, and reduction of $CD38^{+}$ T cells. At 12 wks $CD14^{+}HLA\text{-}DR^{neg}$ MDSCs reached the lowest peripheral blood level without further changes in the lymphoid cell subsets. At opposite, NR pts showed a progressive increase of M-MDSCs and inflammatory/immunosuppressive monocytes ($CD14^{+}PD\text{-}L1^{+}$), associated at 12 wks with a significant upregulation of senescent ($KLRG1^{+}CD28^{-}CD57^{+}$) $CD8^{+}$ T cells and $CD38^{+}$ T cells. Nivo induced a decrease of plasma IL-8, Pentraxin 3, PCSIK9 and miR-125b, and an increase of VEGFR2, all of which were associated with good response at 12 wks. Integration of PBIP with tumor tissue results will pair systemic immunomodulations with tumor microenvironment.

Conclusions: Specific kinetics of immunosuppressive myeloid cell subsets versus memory/effector T cells early during NIVO associate with outcome. Combining dynamic peripheral blood variables with clinical information may give rise to novel biomarkers for tailored therapeutic decision-making in mRCC pts.

Clinical trial identification: NCT04891055.

Background: While the benefit of CABO in mRCC is well established post-tyrosine kinase inhibitor, its comparative effectiveness vs SUN after 1L NIVO+IPI is uncertain.

Methods: A target trial emulation was designed using data from the IMDC to estimate the effect of second-line (2L) CABO versus SUN within one year of discontinuing 1L NIVO+IPI on overall survival (OS). Patients (pts) diagnosed after January 1, 2017, were followed from initiation of 2L until death or last known contact. Inverse-probability of treatment weighting was used to adjust for hemoglobin, calcium, platelets, and neutrophils at 2L, Karnofsky performance score (KPS) at 2L, time from diagnosis to initiation of 2L, and response to 1L NIVO+IPI. Treatments were compared using adjusted Kaplan-Meier curves and adjusted hazard ratios (HR) from a Cox regression model. Missing data were addressed with multiple imputation by chained equations. E-values were used to assess the likelihood findings could be explained by residual confounding.

Results: 121 and 123 pts who received CABO and SUN after 1L NIVO+IPI were included. Among the baseline characteristics, only the proportion with a KPS < 80% differed significantly between CABO (21%) and SUN (45%) (p = 0.002) (Table). The objective response was 27% (21/79) for CABO vs 20% (18/89) for SUN with a median time to treatment failure of 8.5 (95% CI: 6.9-12.9) and 4.5 (95% CI 3.7-5.8) months. Median OS was 21.4 (95% CI 17.9—NA) months from initiation of CABO and 10.1 (95% CI 7.6—17.7) months for SUN (Adjusted HR 0.44 (95% CI: 0.23-0.85)). This corresponds to an E-value of 2.91 suggesting a low likelihood of findings being due to residual confounding alone.

Conclusions: This investigation provides real-world evidence supporting CABO as a 2L treatment option for mRCC following NIVO+ IPI .

Table: 1902P Characteristics of pts receiving 2L CABO and SUN

	CABO (n = 121)	SUN (n = 123)	P-value
Mean age (SD)	61.6 (11.03)	60.6 (9.27)	0.16
Male	90/121 (74.4)	94/123 (76.4)	0.82
Non-clear cell histology	14/110 (12.7)	10/63 (15.9)	0.73
Sarcomatoid	15/86 (17.4)	16/61 (26.2)	0.28
KPS < 80%*	18/86 (20.9)	35/78 (44.9)	0.002
Time from diagnosis to treatment < 1 year	100/121 (82.6)	96/121 (79.3)	0.62
Hemoglobin < LLN*	69/106 (65.1)	74/109 (67.9)	0.77
Neutrophils > ULN*	23/103 (22.3)	23/108 (21.3)	0.99
Platelets > ULN*	16/107 (15.0)	24/109 (22.0)	0.25
Calcium > ULN*	6/99 (6.1)	9/97 (9.3)	0.56

LLN, lower limit of normal; SD, standard deviation; ULN, upper limit of normal. *: At 2L.

Background: L+P is a standard of care (SoC) in 1L RCC based on significantly improved efficacy versus S in the CLEAR study [Motzer 2021]. We report tumor response by baseline metastases at the final prespecified overall survival analysis timepoint (cutoff date: 31 Jul 22).

Methods: Treatment-naive adults with RCC were randomized to L (20 mg orally QD in 21-day cycles) plus P (200 mg IV Q3W) or L (18 mg orally QD in 21-day cycles) plus everolimus (5 mg orally QD in 21-day cycles) or S (50 mg orally QD; 4 wks on/2 wks off). This post hoc analysis examined response by baseline metastases in L+P (n=355) vs S (n=357) arms. Objective response rate (ORR), complete response (CR) rate, partial response (PR) rate, and progression-free survival (PFS) via independent imaging review (IIR) per RECIST v1.1 by baseline metastatic characteristics (site of metastasis [lung, lymph node, bone, liver, brain], number of metastatic sites [1 vs ≥2] and sums of diameters of target lesions [≥60 mm vs <60 mm]) are analyzed. Odds ratios (ORs) for ORR and hazard ratios (HRs) for PFS with 95% CIs are reported.

Results: The most common metastatic site by IIR at baseline was lung (L+P: 71.0%; S: 63.9%); 22.5% and 24.9% of pts, respectively, had bone metastases. 65.1% Of pts randomized to L+P and 66.1% of pts randomized to S had metastases at ≥2 sites. ORR favored L+P irrespective of metastatic site (Table). ORR favored L+P in pts with 1 (OR, 2.98 [95% CI 1.71, 5.21]) or ≥2 metastatic sites (OR, 5.06 [95% CI 3.40, 7.53]), and in pts with target lesion diameter sums ≥60 mm (OR, 10.50 [95% CI 6.08, 18.13]) or <60 mm (OR 3.14 [95% CI 1.94, 5.07]). PFS favored L+P vs S across subgroups (Table). CR and PR rates were higher in L+P vs S across subgroups (to be reported).

Conclusions: Tumor response favored L+P in all subgroups of interest, particularly in patients with increased burden of disease. Data further support L+P as a SoC in pts with 1L RCC.

Background: Brain (BM) and bone metastases (BOM) in renal cell carcinoma (RCC) are associated with poor outcome. We evaluated real-world treatment paradigms of RCC patients with BM and BOM.

Methods: We retrospectively analyzed RCC patients with BM and BOM treated at 9 German tertiary cancer centres from 2003 to 2023. Adverse events (AE) were reported according to CTCAE 5.0, objective response rate (ORR) according to local standard. Progression free survival (PFS) and overall survival (OS) were calculated from start of treatment to progression or death.

Results: We included 349 patients with a median age of 64 years (IQR 55-71). 93% of all patients had BOM, 15% BM and 8% both. Most patients (86%) had clear cell RCC, 5% of all patients had sarcomatoid differentiation. 82% of patients had an ECOG PS of 0/1. IMDC risk was favorable/intermediate/poor in 19/58/23%. 76% received prior nephrectomy. Patients with BOM received first-line IO-combinations in 64% (IO-IO: 39%, TKI-IO: 61%), TKI-monotherapy in 36%, while patients with BM received IO-combinations in 73% (IO-IO: 42%, TKI-IO: 58%) and TKI in 27%. IO-based first-line therapy increased from 2003 to 2023. AE of all grades occurred in 87% and 50% during IO-based therapy or TKI monotherapy, and CTCAE grade $\geq$ 3 in 44% or 21%. ORR and survival outcomes with median follow-up of 33 months (IQR 14-78) are described in table. 49% and 50% of all patients with BOM and BM received second-line treatment, with Cabozantinib (34%; 31%) and Nivolumab (19%, 27%) being the most common treatment options.

Table: 1904P

Parameter	Total (%; n=270)			BOM (%; n=250)			BM (%; n=45)		
	TKI n=95	IO-IO n=69	IO-TKI n=106	TKI n=89	IO-IO n=62	IO-TKI n=99	TKI n=12	IO-IO n=19	IO-TKI n=14
ORR; %	40	29	57	38	27	58	58	41	42
SD; %	36	29	31	37	31	32	25	28	21
PD; %	24	42	12	25	42	10	17	21	37
ORR vs. SD vs. PD	p<0.001			p<0.001			p=0.750		
mPFS; months, 95% CI	7 (5.2-8.8)			7 (5.2-8.2)			6 (3.1-8.9)		
mOS; months, 95% CI	39 (29.5-48.5)			39 (29.8-48.2)			39 (19.1-58.9)		

Conclusions: RCC patients with BOM and BM are increasingly treated with IO-combinations but lead to higher rates of AE grade $\geq$ 3. In patients with BOM, IO-TKI revealed higher ORR compared to IO-IO combination, but not in patients with BM. Small sample size and retrospective design are major limitations of our analysis. Prospective studies evaluating treatment options for BOM and BM in patients with RCC is critical.

1905P Heterogeneity in tertiary lymphoid structures predicts the distinct prognosis and immune microenvironment of clear cell renal cell carcinoma

W. Xu, H. Zhang, D. Ye

Urology, Fudan University Shanghai Cancer Center, Shanghai, China

Background: Tertiary lymphoid structures (TLS) are organized aggregates of immune cells that form postnatally in non-lymphoid tissues and arise under physiological conditions. However, the clinical and immunological implications of heterogeneous subpopulations of TLS in clear cell renal cell carcinoma (ccRCC) remain to be elucidated.

Methods: H&E, immunohistochemistry and 12-marker multispectral fluorescent were used to evaluate the spatial location and maturation status of TLS with TME cell-infiltrating characterizations. We comprehensively assessed the prognostic value of TLS heterogeneity in 395 patients with ccRCC from two independent cohorts using log-rank tests, Cox hazards models, and scoring nomograms. Associations between TLS heterogeneity and immunologic activity of TME were assessed using quantified lymphocytes infiltration fraction.

Results: By pathological review, TLS were identified in 34.2% of the ccRCC samples. For ccRCC patients, the presence of intratumoral TLS markedly correlated with both superior progression-free survival (PFS) and overall survival (OS), while the peritumoral TLS exerted the opposite predictive trend of clinical outcomes. Multivariate Cox analysis revealed that the presence of intratumoral TLS was prominently correlated with better outcomes. Additionally, the novel nomograms incorporating the presence of intratumoral TLS prominently predicted the probability of 8-year PFS and OS of ccRCC (AUC >0.80). Moreover, a higher proportion of early TLS was found in peritumoral TLS (P=0.016), while intratumoral TLS were mainly composed of secondary follicle-like TLS (P=0.004). Interestingly, in ccRCC samples with the presence of peritumoral TLS enriched with primary follicle-like TLS, the proportion of PD-L1$^+$ tumor-associated macrophages and Treg infiltration in the stroma were prominently increased, showing a typical suppressive tumor immune microenvironment.

Conclusions: In conclusion, this study revealed the predictive value of TLS heterogeneity on the progression and immunological responses of ccRCC for the first time. The intratumoral TLS could be used to assess both the prognostic patterns and the unique TME characteristics of each patient.

Background: In the 2022 WHO classification more than 20 entities of renal cell carcinomas (RCC) were defined. Several molecularly defined RCC were separated. There is urgent need for studies investigating well defined patients with these specific entities. One prerequisite is an exact classification of non-clear cell RCC (nccRCC) including histopathological and molecular diagnostics.

Methods: The SUNNIFORECAST study (NCT03075423) is a phase 2 randomised investigator-initiated trial of nivolumab with ipilimumab vs. standard of care in patients with previously untreated and advanced nccRCC. For study inclusion a reference pathology to confirm diagnosis of nccRCC was mandatory.

Results: 350 cases were submitted for reference pathology as paraffin blocks or unstained slides. Diagnoses was done by HE staining, immunohistochemistry and molecular testing. Reference pathology confirmed the diagnoses of nccRCC in 334 of 350 cases. Only few cases were diagnosed in reevaluation as ccRCC, liposarcoma or epithelioid angiomyolipoma. Histopathological diagnoses included papillary RCC (n=138-41%), chromophobe RCC (n=58-17%), RCC, NOS, mostly with sarcomatoid pattern (n=46-14%) TFE3 or TFEB altered RCC (n=25 and n=1,8%), FH-deficient RCC (n=33-10%), SDHB-deficient RCC (n=4-1%), SMARCB1-deficient renal medullary carcinoma (n=9-3%), collecting duct carcinoma (n=14-4%) and tubulocystic RCC (n=1). Interestingly no tumors out of the group of other oncocytic tumous or clear cell papillary renal cell tumors were detected. Compared to primary pathology diagnosis changed in 116/350 cases. There was no correct primary diagnosis in 28/33 cases of FH-deficient RCC, 3/4 cases of SDHB deficient RCC and 17/26 cases of translocation RCC. All chromophobe RCC showed sarcomatoid dedifferentiation or coagulative tumor necrosis. In papillary renal cell carcinoma, micropapillary and microcystic architecture was very frequently detected in G1/G2 tumors.

Conclusions: Reference pathology is a prerequisite for clinical studies investigating ncc RCC. The diagnosis of molecular defined RCC is still problematic in daily diagnosis. The study was supported by a grant of BMS (BMS).

Clinical trial identification: NCT03075423.

Background: ICB can achieve durable benefit in aRCC, but reliable biomarkers are lacking. Despite ongoing research, current aRCC biomarkers fail across trials.

Methods: We performed a comprehensive biomarker discovery in our in house, real world aRCC transcriptomic dataset of ICB treated patients (anti-CTLA4+anti-PD1 and anti-PD1) with corresponding human leukocyte antigen (HLA) genotypes to characterize antigen presenting features. Using machine learning (ML) as a wrapper, a transcriptomic biomarker set reflecting HLA promiscuity (HLA*pr*) was developed. We studied its impact on outcome in our ICB treated cohort, in external ICB treated aRCC cohorts (IMmotion150/Miao *et al*/Choueiri *et al*, Javelin101) and post-nephrectomy patients (TCGA KIRC).

Results: Increased tumor-relevant antigen binding specificity of HLAs over other antigens (low HLA*pr*) correlated with improved overall survival (OS) after ICB (hazard ratio (HR) 0,4; 95% CI 0,21-0,75, p=0,004, n=98), independent of IMDC risk groups on multivariable analysis, and with a trend towards longer progression free survival (PFS) (HR 0,69, 95%CI 0,38-1,27, p=0,2). Analysis of immunopeptidome-derived and experimentally-validated HLA allele-antigen pairs confirmed that HLA alleles with lower HLA*pr* and correlated with OS upon ICB preferentially bound neo-antigens. A ML based signature was developed that cross-linked transcriptomic footprints with low HLA*pr*, which correlated with OS in our ICB treated cohort (HR 0,56, 95%CI 0,34-0,94, p=0,03), and trended towards correlation with PFS (HR 0,66, 95%CI 0,42-1,03, p=0,07). The signature correlated with PFS in external ICB treated cohorts Javelin101 (HR 0,73, 95%CI 0,54-0,99, p=0,04, n=354) and IMmotion150/Miao *et al*/Choueiri *et al* (HR 0,47, 95%CI 0,26-0,86, p=0,015, n=207) and with OS in TCGA KIRC (HR 0,52, 95%CI 0,38-0,71, p<0,001, n=511). In Departmenth tumor immune analyses identified antigen presentation, interferon signalling and myeloid-T cell crosstalk as determinants of ICB responders.

Conclusions: In Departmenth multi-omics analysis revealed critical importance of antigenic myeloid-T cell crosstalk, driven by high neo-antigenicity, to ensure adequate ICB response in aRCC.

Clinical trial identification: S53479/S63833.

Background: Increased heterogeneity in outcomes has been observed post nephrectomy in pts with RCC with standard clinical parameters being primarily used for risk assessment. Currently, no blood-based biomarkers are available that can predict recurrence or response to therapy. Herein, we demonstrate the utility of ctDNA in identifying MRD and assessing concordance with radiographic imaging in this pt population.

Methods: This real-world evidence-based multi-institutional study included a cohort of 82 pts with stages I-IV RCC who underwent nephrectomy (+/- metastasectomy), with 41 pts receiving adjuvant therapy (AT) (Table). Longitudinal ctDNA testing on post nephrectomy plasma samples (n=256) was performed using a tumor-informed ctDNA assay (Signatera™). ctDNA results were analyzed and association with clinical outcomes was assessed.

Results: In this cohort, the majority of the pts (75.6%; 62/82) were serially ctDNA negative and 91.9% (57/62; negative predictive value) of these showed no evidence of disease (NED) or non-progressive disease (partial response or stable disease) on imaging at the end of the follow-up. Longitudinal ctDNA detection was 24.3% (20/82; any time positivity) and 65% (13/20) of these demonstrated concordance between ctDNA status/dynamics and imaging. Among the 13 concordant pts, 53.8% (7/13) were ctDNA positive and relapsed, and among the remaining 7, 5 had insufficient imaging/ctDNA testing and 2 were discordant with positive ctDNA and NED on imaging.

Table: 1908P Patient demographics and clinical features (N=82)

Median Age (years)	66 (range: 21-88)
Median follow-up from time of surgery (weeks)	35.7 (range: 7.3 - 476)
Number of Relapse Cases	13 (16%)
Postsurgical clinical NED status	
Yes	74 (90.2%)
No	8 (9.8%)*
Subtype	
Clear cell	55 (67.1%)
Non-clear cell	10 (12.2%)
Unclassified	17 (20.7%)
Stages	
I	1 (1.2%)
II	9 (10.9%)
III	57 (69.5%)
IV	13 (15.9%)
Unknown	2 (2.4%)

*all 8 were stage IV patients

Conclusions: Overall, we demonstrate the utility of ctDNA testing for MRD detection. Future prospective studies in RCC would be needed to validate the utility of ctDNA in informing clinical decision-making.

1909P Baseline cytokine levels according to the line of treatment in patients with metastatic clear cell renal cell carcinoma treated with nivolumab: NIVOREN GETUG-AFU 26 translational study

L.T. Rainho[1], L. Albiges[2], R. Flippot[2], L. Carril Ajuria[2], C. Dalban[3], B. Escudier[1], M. Naigeon[4], A. Desnoyer[5], M. Teixeira[1], N. Chaput-Gras[6]

[1]Oncology Department, Gustave Roussy, Villejuif, France; [2]Department of Medical Oncology, Gustave Roussy, Villejuif, France; [3]Centre Léon Bérard, Lyon, France; [4]Laboratoire d'immunomonitoring en oncologie, Institut Gustave Roussy, Villejuif, France; [5]Laboratory of Immunomonitoring in Oncology, Gustave Roussy - Cancer Campus, Villejuif, France; [6]Hematology Department, Institut Gustave Roussy, Villejuif, France

Background: The translational study NIVOREN GETUG-AFU 26 explored baseline cytokine correlation with outcomes under nivolumab in patients with metastatic renal cell carcinoma. We previously identified five cytokines (IL-6/IL-8/IL-7/VEGF/4-1BB) as potential serum-derived biomarkers of immune checkpoint inhibitors outcomes (N=80), subsequently validated (N=233), we confirmed a significant negative association between IL-6/IL-8/VEGF/BAFF/CXCL13 and worse OS (Carril-Ajuria et al. 2022). In this report, we present the baseline cytokine concentrations according to the line of treatment and investigate their additional prognostic value.

Methods: During the trial, blood samples were collected prospectively. Using the MSD-assay, we measured a panel of eight cytokines (VEGF, VCAM-1, IL-6, IL-7, IL-8, BAFF, 4-1BB, and CXCL13) at baseline. We evaluated the median cytokine levels using the Kruskal-Wallis test. The patients were categorized based on whether they underwent a single line of treatment or multiple lines of treatment.

Results: Overall, 353 patients were included in our analysis among 720 patients treated with nivolumab in the trial. Of these patients, 205 had received only one line of prior treatment, while 148 had received two or more lines of prior treatment. We found that patients who had undergone multiple lines of treatment had significantly higher levels of two cytokines, IL-6 and BAFF. IL-6 is known to be associated with protumoral inflammation and neutrophil activation, while BAFF regulates the trafficking and maturation of B cells.

Table: 1909P

Cytokines Median (pg/ml)	1 line of prior systemic therapy N=205	≥ 2 lines of prior systemic therapy N=148	Kruskal-Wallis test
IL-6	2.8 (0,4 - 276,1)	3,9 (0,5 - 802,7)	P=0.014
IL-7	6,8 (1,4- 29,3)	6.7 (1,9 — 29,7)	P=0.372
IL-8	13,5 (4,3 - 2599,9)	16 (4,3 — 2793,3)	P=0.177
VEGF	46,3 (2,6 - 681,6)	57,7 (7,9 — 798,4)	P=0.262
4-1BB	48,1 (0,1 - 344,2)	46,7 (0,3 — 59,5)	P=0.455
CXCL13	72,7 (20,2 - 705,7)	74,9 (16,6 — 800,4)	P=0.803
BAFF	1159,2 (346,7 - 9788,4)	1356,6 (342,5 — 10555,7)	P=0.004

Conclusions: Patients demonstrated a gradual enrichment of IL-6 and BAFF the number of prior lines of systemic therapy: patients more heavily pretreated presented higher baseline levels of those two cytokines. Our findings highlight the potential of baseline cytokine levels as a prognostic tool for metastatic clear cell renal cell carcinoma.

1910P Evaluation of a genome-wide methylome enrichment platform for circulating tumor DNA quantification and prognostic performance in renal cell carcinoma (RCC)

B.I. Rini[1], J. Zhang[2], O. Hall[2], J. Bergener[3], Y. Wang[2], B. Brown[2], J. Min[3], S.Y. Shen[4], N. Fleshner[5], A. Polio[2], E. Sosa[2], S. Bratman[6], B. Allen[7], K. Brown[8], A. Licon[3], A-R. Hartman[6], D.D. De Carvalho[6], B. Ho Park[9], G. Liu[10]

[1]Hematology Oncology, Vanderbilt Ingram Cancer Center, Nashville, TN, USA; [2]Biometrics, Adela, Inc., Foster City, CA, USA; [3]Data Science and Bioinformatics, Adela, Inc., Foster City, CA, USA; [4]Research & Development, Adela, Inc., Foster City, CA, USA; [5]Surgical Oncology, Princess Margaret Cancer Centre, Toronto, ON, Canada; [6]Executive, Adela, Inc., Foster City, CA, USA; [7]Clinical Development, Adela, Inc., Foster City, CA, USA; [8]Medical Affairs, Adela, Inc., Foster City, CA, USA; [9]Hematology Oncology, Vanderbilt Ingram Cancer Center, Nashville, TN, USA; [10]Medical Oncology Department, UHN - University Health Network - Princess Margaret Cancer Center, Toronto, ON, Canada

Background: Circulating tumor DNA (ctDNA) can be utilized to identify the presence of cancer as well as minimal residual disease. Quantification of ctDNA using plasma-based tests can be a useful cancer management tool to assess prognosis; however, some methodologies also require tumor tissue for analysis or are limited to tumor types that tend to have higher amounts of associated ctDNA. Here we demonstrate the feasibility of using a tumor-uninformed genome-wide methylome enrichment platform to quantify ctDNA in plasma and predict prognosis in RCC.

Methods: Biobanked pre-treatment samples from individuals with newly diagnosed stage I-IV RCC (University Health Network, Ontario Tumor Biobank) were analyzed with a bisulfite-free, non-degradative genome-wide DNA methylation enrichment platform using 5-10 ng of cell-free DNA isolated from plasma. ctDNA was quantified from average normalized counts across informative regions. Events were defined as cancer recurrence or progression. A ctDNA quantity threshold was set such that 95% of samples without an event fell below the threshold (i.e., 95% specificity). Time to event was compared for samples with ctDNA quantities above the threshold to those below the threshold.

Results: The cohort included 151 samples [64 stage I, 2 stage II, 23 stage III, 15 stage IV, 47 with unknown or incomplete stage information]. There was a median follow-up of 15.4 months and a total of 21 events. Samples with ctDNA quantities above the threshold were significantly more likely to recur or progress than those below the threshold [hazard ratio 13.28 (95% CI 5.47, 32.26), log-rank $P<0.001$].

Conclusions: This analysis demonstrates the feasibility of using a blood-based, tumor-uninformed genome-wide methylome enrichment platform for ctDNA quantification and prognostic prediction in renal cancer. This is a promising demonstration of prognostic performance in a cancer type that is typically difficult to detect due to low amounts of ctDNA. Additional evaluation in post-treatment and longitudinal samples will further test the performance of this platform.

1911P Effect of VHL mutations on efficacy of immune checkpoint inhibitors in renal cell carcinoma

G. Yu[1], Q. Zhang[2], Q. Duan[2]

[1]Department of Urology, Friendship Hospital in Urumqi, Urumqi, China; [2]The Medical Department, Jiangsu Simcere Diagnostics Co., Ltd., Nanjing, China

Background: Mutations of the von Hippel-Lindau (VHL) tumor suppressor gene occur in the majority of sporadic renal-cell carcinomas (RCC). Certain VHL mutations correlate with low expression of classical HLA-I molecules and HLA-E expression that determine higher NK susceptibility. Therefore, VHL mutation maybe a predictor of responses to immune checkpoint inhibitors (ICIs). Our research aims to elucidate its mutation association with ICI efficacy.

Methods: In order to investigate the correlation between VHL mutation and ICI efficacy in the RCC, we used cBioportal to collect clinical and mutation data of 151 ICI-treated RCCs from MSKCC cohort. Gene expression and WES data of 313 samples were obtained from the TCGA database for further analysis of potential biological mechanisms between VHL-mutant and VHL-wildtype tumors. Tumor mutation burden (TMB) was calculated as the total number of somatic non-synonymous mutations per megabase in both MSKCC and TCGA cohorts. CIBERSORT algorithm was applied to infer 22 human immune cell type proportions in TCGA RCCs.

Results: In the MSKCC immunotherapy cohort, we observed 70.2% (106/151) patients harbored VHL mutation, while TCGA had lower mutation frequency with 50.5% (158/313). As indicated by Kaplan-Meier analysis, the patients with VHL mutation had significantly better OS in the MSKCC cohort ($P < 0.001$, median OS: 50 months vs 26 months). This link was still existing when controlling for age, sex, ICI types, TMB and metastasis in the multivariate Cox regression analysis ($P = 0.005$, $HR = 0.45$, 95%CI = 0.26-0.78). As expected, the VHL-mutant group had higher TMB than that of the VHL-wildtype group in both the MSKCC cohort ($P < 0.001$) and TCGA cohort ($P = 0.047$). Immune cell analysis showed that CD8+ T cells, CD4 naïve T cells, T follicular helper cells and Macrophage M1 cells were abundant in the VHL-mutant group (both $P < 0.05$). These results indicated VHL-mutant tumors had an activated antitumor immune microenvironment.

Conclusions: VHL mutations might be a potential biomarker to predict the efficacy of immunotherapy for RCC. Considering the heterogeneity among the patients and other confounding factors, further prospective validation cohorts are warranted.

1912TiP STELLAR-304: A randomized phase III study of zanzalintinib (XL092) and nivolumab in non-clear cell renal cell carcinoma (nccRCC)

S.K. Pal[1], T.B. Powles[2], R. Kanesvaran[3], C-H. Lee[4], M. Liu[5], Z. Wang[6], A. Bhatt[7], P. Patel[8], C. Suarez Rodriguez[9]

[1]Department of Medical Oncology and Therapeutics Research, City of Hope Comprehensive Cancer Center, Duarte, CA, USA; [2]Department of Medical Oncology, Barts Health NHS Trust Saint Bartholomew's Hospital, London, UK; [3]Department of Medical Oncology, National Cancer Centre Singapore, Singapore; [4]Department of Medical Oncology, Memorial Sloan Kettering Cancer Center, New York, NY, USA; [5]Department of Global Drug Development, BMS, New York, NY, USA; [6]Department of Biometrics, Exelixis, Inc., Alameda, CA, USA; [7]Department of Clinical Science, Exelixis, Inc., Alameda, CA, USA; [8]Department of Clinical Development, Exelixis, Inc., Alameda, CA, USA; [9]Medical Oncology, Vall d'Hebron Institute of Oncology (VHIO), Hospital Universitari Vall d'Hebron, Vall d'Hebron Barcelona Hospital Campus, Barcelona, Spain

Background: nccRCCs are a heterogenous group of rare histologic subtypes, each with distinct biology and response to treatment. There have been few dedicated randomized phase 3 studies in nccRCC, highlighting an urgent unmet need for effective therapies. Sunitinib is the only TKI to have shown a clinical benefit (vs everolimus) in a broad range of histologic subtypes of metastatic nccRCC (Armstrong et al. *Lancet Oncol* 2016). To date, no single agent or combination has shown a significant overall survival (OS) benefit over sunitinib in any nccRCC subtype. Zanzalintinib (XL092), a novel TKI of VEGFR2, MET, AXL, and MER, has shown antitumor and immunomodulatory activity alone, and synergistic antitumor effect with PD1 inhibition, in animal models (Hsu et al. *Mol Cancer Ther* 2023). In a phase 1 study of metastatic solid

tumors including RCC, zanzalintinib showed promising clinical activity and a manageable toxicity profile, alone and with an immune checkpoint inhibitor (ICI) (Sharma et al. *ESMO* 2022 Abs 481P). STELLAR-304 was designed to assess the efficacy and safety of zanzalintinib + nivolumab versus sunitinib in first-line nccRCC (NCT05678673).

Trial design: STELLAR-304 is a global, randomized, open-label study of adults with unresectable/advanced/metastatic nccRCC that is measurable per RECIST v1.1. The trial includes papillary, unclassified, and translocation-associated histologies (sarcomatoid features are allowed); chromophobe, renal medullary carcinoma, or pure collecting duct histology are excluded. Histologies are confirmed by central pathology review. Prior systemic anticancer therapy for advanced or metastatic nccRCC is not permitted; however, 1 prior systemic adjuvant therapy, including ICI and excluding sunitinib, is allowed for completely resected RCC if recurrence occurred $\geq$6 months after the last adjuvant therapy dose. Patients (N=291) are randomized 2:1 to zanzalintinib + nivolumab or sunitinib alone. The primary endpoints are PFS and ORR per RECIST v1.1 by blinded independent radiology committee. The secondary endpoint is OS; safety will also be assessed. STELLAR-304 is currently recruiting patients in 29 countries in Europe, North and South America, and the Asia-Pacific region.

Clinical trial identification: NCT05678673.

Background: In the LMS-04 study primary analysis (NCT02997358), the combination of dox + trab demonstrated a significant progression-free survival (PFS) benefit (12·2 months *versus* 6·2 months], adjusted hazard ratio (HR) 0·41 [95% CI 0·29—0·58]; p<0·0001) in 1st-line treatment of patients with advanced LMS (Pautier; Lancet Oncol 2022). Herein, we report the updated PFS (uPFS) and final results of overall survival (OS) analyses (planned when all pts had at least 3 years of follow-up).

Methods: Pts received either dox alone 75 mg/m^2 (arm A) or dox 60 mg/m^2 followed by trab 1.1 mg/m^2 as a 3-hour infusion (arm B), repeated every 3 weeks for up to 6 cycles (cy) followed in arm B by trab in non-progressive pts up to 17 cy. Surgery for residual disease was permitted. Randomisation was stratified by tumour location (uterine *versus* soft tissue) and disease (locally advanced *versus* metastatic). The analysis of PFS and OS was adjusted for stratification factors.

Results: Overall, 150 pts with LMS (67 with uterine LMS and 83 with soft-tissue LMS), and mostly with metastatic disease (90%), were enrolled. The median duration of follow-up was 54.9 months [95% CI = 51.25-60.48] with 107 deaths (60 in arm A and 47 in arm B). Median uPFS was significantly longer with dox + trab *versus* dox alone (12.19 mo [95% CI = 10.09-15.57] *versus* 6.21 mo [95% CI = 4.07-7.06] with adjusted HR: 0.37 [95%CI = 0.26-0.53] and p<0.0001). Median OS was also significantly longer with the association (33.08 [95% CI = 26.22-47.54] *versus* 23.78 months with dox alone [95% CI = 18.86-30.68], adjusted HR=0.65 [95% CI = 0.44-0.95] p=0.0253). No new safety signal was observed.

Conclusions: dox + trab combination can be considered as first -line treatment for metastatic/advanced uterine and soft-tissue LMS.

Clinical trial identification: NCT02997358.

1914MO The clinico-radiological outcome of desmoid type-fibromatosis after discontinuing the sorafenib treatment in responders: Single-arm phase II clinical trial

B. Bharath[1], S. Rastogi[1], V. Garg[2], G. Tansir[1], E. Dhamija[3], A. Barwad[4], S. Kaur[5], S. Gamanagatti[3], S. Bhoriwal[6], M. Khan[7]

[1]Medical Oncology, AIIMS - All India Institute of Medical Sciences, New Delhi, India; [2]Medical Oncology Department, Princess Margaret Cancer Centre, Toronto, ON, Canada; [3]Radiodiagnosis, AIIMS - All India Institute of Medical Sciences, New Delhi, India; [4]Pathology, AIIMS - All India Institute of Medical Sciences, New Delhi, India; [5]Physiology, AIIMS - All India Institute of Medical Sciences, New Delhi, India; [6]Surgical Oncology, AIIMS - All India Institute of Medical Sciences, New Delhi, India; [7]Biostatistics, AIIMS - All India Institute of Medical Sciences, New Delhi, India

Background: The treatment duration of sorafenib in desmoid-type fibromatosis is not established. Finding the optimal duration to improve the quality of life of patients with DTF remains important.

Methods: This is a single arm, Simon's phase 2 study started in July 2021 and is still ongoing. Patients with extremity DTF on sorafenib were screened for inclusion and sorafenib was discontinued. After discontinuation, patients were examined clinically every 3 months and MRI every 6 months. The EORTC QLQ C30 questionnaire was administered every 3 months for 1 year. RECIST 1.1 criteria were used for radiological assessment. The primary endpoint was progression-free survival (PFS) at 1 year.

Results: There were 33 patients with a median age of 28.5 years and the female-to-male ratio was 1.3. Sorafenib at a dose of 200 mg/day was used in 55% of the patients. The median duration of sorafenib was 25 months. At enrolment, one patient was in CR, 21 (61.7%) in PR, and 12 (35.3%) patients had SD. The median duration of follow-up after enrolment was 13 months. 20 patients completed 1 year of follow-up. Of 20 patients, who completed a 1-year follow-up, 19 patients had SD. The change in tumor size at 1 year ranged between a decrease of 21% to an increase of 32% (median change of 2%). Of 33 patients, 3 were restarted on sorafenib, 2 because of worsening pain (radiologically SD), and 1 because of radiological PD. There was significantly more pain at the end of 1 year of stopping sorafenib measured on the EORTC scale but the difference in the global health status (GHS) and other parameters was not significant (Table).

Table: 1914MO Demographic details and results

Variable	Values (N = 33)
Age (Median ± SD) in years	28.5 ± 9.4
Gender n (%) Male Female	15 (44.1%) 19 (55.9%)
The duration of sorafenib treatment before enrollment Median ± SD in months	25.4 ± 11.8 months
Disease status at 1 year of stopping sorafenib SD PD	N = 20 19 (95%) 1 (1%)
PFS rate at 1 year	95%
The difference in the mean EORTC scores (Compared between the time of stopping sorafenib and at 1-year completion) GHS Pain	82.69 ± 21.9 vs 79.48 ± 20.58, p = 0.529 21.1 ± 29.1 vs 29.4 ± 7.6, p = 0.013

Conclusions: Sorafenib can be stopped safely after 1 year of treatment for extremity fibromatosis without compromising the quality of life of patients. However, clinical follow-up at regular intervals is required to assess for the symptoms and disease progression.

1915MO Fear, anxiety and depression in gastrointestinal stromal tumor (GIST) patients in the Netherlands: Data from a cross-sectional multicenter study

D. van de Wal[1], D. Den Hollander[2], I.M. Desar[2], H. Gelderblom[3], A.W. Oosten[4], A.K.L. Reyners[5], N. Steeghs[1], W.T.A. Van Der Graaf[1], O. Husson[6]

[1]Medical Oncology Department, NKI-AVL - Netherlands Cancer Institute/Antoni van Leeuwenhoek Hospital, Amsterdam, Netherlands; [2]Medical Oncology Department, Radboud University Medical Center, Nijmegen, Netherlands; [3]Medical Oncology Department, LUMC - Leids University Medical Center, Leiden, Netherlands; [4]Medical Oncology Department, Erasmus MC, Rotterdam, Netherlands; [5]Medical Oncology, UMCG - University Medical Center Groningen, Groningen, Netherlands; [6]Psychosocial Research And Epidemiology Department, NKI-AVL - Netherlands Cancer Institute/ Antoni van Leeuwenhoek Hospital, Amsterdam, Netherlands

Background: The introduction of tyrosine kinase inhibitors (TKIs) has led to a phenomenal progress in the treatment of gastrointestinal stromal tumors (GIST). Prolonging the survival of GIST patients may also entail more psychological and emotional distress. This study aims to investigate (1) the prevalence of anxiety, depression and fear of cancer recurrence or progression (FCR) in GIST patients on TKI treatment or not on TKI treatment, (2) factors associated with anxiety, depression and severe FCR, and (3) the relationship between anxiety, depression, severe FCR and global quality of life.

Methods: In a cross-sectional population-based survey study, Dutch GIST patients completed self-report questionnaires including the Hospital Anxiety and Depression Scale (HADS), Cancer Worry Scale (CWS) and the EORTC QLQ-C30.

Results: A total of 328 (response rate 63%) patients responded, 108 (32.9%) of whom received TKI treatment at time of the questionnaire. Patients on TKI treatment had a significantly higher prevalence of symptoms of depression (21.5% vs 8.7%, p=0.001) and severe FCR (59.3% vs 35.4%, p=<0.001) compared to those not on TKI treatment, while anxiety did not differ between the groups (18.7% vs 13.0%). Patients on TKI treatment had 2.3 (95% CI 1.1-4.9; p=0.025) and 2.7 (95% CI 1.6-4.5; p=<0.001) higher odds of experiencing symptoms of depression and severe FCR, respectively, than those not on TKI. Other factors associated with symptoms of depression and severe FCR were younger age at diagnosis and having more than two comorbidities. Global quality of life was significantly lower in patients who experienced symptoms of anxiety (64.9 vs 82.8, p=<0.001), depression (59.8 vs 83.2, p=<0.001) or severe FCR (73.2 vs 85.0, p=<0.001) as compared to patients who were not anxious, depressed or experienced severe FCR.

Conclusions: GIST patients on TKI treatment are more prone to experience symptoms of depression and severe FCR than those not on TKI treatment, which can significantly impair their global quality of life. Given the high prevalence of FCR and symptoms of depression, this deserves more attention in clinical practice and appropriate interventions should be provided.

1916MO A first-in-human phase I trial of NB003, a potent and selective KIT/PDGFRa inhibitor, in patients with advanced gastrointestinal stromal tumors (GIST)

P. Chi[1], L. Shen[2], J. Li[2], J. Zhang[3], K. Hu[4], L. Zhang[4], Y. Xu[4]

[1]Department of Medicine, Memorial Sloan Kettering Cancer Center, New York, NY, USA; [2]GI Oncology Department, Peking University Cancer Hospital and Institute, Beijing, China; [3]Department of Medical Oncology, Fudan University Shanghai Cancer Center, Shanghai, China; [4]Clinical Development, Ningbo Newbay Technology Development Co., Ltd., Ningbo, China

Background: NB003 is a potent and selective small-molecule tyrosine kinase inhibitor (TKI) of KIT and PDGFRα, designed to inhibit a broad range of primary and acquired imatinib-resistant mutations in KIT/PDGFRα in GIST. This study is aimed to determine the safety and tolerability, the MTD, and the RP2D of NB003 in patients (pts) with advanced GIST.

Methods: This is a phase 1, multicenter, open-label, dose-escalation study of adult pts with confirmed GIST who progressed on or intolerant to imatinib and other standard of care treatments. A BOIN dose-escalation design was used; pts received oral NB003 in 7 dose levels (DL), ranging from 3mg to 40mg twice daily (BID). The primary endpoint was safety and tolerability. Other endpoints were PK, PD, and early efficacy signal by mRECIST.

Results: As of 19 April 2023, 23 pts (median age, 56.0) were enrolled; 60.9% were male and 78.3% had ECOG PS 1. 78.3% received at least 4 lines of prior TKIs. The most frequent treatment-related adverse events (TRAEs) were CPK increased (95.7%), AST increased (87.0%), face oedema (82.6%), periorbital oedema (82.6%), WBC decreased (78.3%), anaemia (73.9%), neutrophil count decreased (69.6%), amylase increased (65.2%), platelet count decreased (47.8%), lipase increased (43.5%), ALT increased (34.8%), fatigue (34.8%) and oedema peripheral (34.8%). 2 pts from 40 mg BID DL (Grade 3 fatigue, Grade 3 face oedema) and 1 pt from 30mg BID DL (Grade 3 febrile neutropenia, Grade 3 rash maculo-papular) experienced DLTs. TRAE (face oedema) leading to permanent discontinuation in 1 patient at 40mg BID. 3 of the 19 evaluable pts had confirmed and 2 pts had unconfirmed RECIST partial responses (PRs). The confirmed ORR was 15.8% (3/19), disease control rate (DCR: PR + stable disease [SD]) was 78.9% (15/19). The increase of drug exposure was approximately dose proportional at steady state.

Conclusions: NB003 has a manageable toxicity profile and promising clinical activity in heavily pretreated pts with advanced GIST harboring a broad spectrum of acquired imatinib-resistant mutations. The 20mg and 30mg BID doses are selected for further investigation in the phase I RP2D confirmation cohort.

Clinical trial identification: NCT04936178.

1917MO CHAPTER-GIST-101: A phase I study of pimitespib combined with imatinib in patients with imatinib-refractory gastrointestinal stromal tumor

Y. Naito[1], Y. Komatsu[2], Y. Kurokawa[3], H. Hirano[4], T. Nishida[5], T. Doi[6]

[1]Department of General Internal Medicine, National Cancer Center Hospital East, Kashiwa, Japan; [2]Cancer Center Department, Hokkaido University Hospital, Sapporo, Hokkaido, Japan; [3]Gastroenterological Surgery Department, Graduate School of Medicine/Faculty of Medicine, Osaka University, Suita, Osaka, Japan; [4]Department of Gastrointestinal Medical Oncology, National Cancer Center Hospital, Tokyo, Japan; [5]Surgery Department, NCCH - National Cancer Center Hospital, Chuo-ku, Japan; [6]Experimental Therapeutics Department, National Cancer Center Hospital East, Kashiwa, Japan

Background: Pimitespib (PIMI), a novel heat shock protein 90 inhibitor, was approved in Japan for patients (pts) with advanced gastrointestinal stromal tumor (GIST) after chemotherapies based on the results of the phase 3 study (CHAPTER-GIST-301). PIMI showed anti-tumor activity in an imatinib (IMA)-resistant GIST xenograft model and enhanced the activity when combined with IMA. Thus, PIMI + IMA could be effective in pts resistant to IMA. Here, we will present the results from dose-escalation part of the study (NCT05245968), of PIMI + IMA in pts with IMA-refractory GIST.

Methods: Pts with histologically confirmed, IMA-refractory GIST in second-line setting were eligible. Once daily dose of 120 mg (DL1) or 160 mg (DL2) PIMI was administered orally on a 5-day on/2-day off schedule, and 400 mg of IMA was administered once daily on a standard 3+3 dose escalation. The primary endpoint was to determine dose-limiting toxicity (DLT) and maximum tolerable dose (MTD) of PIMI + IMA. The secondary endpoints included progression-free survival (PFS), objective response rate (ORR), disease control rate (DCR), and safety.

Results: Twelve pts (DL1 [n=6] and DL2 [n=6]) who were treated with IMA in first-line setting for median 21.7 months (mos) were enrolled in Japan. No DLTs were

observed at both doses and the MTD was at DL2. The common (≥ 60%) treatment-related adverse events (TRAEs) in DL1 and DL2 were diarrhea (83.3%/ 100%), nausea (50%/ 83.3%), night blindness (16.7%/ 83.3%), blood creatinine increased (33.3%/ 66.7%), dysgeusia (16.7%/ 66.7%) and decreased appetite (0%/ 66.7%), respectively. No serious TRAEs, TRAEs leading to study discontinuation or death were observed. The ORR was 8.3% (one confirmed partial response) and the DCR was 91.7%. 66.7% showed tumor shrinkage and 58.3% were stable for more than 6 mos. Median PFS was 12.9 mos (95% CI, 2.8 — not calculated).

Conclusions: PIMI + IMA combination was well tolerated with no new concerns at DL1 and DL2. It was effective despite pts being refractory to IMA, even when compared to those reported in previous studies on second-line setting with sunitinib. The expansion part of this study to evaluate safety and efficacy is currently recruiting pts globally at DL1, that has a better safety profile.

1918MO Circulating tumor DNA in relation to tumor volume in gastro-intestinal stromal tumors

R.F. Bleckman[1], C. Haag[2], R.H. Mathijssen[3], N. Steeghs[4], H. Gelderblom[5], I.M. Desar[6], A. Ter Elst[7], E. Schuuring[7], A.K.L. Reyners[1]

[1]Medical Oncology, UMCG - University Medical Center Groningen, Groningen, Netherlands; [2]Radiology, UMCG - University Medical Center Groningen, Groningen, Netherlands; [3]Medical Oncology Department, Erasmus MC Daniel den Hoed Cancer Center, Rotterdam, Netherlands; [4]Department of Clinical Pharmacology, Division of Medical Oncology, Netherlands Cancer Institute/Antoni van Leeuwenhoek Hospital, Amsterdam, Netherlands; [5]Medical Oncology Department, LUMC - Leids Universitair Medisch Centrum, Leiden, Netherlands; [6]Medical Oncology Department, Radboud University Medical Center, Nijmegen, Nijmegen, Netherlands; [7]Pathology Department, UMCG - University Medical Center Groningen, Groningen, Netherlands

Background: Locally advanced/metastatic gastro-intestinal stromal tumors (GIST) are followed with 3-6 monthly CT-scans to evaluate treatment response with tyrosine kinase inhibitors (TKIs). As a result, patients are exposed to accumulative levels of radiation. Therefore, a growing interest on the use of circulating tumor DNA (ctDNA) to monitor treatment response has arisen. Previous research reported the correlation of ctDNA with tumor volume as new tool for monitoring treatment response. The aim of this exploratory study was to evaluate the use of ctDNA testing in GIST patients treated with TKIs, and to compare changes in the levels of ctDNA with tumor volume (3D) with CT-scan results assessed according to RECIST 1.1.

Methods: 147 plasma samples from 7 GIST patients with a KIT exon 11 mutation were prospectively collected before or during treatment and follow-up between 2014-2021. Plasma ctDNA levels were determined using a validated KIT exon 11 digital droplet PCR (ddPCR) drop-off assay. RECIST outcome was extracted from routine imaging reports of follow-up CT scans. Clinical relevant samples were selected based on RECIST outcome (response to treatment or progressive disease) or start of a new treatment line. Total tumor volume measurements with a semi-automated manner, allowing for manual correction, were performed by an independent radiologist.

Results: 101 clinically relevant plasma samples were analyzed. In all baseline samples the primary tumor KIT exon 11 mutation could be detected in ctDNA, ranging from 1.54 to 2287.81 copies per mL plasma. Upon response to treatment, ctDNA completely disappeared in all patients. At progressive disease, ctDNA could be, at least once, detected in 6 of 7 patients. Higher tumor volumes (from 450 mL) correlated with higher levels of ctDNA. In each individual patient with progressive disease on imaging, undetectable ctDNA was consistent with lower tumor volumes than detectable ctDNA.

Conclusions: Total tumor volume measurement is the most accurate indicator of GIST disease activity. No absolute cut-off value of tumor volume in which ctDNA could be detected could (yet) be determined to indicate active (progressive) disease. CtDNA can be a promising and cost-effective additional follow-up tool to monitor treatment response.

Background: BOT, a multifunctional Fc-enhanced anti-CTLA-4 antibody, enhances T cell priming, activation, and memory formation, depletes intratumoral Tregs and minimizes complement fixation. BOT±BAL has shown effectiveness across a wide variety of 'cold'/ I-O—resistant solid tumors. We report results from an expanded phase Ib study in refractory metastatic sarcoma treated with BOT+BAL (NCT03860272).

Methods: Pts received BOT 1 or 2 mg/kg every 6 wks (or fixed-dose equivalent) + BAL 3 mg/kg every 2 wks. Endpoints include overall response rate (ORR), disease control rate (DCR; best response of stable disease [SD], complete [CR] or partial response [PR]), progression free survival (PFS), overall survival (OS), and safety.

Results: We report on 22 evaluable pts who started treatment by Dec 5, 2022 with at least one 6-wk scan and ≥18 wks follow-up (data cutoff: May 3, 2023). Median age was 62 (range 40—80). Most common histologies were leiomyosarcoma, angiosarcoma (including 5 visceral) and liposarcoma. Median number of prior lines was 3, 18% had failed immunotherapy and median follow-up was 6.5 mos (range 1.4—26.1). ORR by RECIST1.1 was 27% (6/22; 95% CI 11—50) and median duration of response (DOR) was not reached across multiple subtypes. Six additional pts had meaningful clinical benefit: 1 with minor early progression (followed by a deep, durable ongoing response of 108+wks; 98%); 1 with an unconfirmed CR; and 4 with SD at 24 wks (3 ongoing). DCR was 68%, 6mo PFS was 50% (95% CI 26—70), and 12-mo OS was 82% (95% CI 52—94). More than 20 additional pts have been treated, and mature efficacy and safety data along with preliminary biomarker analyses will be presented. Safety profile (N=22) remains favorable and consistent with previously reported data. Any grade treatment-related adverse events (TRAEs) occurred in 91% of pts, grade 1-2 TRAEs 77%, grade 3 TRAEs 14% and no grade 4/5 TRAEs. The only grade 3 TRAEs occurring in >1 pt was diarrhea/colitis (9%). No treatment-related deaths occurred.

Conclusions: BOT+BAL exhibits significant efficacy with durable responses in pts with poorly immunogenic, refractory sarcomas, with a manageable safety profile. The expanded phase Ib study is ongoing.

Clinical trial identification: NCT04121676.

Background: Regorafenib (R) has been approved as 3d line in mGIST patients (pts), with a median progression-free survival (mPFS) of 4.9 months (GRID study). R can alleviate the immunosuppressive GIST tumor micro environment by several mechanisms such as modifying the polarization of tumor-associated macrophages, reducing T regs infiltration. Thus, combining anti-PD1/PDL1 agents with anti-angiogenics appears promising in this population.

Methods: This is a single-arm open-label multicentric phase II trial assessing the efficacy and safety of R (160 mg QD 3weeks/4) + Avelumab (A) (10 mg/kg every 2 weeks) combination in pts with mGIST. The primary endpoint was the 6-month progression-free rate (6-month PFR) based on RECIST 1.1 criteria after central review. Secondary endpoints included: 6-month objective response, 1-year PFS, 1-year overall survival (OS), and safety using NCI-CTCAE v5.0. Correlative studies were planned from pts tumor samples obtained at baseline.

Results: Between November 2018 to July 2022, 50 pts were enrolled in 6 centers. Median age was 64 (range: 26-82). Median follow-up was 28.6 months (95% CI: 15.5 − 35.2). Median number of previous treatment lines was: 2 (range: 1-4). 42 (84%) pts experienced at least 1 dose modification or treatment interruption due to R and/or A. The most common grade 3/4 adverse events were: Palma-plantar erythrodysesthesia syndrome (18% of pts), hypertension (14%), diarrhea and maculopapular rash (12% each). No death was related to the treatment. Among the 46 assessable pts, 6-month PFR is 37% (N=17): 3 (6.5%) had partial response, 14 (30.4%) a stable disease, 23 (50%) a progressive disease, 6 were not evaluable. 24 (52.2%) had tumor shrinkage. Median PFS and OS are 5.5 months (95% CI: 3.6 − 7.5) and 19.5 months (95% CI: 13.7-33.5) respectively. 22% of pts are progression-free at one year. 6-month and 1-year OS rates are 93.5% (95% CI: 81.1-97.8) and 70.8% (95%CI: 55-81.9) respectively.

Conclusions: Regomune is the largest prospective study evaluating an approved TKI in combination with an IO agent in pts with advanced GIST. A subset of pts derived long term clinical benefit. Correlative studies will be presented at the meeting.

Clinical trial identification: NCT03475953.

1921MO Patterns of care, outcome and molecular landscape of PATZ1-rearranged sarcomas identifies two prognostic profiles: A cohort study from the French Sarcoma Group (FSG)

H. Vanacker[1], F. Le Loarer[2], M. Karanian[3], A. Meurgey[3], A. Dufresne[1], S. El Zein[4], J-Y. Blay[1], O. Collard[5], I.L. Ray-Coquard[1], W.A. Waissi[6], D. Pissaloux[7], S. Paindavoine[8], A. Houlier[8], G. Pierron[9], P. Meeus[10], F. Tirode[8], M. Brahmi[5]

[1]Medical Oncology Department, Centre Léon Bérard, Lyon, France; [2]Pathology, Institut Bergonié, Bordeaux, France; [3]Pathology, Centre Léon Bérard, Lyon, France; [4]Pathology, Institut Curie, Paris, France; [5]Medical Oncology, Institute de Cancerologie de la Loire, Saint-Priest-en-Jarez, France; [6]Radiation Oncology Department, Centre Léon Bérard, Lyon, France; [7]Translationnal research, Centre Léon Bérard, Lyon, France; [8]Cancer Research Center of Lyon, Centre Léon Bérard, Lyon, France; [9]Somatic Genetic Unit, Institut Curie, Paris, France; [10]Surgical Oncology, Centre Léon Bérard, Lyon, France

Background: PATZ1 rearranged sarcomas (PRS) belong to the "round cell sarcomas with EWSR1—non-ETS fusions" group in 2020's WHO classifications. With only small case series (<10 cases) reporting deep clinical and histological heterogeneity, uncertain prognosis and absence of standard of care, PRS imperatively require further clinico-molecular characterization.

Methods: Pediatric and adult patients from 13 French centers with a diagnosis of PRS from 2011 to March 2023 were included. All PRS diagnosis were histologically and molecularly reviewed by 4 expert pathologists. Patients and tumors characteristics were collected from the national NETSARC+ database (netsarc.sarcomabcb.org) and whole exome-RNAseq was performed with FFPE material.

Results: Seventeen patients were included with a mean follow up of 44 months including 16 with EWSR1::PATZ1 and one with MN1::PATZ1 fusions. Clinical data were heterogeneous in term of baseline clinical characteristics, histopathology, management and outcome. In univariate analyses, age, tumor size, FNCLCC-grade, adjuvant systemic therapy for non-metastatic disease did not correlate to overall survival (OS) whereas stage, Ki67 and some transcriptomic signatures -relative to cell cycle- did. A group of patients with metastasis or Ki67>30% had aggressive clinical course and poor responses to treatment (whether Ewing-like regimen or other). A distinct group of patients had indolent profiles and were long-term free of recurrence (>5years) after surgery alone without adjuvant chemo/radiotherapy.

Table: 1921MO Univariate analysis of OS using the Cox model: Median OS is 33.5 months (range 5 :120)

Parameter	Variable	N=	HR	CI95%	P-Value	P level[1]
Age	Continuous	17	1.01	(0.98;1.05)	0.378	ns
Sex	M vs F	11 vs 6	2.02	(0.279;7.24)	0.279	ns
Tumor size (mm)	Continuous	17	1.02	(0.99;1.04)	0.053	ns
Primary site	Trunk vs others	7 vs 10	1.4	(0.43;4.70)	0.55	ns
Stage (initial)	Localized/ loc.Adv. vs Metastatic	10 vs 7	21.1	(2.942;2.94)	2.942	**
Ki67% (adult)	Continuous	9	1.02	(1.02;)	0.0274	*
Grade (FNCLCC)	Grade 2 vs 3	8 vs 7	0.59	(0.16;2.15)	0.427	ns
RNAseq cell cycle G2_M score	Continuous	15	4.1243	(1.33;12.76)	0.0139	*
Adjuvant systemic treatment	Systemic treatment vs Surveillance	7 vs 3 all no metastasis	0.46	(0.04;4.9)	0.52	ns

1 level of significance: p>0.05:ns; p<0.05:,p<0.01:**;p<0.001:***

Conclusions: Our study suggests that the natural history pf PRS differs from Ewing sarcomas. We reveal that some good prognosis PRS are cured with surgery alone while others are aggressive. Stage and ki67 should help to identify those patients while further molecular analyzes are pending.

Background: Advanced angiosarcoma comprises an aggressive sarcoma subset that exhibits poor prognosis and short-term duration of responses. Series treated with anthracyclines or taxanes reported an mPFS that ranged from 2.7 to 3.7 m. A trial with sorafenib reported a mPFS of 1.8 and 3.8 m, 6-m-PFSr of 25% and 31% (9m-PFSr of 0 and 3.8%), ORR of 15 and 13% and mOS of 9 and 12 m, for superficial and visceral cohorts respectively. As IMMUNOSARC I master-trial exploring sunitinib (S) plus nivolumab (N) in sarcoma detected signal of activity in angiosarcoma patients, a specific cohort of vascular sarcomas was designed as phase II trial in IMMUNOSARC II (NCT03277924).

Methods: Advanced, recently progressing, measurable and centrally reviewed vascular sarcomas (angiosarcoma, intimal sarcoma and epithelioid hemangioendothelioma) were enrolled and treated with S: 37.5 mg/d in first 14 days, then continued with 25 mg/d, along with N 240 mg every 2 weeks up to progression or intolerance. Imaging tests were assessed every 8 weeks. The main endpoint was 6m-PFSr, and the statistical assumptions were obtaining a 6m-PFSr in at least 11 patients out of 23 patients, with H_0=30% and H_1=60% (α 0.05; β 0.10).

Results: Patients with angiosarcoma (17), EHE (6) and intimal sarcomas (3) were accrued from Oct. 2019 to Apr. 2023 in 8 centers from Spain, Italy and UK. Patients had a median age of 60 y (25-82), F=20/M=6 distribution and a median of previous lines of 2 (0-5). Median follow-up was 24 m (5.9-42.1). The 6m-PFSr was 45% (23-66) for 23 evaluable patients. Considering angiosarcoma patients, there were 5 (33%) PR, 7 (47%) SD and 3 (20%) PD out of 15 evaluable patients. The mPFS was 3.93 m and the 6m-PFSr was 36% (11-61). The mOS was 15.73 m (1.83-29.64). End-of-treatment reasons were PD 71%, toxicity 22% and doctor decision 7%. Most common grade 3-4 TREAEs were neutropenia (11.8%) and asthenia (11.8%).

Conclusions: S and N combination has demonstrated to be active in advanced vascular sarcomas. This activity favorably compares with that previously reported for sorafenib activity. Even though the outcome did not reach the H1, antiangiogenics and PD1 inhibitors deserve to be explored, maybe with other combinations, in vascular sarcomas.

Clinical trial identification: NCT03277924.

1923P Combined analysis of phase III ANNOUNCE study and phase II study exploring olaratumab in advanced soft tissue sarcoma

Y. Naito[1], K. Sakamaki[2], S. Morita[3], T. Mukohara[4], T. Akimoto[5]

[1]Department of General Internal Medicine, National Cancer Center Hospital East, Kashiwa, Japan; [2]Department of Biostatistics and Epidemiology, Yokohama City University Graduate School of Medicine, Yokohama, Japan; [3]Department of Biomedical Statistics and Bioinformatics, Graduate School of Medicine and Faculty of Medicine Kyoto University, Kyoto, Japan; [4]Department of Medical Oncology, National Cancer Center Hospital East, Kashiwa, Japan; [5]Department of Radiation Oncology, National Cancer Center Hospital East, Kashiwa, Japan

Background: Doxorubicin remains the standard of care for most of advanced soft tissue sarcoma. However, survival for patients with advanced soft tissue sarcoma is unsatisfactory. Consequently, there is an urgent need for new treatments. Olaratumab is a monoclonal antibody directed against the platelet-derived growth factor receptor and has been studied in soft tissue sarcoma. In a phase II study, olaratumab in combination with doxorubicin showed an overall survival benefit over doxorubicin alone. However, a confirmatory phase III ANNOUNCE study failed to demonstrate the benefit of olaratumab. One possible explanation of the contradictory results is that the dose of doxorubicin used in each trial is significantly different. Therefore, we examined the effect of doxorubicin dose on survival using individual data from the phase II and phase III studies.

Methods: Individual patient data were retrieved from the Vivli platform (https://vivli.org/) after study proposal approval. Patient characteristics including clinicopathologic findings, progression-free and overall survival (OS) data, and doxorubicin dose were analyzed. Cox proportional hazard model was used to estimate the effect of doxorubicin dose on survival.

Results: A total of 632 patients (128 from phase II and 504 from phase III study) were included in the current study. Median age was 58 years, 267 (42.2%) were male, 375 (59.3%) were performance status 0, and 282 (44.6%) had leiomyosarcoma. Median cumulative doxorubicin dose was 449 mg/m^2 in all patients, 426 mg/m^2 (488 in phase II and 409 in phase III) for doxorubicin with olaratumab arm and 451 mg/m^2 (300 in phase II and 483 in phase III) for doxorubicin alone arm. In the combined analysis olaratumab showed marginal OS benefit (HR: 0.83, 95%CI: 0.69-1.01, p-value: 0.061). Cumulative doxorubicin dose had statistically significant impact on OS (HR for difference in dose of 75mg/m^2: 0.80, 95%CI: 0.77-0.83, p-value: $<$0.001).

Conclusions: Cumulative doxorubicin dose had a significant impact on OS, with a HR of 0.80 for the difference by doxorubicin dose per cycle, which may explain the discrepancy between the phase II and phase III results. Our investigation reaffirms the importance of doxorubicin in advanced soft tissue sarcoma.

1924P Targeting microenvironment and cellular immunity in sarcomas with trabectedin combined with metronomic cyclophosphamide: The TARMIC study

C-M. Sun[1], I. Hernandez[2], M. Spalato Ceruso[3], M. Toulmonde[3], C. Sautes-Fridman[4], W-H. Fridman[5], A. Bessede[6], A. Italiano[7]

[1]Ile de France, INSERM UMRS1138 - Laboratory of Integrative Cancer Immunology, Paris, France; [2]Bioinformatics, Universite Sorbonne, Paris, France; [3]Medical Oncology Department, Institute Bergonié - Centre Régional de Lutte Contre le Cancer (CLCC), Bordeaux, France; [4]Immuno-Oncology Department, Centre de Recherche des Cordeliers, Paris, France; [5]Cancer, Immunology, Immunopathology, Centre de Recherche des Cordeliers, Paris, France; [6]Immusmol, Explicyte, Bordeaux, France; [7]Early phase Trials Unit, Institute Bergonié, Bordeaux, France

Background: Recent pre-clinical data have suggested that the antitumor activity of trabectedin is not only related to their effects on tumor cells, but also on its ability to affect the tumor microenvironment (TME), in particular tumor associated macrophages and their pro-tumoral functions. We report results of the phase II part of the first study evaluating trabectedin in combination with metronomic chemotherapy on the TME of patients (pts) with advanced sarcomas.

Methods: TARMIC is an open-label multicenter phase I/II study of trabectedin in combination with low-dose cyclophosphamide in pts with advanced STS. The RP2D was of 0.5 mg/m^2. Primary endpoint was 6-month non progression rate. Secondary endpoints included efficacy and evaluation of impact on TME through mandatary tumor biopsies at baseline and after one cycle of treatment.

Results: 30 patients (17 males, 13 females) have been included. Median age was 67 years (23 − 80). The two most frequent histologies were undifferentiated pleiomorphic liposarcoma (n=9) and leiomyosarcoma (n=7). The median number of previous lines of treatment was 2 (range 1-5). The most frequent adverse events were: grade 1/2 fatigue (86.7%), nausea (66.7%) and anemia (66.7%). 24 pts were eligible and assessable for efficacy. Best objective response as per RECIST based on central review was: partial response for 2 (8.3%), stable disease for 9 (37.5%) and progressive disease for 13 pts (54.2%) respectively. 3 pts (12.5% IC95% [2.7%; 32.4%]) were progression-free at 6 months indicating that the first endpoint was not reached. Median progression-free survival and overall survival were 1.9 months (95% CI: [1.7; 4.4]) and 12.0 months (95% CI: [5.8; -]), respectively. RNA sequencing of paired biopsies indicated that patients with activation immune response and Th17 differentiation had a better outcome. Increase in CD8 T cell density was significantly associated with improved PFS. No impact of trabectedin on macrophage infiltration was observed.

Conclusions: We report the first clinical study investigating the immunological activity of trabectedin in patients with advanced STS. Modulation of TME under trabectedin appear to be correlated with outcome.

Clinical trial identification: NCT02805725.

1925P Results of SOC-2082 phase II study using metronomic gemcitabine, doxorubicin, and docetaxel plus nivolumab as second/third-line therapy for advanced leiomyosarcoma

N.S. Chawla[1], N. Omelchenko[1], S. Makrievski[1], G. Leão De Melo[1], D. Brigham[1], A. Ahari[1], V.S. Chua Alcala[2], A. Moradhkani[1], D. Quon[1], S. Wong[1], S.P. Chawla[3], E.M. Gordon[1]

[1]Medical Oncology, Sarcoma Oncology Research Center, Santa Monica, CA, USA; [2]Clinical Research, Sarcoma Oncology Research Center, Santa Monica, CA, USA; [3]Oncology Department, Sarcoma Oncology Research Center, Santa Monica, CA, USA

Background: Metronomic dosing of gemcitabine, doxorubicin and docetaxel causes less severe side effects than standard chemotherapy for advanced leiomyosarcoma.

Methods: Primary objective: To assess progression-free survival (PFS); Secondary objectives: (1) To evaluate the best overall response, (2) PFS rate at 6 and 9 months, (3) Overall survival (OS) rate at 6, 12 months, and (4) Incidence of treatment-related adverse events (TRAEs). Inclusion criteria: Previously treated male and female subjects, ≥ 18 years of age, pathologically confirmed diagnosis of locally advanced, unresectable, or metastatic leiomyosarcoma, measurable disease by RECIST v1.1, and acceptable hematologic and organ functions. Exclusion Criteria: History of autoimmune disorder. Treatment schedule: Metronomic doses of gemcitabine (600 mg/m^2 max:1000 mg), doxorubicin (18 mg/m^2; max: 32 mg), docetaxel (25 mg/m^2; max:42 mg) on Day 1 and Day 8, and nivolumab (240 mg) on Day 1 only. Repeat treatment cycles may be given every three weeks if the toxicity grade is ≤1.

Results: Efficacy (n=17). This population completed at least one treatment cycle and had a follow-up CT or MRI scan at week 6. Confirmed best overall response = 4 PR, 11 SD, 2 PD. The overall response rate was 23.5%, disease control rate (CR+PR+SD) was 88.2%. The median PFS was 6.3 (95% CI: 2.837-7.363) months; 6-month PFS rate 53%. As of data cut-off date, the median OS was >14.6 months. Safety (n=18): This population had at least one dose of study drugs. Grade 3/4 TRAEs include thrombocytopenia (50%), neutropenia (44%), white blood cell count decreased (38.9%), anemia (22.2%), nausea (16.7%), anorexia (5.6%), diarrhea (5.6%), fatigue (5.6%), rectal bleeding (5.6%), transaminitis (5.6%). There were no unexpected adverse events reported. As of data cut-off date, the median OS was >14.3 months.

Conclusions: Taken together, the data suggest that nivolumab plus metronomic doses of gemcitabine, doxorubicin, and docetaxel (1) may have synergistic activity, and (2) is an effective second/third -line therapy for advanced leiomyosarcoma with manageable toxicity.

Clinical trial identification: NCT04535713.

Background: Pain relief and improvement of quality of life (QoL) is a critical objective in the therapy of patients (pts) with symptomatic advanced soft-tissue sarcoma (STS). The combination of trabectedin (T) and low-dose radiotherapy (RT) showed unprecedent activity in a previous study showing an overall response rate (ORR) of 60% by central review. This study further explores this combination, with the aim of analyzing the QoL improvement in sarcoma patients.

Methods: Pts with pretreated advanced/unresectable STS and symptomatic lesions were eligible to receive T 1,5mg/m^2 every 24h and RT 30Gy in 10 fractions (or 45 Gy in 25 fractions if the lesion was in limbs) on the symptomatic lesion/s, then T up to progression or unacceptable toxicity. Primary end-point was ORR by RECIST on the irradiated lesion. Secondary endpoints included QoL assessments (Brief pain inventory (BPI), EORTC QLQ C30), progression-free survival (PFS) and overall survival (OS). With H0 (10%), H1 (35%), (α 0.05 and β error 0.1), 27 evaluable pts were necessary.

Results: From June/2021 to March/2023, 33 pts were included (18M/15F, median age 53y (22-75), median previous lines 1 (0-4), ECOG 0/1 in 15/18 pts) and 26 pts were evaluable for response (efficacy population). Among the 26 evaluable pts, ORR in the irradiated lesions according to local assessment was 42.3% (1 CR, 10 PR, 13 SD, 2 PD). With a median FU of 7 months (mos) (95% CI 1-13), 18 pts have progressed, with a median PFS of 5.2 mos (95% CI 3.77-6.62) and 6m-PFS 44% (95% CI 23-64). During therapy, 17/33 (55%) of pts experienced a decrease of at least 2 points in the worst pain assessment of the BPI, with a median reduction of 2 points (range 0-8). 20/33 (64%) pts and 16/33 (52%) of pts reported an improvement of at least 1 point (on a scale 1-7) in their global health assessment and in their own QoL evaluation respectively. The main treatment-related G3-4 toxicities were neutropenia (18.2%), febrile neutropenia (9.1%), and ALT increased (9.1%). No toxic deaths have occurred.

Conclusions: Trabectedin plus palliative RT is a safe and active therapeutic regimen, able to induce clinical improvement in more than half of symptomatic sarcoma patients, and with a manageable toxicity profile.

Clinical trial identification: NCT05131386.

Background: Epithelioid hemangioendothelioma (EHE) is an ultrarare sarcoma whose natural history and treatment are not well defined. We report on the presentation and outcome of the nationwide exhaustive series of 267 patients with EHE in the NETSARC+ network since 2010 in France.

Methods: NETSARC (netsarc.org) is a network of 26 reference sarcoma centers with specialized multidisciplinary tumor boards (MDTB), funded by the French NCI (INCA). Since 2010, presentation to an MDTB and second pathological review are mandatory for sarcoma patients. Patients' characteristics are collected in a nationwide database regularly monitored. Exhaustivity in the collection of cases was reached since 2013. The characteristics of patients with EHE at diagnosis are presented as well as progression-free survival (PFS), overall survival (OS), and outcome under treatment.

Results: 267 patients with EHE were included in the NETSARC+ database since 2010. Median age in the series was 51 (range 10-90) years, 58% were women. Median tumor size was 37mm (4-220). 48%, 42%, and 10% were visceral, soft parts, or bone primaries. The most frequent sites were liver (28%), lung (13%). 40% were reported as metastatic at diagnosis. With a median follow-up of 20 months, OS and PFS rates at 24 months were 82% and 67%, with 10-years projected OS and PFS of 62% and 21% respectively. Male and M+ patients at diagnosis had a significantly worse OS, but not PFS. Local treatment was associated with a favorable survival in localized but not in advanced stage. For 23 patients receiving medical treatment, PFS and OS were 50.2% and 33.2% at 60 months were respectively.

Conclusions: EHE is a frequently metastatic sarcoma at diagnosis with a unique natural history. This study shows in an exhaustive nationwide series over 12 years that most patients progressed but are still alive at 10 years, both in localized and metastatic stages.

Background: Sclerosing Epithelioid Fibrosarcoma (SEF) and Low Grade Fibromyxoid Sarcoma (LGFMS) are ultrarare sarcomas (incidence 0.15 and $0.51/10^6$/year respectively, PMID: 33630918) with close/similar translocations whose natural history and optimal treatment are not well known. We report on the nationwide exhaustive series of 330 patients with SEF or LGFMS in NETSARC+ since 2010.

Methods: NETSARC (netsarc.org) is a network of 26 reference sarcoma centers with specialized multidisciplinary tumor boards (MDTB). Since 2010, pathological review is mandatory for sarcoma patients and patients' characteristics are collected in the NETSARC+ nationwide database. The characteristics of patients with SEF and LGFMS and their outcome are presented and compared.

Results: 35/73 (47.9%) and 125/257(48,8%) of patients with SEF and LGFMS were female. More primary visceral, bone and trunk primary sites were observed in SEF ($p<0.001$). 30.1% of SEF vs 4.3% of LGFMS were metastatic at diagnosis ($p<0.0001$). Median size of the primary tumor was 51mm (range 10-90). For LGFMS vs 80mm (20-320) for SEF ($p<0.001$). Median age of LGFMS was 12 years younger than that of SEF (43 [range 4-98] vs 55 [range 10-91], $p<0.001$). Neoadjuvant treatment was more often given to SEF (16.4% vs 8.6%, $p=0.05$). More patients with LGFMS were operated first in reference centers (51% vs 26%, $p<0.001$).The R0 rate was 41% in LGFMS vs 16% in SEF ($p<0.001$). Median PFS of SEF and LGFMS were 32 and 136 months ($p<0.0001$) respectively. The median OS was not reached. 50-months OS was 92.6% vs 81% fr SEF ($p=0.05$). Median survival was 77 months after first relapse, similar for SEF and LGFMS. In multivariate analysis for PFS, SEF histotype, size of the tumor, met at diagnosis were independently correlated to survival. In multivariate analysis for OS, age, size of the tumor, met at diagnosis, but not SEF, independently correlated to survival.

Conclusions: Although sharing close molecular alterations, SEF and LGFMS have a very different natural history, clinical presentation and outcome with a higher risk of metastatic relapse in SEF. Survival after relapse is longer than with other sarcomas, and similar for SEF and LGFMS.

Background: There is an unmet need for more effective and well tolerated systemic therapy for desmoid tumors (DT, aggressive fibromatosis). Gamma secretase inhibitors (GSIs) have shown antitumor activity against DT. AL102 is a potent, oral, selective GSI under investigation for treatment of DT.

Methods: RINGSIDE is a phase 2/3 study for pts with progressing DT. In the open-label phase 2 study, adults with progressing DT ($\geq$10% unidimensional growth $\leq$18 mo or DT-related pain requiring non-opioid medication) were randomized to 3 dose regimens: 1.2 mg QD (once daily), 2 mg intermittent BIW (2 days on 5 days off), or 4 mg intermittent BIW. RINGSIDE phase 3 is a double-blind, placebo-controlled study evaluating the chosen dose regimen from phase 2 (1.2 mg QD). We report updated efficacy and safety results from RINGSIDE phase 2.

Results: All 42 phase 2 pts enrolled as of Mar 2022. As of Jan 3, 2023, median time on study was 10.5 mo (range 0.8 – 14.7) and 30 pts (71%) were still on study, 10 (24%) of whom rolled over to an open-label extension. Mean age was 40 yrs, 74% were women, and 69% had received prior DT therapy. The best response in the evaluable population by blinded independent central review (BICR) was partial response in 6/12 pts (50%) for 1.2 mg QD, 3/13 pts (23%) for 4 mg BIW, and 5/11 pts (46%) for 2 mg BIW. Disease control rate was 100%, 91%, and 97%, respectively. Deeper, more rapid and maintained response was observed with 1.2 mg QD. Median volume change (BICR) from baseline was -52% for 1.2 mg QD, -10% for 4 mg BIW, and -15% for 2 mg BIW at Week 16 and -76%, -36%, and -52%, respectively, at Week 28, with similar patterns for T2 signal intensity (reduced tumor cellularity). The 5 most common Grade 1-2 treatment-emergent adverse events (TEAE) were diarrhea, nausea, fatigue, alopecia, and dry skin. Grade 3 drug-related TEAE were reported in 10/42 (24%) pts. There were no Grade 4-5 or serious drug-related TEAE and no new safety signals. Final phase 2 data will be reported.

Conclusions: AL102 was well tolerated with a safety profile consistent with other GSIs. Tumor response, volume reduction and T2 signal reduction were observed earlier with 1.2 mg QD, with deeper and maintained treatment responses. This dose was selected for RINGSIDE phase 3 (currently enrolling).

Clinical trial identification: NCT04871282.

Background: Combined chemotherapy and anti-PD-1/PD-L1 antibody has shown a synergistic antitumor effect in several types of cancers. This study evaluated the efficacy and safety of avelumab plus gemcitabine in patients with leiomyosarcoma (LMS) who failed first-line chemotherapy.

Methods: This is a phase II, multicenter, open-label, single-arm study (NCT03536780). Patients with unresectable, locally advanced, or metastatic LMS received avelumab 10 mg/kg on days 1 and 15 (up to 24 months), plus gemcitabine 1,000 mg/m^2 on days 1, 8, and 15 of a 28 day cycle until disease progression or intolerable toxicity. The primary endpoint was objective response rate (ORR). The secondary endpoints included duration of response (DOR), progression free-survival (PFS), overall survival (OS), and safety.

Results: Thirty-eight patients were enrolled between October 2018 and May 2022. Responses were observed in 7 out of 35 evaluable patients (ORR, 20%; 95% confidence interval [CI], 8–37%): 1 complete response and 6 partial responses. Disease control rate was 71.4%. Median DOR was 21.0 months (range, 7.6–32.7+ months). With median follow-up of 22.3 months, median PFS was 5.6 months (95% CI, 2.9–8.3 months) and median OS was 24.4 months (95% CI, 18.5–30.3 months). There was no grade 5 adverse event (AE). In safety analysis set (n=37), grade 3–4 AE occurred in 25 (67.6%) patients; neutropenia (n = 19, 51.4%) was the most common. Immune-mediated AEs occurred in 4 (10.8%) patients (hepatitis, n = 2; hypothyroidism, n = 2). There was no significant difference in ORR between PD-L1 -positive (SP263 tumor proportion score $\geq$1%) and PD-L1 -negative groups (25.0% [3/12] vs. 21.1% [4/19]; P=1.000).

Conclusions: Avelumab plus gemcitabine showed favorable toxicity profiles in patients with LMS. Although the primary endpoint for ORR (35% for P1) was not reached, the DOR, PFS, and OS observed are encouraging. Next-generation sequencing and immune phenotype analyses will be presented.

Clinical trial identification: NCT03536780.

1931P Ultra-rare sarcomas have worse survival compared to non-ultra-rare sarcomas: A national cancer registry study

M-J. Lee[1], R.C-J. Chiang[2], Y-W. Yang[2], B-Z. Zhuang[2], W-C. Lee[2], C-C. Li[3], T.W-W. Chen[4]

[1]Department of Oncology, National Taiwan University Hospital Hsin-Chu Branch, Hsinchu City, Taiwan; [2]Taiwan Cancer Registry Center and Institute of Epidemiology and Preventive Medicine, National Taiwan University, Taipei City, Taiwan; [3]Department of Medical Oncology, National Taiwan University Cancer Center, Taipei City, Taiwan; [4]Department of Oncology, National Taiwan University Hospital, Taipei City, Taiwan

Background: Our understanding of the clinical characteristics, survival rate, and prognostic factors of ultra-rare sarcomas (URSs) is limited due to the low incidence. The aim of this study is to understand the clinical differences among URS, non-URS (NURS), and other non-sarcoma solid tumors (NSST).

Methods: Clinical demographics and survival of solid tumor patients(pts) of Taiwan Cancer Registry diagnosed between January 1, 2002, and December 31, 2019, were retrieved. URS included sarcoma histologies with an incidence $<$ 1/1,000,000 persons. The annual percent change (APC) was computed to summarize the change in incidence for the recent years. Overall survival (OS) was estimated from the time of diagnosis to death or the last follow-up. The impact of gender, age, diagnosis period (2002-2010 vs. 2011-2019), and histology type on OS were estimated by Cox proportional hazard method.

Results: A total of 1,578,049 pts were included (URS [n=2,154], NURS [n=32,454], and NSST [n=1,543,441]). Among all sarcoma pts, 6.2% were URS; the top three most common histologies of URS were endometrial stromal sarcoma (n=292), pleomorphic liposarcoma (n=212), and epithelioid sarcoma (n=209). The APC of URS continued a surging trend from 2002 to 2019 (APC 3.81, $p < 0.05$) while the APC of NURS and NSST decelerated after 2010. URS pts are younger ($p < 0.001$) and more likely to be female ($p < 0.001$). In the multivariate analysis adjusted for gender, age, and diagnosis period, URS pts had worse OS than NURS pts (HR 1.70, 95% CI 1.59-1.81, $p < 0.001$). When all pts were divided into four age groups (0-18, 18-40, 40-70, and $>$70), the negative impact of URS on OS was most significant in adolescents and young adults (AYA, age 18-40) (HR:2.23; 95% CI, 1.94-2.55; $p < 0.001$). Unlike NSST, where the OS improved in the past decade (HR:0.84, 95% CI, 0.83-0.84, $p < 0.001$), OS of URS and NURS both worsened (URS: HR:1.14, 95% CI, 1.01-1.30; $p < 0.05$; NURS: HR:1.05, 95% CI, 1.02-1.09, $p < 0.005$) in the period 2011 to 2019 compared to 2002 to 2010.

Conclusions: Our findings showed that the incidence of URS is increasing but the OS worsened. Among different age groups, the detrimental effect of URS was most prominent in the AYA pts. Awareness of URS and precision medicine-based therapies for URS are desperately needed.

Background: Local recurrence after radical surgery for retroperitoneal soft tissue sarcoma (RPS) occurs in 41—50% of patients and constitutes a major cause of death. CEB-01 is a biocompatible and biodegradable membrane implant with PLGA nanofibers entangled with SN-38 for a steady delivery. When placed in the surgical bed after RPS resection, it may increase local control rates and survival.

Methods: This is a multicentre, first in human trial (EudraCT: 2018-001026-25) following a 3+3 dose escalation design, and an expansion cohort at the recommended phase II dose (RP2D). Efficacy is evaluated using RECIST 1.1. Primary objective is RP2D. Safety, pharmacokinetics (PK) are secondary objectives.

Results: At present, 10 patients (pts) have been enrolled: 3 female / 7 male; mean age 62.1 years (40 - 77) with dedifferentiated liposarcoma (LPS) (5 cases), well differentiated LPS (3), LPS (1), and leiomyosarcoma (1). 7 pts had unresected primary lesions, and 3 were locoregional relapses. Post-surgery margins were R0 (7), R1 (2) and unknown (1). CEB-01 was implanted in 3 dose-increasing cohorts: 1st) 2 membranes of 180 cm^2 each, 25 mcg/cm^2, total 9 mg; 2nd) 2 x 180 cm^2, 50 mcg/cm^2, total 18 mg and 3rd) 4 x 180 cm^2, 50 mcg/cm^2, total 36 mg. No dose limiting toxicity (DLT) has been observed in any of the cohorts. The expansion phase is ongoing. Adverse events are similar to those post-surgery of RPS. Death (3 pts), after abdominal infection, bleeding (both unrelated) or retroperitoneal haemorrhage (related). After a median follow-up of 16.3 months (2.1 to 24.9), 2 (with the lower dose) local recurrences in the area of the implant have been observed after 5.5- and 8.6-months post-surgery. 2 pts completed 24 months of follow-up. In 5 ongoing pts no recurrences have been observed after 2.1 to 17.8 months of follow-up (median 16.2 months). SN-38's PK shows dose linearity, half-life ranging from 287 - 372 hours, Cmax: 0.76 - 3.58 ng/ml and AUC 0-t: 118 - 321 ng/ml*h. Blood levels of SN-38 were detectable 28 days after surgery.

Conclusions: With CEB-01 no DLT has been observed. Local recurrence occurred in 2 out of 10 pts at 5.5- and 8.6-months post-surgery. CEB-01 provides a local steady and prolonged release of SN-38, with a much lower Cmax than when SN-38 is administered as irinotecan.

Clinical trial identification: NCT04619056.

1933P Perioperative chemotherapy could reduce the risk of recurrence in resected leiomyosarcoma of the vena cava (LMS-VC): A retrospective bi-centric series on 41 patients

T. Bertrand[1], M. Faron[2], O. Mercier[3], C. Ngo[4], C. Le Pechoux[5], A. Levy[6], J. Issard[3], C. Henon[7], C. Honoré[8], E. Fadel[3], A. Le Cesne[9]

[1]Surgical Oncology, Institut Gustave Roussy, Villejuif, France; [2]Surgical Oncology/Biostatistics & epidemiology INSERM 1018, Institut Gustave Roussy, Villejuif, France; [3]Thoracic and Vascular Surgery and Heart—Lung Transplantation, Centre Chirurgical Marie Lannelongue, Le Plessis-Robinson, France; [4]Biology and Pathology, Institut Gustave Roussy, Villejuif, France; [5]Radiation Oncology Department, Institut Gustave Roussy, Villejuif, France; [6]Radiation Oncology Department, Gustave Roussy - Cancer Campus, Villejuif, France; [7]Medical Oncology Department, Institut Gustave Roussy, Villejuif, France; [8]Surgical Oncology, Gustave Roussy - Cancer Campus, Villejuif, France; [9]Medical Oncology Department, Gustave Roussy - Cancer Campus, Villejuif, France

Background: Leiomyosarcoma of the vena cava (LMS-VC) is a rare sarcoma with poor oncological outcome. The role of perioperative chemotherapy (CT) and/or radiotherapy (RT) remains unclear.

Methods: All consecutives cases of pathologically confirmed LMS-VC resected between 2003 and 2022 in two tertiary referral centers were retrospectively collected. Perioperative treatments were discussed in a multidisciplinary tumor board for large tumors with/without organ involvement. CT were based on adriamycin regimens. The surgical strategy aimed to obtain a complete en-bloc resection of the LMS-VC. We evaluated disease-free survival (DFS) and overall survival (OS) using Kaplan-Meier estimates with a Cox model.

Results: Forty-one patients were identified, with a median age of 57.5 years. LMS-VC median size was 9.5 cm (interquartile range [6.8-12.5] cm) with 67.5% of complete obstruction (no outflow at CT scan). The Kieffer levels (K) were K1, K2 and K3 in 9(22%), 23(56%) and 9(22%) patients respectively. At surgery, 55% had a nephrectomy and 20% a minor hepatic resection. Vena cava was replaced by prosthetic graft in 40% of patients and 32.5% had no reconstruction. Severe complications (Clavien-Dindo$\geq$3) occurred in 12(30%) cases. No postoperative mortality was reported. R0 was obtained

in 29(71%) patients, R1 in 11(27%) and one patient had a R2 resection. FNCLCC grades were 1, 2 and 3 in 5(12%), 26(63%) and 10(24%) cases respectively. Twelve (30%) patients received CT with 10 and 2 in pre and postoperative setting respectively, only in FNCLCC grade 2 or 3. Five (12%) patients received adjuvant RT. After a median follow-up of 70 months, median DFS was 22 months and median OS was 55 months. Among the 27 recurrences, 24 were distant. The multivariate analysis identified FNCLCC grade (Hazard Ratio (HR), 20; 95% confidence interval [CI], 2.29 to 175 for grade 2 vs 1 and 65.6; 95% CI, 6.30 to 683 for grade 3 vs 1; $p<0.001$) and pre and/or postoperative chemotherapy (HR, 0.38; 95% CI, 0.16 to 0.92; $p=0.026$) as main prognostic factors.

Conclusions: LMS-VCs have high risk of distant recurrence, evaluated as 58% in this cohort. Pre and/or postoperative chemotherapy and FNCLCC tumor grade were associated with improved DFS.

1934P Pharmacokinetics of unesbulin in a phase Ib study of patients with advanced leiomyosarcoma

B.A. Van Tine[1], M.A. Ingham[2], S. Attia[3], C.F. Meyer[4], J.D. Baird[5], D. D'Silva[5], K. O'Keefe[5], R. Kong[6], P. Maliakal[6], L. Gao[6], G.K. Schwartz[7]

[1]Medical Oncology, Washington University in St Louis, St. Louis, MO, USA; [2]Hematology and Oncology, Columbia University Medical Center, New York, NY, USA; [3]Medical Oncology, Mayo Clinic, Jacksonville, FL, USA; [4]Medical Oncology, Johns Hopkins Sidney Kimmel Comprehensive Cancer Center, Baltimore, MD, USA; [5]Commercial Development, PTC Therapeutics, Inc., South Plainfield, NJ, USA; [6]Clinical Development, PTC Therapeutics, Inc., South Plainfield, NJ, USA; [7]Medical Oncology, Columbia University Medical Center, New York, NY, USA

Background: Patients with metastatic or unresectable leiomyosarcoma (LMS) have a poor prognosis and a high risk of relapse with limited therapeutic options. In a phase 1b dose escalation study, unesbulin, an oral microtubule polymerization inhibitor, plus dacarbazine (DTIC), showed promising efficacy and tolerability in patients with advanced LMS. Here we report the results of drug-drug interactions (DDI) and the impact of food on the PK of unesbulin (NCT03761095).

Methods: This analysis evaluated the PK of unesbulin 300 mg in patients with advanced LMS. The DDI was investigated by staggering or coadministering unesbulin with DTIC. For the food effect assessment (FEA), patients received DTIC 1000 mg/m^2 on Day 1 and unesbulin 300 mg twice weekly starting Day 2 of every cycle (21 day/cycle schedule). Unesbulin was administered under fasted conditions on Day 2 and under fed conditions (low-fat diet) on Day 5. Blood samples for the FEA were collected at predose and up to 72 hours postdose.

Results: When DTIC was coadministered with unesbulin, the C_{max}, and $AUC_{0\text{-}24h}$ of 5-aminoimidazole-4-carboxamide (an inactive metabolite of DTIC) were reduced by 77.4% and 61.7%, respectively. No apparent difference was observed in mean unesbulin exposure when administered with or without food, but the inter-subject variability (CV%) reduced significantly from 42% - 59% under fasted condition to 19% - 29% with a low-fat diet.

Table: 1934P

	T_{max}* (h)	$T_{1/2}$† (h)	C_{max}† (ng/mL)	$AUC_{0\text{-}48}$† (h*ng/mL)	$AUC_{0\text{-}inf}$† (h*ng/mL)
Fed	4.0 (3.0-6.0)	13 (18.0%)	1240 (28.6%)	18400 (19.0%)	20000 (21.5%)
Fasted	4.0 (3.0-6.0)	15 (45.0%)	1090 (42.3%)	21800 (52.8%)	22400 (59.1%)
Ratio (Fed/Fasted)			1.186	0.939	1.009

*Reported as median (minimum-maximum); †Reported as mean (CV%).

Conclusions: The DDI evaluation showed that CYP1A2-mediated inhibition of DTIC metabolism can be mitigated by staggering unesbulin and DTIC doses by one day. Results showed no clinically meaningful difference in mean unesbulin exposures when administered with or without food. However, administering unesbulin with a low-fat diet is recommended as it reduces the inter-subject variability. Unesbulin is being evaluated in an ongoing randomized, placebo-controlled, phase 2/3 trial, SUNRISELMS (NCT05269355).

1935P Exploration of tertiary lymphatic structure in soft tissue sarcoma for the prognostic and immunotherapy response

W. Xiang-Xu, R. Jing-Yi, W. Xiao-Wen, Z. Hong-Mei

[1]Department of Clinical Oncology, Xijing Hospital, Fourth Military Medical University, Xi'an, China

Background: The tertiary lymphoid structure (TLS) is an important part of the tumor microenvironment. It generates circulating immune cells and inhibits tumor growth and progression, which is closely related to the efficacy of immunotherapy.

Methods: This study collected the transcriptome information and clinical data of 10327 tumor samples and 730 normal samples of 33 cancer types from the TCGA database. Based on previous literature, three sets of TLS-related gene sets were selected and merged into the total TLS gene set. The TLS enrichment scores were calculated by the GSVA algorithm. Further, utilize TIMER 2.0 and CIBERSORTNE algorithms to analyze the distribution of tumor-infiltrating immune cells. Based on the enrichment score of TLS, sarcoma patients were divided into three TLS subtypes via the "hclust" R package. TLS-related prognostic core genes were screened via Lasso Cox

and multivariate Cox regression and further used to establish the TLS-related prognostic signature. The public immunotherapy cohorts and our center immunotherapy patients were used to validate the efficacy of immunotherapy.

Results: The TLS gene set enrichment score established in this study is significantly positively correlated with immune cell infiltration such as T cells, B cells, and DC cells, which can reflect the TLS status in tumor tissue. Kaplan Meier survival analysis showed that patients with high TLS had better overall survival and progression-free survival compared to patients with low TLS. Through Lasso Cox and multivariate Cox regression, two TLS-related prognostic core genes (TNFRSF14 and DUSP9) were ultimately screened, and a TLS-related prognostic signature was established. Immunohistochemistry showed that the expression of TNFRSF14 was increased and the expression of DUSP9 was reduced in patients with soft tissue sarcoma who achieved optimal immunotherapy.

Conclusions: The TLS-Total gene set, TLS-related prognostic signature, TNFRSF14, and DUSP9 selected in this study can predict the prognosis of patients with soft tissue sarcoma. TNFRSF14 and DUSP9 are associated with immune cell infiltration, which can indicate the efficacy of immunotherapy and may become new predictive markers of immunotherapy efficacy.

Background: Desmoplastic small round cell tumor (DSRCT) is an ultra-rare soft-tissue sarcoma characterized by an *EWSR1::WT1* gene fusion that affects predominantly male adolescents and young adults. Despite intensive multi-modality treatment outcomes remain dismal, with only 25% of patients being alive after five years. Beyond conventional therapies, novel, molecular mechanism-aware therapies are urgently needed.

Methods: Patients with advanced DSRCT underwent multilayered molecular profiling as part of NCT/DKFZ/DKTK MASTER (Molecularly Aided Stratification for Tumor Eradication Research), a prospective, multicenter observational study that applies whole-genome/exome, transcriptome, methylome, and — more recently — mass spectrometry-based (phospho-)proteome analysis in young adults with advanced malignancies and patients with rare cancers to inform clinical decision-making and the design of molecularly stratified clinical trials.

Results: Between 2013 and 2022, 29 patients with DSRCT were analyzed with a median follow-up of 17 months (range, 0—48). The median age at the time of molecular analysis was 30 years (range, 18—56). The median time between diagnosis and molecular analysis was 12 months (range, 1—216). The median survival and the 4-year survival rate from registration were 2.4 years (95% confidence interval [CI], 1.4—3 years) and 7.4% (95% CI, 1.2—45.2%), respectively. In 8 of 9 samples with available proteomics data, we observed pronounced activation of ERBB (also called HER) signaling and high *ERBB2* mRNA expression levels, providing a rationale for personalized therapy with ERBB2-specific antibody-drug conjugates. In addition, selected somatostatin receptor family members, i.e., SSTR3 and 5, were highly expressed in all patients with available transcriptome data, providing the basis for treatment with pasireotide, a novel multireceptor-targeted somatostatin receptor ligand, within an academic clinical trial, which is currently being prepared.

Conclusions: We describe the molecular profiles of patients with DSRCT enrolled in MASTER and demonstrate the utility of broad molecular profiling for the clinical management of this disease, including the application of targeted treatment strategies.

1937P KM-subtraction meta-analysis of randomized controlled trials of adjuvant chemotherapy for localized resectable soft-tissue sarcoma

Q.J. Low[1], M. Lee[2], W.G. Ru Andrew[3], K.Y. Fong[3], Z.X. Choo[4], A.D. Jeyasekharan[5]

[1]National University Hospital, 5 Lower Kent Ridge Road Singapore 119074., NUH - National University Hospital (S) Pte. Ltd., Singapore; [2]Medical Oncology, NCIS - National University Cancer Institute Singapore, Singapore; [3]Hematology Oncology, NUH - National University Hospital (S) Pte. Ltd., Singapore; [4]Internal Medicine, NUH - National University Hospital (S) Pte. Ltd., Singapore; [5]Haematology-Oncology, NCIS - National University Cancer Institute Singapore, Singapore

Background: The role of adjuvant chemotherapy for patients with a resected extremity soft tissue sarcoma (STS) is controversial. Prior individual patient data meta-analyses are limited by omission of certain randomized controlled trials. The objective of this systematic review was to reassess the efficacy of adjuvant chemotherapy in resected STS, harnessing the ability of a new method termed Kaplan Meier (KM) subtraction to obtain patient level information.

Methods: A comprehensive literature search was performed to identify RCTs of adjuvant chemotherapy for adult patients diagnosed with localized resectable soft-tissue sarcoma. We searched PubMed, Web of Science, Cochrane Controlled Trials Register, UKCCCR Register of Cancer Trials, Physicians Data Query, EMBASE, MEDLINE and CancerLit (until December 2022). Data on the following endpoints were evaluated: disease free survival (DFS) and overall survival (OS). Data were summarized as hazard ratios (HR) with 95% confidence intervals (CI). Two reviewers independently assessed eligibility and quality of the studies using a modified version of the Detsky Quality Scale. The outcome measures were disease free survival (DFS) and overall survival (OS) calculated through the fixed effect or random effect model. We applied KM subtraction in R to obtain individual patient level data from the trials for subsequent metanalysis.

Results: A total of 24 trials representing 5936 patients were be included in the final analysis. The disease-free survival hazard ratio was 1.76 (95% CI 1.38-2.24) in favour of adjuvant chemotherapy. The overall survival hazard ratio was 1.30 (95% CI 1.11-1.53) favouring adjuvant chemotherapy. For adjuvant chemotherapy with doxorubicin alone, the hazard ratio of DFS and OS were 1.78 (95% CI 1.10-2.88) and 1.47 (95% 1.01-2.13).

Conclusions: This is the largest individual patient meta-analysis to-date of adjuvant doxorubicin and ifosfamide based chemotherapy in localized resectable soft-tissue sarcoma, and confirms a survival benefit (particularly for single-agent doxorubicin) with respect to disease free survival and overall survival.

1938P Assessment of clinical benefit of cancer drugs recommended in National Comprehensive Cancer Network (NCCN) guidelines for advanced soft tissue sarcomas (STS) and bone sarcomas (BS)

M. Aguado Sorolla[1], R. Teres Lleida[2], A. Piedra[1], A.R. Cardozo[1], F. Bosma[3], P. Cerda Serda[1], A. Lopez Pousa[1], A. Tibau[1], A. Sebio Garcia[1]

[1]Medical Oncology Department, Hospital de la Santa Creu i Sant Pau, Barcelona, Spain; [2]Department Medical Oncology, Hospital de la Santa Creu i Sant Pau - Consultes Externes, Barcelona, Spain; [3]Oncology Department, Hospital de la Santa Creu i Sant Pau, Barcelona, Spain

Background: Magnitude of clinical benefit from drugs used in tumours must be evaluated using validated and reproducible tools. European Society for Medical Oncology-Magnitude of Clinical Benefit Scale version 1.1 (ESMO-MCBS) and American Society for Medical Oncology (ASCO) Value Framework (ASCO-VF) are the most important. Here, we evaluate characteristics and outcomes of clinical trials supporting drugs used in STS and BS, and their association with ESMO-MCBS and ASCO-VF.

Methods: We reviewed publications between January 1988 and December 2022 that support the recommendations of NCCN guidelines version 1.2023 for STS and 3.2023 for BS (gastrointestinal stromal tumours were excluded). We collected data regarding trial characteristics, efficacy, toxicity and quality of life (QoL). ESMO-MCBS and ASCO-VF were applied. Substantial clinical benefit was defined as a grade 4 or 5 (in a scale from 1 to 5) for ESMO-MCBS and a $\geq$45 for ASCO-VF.

Results: We identified 119 studies (71 for STS and 48 for BS) that support the use of 49 drugs or combinations. ESMO-MCBS could be applied in 58 trials (48.7%). Of them, 37 (64%) were single arm and 21 (36%) randomized clinical trials (RCT; 13 phase III and 8 phase II). ASCO-VF could only be applied in 10 of the previously described (6 phase III and 4 phase II RCT). QoL was reported in 17.2% (10/58), all published beyond 2011. Among these, only 1 (10%) showed improvement in QoL. Only 33.3% of RCT (7/21) demonstrated improvement in overall survival. Ten (17.2%) trials, all of them RCT, met the ESMO-MCBS substantial benefit threshold (7 involving STS and 3 BS). Only 4 of these met the ASCO-VF criteria (all for STS). Spearman's correlation coefficient between scales was 0.65.

Conclusions: Less than half of the studies supporting the NCCN recommendations for the prescription of drugs in advanced sarcomas can be evaluated using validated scales to assess the magnitude of their clinical benefit. Substantial clinical benefit was only achieved in a minority of those. QoL analysis should be incorporated in further studies to better evaluate their actual clinical benefit. Correlation among ESMO-MCBS and ASCO-VF was noteworthy.

Background: Shasqi is a clinical stage biotech that uses click chemistry, a Nobel Prize winning technology, to selectively activate cancer treatments at the tumor. The Click Activated Protodrugs Against Cancer (CAPAC®) platform comprises of 1) tumor targeting agents, which carry an activator, and 2) attenuated cancer drugs, which are selectively activated at the tumor by the targeting agent through click chemistry, maximizing therapeutic index and minimizing toxicities. We have demonstrated clinical proof of concept with SQ3370, which uses an intratumorally injected biopolymer (bp) with a doxorubicin (Dox) protodrug injected systemically (NCT04106492).

Methods: Patients (pts) received 10/20 mL bp and protodrug IV QDx5. Key eligibility: locally advanced or metastatic solid tumors, $\leq$ 300 mg/m^2 prior Dox exposure and no limit to prior systemic therapies. Objectives: safety, determining recommended phase 2 dose (RP2D), pharmacokinetics (PK), and immune profiling.

Results: 38 pts were treated: 30 with 10 mL bp and 8 with 20 mL bp at 9 escalating protodrug dose levels up to 15x of clinical Dox dose/cycle. Most pts had sarcoma (63% at 10 mL; 88% at 20 mL) and metastases (83% at 10 mL; 63% at 20 mL). 93% (10 mL) and 88% (20 mL) pts received prior systemic therapies including prior Dox in 40% (10 mL) and 88% (20 mL) pts. Median age was 62 (26-92; 10 mL) and 58 (23-84; 20 mL). Frequent AEs in bp group: 10 mL - nausea (17; 57%) and fatigue (15; 50%); 20 mL - anemia (4; 50%) and nausea (4; 50%). Best response was SD in 58% (10 mL) and 71% (20 mL). Disease control rate (CR+ PR+ SD $\geq$ 60 days) was 58% (10 mL) and 71% (20 mL). MTD was not reached in either bp cohort; myelosuppression was not dose-limiting. Based on systemic Dox exposure, 12x was selected as the RP2D. PK and immune profiling support safety findings and will be presented. SQ3370 induced a shift towards a T-cell permissive tumor immune microenvironment.

Conclusions: SQ3370 is the first clinical click chemistry-based cancer therapy. The results show the following: the biopolymer activates protodrug in patients; that the Dox protodrug is not a vesicant; PK data demonstrates activation of protodrug; reaction achieves liberation of Dox; click chemistry favorably alters PK and safety of the payload.

Clinical trial identification: NCT04106492.

Background: Synovial sarcoma (SySa) is a rare soft-tissue malignancy occurring predominantly in the lower extremities of young adults. It is driven by a unique SS18::SSX fusion gene. In locally advanced/metastatic SySa, treatment options are limited, and it is of high interest to identify targetable molecular alterations.

Methods: Within the MASTER precision oncology program of DKFZ, NCT Heidelberg/Dresden, and DKTK (ClinicalTrials.gov Identifier: NCT05852522), patients with advanced SySa were analyzed by whole-genome/exome (WGS/WES) and RNA sequencing to inform the care of individual patients and provide starting points for interventional clinical trials in adolescents and young adults. Median age at the time of molecular analysis was 37 years (range, 22—65 years), and 45% of patients were female. Median time between diagnosis and molecular analysis was 29 months (range, 2—288 months). Median follow-up for survival was 89 months.

Results: Between 2013 and 2022, 69 patients were studied. Median survival and 3-year survival rate after molecular analysis were 14 months (95% confidence interval [CI], 12—19 months) and 8% (95% CI, 3—22%), respectively. Molecular profiling included WES (n=33) or WGS (n=32) as well as RNA sequencing (n=56). Beyond SS18::SSX fusions, the most common somatic and germline single-nucleotide variants and small insertions/deletions affected TTN (17%), NIPBL (9%), CTNNB1 (8%), ATM, TAF1L, TP53, MADD, and COL7A1 (each 6%). Based on the presence of a significant single-base substitution signature 3 (SBS3), two patient groups could be distinguished (group 1, SBS3 present, 28 patients; group 2, SBS3 absent, 37 patients). The most frequent genomic gains involved chromosomes 8 and 12; the most frequent deletions involved chromosomes 3 and 11. Comparative analysis of SSTR1, SSTR2, SSTR3, SSTR4, and SSTR5 expression between the SySa cases (n=56) and the entire MASTER cohort (n=3,023) revealed significant differences for SSTR2, SSTR4, and SSTR5, with top 10% expression in 13, 31, and 22 patients, respectively.

Conclusions: Our study demonstrates the utility of broad molecular profiling in patients with advanced SySa for identifying subgroups of patients, whose molecular profiles may inform the design of future clinical trials.

1941P Preliminary efficacy and safety of SHR-2554 in advanced epithelioid sarcoma: A phase II trial

H. Hu[1], Y. Zhou[1], X. Ding[1], Y. Zhang[1], J. Liang[1], H. Xu[1], L. Tian[2], C. Zhao[2]

[1]Oncology Department, Shanghai Sixth People's Hospital, Jiaotong University, Shanghai, China; [2]Research&Development, Jiangsu Hengrui Pharmaceuticals Co., Ltd., Shanghai, China

Background: Epithelioid sarcoma (ES) is a rare and aggressive subtype of soft-tissue sarcoma. The loss of INI1 expression which leads to oncogenic dependence on the transcriptional repressor EZH2 has been observed in over 90% of ES. There remains a need for effective and safe treatment options for patients (pts) with advanced ES. We investigated the efficacy and safety of SHR-2554, an oral selective EZH2 inhibitor, in pts with refractory ES.

Methods: Pts were eligible if they were aged 12 years or older with histologically confirmed advanced or metastatic ES. Other key inclusion criteria: the presence of measurable disease according to RECIST 1.1; an ECOG performance status of 0-1; progressive disease after at least one line of adriamycin containing chemotherapy; documented loss of SMARCB1 (INI1) alterations or the upregulated mRNA level of EZH2. Pts received SHR2554 (350 mg, bid, po) until disease progression or unacceptable toxicity. The primary endpoint was progression-free rate at 12 weeks. A Simon two-stage design was applied. Success at stage 1, which would enroll 9 pts, required ≥3 pts remaining progression-free at 12 weeks.

Results: Between Jul 2021 and Dec 2022, a total of 9 pts were enrolled and received SHR-2554. The median age was 44 years and 33.3% were males. 5 (55.6%) pts had received previous immunotherapy targeting PD-1/L1 and 4 (44.4%) pts had received previous antiangiogenesis therapy. The median line of previous treatment was 2 (range 1-4). Loss of INI1 was confirmed in 6 (66.7%) pts. 5 (55.6%) pts remained progression-free at 12 weeks, which allowing to move on to stage 2. Based on investigator assessments, one (11.1%) of 9 pts had a confirmed partial response at data cutoff. The median progression-free survival was 3.8 months (95% CI: 1.2—NA). Adverse events (AEs) were generally mild. The most common treatment-related AEs were anaemia (3, 33.3%). No serious treatment-related AEs were observed.

Conclusions: SHR-2554 showed promising efficacy and an acceptable safety profile in pts with refractory ES, warranting further investigation.

Clinical trial identification: ChiCTR2100046099.

1942P Non-metastatic malignant phyllodes tumors of the breast (B-MPT): A retrospective analysis from a referral center

C. Valenza[1], T.M. De Pas[2], G. Castellano[1], C. Santoro[1], A. Corona[3], G. Chiappini[3], G. Vivanet[1], D. Trapani[1], F. Conforti[2], S. Coppola[3], D. Mattar[4], P. Veronesi[5], E. Pennacchioli[3], G. Curigliano[1]

[1]Department of Oncology and Hemato-Oncology, University of Milan, European Institute of Oncology IRCCS, Division of New Drugs and Early Drug Development for Innovative Therapies, Milan, Italy; [2]Oncology Unit, Humanitas Gavazzeni, Oncology Unit, Bergamo, Italy; [3]Division of Melanoma, Soft Tissue Sarcomas and Rare Tumors, European Institute of Oncology IRCCS, Milan, Italy; [4]Division of Breast Surgery, European Institute of Oncology IRCCS, Milan, Italy; [5]Department of Oncology and Hemato-Oncology, University of Milan, European Institute of Oncology IRCCS, Division of Breast Surgery, Milan, Italy

Background: B-MPT accounts for <1% of breast neoplasms. The standard treatment for non-metastatic disease consists of wide local excision. Type of excision and adjuvant treatments are still matter of debate. Because of its rarity, only few case series with less than 100 B-MPT patients (pts) are available.

Methods: We conducted a retrospective single-centre observational study to describe outcomes and possible prognostic factors of pts with B-MPT. Data of consecutive patients aged ^{3}18 years old, with a histologically confirmed diagnosis of non-metastatic B-MPT, who underwent surgery from January 2000 to December 2021, were collected. The primary endpoint was recurrence-free survival (RFS). Survival was calculated using Kaplan—Meier method. Multivariable analysis was performed with Cox proportional hazards model (significance at p-value<0.05).

Results: 131 pts were included. Patient characteristics are reported in table. All patients received a surgery, 5 adjuvant anthracycline-based chemotherapy and 15 radiation therapy. After a median follow-up of 6.8 years, 36 (28%) pts experienced a disease recurrence: 19 (15%) a distant and 23 (18%) a loco-regional relapse. The median RFS, distant RFS (DRFS) and local RFS (LRFS) were not reached. The 5-year RFS, DRFS and LRFS rates were of 72%, 85% and 82%. At univariate analysis DRFS significantly correlated with the presence of at least one negative pathological prognostic factor (i.e., Size >5 cm, Multifocal disease or Heterologous differentiation [SMH]) (p=.03). If adjusted for type of breast surgery, SMH was associated also with

LRFS (HR 3.3; 95%CI, 1.4-7.8; p=.008). The type of surgery was not prognostic for RFS, DRFS and LRFS.

Table: 1942P Patient characteristics

	N=131
Age at diagnosis, mean (DS)	46.7 (12.7)
Negative pathological prognostic factors	
Size >5 cm - %	43%
Multifocal disease - %	11%
Heterologous differentiation - %	20%
At least one negative prognostic factor - %	62%
Surgery strategy	
Upfront wide local excision with attention to margins - %	45%
Re-excision after previous inadequate resection - %	46%
Inadequate resection without re-excision - %	9%
Type of last breast surgery	
Excisional biopsy (no attempt at margins) - %	9%
Lumpectomy (wide local excision with attention to margins) - %	34%
Mastectomy - %	57%
pR1 - %	14%
Adjuvant chemotherapy - %	4%
Adjuvant radiotherapy - %	11%

Conclusions: Natural history of B-MPT is burdened by local and distant recurrences. Pathological features more than the type of wide local excision seem to represent the most significant prognostic factor for recurrences.

1943P Efficacy and safety of eribulin plus anlotinib and camrelizumab in advanced or metastatic retroperitoneal liposarcoma (RLPS) or leiomyosarcoma (RLMS): A single-center retrospective cohort study

J. Wu, C. Hao, W. Jia, A. Lv, H. Qiu, C. Li, B. Liu, Q. Liu, D. Liu, Z. Wang, R. Sun, X. Wang, G. Xue, X. Tian

Hepato-Pancreato-Biliary Surgery Department, Peking University Cancer Hospital & Institute, Beijing, China

Background: RLPS and RLMS are not sensitive to conventional chemotherapy. We evaluated the efficacy and safety of eribulin plus anlotinib and camrelizumab for RLMS and RLPS.

Methods: Patients (pts) with advanced/metastatic RLPS or RLMS treated with eribulin plus anlotinib and camrelizumab (Q3W) at Peking University Cancer Hospital Sarcoma Center were included in this retrospective analysis. Response (RECIST v1.1) was evaluated every 3 treatment cycles. Adverse event severity was graded per CTCAE v5.0.

Results: From December 17, 2020 to November 18, 2022, 60 pts (27 male; 33 female) were included. 22 pts had RLMS; RLPS subtypes were well-differentiated (n=9), de-differentiated (n=24), and myxoid (MLPS; n=5). Eribulin was given to 21 pts (35%) at 0.7—1.1 mg/m^2, and 39 (65%) at 1.1—1.4 mg/m^2.5 pts (RLMS, n=2; RLPS, n=3) were excluded from efficacy analyses due to drug intolerance and the COVID-19 pandemic. After a median of 5 cycles (range, 2—21), a partial response was observed in 15 pts (27.3%), stable disease in 27 (49.1%) and progressive disease in 13 (23.6%). The objective response rate (ORR) and disease control rate (DCR) were 27.3% and 76.4%, respectively. ORR and DCR in pts with RLMS were 42.1% and 84.2%, respectively; in pts with RLPS, they were 19.4% and 72.2%, respectively. After a median follow up of 11.3 months (mo), 10 pts had complete resection, 2 of whom had pathological complete response (1 with RLMS and 1 with MLPS); 3 other pts had locoregional recurrence after surgery. Median progression-free survival (mPFS) for the remaining 45 pts was 5.8 mo; mPFS for RLPS and RLMS subgroups were 5.5 and 6.2 mo, respectively. Any-grade treatment-related AEs (TRAEs) occurred in 51/60 pts (85.0%), with 22 (36.7%) experiencing grade ≥3 TRAEs. The most common TRAEs were neutropenia (58.3%), proteinuria (23.3%) and anorexia (23.3%). Due to AEs, 15 pts (25.0%) discontinued treatment and 6 (16.7%) reduced their eribulin dose.

Conclusions: Eribulin plus anlotinib and camrelizumab demonstrated clinically meaningful efficacy and a manageable safety profile in pts with advanced or metastatic RLPS or RLMS, especially in those with RLMS.

1944P MAGE-A4 and NY-ESO-1 expression analysed in a synovial sarcoma tissue micro-array

L. De Cock[1], A. Wozniak[1], U. Vanleeuw[1], K. Wyns[1], C-J. Lee[1], R. Sciot[2], P. Schoeffski[3]

[1]Department of General Medical Oncology, KU Leuven - Laboratory of Experimental Oncology, Leuven, Belgium; [2]Department of Pathology, UZ Leuven - University Hospitals Leuven - Campus Gasthuisberg, Leuven, Belgium; [3]Department of General Medical Oncology, Leuven Cancer Institute, University Hospitals Leuven, Leven, Belgium

Background: T-cell based therapies are currently explored in clinical trials (NCT04044768, NCT01343043) in patients with synovial sarcoma (SySa). These therapies are targeting cancer testis antigens like Melanoma-Associated Antigen 4 (MAGE-A4) or New York Esophageal Squamous Cell Carcinoma-1 (NY-ESO-1). We explored the molecular epidemiology of these targets using a tissue micro-array (TMA) from clinical SySa samples.

Methods: We created a TMA consisting of 323 cores from 108 clinical samples (≥2 cores/sample) from archival, paraffin-embedded material originating from 91 individual donors. A sarcoma reference pathologist verified the diagnosis of SySa in the donor sample. Most samples (62%) were collected from the primary tumour, 22% and 16% originated from a metastasis or local recurrence. Slides were stained with MAGE-A4 antibody (#82491, dilution 1:100, Cell Signaling) and NY-ESO-1 antibody (clone E978, dilution 1:200, Sigma), during an overnight incubation. Normal human testis tissue was used as a positive control. Expression of each core was scored as an H-score, defined as: (% stained cells at 0 intensity) × 0 + (% stained cells at 1+ intensity) × 1 + (% stained cells at 2+ intensity) × 2 + (% stained cells at 3+ intensity) × 3. The average of the H-scores from the cores corresponding to the same tumour sample was used for subsequent analyses. Expression of the target was defined as an average H-score ≥ 1 and high expression was defined as an average H-score > 100. Kruskal-Wallis test was used for the statistical analyses.

Results: Expression of NY-ESO-1 and MAGE-A4 was found in 50.9% (55/108) and 68.5% (74/108) of TMA samples. High expression was noticed in 20/108 samples (18.5%) for NY-ESO-1 and in 25/108 samples (23.1%) for MAGE-A4. In 77.8% of the samples there is at least one of these cancer testis antigens expressed. There was no correlation between the expression level and disease status at the sampling moment, nor with clinical outcome of the patient. Additionally, there was no correlation between the expression level and the size of the original tumour.

Conclusions: MAGE-A4 and NY-ESO-1 are expressed in a clinically relevant proportion of SySa cases represented in our TMA, this supports the utility of these antigens as targets for novel cell-based therapies in this disease.

1945P Diagnostic and therapeutic impact of liquid biopsy in soft tissue sarcomas: A case series

T.S. Assi[1], T. Ibrahim[1], R. Ibrahim[1], R. Khoury[1], K. Saleh[1], C. Chahine[1], M. Faron[2], A. Le Cesne[1]

[1]Division of International Patients Care, Gustave Roussy - Cancer Campus, Villejuif, France; [2]Surgical Oncology/Biostatistics & epidemiology INSERM 1018, Institut Gustave Roussy, Villejuif, France

Background: Soft tissue sarcomas (STS) are a group of rare heterogeneous mesenchymal tumours with distinct clinical and molecular features. Current therapeutic approaches in advanced STS are limited to conventional chemotherapy and targeted therapy without significant impact on survival. Liquid biopsy (LB) or cell-free DNA is an innovative tool in cancer practice that detects particular molecular alterations (MA) with diagnostic and therapeutic implications. In this case series, we report the outcomes of LB in a cohort of international STS patients.

Methods: In this prospective cohort, all STS patients from the international department treated in Gustave Roussy Cancer Campus that underwent a LB during their disease course between 01/2022 and 03/2023 were included. Demographic data were gathered with various significant MA.

Results: 18 STS patients were included in this series with a median age of 49 yrs. 9 were men (50%) and all patients had inoperable or metastatic disease at the time of LB. They had a median of 1 prior line of therapy. Three patients had a high TMB (tumour mutational burden) (16.6%) with more than 10 mut/mb. Four patients (22.2%) had targetable MA: Three pts had MSI-high tumors (microsatellite instability, two uterine leiomyosarcoma and 1 with GIST) with high sensitivity to immune checkpoint inhibitors and 1 angiosarcoma patient had BRAF mutation in which a BRAF and MEK inhibitors were introduced. On the other hand, four patients had confirmed STS diagnosis with the detection of fusion transcripts: two had Ewing sarcoma, one had desmoplastic round cell tumour and one patient had the EWSR1-ATF1 fusion transcript which helped changing the diagnosis from suspected melanoma to clear cell sarcoma. Also four patients had genetic counselling after detecting germline mutations (2 NF1 in GIST and MPNST, 1 APC in desmoid tumor and 1 POLD1 in chondrosarcoma). Two patients benefited from haematology referral after confirmed JAK2 mutations.

Conclusions: LB proved to be an attractive technique to detect significant MA in advanced STS, a group of malignant tumors with a challenging diagnosis and therapeutic approach. This tool can be implemented as an adjunct tool to offer novel therapeutic options to patients as well as fine-tuning of the diagnostic process.

Lee Moffitt Cancer Center & Research Institute - Magnolia Campus, Tampa, FL, USA; [11]Medicine Oncology Department, H. Lee Moffitt Cancer Center & Research Institute - Magnolia Campus, Tampa, FL, USA; [12]Urology, The University of Texas M. D. Anderson Cancer Center, Houston, TX, USA; [13]Pathology Department, Foundation Medicine, Inc., Morrisville, NC, USA

Background: BSar are rare and often present at advanced stage with poor prognosis. Limited data on genomic alterations (GA) exist; we evaluated GA and outcomes in separate cohorts.

Methods: 18 (0.2%) pts with Bsar were identified from 11,193 bladder cancers and underwent hybrid capture-based comprehensive genomic profiling (CGP) using DNA only (6 pts) or DNA and RNA seq (12 pts) to assess GA and other biomarkers. Predominant genetic ancestry was assessed using a SNP-based approach and classified as: African (AFR), European (EUR), Central and South American (AMR), South Asian (SAS), or East Asian (EAS). Assessments of tumor mutational burden (TMB), MSI status, genomic signature (GS), gLOH and prediction of germline status were performed. PD-L1 was determined in 2 pts by IHC (1 DAKO 22C3; 1 Ventana SP142). A separate analysis of 317 patients (pts) with stage I-III BSar using NCBD data (2004-2019) was done.

Results: 18 Bsar (11 male, median age 66) were included: 12 leiomyosarcomas (LMS), 3 rhabdomyosarcomas (RMS),3 high grade undifferentiated sarcomas (HGS). 16 pts of EUR ancestry, 1 AMR, 1EAS. Mean driver GA frequency was 4.8 (1-10); mean TMB 2.9 mutations/Mb (0-9.6), all MS stable; 1 tumor was PD-L1 negative, the other had 1-49% TPS. Mean gLOH 10.4% (1.7-16.9%). APOBEC GS was noted in 1/12 (8.3%) with 11/12 (91.7%) with no dominant GS. Relevant germline mutations were predicted in RB1 (pt with prior retinoblastoma), VHL (pt with radiation-treated prostate cancer), PTEN (pt with Cowden Syndrome) and MUTYH (pt with intestinal polyposis); 1 pt with prior Wilms tumor had somatic GA only. Most frequently identified GA:TP53 (78%), ATRX (22%), RB1 (22%), PTEN (22%), CDKN2A (17%) and RICTOR, MLL2, DNMT3A, MTAP, KDM6A, TERT, HGF, NF1 (each 11%). In the BSar NCDB cohort (LMS only, overall survival was shorter in pts treated with surgery (S) and chemotherapy (CM), S and radiotherapy (RT) vs with S alone, HR 2.73 (95%CI 1.28-5.80), HR 2.24 (95%CI 1.03-4.88) respectively, after adjusting for sociodemographic and health factors. Age and tumor size had prognostic role.

Conclusions: CGP of Bsar revealed several GA relevant for clinical trial design and germline mutations requiring dedicated germline testing. Limitations: retrospective nature and confounding.

1947P Predictors and outcomes of recurrent retroperitoneal liposarcoma: New insights into its recurrence patterns

H. Deng[1], Y. Pan[1], B. Wei[2]

[1]General Surgery, Peking University First Hospital, Beijing, China; [2]General Surgery, The First Affiliated Hospital of PLA General Hospital, Beijing, China

Background: The clinical profiles of recurrent retroperitoneal liposarcoma (RLS) need to be explored. The recurrence patterns of RLS are controversial and ambiguous.

Methods: A total of 138 patients with recurrent RLS were finally recruited in the study. The analysis of overall survival (OS) and recurrence-free survival (RFS) was performed by Kaplan−Meier analysis. The nomogram model was built to predict the survival status of patients. Univariate and multivariate analysis were performed for the selection of independent prognostic factors that were correlated with OS or RFS.

Results: Among patients, the 1-, 3-, and 5-year OS rates were 70.7%, 35.9% and 30.9%, respectively. The 1-, 3- and 5-year RFS rates of the 55 patients who underwent R0 resection were 76.1%, 50.8% and 34.4%, respectively. The multivariate analysis revealed that resection method, tumor size, status of pathological differentiation, pathological subtypes and recurrence pattern were independent risk factors for OS or RFS. Patients with distant recurrence (DR) pattern usually had multifocal tumors (90.5% vs. 74.7%, $P < 0.05$); they were prone to experience changes of pathological differentiation (69.9% vs. 33.3%, $P < 0.05$) and had a better prognosis than those with local recurrence (LR) pattern. R0 resection and combined organ resection favored the survival of patients with DR pattern in some cases.

Conclusions: Patients with DR pattern have a better prognosis, and they may benefit more from aggressive combined resection than those with LR. Classifying the recurrence patterns of RLS provides guidance for individualized clinical management of recurrent RLS.

Background: JCOG1306 was a multicenter randomized phase II/III trial comparing perioperative chemotherapy with adriamycin plus ifosfamide (AI) and gemcitabine plus docetaxel (GD) for high-grade non-round-cell sarcomas of FNCLCC classification ≥G2. After the histopathological diagnosis was confirmed by each local institution, specialized sarcoma pathologists reviewed each pathological diagnosis. In this study, we examined the concordance proportion of pathological diagnoses between the local institutional judgment (LIJ) and central judgment (CJ) and its impact on the study.

Methods: A total of 142 patients with proven high-grade non-round-cell sarcoma based on an incisional biopsy were included. We evaluated the concordance between the LIJ and CJ for pathological types and FNCLCC classification.

Results: The concordance proportion for pathological types between the LIJ and CJ was 63.4%. Compared to the LIJ (G1: 0%, G2: 59.9%, G3: 40.1%), the CJ (G1: 15.5%, G2: 61.3%, G3: 23.2%) showed more patients diagnosed with G1, and the concordance proportion for the FNCLCC classification was 62.7%. Histological types diagnosed as G1 were myxofibrosarcoma in 15 patients, myxoid liposarcoma in 6 patients, and fibrosarcoma in 1 patient. The proportion of patients in which the LIJ agreed with the CJ for each histological type was higher for synovial sarcoma (100%) and myxofibrosarcoma (88.2%) and lower for undifferentiated/unclassifiable sarcoma (17.6%). The 3-year survival proportions for 120 patients excluding G1 cases (AI: 59, GD: 61) were 89.8% and 74.9%, respectively, and those for all 143 patients (AI: 70, GD: 73) were 91.4% and 79.2%, respectively.

Conclusions: The present analysis included 15% of G1 patients who were not originally eligible for this trial. However, this did not significantly affect the results, as the AI and GD groups contained similar numbers of G1 patients. Patients with a background of myxoid components tended to be judged as G1 by the CJ. Although the limitations of assigning a grade using an incisional biopsy should be considered, the CJ is still useful for ensuring the accuracy of the clinical trial for such rare cancers.

Clinical trial identification: JCOG1306S1.

1949P Pegylated liposomal doxorubicin (PLD) combined with trabectedin as a treatment option in uterine sarcomas

L. Strobel, M.S. Steinlechner, C. Marth, A.G. Zeimet

Department of Obstetrics and Gynecology, Innsbruck Medical University, Innsbruck, Austria

Background: Conventional use of doxorubicin as a single-agent or in combinations with other drugs in the treatment of uterine sarcomas is associated with dose-limiting toxicities. Doxorubicin plus trabectedin was shown to increase progression-free survival (PFS) at the price of higher toxicity. PLD plus trabectedin revealed to be feasible in larger phase 2 and 3 randomised studies in ovarian cancer. We hypothesise that the therapeutic index of trabectedin plus PLD could be superior to the combination with doxorubicin because of a more favourable toxicity profile.

Methods: In this retrospective single-arm study the clinical outcome was analysed in 21 patients with uterine sarcomas treated with PLD 30 mg/m^2 plus trabectedin 1.1 mg/m^2 every three weeks between January 2000 and April 2023 at the University Hospital in Innsbruck. Response evaluation was done every 3 cycles and every 3 months during the post-treatment follow-up. Toxicity was evaluated according to the National Cancer Institute-Common Terminology criteria, on a total of 148 administered cycles in 33 patients.

Results: In 66% of patients PLD plus trabectedin was given as first-line treatment, in 19% and 14% as second and third-line treatment, respectively. After 6 months one patient (4.8%) achieved complete remission (CR), four others (19%) showed a partial remission (PR), resulting in an objective response rate (ORR) of 24%. Four patients (19%) showing stable disease (SD), resulting in a clinical benefit rate (= ORR + SD) of 43%; progression was recorded in 12 patients (57%). Median PFS was 6.0 months (SD: ±21 months), while median overall survival was 26 months (SD: ±32 months). A median of 4 (range: 1-11) cycles per patient were given. Regarding ≥ grade 3 toxicity, thrombocytopenia was recorded in 9%, anaemia in 12% and neutropenia in 36% of patients. Febrile neutropenia was present in 7 patients (21%). Haematologic toxicity was the most frequent reason for dose delays (25 events) and dose reductions in eight cases.

Conclusions: Compared to conventional doxorubicin plus trabectedin, the herein investigated combination shows limited but similar anti-tumor efficacy in metastatic uterine sarcomas, but exhibits a more favourable toxicity profile.

1950P A single-arm, phase II clinical trial of neoadjuvant pegylated liposomal doxorubicin plus anlotinib in locally advanced soft tissue sarcoma

Y. Chen[1], W. Sun[1], S. Wang[2], Y. Xu[1], T. Hu[1], B. Zheng[1], Z. Sun[1], C. Wang[1], W. Yan[1]

[1]Musculoskeletal Oncology, Fudan University Shanghai Cancer Center, Shanghai, China; [2]Radiology, Fudan University Shanghai Cancer Center, Shanghai, China

Background: Neoadjuvant therapy might improve excision and limb salvage rates in locally advanced soft tissue sarcomas (STS). This phase II trial aimed to investigate the safety and activity of neoadjuvant pegylated liposomal doxorubicin (PLD) plus anlotinib in local advanced STS.

Methods: In this prospective, single-center, single-arm phase II study, major eligible criteria were locally advanced, non-metastasis, treatment-naive STS, age at 14-75 years old, pathological stage IIb/III, ECOG PS 0-2. Patients received PLD (50mg/m^2, IV, D1, Q3W) and anlotinib (12mg/d, PO, D8-21, Q3W) for 2～4 cycles. The primary endpoint was objective response rate (ORR). Secondary endpoints included overall survival (OS), progression-free survival (PFS), pathological complete response (ypT0/is ypN0, pCR) and safety.

Results: From November 2020 to November 2022, 45 patients were recruited. The median age was 47 years (range, 15-75) and 19 were female. The predominant histologies included Spindle cell sarcoma 7 (15.56%), Myxofibrosarcoma 5 (11.11%), Myxoid liposarcoma 5 (11.11%), Malignant peripheral nerve sheath tumor 4 (8.89%), Synovial sarcoma 4 (8.89%), Leiomyosarcoma 3 (6.67%). Median treatment cycles of neoadjuvant therapy were 2 (range, 1-4). The ORR and DCR of 29 patients with at least one assessment as Choi criteria was 62.1% and 100%, respectively. Of 39 (86.67%) patients underwent radical resection, 33 (84.62%) patients had an R0 resection. With a median follow-up time of 11.47 months, the median OS were not reached. Median PFS was 14.19 months, and the 1-year OS rate was 84.23%. The limb salvage rates was observed in 39 (100%) patients. The most common adverse events (AEs) of all grade were mucositis oral 19 (42.22%), proteinuria 13 (28.89%), neutropenia 12 (26.67%), and leucopenia 11 (24.44%). Grade 3/4 AEs were 13 (28.89%). PLD plus Anlotinib was well tolerated without significant unexpected toxic effects.

Conclusions: PLD combined with Anlotinib showed a promising efficacy and acceptable toxicity for patients with locally advanced soft tissue sarcomas, suggesting a potential therapeutic option for this population.

1951P Propranolol monotherapy in angiosarcoma: A window-of-opportunity study (PropAngio)

Embaby[1], K.M. Heinhuis[1], N. Ijzerman[1], A.M. Koenen[2], S. van der Kleij[2], I. Hofland[3], H. van Boven[4], J. Sanders[4], W.T.A. Van Der Graaf[5], R.L. Haas[6], A.D.R. Huitema[7], W. Van Houdt[2], N. Steeghs[5]

[1]Medical Oncology and Clinical Pharmacology Department, NKI-AVL - Netherlands Cancer Institute/Antoni van Leeuwenhoek Hospital, Amsterdam, Netherlands; [2]Surgical Oncology, NKI-AVL - Netherlands Cancer Institute/Antoni van Leeuwenhoek Hospital, Amsterdam, Netherlands; [3]Core Facility of Molecular Pathology & Biobanking, NKI-AVL - Netherlands Cancer Institute/Antoni van Leeuwenhoek Hospital, Amsterdam, Netherlands; [4]Pathology, NKI-AVL - Netherlands Cancer Institute/Antoni van Leeuwenhoek Hospital, Amsterdam, Netherlands; [5]Medical Oncology, NKI-AVL - Netherlands Cancer Institute/Antoni van Leeuwenhoek Hospital, Amsterdam, Netherlands; [6]Radiotherapy Department, NKI-AVL - Netherlands Cancer Institute/Antoni van Leeuwenhoek Hospital, Amsterdam, Netherlands; [7]Pharmacy & Pharmacology, Netherlands Cancer Institute/Antoni van Leeuwenhoek hospital (NKI-AVL), Amsterdam, Netherlands

Background: Angiosarcoma is a rare and aggressive cancer of the endothelial cells. It has been shown that β-adrenergic signaling through the β-adrenoceptors (ADRB) 1 and 2, that are overexpressed in angiosarcoma, promotes tumor growth. Propranolol, a non-selective β-blocker, was able to initiate apoptosis in angiosarcoma cell lines and its anti-tumor activity has been demonstrated in several case reports. The aim of this window-of opportunity trial was to prospectively evaluate the anti-tumor activity of propranolol in patients with angiosarcoma.

Methods: Patients with angiosarcoma with a waiting time of 3 to 6 weeks until start of standard treatment were eligible. Propranolol was dosed 80 mg to 240 mg/day according to a dose titration schedule. The primary endpoint was clinical response rate. Clinical response was defined as either complete response (CR), partial response (PR) (according to RECIST 1.1) or stable disease (SD) with improvement of erythema, edema and thickness. Exploratory objectives included histologic response, PET response and assessment of potential biomarkers for response in tumor tissue by IHC (e.g., ADBR 1/2, PD-L1).

Results: To date, 13 patients with a median age of 67 years (range 52-86) are enrolled and have initiated treatment. The median duration of treatment was 28 days (range 21-42 days). The median dose was 160 mg/day. Three patients showed exceptional good tolerance (blood pressure/heart rate) and could be escalated to the highest dose (240 mg/day). Two patients showed clinical response. The most common adverse event was grade 1/2 bradycardia (85%). There were no grade $\geq$3 adverse events. Preliminary IHC results showed ADBR2 overexpression in the majority of the tumors (12 out of 17 tumor samples, both in responders and non-responders). None of the tumors showed ADBR1 overexpression.

Conclusions: This window-of-opportunity trial did not demonstrate clinical efficacy of propranolol monotherapy in patients with angiosarcoma. Two out of 13 patients did however show clinical benefit. ADBR1 or 2 expression did not correlate with response. Translational research to better comprehend the anti-tumor activity of propranolol for adequate selection of patients in future studies is ongoing (e.g., immune system-based biomarkers).

1952P Efficacy and safety of utidelone in previously treated patients with advanced or metastatic soft tissue sarcomas (HX-SARC02): A prospective, single-arm, phase II study

Y. Jiang, Y. fu, J. Liu, B. Wang, M. Li, H. Zhang, Y. Deng

Department of Medical Oncology, Cancer Center, West China Hospital, Sichuan University, Chengdu, China

Background: Treatment options are limited for patients with advanced or metastatic soft tissue sarcomas (STSs) after failure of anthracycline-based chemotherapy and large-spectrum tyrosine kinase inhibitor. Utidelone, a genetically engineered epothilone analogue, has demonstrated high activity in preclinical and clinical studies against a broad range of tumors. This study aimed to evaluate the efficacy and safety of utidelone in refractory STSs.

Methods: This prospective, single-arm, phase II trial included patients aged 18 years or older with histologically proven advanced and inoperable STSs who had at least received anthracycline-based chemotherapy and large-spectrum tyrosine kinase inhibitor. Patients were treated with intravenously transfused utidelone (30 mg/m^2, day 1-5, every 21 days) until disease progression or intolerable toxicity. The primary endpoint was the median progression-free survival (PFS). Secondary endpoints included objective response rate (ORR), disease control rate (DCR), overall survival (OS) and safety.

Results: Between August 19, 2022 and March 1, 2023, a total of 10 patients were enrolled. As of April 16, 2023, all patients could be analyzed. There were 7 patients with leiomyosarcoma, one patient with synovial sarcoma, one patient with dedifferentiated liposarcoma, one patient with myofibroblastic sarcoma. 10 patients are evaluable for response with median cylces of 4 (1-7), 7 of whom are still under treatment. The median number of previous systemic therapies was two. The median PFS has not been reached. The ORR was 10% and DCR was 80%. Most of the common adverse events (AEs) were grade 1 or 2 and were considered manageable and reversible. Grade $\geq$3 AEs included peripheral neuropathy (1 [10%]), AST increase (1 [10%]) and diarrhoea (1 [10%]). Doses of utidelone were reduced (24 mg/m^2, on day 1-5) in two patients and discontinued in one patient. No treatment-related deaths occurred.

Conclusions: The present study demonstrated a promising anti-tumour activity of utidelone in patients with advanced or metastatic STSs who were previously treated with and refractory to both anthracycline-based chemotherapy and large-spectrum tyrosine kinase inhibitor.

1953P Prognostic value of pretreatment inflammatory markers and other clinicopathological factors for early recurrence in soft tissue sarcoma

P. Van Der Laan[1], W.T.A. Van Der Graaf[1], D. Van Den Broek[2], H. van Boven[3], N. Steeghs[1], W. Van Houdt[4]

[1]Department of Medical Oncology, NKI-AVL - Netherlands Cancer Institute/Antoni van Leeuwenhoek Hospital, Amsterdam, Netherlands; [2]Department of Laboratory Medicine, Netherlands Cancer Institute/Antoni van Leeuwenhoek hospital (NKI-AVL), Amsterdam, Netherlands; [3]Department of Pathology, NKI-AVL - Netherlands Cancer Institute/Antoni van Leeuwenhoek Hospital, Amsterdam, Netherlands; [4]Department of Surgical Oncology, NKI-AVL - Netherlands Cancer Institute/Antoni van Leeuwenhoek Hospital, Amsterdam, Netherlands

Background: The diversity of clinical and pathological characteristics of soft tissue sarcoma (STS) presents a challenge for the prediction of prognosis. Recently, pretreatment inflammatory markers have gained interest as predictive factors for survival in cancer patients. The aim of this study is to evaluate inflammatory markers as a predictive biomarker for early recurrence in STS.

Methods: 118 patients with primary, localized soft tissue sarcoma were retrospectively reviewed for early recurrence. Early recurrence was defined as a disease relapse (local or distant) within the first year after diagnosis. Pretreatment inflammatory markers including leukocytes, interleukin-6 (IL-6), C-reactive protein (CRP), neutrophil-to-lymphocyte ratio (NLR), platelet-to-lymphocyte ratio (PLR) and other variables including tumor grade, tumor Departmenth, location, size, and the presence of tumor necrosis on imaging were analyzed for their association with early recurrence. Survival data was analyzed using Log-rank test and Cox regression to identify prognostic factors for early recurrence.

Results: Pretreatment IL-6 elevation was associated with higher tumor grade, increased size, and necrosis on imaging. Elevated CRP was associated with higher tumor grade, NLR and PLR with tumor Departmenth, and PLR with tumor location. Early recurrences were found in 23 of 118 patients (19.5%): 7 local, 15 distant recurrences and 1 with both manifestations. Univariate analysis revealed that tumor grade (low vs high, $p = 0.008$), tumor Departmenth (superficial vs deep, $p = 0.005$), and IL-6 level (< 7 vs ≥ 7 ng/L, $p = 0.012$) were significantly associated with early recurrence; other inflammatory markers including leukocytes, CRP, NLR and PLR were not. Multivariate analysis did not reveal independent risk factors associated with the development of early recurrences in STS, although the number of cases were low.

Conclusions: Early recurrences in STS are not only associated with higher grade and deeper tumors, but also with increased plasma levels of IL-6.

1954P The risk of second primary gastrointestinal tract GIT malignancy after primary retroperitoneal liposarcoma

B.H. Alshaikh[1], A. Ellaithy[2]

[1]Faculty of Medicine, Sana'a University, Sana'a, Yemen; [2]Faculty of Medicine, Suez Canal University, Ismailia, Egypt

Background: Gastrointestinal tract (GIT) retroperitoneal sarcomas are rare tumors representing 1-2% of all solid malignancies and 20% of sarcomas and the most common subtype is liposarcoma. As reported in the literature, the occurrence of multiple primary tumors in a different site than the first primary site is a rare event in the literature, and there are very limited data about retroperitoneal liposarcoma (RPLS) with only a few case reports and case series, so this study aimed to assess the risk of multiple GIT malignancies after primary RPLS.

Methods: Data of RPLS patients was extracted from Surveillance, Epidemiology, and End-Results (SEER) database diagnosed in 2000-2020. We used an MP-SIR session to calculate the standardized Incidence Ratio (SIR) as Observed/Expected (O/E) with 95% Confidence Intervals (CI) showed significance at $P<0.05$ and the Excessive Absolute Risk (EAR) per 10,000.

Results: In 2257 patients, we observed an increased risk of synchronous and metachronous retroperitoneal malignancy after primary RPLS with EAR of 56.34 (O/E=213.24, 95%CI: 271.30-164.92, $P<0.05$). There was an increased risk for small intestinal cancer in the 0-11 months after primary RPLS with O/E of 31.76 (95%CI: 81.32-8.65; $P<0.05$, EAR=5.31) and appendicular cancer (O/E=45.14, 95%CI: 163.05-5.47; $P<0.05$, EAR=9.86). The overall risk to develop 2nd primary gastric carcinoma (O/E= 1.49, 95%CI: 3.81-0.41; $P>0.05$, EAR =1.13), colorectal cancer (O/E=1,44, 95% CI: 2.30-0.84; $P>0.05$, EAR=4.44), hepatocellular carcinoma (O/E=2.08, 95%CI: 4.52-0.76; $P>0.05$, EAR=2.67), and pancreatic cancer (O/E=1.61, 95%CI: 3.17-0.69; $P>0.05$, EAR=2.60). While there was slightly decreased risk in esophageal carcinoma (O/E=0.56; $P>0.05$, EAR= -0.68) and gall bladder cancer (O/E= 0.00; $P>0.05$, EAR= -0.37).

Conclusions: These results show a significantly increased risk of synchronous and metachronous retroperitoneal cancer by 213-fold through ten years while the peak increase of small intestinal cancer and appendicular cancer as 2nd primary malignancies is during the first-year interval. This highlights the importance of regular screening for tumors of the retroperitoneum, small intestine, and appendix after RPLS diagnosis for early detection and better management plan.

1955P Distinguishing lipomas from atypical lipomatous tumors/ well differentiated liposarcomas in histology slides using deep learning

M. Karanian[1], A. Camara[2], J. Klein[2], T. Marchand[2], C. Maussion[2], V. Rousseau[2], T. Bonnotte[2], R. Perret[3], F. Le Loarer[3], C. Ngo[4], S. Korbi[3], Y. Mansour[3], A. Meurgey[1], M. Jean-Denis[1], A. Italiano[5], J-Y. Blay[6], J.M. Coindre[7]

[1]Bio-pathology, Centre Léon Bérard, Lyon, France; [2]R&D, Owkin France, Paris, France; [3]Pathology, Institute Bergonié - Centre Régional de Lutte Contre le Cancer (CLCC), Bordeaux, France; [4]Biology and Pathology, Institut Gustave Roussy, Villejuif, France; [5]Early phase Trials Unit, Institute Bergonié, Bordeaux, France; [6]Medicine Department, Centre Léon Bérard, Lyon, France; [7]Pathology, Institute Bergonié - Centre Régional de Lutte Contre le Cancer (CLCC), Bordeaux, France

Background: Liposarcomas are fat tissue tumors with an incidence rate of 1 case per 100,000 population per year. Atypical Lipomatous Tumors / Well Differentiated Liposarcomas (ALT/WDLPS) are malignant tumors accounting for around 40-45% of liposarcomas and are particularly challenging to diagnose as they can be easily confused with lipomas, another tumor of mesenchymal origin which is benign. The current diagnosis protocol consists in producing a histology slide from a tumor sample (either obtained by resection or biopsy) so that pathologists can determine the type of tumor. If the visual inspection remains uncertain, or the clinical suspicion of ALT/WDLPS is high, a FISH test is ordered in order to analyze the status of MDM2 gene.

Methods: This is a study on the ability of modern deep learning based AI technologies to automatically classify a whole slide image (WSI) containing fat tissue tumor into lipoma or ALT/WDLPS. Two cohorts were provided by Institut Bergonié (IB), Bordeaux, France and Centre Léon Bérard (CLB), Lyon, France. The IB cohort contains 1103 slides (536 Lipomas / 567 ALT/WDLPS) while the CLB cohort contains 956 slides (668 Lipomas / 288 WDLPS). We propose to use a deep learning pipeline relying on (i) a process mapping a WSI into 4000 (112x112 micrometers) small areas randomly sampled from regions containing matter, (ii) a transformer network that maps image areas into a 768 dimensional vectors and (iii) a multiple instance learning (MIL) head for the computation of a probability of WDLPS at the slide level.

Results: We trained our deep learning model using a 4-fold cross-validation (CV) with 5 repeats. Evaluation is reported in terms of accuracy (ACC), i.e., correct prediction rate. In the IB cohort, the model achieves 84.7% of ACC (std 2.5%). In the CLB cohort, it achieves 90.5% of ACC (std 2.1%).

Conclusions: The trained model exhibits excellent performances on (held-out) test samples in both cohorts. Many improvements can be made to the model by either adding clinical data in the pipeline or learning a multi-cohort model through federated learning.

1956P Neoadjuvant chemoradiotherapy in locally advanced soft tissue sarcoma: NASAR prospective study

J. Martinez-Garcia[1], P. Puertas[2], A. Valcarcel[2], J.A. Fernandez Hernandez[3], P. Sanchez Henarejos[1], M.D. Jimenez Lucas[1], A. Puertes Boix[1], T. Quiros Figallo[1], J.E. Hernandez[4], D. Lopez Motos[4], M.D. Abellan[5], A. Lopez-Sanchez[5], B. Torregrosa[5], I. de la Fuente[6], E. Cardenas[6], J.A. Encarnacion[6], J.L. Navarro[7], J.L. Alonso[1]

[1]Medical Oncology Department, Hospital Clínico Universitario Virgen de la Arrixaca, El Palmar, Spain; [2]Orthopedics and Traumatology Department, Hospital Clínico Universitario Virgen de la Arrixaca, El Palmar, Spain; [3]Surgery Department, Hospital Clínico Universitario Virgen de la Arrixaca, El Palmar, Spain; [4]Pathology Department, Hospital Clínico Universitario Virgen de la Arrixaca, El Palmar, Spain; [5]Radiology Department, Hospital Clínico Universitario Virgen de la Arrixaca, El Palmar, Spain; [6]Radiotherapy Oncology Department, Hospital Clínico Universitario Virgen de la Arrixaca, El Palmar, Spain; [7]Nuclear Medicine Department, Hospital Clínico Universitario Virgen de la Arrixaca, El Palmar, Spain

Background: Patients with locally advanced soft tissue sarcomas (ASTS) have a poor prognosis. Several studies attempt to analyze the role of neoadjuvant chemotherapy (NACT) and radiotherapy (NART).

Methods: Prospective unicentric study in ASTS with neoadjuvant treatment based on epirubicin (60 mg/m^2 day 1 and 2) and ifosfamide (1800 mg/m^2 d1-5), every 3 weeks for 3 cycles, concurrently with NART (46-50 Gy) starting on day 22th. Adjuvant boost of NART may be administered after surgery. ASTS greater than 5 cm, high grade and deep localization, and those initially considered as unresectable were included. Patients were evaluated by radiology before and after of neoadjuvant treatment.

Results: From 2017 until 2022, 22 patients with a median age of 43 years (range, 15-78) were enrolled in the study. 17 were men and 5 women. 13 of them were diagnosed of undifferentiated pleomorphic sarcoma, 2 angiosarcoma, 3 liposarcoma, 2 leiomyosarcoma and 2 other. 17 tumours were located in the extremities, 2 in the scapula and the other in the pelvis. The median size was 10 cm (4- 20 cm). The dose of ASTS and NART was completed in all patients. 13 patients received RT boost after surgery. The response was: 31,8% (7/22) obtained clinical response; 13,6% (3/22) partial response according to RECIST criteria; 76% (13/17) achieved a response by PERCIST criteria; and 73,3% (11/15) achieved a response by DIFUSSION criteria. The surgery was an en bloc complete resection in 95,5% patients (21/22). The histological response was $\geq$ than 90% of necrosis in 63,6% (14/22), with 36,4% complete response (8/22). The most frequent toxicity was delay in wound healing and 59,1% patients with skin toxicity grade 2. With median follow up of 50,1 months (range, 18-96), 10 patients remain without disease (45,5%) and 12 have had pulmonary relapses (54,5%) and only 3 local relapse (13,6%). 7 deaths were registered. Median of progression free survival is 26,1 months (95%IC 8,2 − 44,0) and median overall survival not reached.

Conclusions: Neoadjuvant treatment with ASTS concurrent with NART achieves a very high rate of pathological responses and local control. Nonetheless, systemic relapses remain. PERCIST and DIFUSSION criteria have better correlation with necrosis than the RECIST criteria.

1957P Results from a phase I/II trial of tinostamustine monotherapy in advanced solid tumours (NCT03345485): Safety and efficacy in a subset of patients (pts) with soft tissue sarcoma (STS)

R. Chugh[1], S. Kummar[2], R.E. Schneider[3], T. Janik[4], N. Manamley[5], K. Hilgier[4], J. Strauss[3]

[1]Rogel Cancer Center, University of Michigan, Ann Arbor, MI, USA; [2]Division of Hematology & Medical Oncology, OHSU Knight Cancer Institute - Center for Health and Healing Building 1 - South Waterfront, Portland, OR, USA; [3]Medical Oncology Department, Mary Crowley Cancer Research Center, Dallas, TX, USA; [4]Clinical Development Oncology and Hematology, Mundipharma Research Limited, Cambridge, UK; [5]R&D, Mundipharma International, Cambridge, UK

Background: Tinostamustine, a novel alkylating deacetylase inhibitor, improves drug access to cancer cell DNA strands, breaks them and counteracts damage repair. Here we report safety and efficacy of tinostamustine in a subset of pts with STS from an open-label Ph I/II trial.

Methods: Pts ≥18 years with advanced solid tumours, life expectancy >3 mo, Eastern Cooperative Oncology Group performance status (ECOG PS) ≤2 were enrolled. Ph I dose escalation (standard 3+3 design 60−100mg/m^2) defined the maximum tolerated dose and recommended Ph II dose (RP2D). In Ph II, the objective response rate (complete response + partial response [PR]), together with pts with stable disease (SD) ≥4 mo duration, following the RP2D (80mg/m^2 over 60 min on D1 & 15 of each 4-wk treatment cycle) were determined, and are summarised here using descriptive statistics. Two substudies characterised the effects of tinostamustine (60−80mg/m^2) on cardiac repolarisation.

Results: Forty-nine pts with advanced solid tumours (13 with STS) were enrolled (Table). In Ph II, tinostamustine-related treatment-emergent adverse events (TEAEs) included thrombocytopenia, anaemia, nausea and fatigue. Serious tinostamustine-related AEs were mainly haematological; 1 tinostamustine-related fatal AE (intra-abdominal haemorrhage; ovarian cancer pt) occurred. In the STS subset, a greater proportion of patients experienced tinostamustine-related and serious tinostamustine-related TEAEs compared with the overall Ph II pt population; there were no tinostamustine-related fatal TEAEs. One pt with STS achieved PR as best response, and 3 had SD ≥4 mo duration; 5 pts with STS discontinued treatment due to progressive disease.

Conclusions: Tinostamustine demonstrated modest signals of efficacy with manageable tolerability in pts with STS.

Table: 1957P Demographic & safety data: Pts with advanced solid tumours receiving tinostamustine & the STS pt subset

	Ph II pt population	STS pt subset

1958P Head and neck soft tissue sarcoma: Evaluation of the 8th AJCC as a prognostic tool for patients treated with curative intent in a multidisciplinary cancer center

G.K. Zanetta

Clinical Oncology, AC Camargo Cancer Center - Centro Internacional de Pesquisa (CIPE), São Paulo, Brazil

Background: HN-STS is a challenging disease due to its diverse clinical presentation. In an attempt to refine the prognostication of these pts, the AJCC in its 8th edition proposed a new dedicated T staging group based on cutoffs of 2 and 4 cm for classifying T1, T2 and T3, and surrounding tissue invasion as T4, as opposed to the dichotomic T1-T2 5cm cutoff adopted by the 7th AJCC.

Methods: This is a retrospective study of pts diagnosed with nonmetastatic HN-STS treated with curative intent in a single tertiary hospital, approved by the institutional ethical review committee. The aim was to compare the 8th AJCC T staging to the previous classification as a prognostic tool for HN-STS, added to other variables such as age, histological subtype, grade and regional lymph node metastasis (LNM). AJCC 7th and 8th have been compared regarding T staging with Cohen's kappa coefficient (KC) using inter-rater agreement analysis. The Kaplan-Meier estimator was used to calculate median survival time and differences in time-to-event outcomes were assessed using the log-rank test. Cox proportional hazard model was used to assess the effect of features in overall survival (OS).

Results: From 1997 to 2000, 135 pts were identified in institutional archives. Sarcoma NOS (N=50) and Leiomyosarcoma (N=17) were the most common histologic subtypes, as well as high-grade tumors (N=85). KC of inter-rater agreement was 0.46, statistically significant (p=0.03), indicating poor agreement between both T staging systems. Regarding OS, AJCC 7th (T1 and T2) and 8th (T1, T2, T3 and T4) T size stratification was not statistically different (P=0.42 and P=0.27, respectively). High-grade (71.4% vs 93.6%, P=0.005) and regional LNM (31.3% vs 81.4%, P=0.008) had worse 5-year OS in Cox multivariate analysis. Pts with tumor size>4cm or local invasion, high grade and LNM had 2.30, 7.11 and 4.37-fold increased risk of death respectively.

Conclusions: In our series, neither 7th nor 8th AJCC T size classifications adequately stratified prognostic groups or correlated survival for HN-STS pts. The 8th AJCC T4, the high-grade tumors and regional LNM demonstrated significant worse prognostic impact in pts harboring HN-STS.

1959P Clinicopathological features and survival analysis of orbital rhabdomyosarcoma

F.E.A.E.E. Elawady[1], A. Ellaithy[2]

[1]Ophthalmology, Port Said Specialized Hospital of Ophthalmology, Port Said, Egypt; [2]Faculty of Medicine, Suez Canal University, Ismailia, Egypt

Background: Orbital rhabdomyosarcoma is a very rare childhood malignancy and the most common primary orbital malignancy in children, with incidence of 250 new cases per year. Due to its scarcity, there is not enough data available in the literature regarding its etiology and risk factors. The aim of this study is to explore the clinicopathological features of the disease and to evaluate the overall survival to add new updated evidence to the literature.

Methods: Data of 152 patients was extracted from The Surveillance, Epidemiology and End Results (SEER) database from 17 registries and diagnosed from 2000 to 2020. The following International Classification of Diseases for Oncology was adopted, Third Edition (ICD-O-3), histology code: 8,900, 8,901, 8,902, 8,910, 8,912, and 8,920; and the ICD-O-3/ WHO 2008 site code (eye and orbit). SPSS version 23 was used for data analysis, Kaplan-Meier Curve and Log rank test for survival analysis.

Results: the 1-year and 5-year relative survival for orbital rhabdomyosarcoma was 98.8% and 90.0%. performing COX-regression model for age, race, gender, year of diagnosis and stage showed age (HR=1.031, 95% CI: 1.062- 1.001; P=0.04) and stage (HR=0.03, 95% CI: 0.290- 0.005; P=0.02) were significantly associated with survival

outcome while gender (HR= 2.487, 95% CI: 12.370- 0.500; P= 0.226) and race (HR= 0.902, 95% CI= 6.465-0.126; -P= 0.919) had no statistical significance. However, 93.7% of the sample were white and only 3.1% had distant metastasis. Regarding histological types; we found 114 patients (70.8%) had embryonal rhabdomyosarcoma, 18 patients (11.8%) had the alveolar type and four patients (2.5%) had the spindle type.

Conclusions: The results of this study showed promising survival outcome for orbital rhabdomyosarcoma with increased incidence in the white race and increased risk with age and stage. The most common histological subtype was embryonal rhabdomyosarcoma. These results give clear updated data about orbital rhabdomyosarcoma to understand the nature of this disease better which help in designing a plan of management putting into consideration the age and stage for better outcome.

1960P Clinical outcomes of the patients with alveolar soft part sarcoma developed brain metastasis

Y. Toda[1], E. Kobayashi[1], D. Kubota[2], Y. Miyakita[3], Y. Narita[3], A. Kawai[1]

[1]Musculoskeletal Oncology and Rehabilitation, National Cancer Center Hospital-Tsukiji Campus, Chuo-ku, Japan; [2]Orthopaedics and Motor Organ, Juntendo University International Center (JUIC), Tokyo, Japan; [3]Neuro-Oncology, National Cancer Center Hospital-Tsukiji Campus, Chuo-ku, Japan

Background: Bone and soft tissue sarcomas are uncommon neoplasms that rarely metastasize to the brain. Alveolar soft tissue sarcomas (ASPS) have been reported to have a higher propensity to develop brain metastasis (BM) than other sarcomas. Our study aimed to retrospectively scrutinize the clinical outcome of BM in ASPS.

Methods: 35 patients diagnosed with ASPS between 2006 and 2021 were identified from our database. We evaluated the presence or absence of BM, age at diagnosis, gender, primary lesion site, tumor size, other distant metastases at diagnosis, and prognosis. We compared these clinical characteristics between patients with BM and those without BM (nBM). In the BM group, we also assessed symptoms, duration between diagnosis and BM, treatment for BM, and outcomes.

Results: Fifteen patients (43%) exhibited BM. We observed no significant difference in age at diagnosis, gender, primary lesion site, tumor size, or other distant metastases at diagnosis or median overall survival, compared to the nBM group. Seven cases were asymptomatic when BM was diagnosed. Most symptoms were headache and visual disturbance. The mean duration between diagnosis and BM was 46 months (range: 0-189). BM treatment consisted of gamma-knife radiosurgery in 10 cases, multi-targeted kinase inhibitors (TKI) (pazopanib and/or sunitinib) in eight cases, surgery in three cases, and whole-brain irradiation in three cases. After receiving sunitinib treatment, two patients developed brain hemorrhages. The survival after BM was 33 months (range: 0.5-104).

Conclusions: Approximately half of the ASPS cases included in our study developed BM, with 47% of ASPS patients being asymptomatic at the time of BM detection. Periodic imaging, including the head region, may be advisable. Our analysis did not identify specific clinical features that predict BM in ASPS patients. Selective irradiation and chemotherapy have recently emerged as potential therapeutic options for treating BM in ASPS. These advances may contribute to improved prognosis after BM. However, potential serious adverse events associated with these treatments should be carefully considered. In particular, patients receiving TKI therapy may be at risk for brain hemorrhages and should be closely monitored and managed.

1961P Prevalence of diagnostic discrepancies in soft tissue and bone tumors from initial diagnosis to referral center

K. Thongthammachat[1], J. Chantharassamee[1], S. Muangsomboon[2], A. Nimmannit[3], C. Chandhanayingyong[4], C. Akewanlop[5]

[1]Oncology Department, Faculty of Medicine Siriraj Hospital, Mahidol University, Bangkok, Thailand; [2]Pathology, Faculty of Medicine Siriraj Hospital, Mahidol University, Bangkok, Thailand; [3]Research, Faculty of Medicine Siriraj Hospital, Mahidol University, Bangkok, Thailand; [4]Orthopeadics surgery, Faculty of Medicine Siriraj Hospital, Mahidol University, Bangkok, Thailand; [5]Medicine Department, Mahidol University - Faculty of Medicine, Bangkok, Thailand

Background: Sarcomas are rare malignant tumors and represent a heterogeneous group of tumors. An accurate diagnosis of histology is important for treatment strategies. We assessed the pathological review of all patients diagnosed with sarcoma at Siriraj Hospital over a 5-year period to identify the number of first diagnoses compared to the central expert review.

Methods: Histological data from patients diagnosed with sarcoma at Siriraj Hospital were collected over a 5-year period. The initial diagnoses were compared with a certified soft tissue and bone tumor pathologist.

Results: Of the 185 selected patients, 107 (57%) met the inclusion criteria and were analyzed. Full concordance between primary diagnosis and second opinion (the first pathologist and expert reached identical conclusions) was observed in 35 (32.7%) cases, partial concordance (identical diagnosis of connective tumor but different grade or histological type) in 12 (11.2%) cases, and complete discordance (benign versus malignant, different histological type, or invalidation of the diagnosis of sarcoma) in 60 (56.1%) cases. The rate of discordance was higher in incomplete initial IHC ($p = 0.003$), private laboratory, grade 2 and 3, tumor size $\geq$ 100 mm ($p = 0.01$) and age >18. The most common 'full concordance' histology is osteosarcoma (100%, 4 of 4). The main discrepancies were related to histological type ($n = 60$, 56.1%), subtype ($n = 8$, 7.5%), and grade plus subtype ($n = 4$, 3.7%). The mean duration from diagnosis to treatment was 96 days. Only the complete initial report appeared different in the subgroup <97 days group 39 (73.6%) and 97 days group 14 (26.4%) (p=0.03).

Conclusions: More than 65% of the first histological diagnoses were modified in the second reading, possibly resulting in different treatment decisions. The second opinion of the expert improves the quality of diagnosis and possibly the treatment of patients.

Background: According to retrospective osteosarcoma series, P-glycoprotein (Pgp) overexpression predicts for poor outcome. Mifamurtide, a modulator of innate immunity, which activates macrophages, was approved for localized osteosarcoma. A risk-adapted treatment strategy, with mifamurtide in Pgp- positive patients, was prospectively assessed in the ISG/OS-2 study (NCT01459484). Here we present a correlative study on tumor microenvironment (TME).

Methods: RNA was extracted in pre-treatment FFPE and non-decalcified tissue of 62 localized osteosarcoma patients and 730 immune genes were investigated (Pancancer Immuneprofiling Nanostring). Primary objective: TME analysis in Pgp+ patients at

diagnosis, comparing EFS > 24 months to EFS ≤ 24 months, after mifamurtide treatment. Secondary objective: TME differences in patients Pgp+ and Pgp- (NCT03737435).

Results: The TME of Pgp+ patients with EFS > 24 versus EFS ≤ 24 months showed: a higher infiltration of macrophages and T-cells, and a lower presence of B-cells; the alteration of genes involved in the Toll-like receptor signaling modulation, which is a possible target of mifamurtide, and, the overexpression of the *PD-L1* gene. Overall, Pgp+ compared with Pgp- patients presented a global upregulation of immune response genes, possibly promoting T-cell activation and cytokines production. Pgp+ patients presented also a more complex TME, enriched in T-cells and B-cells.

Conclusions: Pgp+ patients have a more infiltrated and activated microenvironment as compared to Pgp-. Notably, Pgp+ patients with a better response to mifamurtide treatment (EFS> 24) had an increased macrophages and T-cells TME infiltration and expressed genes predicted to be involved in the Toll-like receptor signaling, likely mediating mifamurtide efficacy.

Clinical trial identification: NCT01459484.

1963P Comprehensive profiling of chordoma reveals tumor microenvironment subtypes and unique molecular findings

M. Voropaeva, I. Zhuk, A. Aukhadieva, K. Zirov, A. Makarova, L. Bednyagin, A. Bagaev

Research and Development, BostonGene, Corp., Waltham, MA, USA

Background: Chordoma is a rare type of bone cancer with limited treatment options. Encouraging results showing the efficacy of pembrolizumab, a PD1 checkpoint inhibitor, in chordomas have recently been reported. Here, we performed comprehensive molecular testing to dissect the immune profile of these tumors and elucidate mechanisms of therapy response in chordomas.

Methods: Whole exome sequencing (WES) and whole transcriptome analysis was performed on samples from 14 patients (n = 6 samples from skull base, n = 8 samples from spine) with chordoma. Retrospective analysis of BostonGene's Tumor Portrait® test results identified genomic and transcriptomic alterations of chordomas and classified tumor microenvironment (TME) subtypes according to methods from Bagaev, et al., 2021.

Results: The median age of patients was 54.5 years (range: 26-76 years). The histologic subtypes were conventional (n = 13) and dedifferentiated (n = 1). The median number of prior therapies was 1 (range: 0-3). Transcriptomic-based TME classification revealed 93% (n = 13) of patients had an immune-enriched (IE) TME subtype characterized by high levels of B cells and CD4+ T cells and low levels of tumor-associated macrophages. Only one patient had a fibrotic TME characterized by minimal immune infiltration and a high prevalence of stromal elements. High *CD274* (PD-L1) expression was observed in 57% of samples. *EGFR* expression was high in all samples. In three cases, a 22q deletion was identified. Other clinically actionable events included *SMARCB1* loss (n = 3), *TP53* alteration (n = 2), *BRCA1* loss (n = 1), a combination of *PTEN*, *NF2,* and *TRAF2* loss (n = 1), and *CDKN2A/B* loss (n = 1). All samples were microsatellite stable and had low tumor mutational burden (range: 0.31-1.32 mut/Mb). From this cohort, 50% of patients were matched with at least one clinical trial based on their molecular profiles.

Conclusions: The prevalence of IE TME subtypes in chordomas supports the previously reported response to immune checkpoint inhibitors in chordomas. Together, these findings indicate next-generation sequencing could be a useful tool for informing treatment selection in advanced chordomas.

1964P Biomimetics of three-dimensional (3D) osteosarcoma (OS) models: A scoping review

V. Sandhu, D. Bakkalci, U. Cheema

UCL Centre of 3D Models Health and Disease, Division of Surgery and Interventional Sciences, Charles Bell House, London, UK, UCL - University College London, London, UK

Background: Three-dimensional (3D) cell culture models can recapitulate the native tumour microenvironment (TME) of cancers. However, data on the biomimicry of 3D osteosarcoma (OS) models is unclear. This scoping review (SR) aims to assess how the biomimicry of 3D OS models changes depending on the engineered features of the model. Biomimicry was determined by studying multiple parameters, including cell behaviour and drug resistance.

Methods: The scoping review followed the PRISMA-ScR guidelines and included studies with 3D culture models using osteosarcoma cells. The systematic search, which involved five databases (January 2012-December 2022), identified 293 studies; 70 studies were selected for final analysis: 40 involved drug screening, and 21 included the addition of stromal cells into the model.

Results: Overall, 64% of 3D OS models were scaffold-based compared to self-generated spheroid models. Native scaffolds (42%) comprising mainly collagen/hydroxyapatite predominated, followed by composite scaffolds (22%). For drug screening, both scaffold-based and scaffold-free models were used equally. Thirteen of 15 studies comparing 3D versus 2D drug sensitivity showed decreased sensitivity in 3D models, with several studies showing upregulated resistance genes in 3D models. Furthermore, the use of ECM-mimetic scaffolds and native biomaterials enhanced resistance by OS cells. These suggest biomimetic 3D OS models better recapitulate *in vivo* TME for drug screening. Co-cultures of OS/stroma cells enhanced biomimicry of 3D models and contributed towards osteogenic differentiation, ECM remodelling, mineralisation, angiogenesis, and OS-stromal cells' crosstalk. Seven studies demonstrated selective toxicity of chemotherapeutics towards OS cells while sparing stromal cells, providing helpful evidence for novel therapies development.

Conclusions: This SR highlights the biomimicry of 3D OS models in recapitulating *in vivo* TME. Future work should explore innovative 3D biomimetic models, biomaterials, and advancements in personalised medicine.

[1]Investigational Cancer Therapeutics, The University of Texas M. D. Anderson Cancer Center, Houston, TX, USA; [2]Neurosurgery, MD Anderson Cancer Center, Houston, TX, USA; [3]Orthopedic Oncology, MD Anderson Cancer Center, Houston, TX, USA; [4]Anatomical Pathology, The University of Texas M. D. Anderson Cancer Center, Houston, TX, USA; [5]Anatomical Pathology, MD Anderson Cancer Center, Houston, TX, USA; [6]Radiation Oncology, MD Anderson Cancer Center, Houston, TX, USA; [7]Melanoma Medical Oncology Department, The University of Texas M. D. Anderson Cancer Center, Houston, TX, USA; [8]Sarcoma Medical Oncology Department, The University of Texas M. D. Anderson Cancer Center, Houston, TX, USA

Background: Chordomas are rare neoplasms of notochord origin that can affect the skull base and mobile spine. While surgery and radiation are effective means to treat localized disease, there are no standard systemic therapies to treat locally advanced/metastatic chordomas. We previously published a series of chordoma patients treated with immune checkpoint inhibitors demonstrating limited activity. Here we begin to evaluate the immune microenvironment of chordomas by transcriptional analysis.

Methods: 57 tissue samples (30 spine chordoma, 21 skull base chordoma, 6 normal), previously analyzed by RNA-sequencing analysis and published (PMID: 28844110), were used. Hierarchical clustering was used to evaluate expression of immune-related genes. Gene ontology analysis was performed with GeneAnalytics. Microenvironment Cell Populations-counter (MCP-counter) was used for quantification of immune cell populations. Spearman's rank correlation coefficient and t-tests were used for statistical purposes.

Results: Populations of endothelial cells were significantly different in skull base (SB) samples ($p<0.05$) and mobile spine (MS) samples ($p<0.01$) compared to normal. B cells were significantly different in MS compared to normal ($p<0.05$), and monocytes were significantly different in SB samples compared to normal ($p<0.001$). 19 genes of the Interferon gamma (IFNG) gene pathway were significantly altered ($p<0.05$) in SB samples compared to MS samples but only 4 genes of the IFNG pathway were significantly altered ($p<0.05$) in SB samples compared to normal samples. 9 genes of the IFNG pathway were significantly altered in MS samples compared to normal ($p<0.05$). Hierarchical clustering of immune-related gene expression revealed 3 distinct groups. Gene ontology analysis revealed that group 1 favored NF-kappa B

signaling pathway, group 2 favored the phagosome pathway, and group 3 represented dendritic cell development lineage pathway.

Conclusions: Chordomas of the skull base and mobile spine exhibit diverse immune cell populations and differential expression of mediators of immune response. A comprehensive analysis is needed to further our understanding of the immune microenvironment of chordoma to develop ideal immunotherapeutic strategies.

1966P Extending the interval of denosumab treatment for unresectable giant cell tumor of bone

T. Kunisada, E. Nakata, T. Fujiwara, T. Ozaki

Department of Orthopaedic Surgery, Okayama University Hospital, Okayama, Japan

Background: The necessity of life-long denosumab injection may cause several problems for unresectable giant cell tumors of bone (GCTB). The efficacy and safety of extending the interval of denosumab treatment (de-escalation) for GCTB were investigated.

Methods: The medical records were retrospectively reviewed for nine patients with GCTB that were either unresectable or resectable, but not those of resection candidates, who received de-escalated denosumab treatment at a single institution since 2014. The median age at initial denosumab treatment was 44 years and tumor location consisted of 5 sacral spines, 2 femurs, one thoracic, and one lumbar spine. The denosumab treatment interval was gradually extended to every 8 weeks, 12 weeks, and 24 weeks. The radiographic changes and clinical symptoms were assessed during standard and de-escalated denosumab therapy.

Results: The denosumab interval was de-escalated after a median of 12 (8-16) months of standard 4-weekly treatment. The median duration of de-escalation treatment was 46 (9—75) months. Imaging showed that a good therapeutic response obtained with the 4-weekly treatment was sustained during the 8-weekly and 12-weekly treatments. According to the MD Anderson criteria, GCTB treated with de-escalated denosumab therapy resulted in a complete response in one patient and a partial response in eight patients. The extraskeletal mass reduced significantly with standard treatment, and tumor reduction was sustained during de-escalated treatment. The clinical symptoms significantly improved with standard treatment and remained improved during de-escalated treatment. Two patients remained stable during the 24-weekly treatment, while one developed local recurrence. Eight of the 9 patients had received de-escalated treatment at the latest follow-up. One developed malignant transformation and pulmonary metastases.

Conclusions: 12-weekly de-escalated treatment of denosumab can sustain symptomatic relief, tumor reduction, and new bone formation achieved with standard treatment, resulting in effective maintenance treatment in patients with unresectable GCTB. 24-weekly treatment can also be selected, with careful attention to local recurrence.

Background: Clinical studies have shown overexpression of multiple tyrosine kinase receptors on the surface of osteosarcoma samples. Anlotinib is a multi-targeted tyrosine kinase inhibitor. The combination of anti-angiogenic drugs with chemotherapeutic agents theoretically has the ability to act synergistically. We conducted this trial to explore the efficacy and safety of anlotinib in combination with chemotherapy for treatment naive stage IIB classical osteosarcoma of the extremity.

Methods: This is a multicentric, single-arm, open-lable trial. Eligible patients(pts) were aged 12-40 years with histologically diagnosed primary localized extremity classic osteosarcoma, stage IIB, operable. Pts received anlotinib (10mg, q3w), doxorubicin(A) and cisplatin(P) for the first nine weeks. Pts underwent radical surgery after exclusion of contraindications at week 10. After surgery, pts received AP at weeks 12-14, and anlotinib plus AP at weeks 15-20, drug dose unchanged. Since week 21, anlotinib(12mg) monotherapy was maintained until week 104 or occurrence of an EFS event. The primary endpoint was 24-month EFS rate, secondary endpoints were 36-month EFS rate, local recurrence rate, lung metastasis rate, 3-year OS Rate and safety.

Results: From May 2020 to Apr 2022, 52 eligible pts were enrolled. At the data cut-off date (Mar 2023), 51 pts underwent surgery after 3 cycles of neoadjuvant therapy, while the rates of limb salvage and R0 resection were 80.39%(95%CI:66.88-90.18%) and 100% (95%CI: 93.02-100%), respectively. In best overall response assessment during the neoadjuvant period, ORR was 1.92% (95%CI: 0.05-10.26%) and DCR was 96.15% (95%CI: 86.79-99.53%). The median EFS was not reached, 12 and 18month-EFS rate were 89.03% (95%CI: 75.39-95.33%) and 59.35% (95%CI: 8.64, 89.48%), respectively. The most grade 3/4 treatment-emergent adverse events were neutropenia (46.15%), leukopenia (36.54%), thrombocytopenia (32.69%), anemia (30.77%).

Conclusions: Preliminary results suggested that anlotinib combined with doxorubicin and cisplatin followed by surgery showed favorable efficiency and manageable adverse events in Stage IIB classic osteosarcoma of the extremity.

Clinical trial identification: ChiCTR2000033298.

Background: Metastatic Ewing Sarcoma (MES) has a poor prognosis, and therapeutic options are scarce in this rare disease. Large observational studies are needed to improve patients (pts) care and help designing future clinical trials.

Methods: Treatment characteristics, outcomes, and prognostic factors of pts $>$ 12 year-old treated for a MES in 10 French national reference network centers from 2008 to 2018 and included in the prospective database of the French Sarcoma Group were analyzed. The primary objective was to describe treatment modalities of pts with MES in a real-life setting, including systemic treatment (ST) regimen, access to clinical trials (CT) and loco-regional (LR) procedures. Secondary objectives were to assess pts outcome in terms of time to next treatment (TNT), progression free survival (PFS) and overall survival (OS) for each line of ST, as well as the impact of CT access and LR procedures on TNT, PFS and OS in the metastatic setting.

Results: 156 pts with MES were included, 80 pts were metastatic from diagnosis, 76 pts had a metastatic relapse. Median follow-up was 76.8 months [66.7; 88.5]. Median age was 21 years (12-86), 44 (28.2%) pts were $<$ 18 year old at metastasis diagnosis. Main primary location was pelvic (34.6%). 147 (94%) pts received ST in the metastatic setting, with a median of 3 lines (IQR 2-5). 102 (65.4%) pts received more than 2 lines. 95 (60.9%) of pts underwent LR procedure for metastasis, including radiation therapy (84.2%), radiological procedures (12.6%) or surgery (8.4%). 30 (31.6%) pts had

multiple procedures. Median OS from metastasis diagnosis was 26.6 months [95%CI 21.0; 32.2]. Median TNT was 5.3 months [95%CI 4.9; 5.6] for 1rst line, 5.5 months [95% CI 3.8; 6.8] for 2nd line and 5.5 months [95%CI 3.7; 7.7] and 3.6 months [95%CI 2.5; 4.4] for 3rd and 4rth lines. 66 (44.9%) pts were included in a CT at least once in the metastatic setting, 35 in 1rst line, 28 in 2nd line and 15 and 22 in 3rd and 4rth lines.

Conclusions: This large multicentric observational study details real-world data on patterns of treatments for pts with MES in France. Detailed ST regimens used, median TNT, PFS and OS according to line and ST regimen as well as factors associated with TNT, PFS and OS will be presented at the meeting.

[1]Department of Soft Tissue/Bone Sarcoma and Melanoma, Maria Sklodowska-Curie National Research Institute of Oncology, Warsaw, Poland; [2]Department of Pathology, Maria Sklodowska-Curie National Research Institute of Oncology, Warsaw, Poland; [3]Faculty of Medicine, Medical University of Warsaw, Warsaw, Poland; [4]Osteoncology, Bone and Soft Tissue Sarcomas and Innovative Therapies, Istituto Ortopedico Rizzoli, Bologna, Italy; [5]Anatomy and Pathological Histology, Istituto Ortopedico Rizzoli, Bologna, Italy; [6]Translational Research Department, Centre Léon Bérard, Lyon, France; [7]Department of Biopathology, Centre Léon Bérard, Lyon, France; [8]Medicine Department, Centre Léon Bérard, Lyon, France

Background: Infiltrates of various immune cells play an important role in tumor(tu) microenvironment depending on cells' population. T lymphocytes (Tcells, CD3+) may stimulate or suppress immune response, depending on CD4 or CD8 phenotype, respectively. The other important group of cells are macrophages — anti-tumoral M1-like and pro-tumoral M2-like cells. Immunophenotype of ChS and characterization of immune markers involved in pathogenesis is still poorly understood. The aim of this study was characterization of immune cells infiltrates in ChS subtypes and correlate it with clinical outcomes.

Methods: We enrolled 113 patients(pts) diagnosed with primary ChS: 29 grade(G) 1, 41-G2, 25 -G3 and 18 dedifferentiated/mesenchymal cases. For immunohistochemical assessment tissue microarrays of central and peripheral region of the tu were prepared from formalin-fixed paraffin-embedded tissue blocks. IHC analysis covered CD3 (for T cells overall), CD8 (cytotoxic T cells), CD4 (helper T cells), CD68[PG-M1] (M1-like cells), CD68[KP1] and CD163 (M2-like cells), PD-1+ on lymphocytes, and PD-L1+ on tu cells. The number of positive stained cells per area (mm^2, quantitative methods) was defined. PD-L1 expression was evaluated as percent of positive cells. Correlations between expression of immune cells in central and peripheral regions of tu were assessed, and overall survival(OS) was analyzed.

Results: Median OS of all pts was 141 (95%CI: 37.8-) months. In central region of tu we identified significant positive correlation between presence of M1-like CD68+ and M2-like CD68+ macrophages (rho=0.69, $p<0.001$), as well as CD3 and CD4 cells (rho=0.72, $p<0.001$). The correlation of immune infiltrates presence between central and peripheral region of tu was low (rho $\leq$0.5). In multivariate Cox analysis presence of CD3 cells (HR 2.98, CI:1.43-6.23, $p<0.01$) and expression of PD-L1 (HR 1.01, CI:1.01-1.01, $p<0.01$) in central part of tu, as well as high grade of tu (G3/dedifferentiated/mesenchymal) predicted poorer survival. Other immune infiltrates were not significantly correlated with OS.

Conclusions: Beside high grade, PD-L1 expression and CD3 cell influx in central region of tu are independent poor prognostic factors in ChS.

Background: Metastatic chondrosarcoma (MCS) has a poor prognosis, and there is still no effective therapeutic option for this rare disease. Large observational studies are needed to improve patients (pts) care and help designing future clinical trials.

Methods: Treatment characteristics, outcomes, and prognostic factors of pts treated for a MCS in 9 French national reference network centers from 2008 to 2018 and included in the prospective database of the French Sarcoma Group were analyzed. The primary objective was to describe treatment modalities of pts with MCS in a real-life setting, including systemic treatment (ST) regimen, access to clinical trials (CT) and loco-regional (LR) procedures. Secondary objectives were to assess pts outcome in terms of time to next treatment (TNT), progression free survival (PFS) and overall survival (OS) for each line of ST, as well as the impact of CT access and LR procedures on TNT, PFS and OS in the metastatic setting.

Results: 124 pts with MCS were included, 31 pts were metastatic from diagnosis, 93 pts had a metastatic relapse. Median follow-up was 56.4 months [33.4; 89.6]. Median age was 61.5 years (14-90). Main histology was dedifferentiated chondrosarcoma (42.7%) and main primary location the trunk (34.7%). Main metastatic site was lung (61.3%). 72 (58%) pts received ST in the metastatic setting, with a median of 2 lines (IQR 1-3). 21 (16.9%) pts received more than 2 lines. 50 (40.3%) of pts underwent LR procedure for metastasis, including radiation therapy (52.0%), surgery (26.0%) or radiological procedures (24.0%); 16 (32.0%) pts had multiple procedures. Median OS from metastasis diagnosis was 12.7 months [95%CI 8.2; 14.9]. Median TNT was 4.6 months [95%CI 3.0; 5.9] for 1rst line, 3.4 months [95%CI 2.7; 4.8] for 2nd line and 3.4 months [95%CI 2.0; 7.9] for 3rd line. 12 (16.7%) pts were included in a CT at least once in the metastatic setting, 4 in 1rst line, 5 in 2nd line and 4 in 3rd line.

Conclusions: This large multicentric observational study details real-world data on patterns of treatments for pts with MCS in France. Detailed ST regimens used, median TNT, PFS and OS according to line and ST regimen as well as factors associated with TNT, PFS and OS will be presented at the meeting.

Background: Metastatic osteosarcoma (MOS) has a poor prognosis, and treatment options are scarce in this rare disease. Large observational studies are needed to improve patients (pts) care and help designing future clinical trials.

Methods: Treatment characteristics, outcomes, and prognostic factors of pts $>$ 12 year-old treated for a MOS in 10 French centers from 2008 to 2018 and included in the prospective database of the French Sarcoma Group were analyzed. The primary objective was to describe treatment modalities of pts with MOS in a real-life setting, including systemic treatment (ST) regimen, access to clinical trials (CT) and loco-regional (LR) procedures. Secondary objectives were to assess pts outcome in terms of time to next treatment (TNT), progression free survival (PFS) and overall survival (OS) for each line of ST, as well as the impact of CT access and LR procedures on TNT, PFS and OS in the metastatic setting.

Results: 262 pts with MOS were included, 86 pts were metastatic from diagnosis, 176 pts had a metastatic relapse. Median follow-up was 59.7 months [51.3; 68.4]. Median age was 26 years (12-85), 48 (18.3%) pts were $<$ 18 year old at metastasis diagnostic. Main histology was conventional OS (60.3%) and main primary location was inferior limb (60.3%). 227 (86.6%) pts received ST in the metastatic setting, with a median of 2 lines (IQR 1-3). 101 (38.5%) pts received more than 2 lines. 153 (58.4%) of pts underwent LR procedure for metastasis, including surgery (49.0%), radiation therapy (41.8%) or radiological procedures (13.1%); 46 (30.1%) pts had multiple procedures. Median OS from metastasis diagnosis was 21.5 months [95%CI 18.9-27.0]. Median TNT was 4.9 months [95%CI 4.3-5.7] for 1^{rst} line, 5.6 months [95%CI 4.6-6.3] for 2nd line and 3.9 months [95%CI 3.5-5.1] and 2.9 months [95%CI 1.8-4.2] for 3rd and 4^{rth} lines. 56 (24.7%) pts were included in a CT at least once in the metastatic setting, 29 in 1^{rst} line, 27 in 2nd line and 15 in 3rd line.

Conclusions: This large multicentric observational study details real-world data on patterns of treatments for pts with MOS in France. Detailed ST regimens used, median TNT, PFS and OS according to line and ST regimen as well as factors associated with TNT, PFS and OS will be presented at the meeting.

1972P Molecular mechanism study of recurrence/metastasis for Enneking IIb osteosarcoma

J. Yin[1], Y. Fu[1], G. Huang[1], C. Zou[1], X. Xie[1], J. Huang[2], J. Song[2], F. Pang[2], J. Shen[1]

[1]Department of Musculoskeletal Oncology, The First Affiliated Hospital of Sun Yat-sen University, Guangzhou, China; [2]Medical Department, Shanghai OrigiMed Co., Ltd, Shanghai, China

Background: Osteosarcoma (OS) is a common primary bone malignancy in children and adolescents, with most patients diagnosed with Enneking stage IIB. However, the prognosis for these patients is inconsistent, with over half experiencing recurrence or metastasis under standard treatment. The Enneking staging system alone cannot accurately distinguish the risk group for recurrence and metastasis, highlighting the need for further research into the molecular mechanisms.

Methods: 74 Chinese patients with Enneking stage IIB OS under standard treatment were included, followed up for over two years. Targeted deep sequencing was performed by YUANSU panel (OrigiMed, Shanghai, China) with 706 cancer-related genes and the Kaplan-Meier method was used to calculate survival curves.

Results: The cohort included 74 patients, 50 males and 24 females, with 40 experiencing recurrence or metastasis and 34 not. The high frequency mutated genes in IIB primary OS were found to be *TP53 (33%) FLCN (29%) GID4 (29%) NCOR1 (28%) VEGFA (24%) CCND3 (21%)*. The group with recurrence or metastasis had significantly higher TMB than the group without ($p<0.05$). Survival analysis revealed that genetic mutations in *MCL1, MYC, TFEB, CCND3, AURKB, ALOX12B*, and *VEGFA* increase the likelihood of recurrence and metastasis in IIB OS patients. (*MCL1/MYC/TFEB/CCND3/AURKB/ALOX12B, $p<0.05$; VEGFA, $p=0.065$*); Abnormalities in the MYC, WNT, and Cell cycle pathways are associated with a worse prognosis (*MYC/WNT, $p<0.05$; Cell cycle, $p=0.057$*). These results indicate that genetic variants and pathway abnormalities are significant risk factors for IIB OS.

Conclusions: Our study represents the largest cohort investigating the molecular mechanisms of Chinese IIB OS. Mutations of *MCL1/MYC/TFEB/CCND3/AURKB/ALOX12B/VEGFA* genes and MYC/WNT/cell-cycle pathways are high-risk factors for recurrence/metastasis. Given the high mutation frequency and poor prognosis of patients with VEGFA and cell cycle signaling pathway abnormalities, anti-angiogenic agents and cell cycle inhibitors may be more effective treatment options compared with standard therapy. Further studies are needed to confirm their efficacy.

Legal entity responsible for the study: The First Affiliated Hospital of Sun Yat-sen University.

Background: GIST treatment has been transformed by TKIs but resistance is a challenge in managing advanced disease. Pts with SDH-deficient GIST typically present with TKI-insensitive, multifocal/multinodular disease. Olverembatinib is a novel, potent, multitargeted TKI with promising preclinical activity against GIST.

Methods: Antitumor activity of olverembatinib was evaluated via a panel of SDH-deficient cell lines. SDH knockdown was performed in PC12 cells to assess potential mechanisms of action. The aim of the phase 1 study was to assess safety and efficacy (RECIST v1.1) of olverembatinib, orally once every other day (QOD) in 28-day cycles, in pts with TKI-resistant, metastatic, SDH-deficient, IHC-confirmed GIST.

Results: Olverembatinib had superior antiproliferative effects on SDH-deficient cancer cell lines, and the increased sensitivity could be ascribed to FGFR pathway upregulation. As of January 15, 2023, 20 pts had received $\geq$ 1 dose of olverembatinib and 19, 1-4 TKIs (Table). The dose range of olverembatinib was 20-50 mg and median (range) treatment duration 7.8 (1.81-42.3) mo. 5/20 pts experienced PR as best response. Of 16 evaluable pts receiving $>$ 4 cycles, the clinical benefit rate (CBR; CR + PR + stable disease [SD] $>$ 4 cycles) was 93.8% (15/16); the longest treatment duration was 42 mo. All pts experienced TEAEs (mostly grade 1 or 2 [G1-2]); 2 had G3 AEs; the only hematologic AE with incidence rate $\geq$ 20% was anemia (55%). 15 (75%) pts had TRAEs (G3 neutropenia [n = 1]). No treatment-related SAEs were reported.

Conclusions: Olverembatinib was effective in SDH-deficient tumors preclinically. In the phase 1 study, it was well tolerated up to 50 mg QOD and showed antitumor activity in pts with TKI-resistant, SDH-deficient GIST. 5 PRs were reported in 20 evaluable pts, and 15 SDs among 16 pts treated $\geq$ 4 cycles (93.8% CBR). These promising data warrant further investigation. Study: HQP1351SJ003.

Background: In the intermediate-risk (I-R) GIST patients, the choice of adjuvant imatinib is challenging. Historically, patient risk stratification is based on tumor size, mitotic index, tumor location, and tumor rupture. Innovative measures from NGS, such as the *KIT*-Variant Allele Frequency (VAF), may act as surrogate of tumor burden, and thus might negatively correlate with prognosis of localized GIST patients, along with specific tumor genotyping.

Methods: We used real-world data from a multicenter, hospital-based, retrospective/prospective cohort study to develop a prognostic nomogram integrating VAF levels and type/gene location of *KIT* mutations. The receiver operating characteristic (ROC) analysis was used to classify "low" vs "high" VAF values, further normalized on neoplastic cellularity (nVAF). The optimal cut-off was 50% (AUC 0.84; p-value < 0.02). Cox regression/nomogram models were developed in SPSS and R, respectively.

Results: Overall, data from 240 GIST patients treated between 2015 and 2022 at 6 Oncologic Centers in the EURACAN Network were collected. The cohort of I-R patients with tumors harboring *KIT* mutations, without adjuvant imatinib, included 66 patients. Diameter of primary tumor >5 cm ($p=0.005$), mitosis >5/mmq ($p<0.001$), no-gastric site of origin ($p=0.01$), *KIT* Exon 11 deletions or delins involving codons 557 and/or 558 ($p<0.001$), and nVAF $> 50\%$ ($p=0.006$), were significantly associated with Relapse-Free Survival (RFS). At the median follow-up of 24 months, RFS rate of I-R cohort was 74.4% in the high-nVAF group vs 100% in the low-nVAF group. When RFS between the 2 groups was compared, I-R patients with high-nVAF showed poorer RFS than low-nVAF group. Nomogram analysis including *KIT*-PVs—nVAF, and the presence/absence of 557/558 del/delins, predicted 2-year RFS.

Conclusions: Prognostication in the intermediate-risk subgroup is still challenging for optimal patient selection for adjuvant imatinib. In this sub-population the use of a nomogram incorporating nVAF and type/gene location of *KIT* mutations, might represent a more accurate tool in the clinical decision-making process.

1975P Systemic therapy for KIT/PDGFRA wild-type GIST

M. Brahmi[1], A. Dufresne[1], A. Pattee[1], H. Vanacker[1], A. Meurgey[2], D. Pissaloux[2], P. Meeus[3], M-P. Sunyach[4], M. Karanian[2], A. Bouhamama[5], F. Tirode[6], P. Cassier[1], I.L. Ray-Coquard[1], J-Y. Blay[1]

[1]Medical Oncology Department, Centre Léon Bérard, Lyon, France; [2]Biopathology, Centre Léon Bérard, Lyon, France; [3]Surgical Oncology, Centre Léon Bérard, Lyon, France; [4]Radiation Oncology, Center Leon Bérard, Lyon, France; [5]Radiology, Centre Léon Bérard, Lyon, France; [6]Cancer Research Center of Lyon, Centre Léon Bérard, Lyon, France

Background: Patients (pts) with metastatic KIT/PDGFRA wild-type (KPWT) gastrointestinal stromal tumours (GIST) usually do not derive any benefit from upfront treatment with imatinib. Most of the studies reported so far include case reports or small series and treatment patterns widely differed according to the medical teams. More studies are therefore needed to define the optimal management of metastatic KPWT GIST pts. The primary aim of this retrospective study was to assess the outcome of pts with KPWT GIST treated by Tyrosine Kinase Inhibitors (TKI) in our institution.

Methods: We conducted a retrospective study at a single institution, the Centre Léon Bérard (CLB). The national sarcoma database (https://netsarc.sarcomabcb.org/) was searched for pts with a diagnosis of KPWT GIST treated at the CLB. Data were extracted from individual patients' files. All cases were reviewed by an expert sarcoma pathologist. In the absence of a known neurofibromatosis type 1 (NF1) or SDH-deficiency, whole exome-RNAseq was performed on FFPE material.

Results: In total, 86 pts with metastatic KPWT GIST were identified, with a median age at diagnosis of 55 [10-80], a sex-ratio of 0.9 and a median tumor size of 65 mm [11-260]. The primary tumor was in the stomach for 42 pts (49%) and in the duodenum for 40 (47%). The vast majority were *KIT* and *DOG1* positive by IHC (98 and 92%, respectively). Among the 86 pts, 31 (36%) had a metastatic disease, either synchronous ($N=15$) or metachronous ($N=16$). The majority of these cases were NF1-associated GIST (N=13, 42%), 7 were SDH-deficient GIST (23%), one was NTRK-rearranged GIST (*RBPMS::NTRK3*), one harboured TSC1 variant (T314M) and no significant mutation/fusion was detected in 9 GIST. While none of the 31 pts responded to imatinib, 3/3 pts had a partial response with lenvatinib (all SDH-deficient GIST), 1/3 with pazopanib, 2/20 (10%) with sunitinib and 2/10 (20%) with regorafenib. Interestingly, the highest duration of response PFS was with pazopanib (111 months).

Conclusions: This retrospective series of KPWT GIST is one of the largest with this rare disease. Although there was no response to first line TKI imatinib, some long responders are reported with anti-angiogenic TKI and warrant additional investigation through prospective trials to validate those results.

1976P Financial difficulties experienced by gastrointestinal stromal tumor (GIST) patients in the Netherlands: Data from a cross-sectional multicenter study

D. van de Wal[1], D. Den Hollander[2], I.M. Desar[2], H. Gelderblom[3], A.W. Oosten[4], A.K.L. Reyners[5], N. Steeghs[1], W.T.A. Van Der Graaf[1], O. Husson[6]

[1]Medical Oncology Department, NKI-AVL - Netherlands Cancer Institute/Antoni van Leeuwenhoek Hospital, Amsterdam, Netherlands; [2]Medical Oncology Department, Radboud University Medical Center, Nijmegen, Netherlands; [3]Medical Oncology Department, LUMC - Leids University Medical Center, Leiden, Netherlands; [4]Medical Oncology Department, Erasmus MC, Rotterdam, Netherlands; [5]Medical Oncology Department, UMCG - University Medical Centre Groningen, Groningen, Netherlands; [6]Psychosocial Research And Epidemiology Department, NKI-AVL - Netherlands Cancer Institute/Antoni van Leeuwenhoek Hospital, Amsterdam, Netherlands

Background: Financial difficulties get little attention in daily clinical practice, while they can have a considerable impact on treatment outcomes and the patient's quality of life. This study aims to explore the prevalence of financial difficulties among GIST patients, with a distinction in patients on tyrosine kinase inhibitor (TKI) treatment or not on TKI treatment, and investigate associations between financial difficulties and sociodemographic and clinical characteristics, work, cancer-related concerns, anxiety and depression.

Methods: A cross-sectional study was conducted among Dutch GIST patients between September 2020 and June 2021. Patients completed nine items regarding financial difficulties of the EORTC item bank, work-related questions, Hospital Anxiety and Depression Scale (HADS), Cancer Worry Scale (CWS) and EORTC QLQ-C30.

Results: In total, 328 GIST patients participated (response rate 63.0%), of which 108 (32.9%) were on TKI treatment. Experiencing financial difficulties was associated with significantly lower global quality of life (67.8 vs 81.6, $p=<0.001$) as compared to patients who did not report financial difficulties. Patients with financial difficulties also more frequently reported symptoms of anxiety (41.7% vs 11.5%, $p=<0.001$) and depression (36.1% vs 10.1%, $p=<0.001$), had more fear of cancer recurrence or progression (73.0% vs 39.9%, $p=<0.001$), and were more often concerned about dying from GIST both in the near future (64.9% vs 34.9%, $p=<0.001$) and in the long run (75.7% vs 49.5%, $p=0.003$). The odds of experiencing financial difficulties was 16.4 (95% CI 1.24-217.1; $p=0.03$) times higher in patients that were less able to work. Patients currently treated with TKIs experienced significantly more financial difficulties compared to patients not on TKIs (17.6% vs 8.7%, $p=0.02$).

Conclusions: Even in a country where the costs of TKIs and follow-up care are covered by health insurance, financial difficulties can be present in GIST patients, especially in patients on TKI treatment. Given the association between financial difficulties with quality of life, anxiety, depression and cancer-related concerns, more support should be provided to patients.

1977P A registry-based analysis of the projected genomic landscape among unclassified KIT/PDGFRA wildtype mutations in patients with gastrointestinal stromal tumors

J. Call[1], D. Evans[1], S. Kaur[1], S. Rothschild[2]

[1]Data Management & Research, The Life Raft Group, Wayne, NJ, USA; [2]The Life Raft Group, Wayne, NJ, USA

Background: Gastrointestinal stromal tumors (GIST) are characterized by multiple subtypes with distinct biological features. Here, we report the frequency of classified mutations and the projected frequency of unclassified KIT/PDGFRA Wildtype (KIT/PDGFRA WT) mutations in GIST patients that received mutational testing.

Methods: This data was supplied by the Life Raft Group (LRG) Registry. Of 2465 patients, 55.3% (n=1363) had mutational testing (Tested) and 44.7% (n=1102) did not (Untested). We used the distribution of classified KIT/PDGFRA WT that had further testing to estimate the frequency in unclassified KIT/PDGFRA WT. By assuming the distribution of unclassified Wildtype patients is similar to the classified patients, we projected the entire cohort by multiplying the percentage of each classified KIT/PDGFRA WT mutation to the total number of unclassified KIT/PDGFRA WT patients (n=101).

Results: *Tested Patients* Out of 1363 Tested patients, the distribution was: KIT 77.8% (n= 1060), PDGFRA 7.6% (n= 104), SDHx 4.8% (n= 66), NF1 1.5% (n= 20), BRAF (includes 1 fusion) 0.6% (n= 8), ETV6-NTRK3 fusion 0.2% (n= 2), PTCH1 0.1%(n=1), NTRK 0.1%(n=1). *KIT/PDGFRA WT* Approximately half (49.2%, n= 98) of KIT/PDGFRA WT patients had further testing (classified), e.g., SDHx, NF1, BRAF, etc. The other half (50.8%, n=101) had no further or inconclusive testing (unclassified), which are recorded as "Wildtype" (WT) in the registry. Table displays the projected number of patients in unclassified WT and the overall projection of all Tested patients.

Table: 1977P Known and projected mutation distribution

Gene	Tested Patients (Known) n=(%)	Classified WT KIT/PDGFRA Mutation Rate % (n=98)	Projected No of Patients in Unclassified WT (n=101)	Known & Projected Patients	Projected Rate (%)
Kit	1060 (77.8%)	NA	NA	1060	77.8%
PDGFRA	104 (7.6%)	NA	NA	104	7.6%
Unclassified WT	101 (7.4%)	NA	-	NA	NA
SDHA	31 (2.3%)	31.6	32	63	4.6%
SDHB	21 (1.5%)	21.4	22	43	3.2%
NF1	20 (1.5%)	20.4	21	41	3.0%
SDHC	9 (0.7%)	9.2	9	18	1.3%
BRAF	7 (0.5%)	7.1	7	14	1.0%
SDH-C Epimutant	4 (0.3%)	4.1	4	8	0.6%
ETV6-NTRK3 Fusion	2 (0.1%)	2.0	2	4	0.3%
AGAP3-BRAF Fusion	1 (0.1%)	1.0	1	2	0.1%
SDHD	1 (0.1%)	1.0	1	2	0.1%
NTRK	1 (0.1%)	1.0	1	2	0.1%
PTCH1	1 (0.1%)	1.0	1	2	0.1%
Total	1363 (100%)	100%	101	1363	100%

Conclusions: By using the methods described, we were able to project the frequency of mutations in LRG registry patients and identified a higher frequency of unclassified mutations. A well-defined mutation can provide important information to optimize clinical decision-making, including diagnosis, prognosis, treatment selection, and monitoring treatment response.

1978P Identification of SDH-deficient GIST increases after the implementation of diagnostic algorithm in Life Raft Group (LRG) patient registry data

D. Evans[1], J. Call[1], S. Kaur[1], S. Rothschild[2]

[1]Data Management & Research, The Life Raft Group, Wayne, NJ, USA; [2]The Life Raft Group, Wayne, NJ, USA

Background: Succinate dehydrogenase (SDH) deficient GISTs account for less than 10% of all GISTs and exhibit distinct biological features when compared to those that harbor KIT/PDGFRA mutations. SDH-deficient GIST commonly affects young adolescents with a baseline metastatic presentation and are frequently insensitive to tyrosine kinase inhibitors. The immunohistochemical (IHC) loss of SDH subunit B (SDHB) is a characteristic marker of SDH-deficient GIST, which is suggestive of the loss of function in the entire SDH-complex. With data from the LRG Patient Registry, a diagnostic algorithm illustrating the need for wider use of targeted diagnostic procedures was implemented in the College of American Pathologists (CAP) guidelines to facilitate the identification and treatment of SDH-deficient patients. Here, we aim to evaluate the results within our data after the implementation of such an algorithm.

Methods: The LRG Patient Registry is a global longitudinal natural history study that is supported by medical records, including pathology and genomic reports. Two datasets from the LRG Patient Registry were used in this study, with the data cutoff points being 2017 and 2022. A comparison of the total number of SDHx patients reported in each dataset was conducted. SDH-deficient patients reported an SDHx mutation and/or loss of SDHB IHC expression.

Results: Out of the (n=750) global patients that reported their mutation in 2017, 28 (3.7%) were identified as SDH-deficient. When comparing with the 2022 dataset, (n = 1387 with mutational results) 83 (6.0%) were identified as SDH-deficient. This represents a 60% increase in identified patients.

Conclusions: The absence of SDHB IHC staining as part of the regular pathology protocol led to the under-identification of SDH-deficient patients. This study emphasizes the significance of SDHB IHC staining and advanced mutational testing in the LRG Patient Registry population. It is encouraged that the use of SDHB IHC should be included in additional guidelines to optimize the identification, diagnosis, and management of SDH-deficient GIST patients.

1979P phase I trial of pembrolizumab in HIV-associated Kaposi sarcoma (KS)

K. Lurain[1], R. Ramaswami[1], I. Ekwede[1], V. Eulo[2], G. Goyal[2], M. Menon[3], T.A. Odeny[1], E. Sharon[4], M. Wagner[3], C-C. Wang[5], N. Bhardwaj[6], M. Abdul-Hay[7], J. Kaiser[3], A. Wright[3], R. Yarchoan[1], S.P. Fling[3], Q. Lu[8], T.S. Uldrick[3]

[1]HIV and AIDS Malignancy Branch, Center for Cancer Research - National Cancer Institute, Bethesda, MD, USA; [2]Hematology Oncology, University of Alabama at Birmingham, Birmingham, AL, USA; [3]Hematology Oncology, Fred Hutchinson Cancer Research Center, Seattle, WA, USA; [4]Division of Cancer Treatment & Diagnosis, National Cancer Institute, Bethesda, MD, USA; [5]Hematology Oncology, UCSF - University of California San Francisco, San Francisco, CA, USA; [6]Hematology Oncology, Tisch Cancer Institute, Icahn School of Medicine at Mount Sinai, New York, NY, USA; [7]Hematology Oncology, NYU Langone Health - Perlmutter Cancer Center - 34th Street, New York, NY, USA; [8]Biostatistics, Cytel Singapore Pte. Ltd, Great World City West, Singapore

Background: Cancer Immunotherapy Trials Network 12, a phase 1 multicenter study of pembrolizumab (pembro) in advanced HIV-associated cancers showed safety across a range of cancers in patients (pts) with controlled HIV (Uldrick et al. *JAMA Oncology* 2019). We report results from the expanded KS cohort.

Methods: Pts with HIV+ KS, CD4 count (CD4) ≥50 cells/μL, antiretroviral therapy (ART) for ≥4 weeks, HIV viral load ≤200 copies/mL with or without prior KS therapy were eligible. Pts received pembro 200 mg q3 weeks for up to 35 cycles. The primary objective was safety by NCI Common Terminology Criteria for Adverse Events; the secondary objective was KS response rate by AIDS Clinical Trials Group Criteria. Progression-free survival (PFS) and duration of response (DOR) were evaluated by Kaplan-Meier (KM) methodology.

Results: 32 men [median (med) age 45 years; 16 White, 15 Black, 7 Latino] with HIV+ KS were enrolled. Baseline med CD4 was 274 cells/μL. 9 pts had no prior systemic KS therapy. Pts received a med of 10 cycles of pembro. 2 pts completed 35 cycles and/or 2 years of treatment, 6 have ongoing treatment, and 24 stopped treatment before 35 cycles [progressive disease (9), unacceptable toxicity (5), declined further treatment (3), death (1), other reasons (6)]. Med CD4 increase at end-of-treatment was 50 cells/μL (p=0.046). 13 pts (41%) had grade (G) ≥2 pembro-related treatment-emergent adverse events (AE), including 1 previously reported pt who died of polyclonal HHV8-related B cell lymphoproliferation. 10 (31%) pts had ≥1 immune-mediated AE (imAE) [G1 (1), G2 (5), G3 (4)] with 7 (22%) requiring systemic steroids. Of the 28 evaluable pts, 17 had a partial response (including 6 with CD4 <200 cells/μL), 8 had stable disease, and 3 had progressive disease as best response to pembro. The overall response rate (ORR) was 60.7% (95% CI: 40.6-78.5) and did not differ by CD4. Notably, the ORR was 85.7% (95% CI: 42.1-99.6) in pts without prior KS therapy. Med PFS was 28.2 mo (95% CI: 4.2-non-calcuable). The KM probability estimate of a DOR ≥ 12 months was 91.7% (95% CI: 53.9-98.7).

Conclusions: Pembro leads to a durable, high response rate, particularly as first systemic KS therapy, and is associated with CD4 immune reconstitution. Although 31% of pts had imAEs, they were successfully managed following standard guidelines.

Clinical trial identification: NCT02595866.

1980P Artificial intelligence analysis shows enhanced CCNG1 expression in sarcoma tumors, a novel biomarker for DeltaRex-G tumor targeted retrovector encoding a CCNG1 inhibitor gene

S.P. Chawla[1], N. Omelchenko[2], C. Eid[2], S. Jeffrey[2], Z. Shekhovtsova[3], K. Suryamohan[3], E. Younesi[2], A. Omelchenko[2], A. Ahari[2], C. Valencia[2], N.S. Chawla[4], D. Brigham[5], E.M. Gordon[2]

[1]Oncology Department, Sarcoma Oncology Research Center, Santa Monica, CA, USA; [2]Medical Oncology, Sarcoma Oncology Research Center, Santa Monica, CA, USA; [3]Medical Oncology, Boston Gene, Inc., Waltham, MA, USA; [4]GU postdoctoral fellow, City of Hope Comprehensive Cancer Center, Duarte, CA, USA; [5]Medical Oncology, Aveni Foundation, Santa Monica, CA, USA

Background: In phase 1/2 studies using DeltaRex-G targeted retrovector bearing a CCNG1 inhibitor gene for advanced sarcoma, long term survival reports showed that four (7%) patients with chemotherapy resistant advanced sarcoma were alive > 10 years from DeltaRex-G treatment initiation. Expanded access for DeltaRex-G, is currently open for advanced sarcoma patients. (NCT04091295). In this study, we analyzed CCNG1 expression in tumors of patients who are being followed at our Cancer Center to identify those who might respond favorably to DeltaRex-G therapy.

Methods: Archived formalin-fixed paraffin embedded (FFPE) tumor specimens (n=65) from patients with sarcoma were collected, processed, and subjected to RNA sequencing. Briefly, RNA-seq libraries were sequenced to generate 50 million reads that were aligned using Kallisto v0.42.4 to GENCODE v23 transcripts with default parameters. A gene expression level is presented as low/medium/high depending on the expression level of a such gene in patients of the reference cohort. Low = <17%; Medium = 17%-83%; High = >83%.

Results: Thirty male and 35 female subjects, ages ranging from 16 to 87 years were studied. Four (6%) tumors showed high CCNG1 expression, forty-seven (72%) tumors had medium expression, and fourteen (22%) tumors had low CCNG1 expression. Seven of 65 patients had osteosarcoma, of which 4 were male, three females, ages ranging from 16 to 57 years. The osteosarcoma tumors showed 86% with medium CCNG1 expression and 14% with low CCNG1 expression. Five patients with medium CCNG1 expression had metastatic disease while one patient with low and one with medium CCNG1 expression had localized disease. Of note, one participant with advanced chondrosarcoma had clinical benefit (stable disease) by RECISTv1.1 and is alive 3 years after DeltaRex-G treatment initiation. AI analysis of his tumor showed 74% CCNG1 expression.

Conclusions: Taken together, these data suggest that (1) 90% of sarcoma tumors have high to medium CCNG1 expression and (2) Four of 5 (80%) osteosarcoma tumors have medium CCNG1 expression. Prospective studies are planned to correlate CCNG1 expression level with response to DeltaRex-G therapy.

1981P Histopathological diagnostic discrepancies in bone and soft tissue tumors referred to a specialist sarcoma center and its clinical impact

A. Kawai

Musculoskeletal Oncology Department, National Cancer Center Hospital, Tokyo, Japan

Background: Histopathological diagnosis of sarcomas is challenging because of their rarity, diverse histological findings, and constantly evolving diagnostic criteria. In this study, we attempted to clarify discrepancies between histopathological diagnoses made by general pathologists at referral hospitals and diagnoses made by specialist pathologists at a tertiary cancer hospital, with a focus on its clinical impact in the era of genome medicine.

Methods: We analyzed 628 specimens from 624 consecutive-referral patients, who visited a specialist sarcoma center for treatment between April 2017 and March 2019. Differences between the first diagnosis provided at another hospital by non-expert pathologists and the diagnosis reviewed by a specialist pathologist at the sarcoma center were evaluated and classified into four categories: agreement, non-agreement, specified, and de-specified.

Results: Of the 628 specimens, pathological diagnosis matched in 403 (64.2%) specimens whereas some change was noted in 225 (35.8%) specimens. The changes in pathological diagnoses were as follows: non-agreement, 153 specimens (24.3%); specified, 52 (8.3%); and de-specified, 20 (3.2%). The benign/malignant judgment had changed for 92 specimens (14.6%). The main reason for the discrepancies was the difference in interpretation of tumor histology, which accounted for 48.9% of the cases. The unavailability of immunostaining and genetic analysis accounted for 24.4% and 8.9% of the discrepancies, respectively. The treatment was changed in 91 cases (14.5%) due to changes in the pathological diagnoses. The number of changes in surgical treatment, medical treatment, and both were 40 (6.4%), 44 (7.0%), and 7 (1.1%), respectively.

Conclusions: Our study shows that over 35% of first histopathological diagnoses of bone and soft tissue tumors were modified by expert pathologists at a tertiary cancer hospital and resulted in different treatment decisions in about 15% of cases. Given the therapeutic implications of a misdiagnosis, ensuring accurate histopathological diagnosis using some public mechanisms is of vital importance in cases of these rare tumors.

1982P Transcriptomic analysis and tumor microenvironment (TME) classification reveals unique immune biology in HIV patients with Kaposi sarcoma (KS)

J. Yang[1], A. Sevkoplyas[2], S. Podsvirova[2], A. Tyshevich[2], M. Wang[1], M. Lee[1], H. Narvel[1], K. Zornikova[2], N. Shin[2], N. Kotlov[2], E. Postovalova[2], L. Paoluzzi[3], C. Zhu[4], B. Halmos[1], X. Zang[1], H. Cheng[1]

[1]Medical Oncology, Albert Einstein College of Medicine, Bronx, NY, USA; [2]BostonGene, Corp., Waltham, MA, USA; [3]Research and Development, Regeneron Pharmaceuticals, Inc., Sleepy Hollow, NY, USA; [4]Pathology, Montefiore Medical Center - Moses Campus, Bronx, NY, USA

Background: KS, associated with human herpesvirus 8 (KSHV) infection, is a tumor originating from endothelial cells. As a common tumor associated with AIDS, KS is typically more aggressive in HIV-positive (HIV+) than in HIV-negative (HIV-) patients (pts). While antiretroviral therapy helps control KS in HIV+ pts, chemotherapy remains the first-line treatment (Tx) in advanced KS but is limited by modest responses and dose-limiting toxicities. The TME has been shown to play a critical role in KS development and progression. Here, we sought to understand the TME in KS, with a specific focus on the differences in HIV status.

Methods: Whole transcriptomic profiling was performed on 13 retrospective samples from 9 pts (HIV+: n = 6, HIV- n =3; mostly baseline, except 2 HIV- and 2 HIV+ pts had paired samples before and after Tx). A deconvolution algorithm Kassandra was used to predict cellular composition with pre-training on sarcoma samples, and EdgeR was used for differential expression analysis. TME subtypes were classified based on a previous study (Bagaev et al., 2021) assessing sarcoma-related gene expression patterns.

Results: All KS samples were enriched with endothelial cells and had characteristics of a typical sarcoma TME with an abundance of macrophages and normal amounts of B cells. Most HIV- pts had an Immune-Enriched, Non-fibrotic subtype, while HIV+ pts had immune-Enriched, Fibrotic or Fibrotic TMEs. Decreased angiogenic signatures were observed after Tx in HIV+ pts with paired samples. Expression levels of chemokines (CXCL2, CXCL8, CXCL11), chemokine receptors (CCR1-7, CXCR1-2), and CCL factors were higher in pre-Tx HIV- pts versus post-Tx and post-TX HIV+ pts versus pre-TX. PD-L1 and PD-L2 expressions were higher in HIV- pts before Tx and in HIV+ pts after Tx. In 3 HIV- and 2 HIV+ pts, for whom TCR.

Conclusions: Our results showed distinct transcriptomic features and TMEs between HIV+ and HIV- KS in responses to Tx. Future larger cohorts and research into the unique T cell clonotypes may help yield novel therapeutic avenues in KS.

1983P Palliative spatially fractionated stereotactic radiation therapy (Lattice) for large sarcoma

G. Studer[1], M.S. França[2], C. Glanzmann[3], B. Fuchs[4], C.A.J. da silva[5], B.B. Lopes David[6], G.S. Franca[7]

[1]Radiation Oncology, Luzerner Kantonsspital, Lucerne, Switzerland; [2]Oncology, Hospital da Baleia - Fundacao Benjamin Guimaraes (FBG), Belo Horizonte, São Paulo, Brazil; [3]Radiation Oncology, LUKS, Lucerne, Switzerland; [4]Surgery, LUKS, Lucerne, Switzerland; [5]1003 Estrada de Camorim, INCA - Hospital do Cancer II, Rio de Janeiro, Brazil; [6]Clínicas research, INCA - Instituto Nacional de Cancer José Alencar Gomes da Silva, Rio de Janeiro, Brazil; [7]Radiotherapy - Hospital Oncobio, Grupo Oncoclinicas, Grupo Oncoclinicas - ONCOBIO, Nova Lima, Brazil

Background: Awareness and respective publication numbers on Spatially Fractionated RT (SFRT) rapidly increased over the past years. Lattice Radiotherapy (LRT) as one form of SFRT is a promising treatment option for patients with large inoperable and/or metastatic tumors. Since first reports on clinical LRT use in ∼2010, all confirm unexpectedly high tumor responses with excellent treatment tolerance. Questions regarding best dose-volume/fractionation/geometrical solutions are unanswered - several approached are in early testing. Similarly, knowledge regarding outcome over time (extent, duration of treatment effects) are hardly known yet. Only few case reports were published on LRT in sarcoma. We aimed to assess early outcome of a multi-center retrospective sarcoma patient cohort treated with LRT.

Methods: This retrospective cohort analysis included 22 palliative patients treated from 08.2020-04.2023 with LRT for 28 large (>10cm) sarcomatous lesions of different subtypes. Data were prospectively collected. LRT was performed at 2 Centers (A: Instituto Oncobio, Minhas Gerais (Brazil), B: LUKS Universitary Teaching Hospital (Switzerland)). Mean/median GTV measured 1029/780cc (74-4778). Center A used 1 single fraction with doses of 15-20Gy to the intra-lesional vertices, followed by 5 (n=6) or 15-16 fractions (n=4) with 25Gy or ∼40Gy respectively, to the entire tumor.

Center B applied 5 fractions of 20-25Gy to the entire tumor with a simultaneous integrated boost dose of 60-65Gy to the vertices. Follow up intervals of this palliative cohort had to be adjusted to the individual situation. Primary outcome measure included subjective early clinical effect and objective tumor shrinkage.

Results: Mean/median FU was 7.1/6 mo. (0.5-24). 7/22 pats died after mean 4 mo. (0.5-6). Subjective statements at LRT completion were available in all pats: no change in 2/22, substantial fast relief of symptoms in 20/22; no >G1 side effects. FU imaging was assessable from 20/28 lesions: mean/median shrinkage of 43/25% (0-100%) after mean/median 7/3.5 mo. (0.5-22), including 9 lesions with previous RT.

Conclusions: LRT in sarcoma translated into fast subjective symptom relief and related objective tumor shrinkage. A phase 2 trial is provided to test different LRT schedules.

1984P Sex differences in anticancer treatment delivery and toxicity in patients with sarcoma in a reference center

I. Tortorelli[1], B. Chiusole[1], F. Murtas[1], A. Galiano[1], M. Bolshinsky[1], S. Ahcene Djaballah[2], C. De Toni[1], S. Vizzaccaro[1], M. Maruzzo[1], U. Basso[1], A. Banzato[3], M. Coppola[4], V. Zagonel[1], A. Brunello[1]

[1]Oncology 1 Unit, Veneto Institute of Oncology IOV - IRCCS, Padua, Italy; [2]Oncology 3 Unit, Veneto Institute of Oncology IOV - IRCCS, Padua, Italy; [3]Cardiology Unit, Veneto Institute of Oncology IOV - IRCCS, Padua, Italy; [4]Pharmacy Unit, Veneto Institute of Oncology IOV - IRCCS, Padua, Italy

Background: In the era of precision medicine, despite mounting evidence that women might be more susceptible to toxicity from chemotherapy (CT), sex influence on treatment effects and the biology of non-sex-related cancers have largely been ignored. Due to their rarity, data on patients (pts) with sarcoma are scarce.

Methods: We reviewed data of pts with sarcoma treated between 2015 and 2022 at Veneto Institute of Oncology. Delays/reductions were evaluated in the first 9 weeks of CT and expressed as relative dose intensity (RDI): ratio of delivered dose intensity (mg/m^2 per week) to theorical dose intensity. Kaplan-Meier, log-rank and Cox regressions were used. Sex differences in RDI, adverse events (AEs) and impact of RDI on disease-free survival (DFS), progression-free survival (PFS) and overall survival (OS) were analyzed.

Results: Overall, data for 197 pts were available (109 treatments for localized disease: 69 neoadjuvant/40 adjuvant setting; 127 first -line treatments for advanced disease). Median age was 57 years, males were 112 (57%). Soft tissue sarcomas were 167 (85%), bone sarcomas were 30 (15%). Grade $\geq$ 3 AEs were observed in 60% of pts. Male had a lower risk of severe non-hematologic AEs (OR 0.5; p=0.04), while no significant sex differences were observed for all severe AEs. Dose was reduced upfront in 46% of female Vs 28% of males (p=0.007). Also, males less often had RDI <85% (OR 2.4; p=0.002). Survival outcomes were similar in both sexes, though comparisons might suffer from biases due to different distribution of histotypes within sexes. In the localized disease setting, worse survival was observed for males receiving RDI <85% compared to $\geq$85% (median OS 36.6 m Vs 63.7 m, p=0.004; median DFS 11.1 m Vs 26.3 m, p=0.03) whereas no significant differences at the 85% threshold of RDI were found for females.

Conclusions: Greater risk of AEs and lower RDI in women treated for sarcoma add to the evidence that a sex-difference in treatment delivery and outcomes exists. Despite a global lower RDI, survival outcomes for female were not worse compared to male. Interestingly, RDI <85% did not negatively affect survival outcomes in women (standard dosing based on "male" standards?). Such data call for optimization of drug dosing by sex to be considered in trial design.

1985P Expert sarcoma care is the need of the hour: Diagnostic and management challenges at a tertiary-care centre in India

G. Tansir[1], S. Rastogi[1], A. Barwad[2]

[1]Department of Medical Oncology, AIIMS - All India Institute of Medical Sciences, New Delhi, India; [2]Pathology, AIIMS - All India Institute of Medical Sciences, New Delhi, India

Background: Sarcomas are rare mesenchymal tumors that require multidisciplinary care. Referral centres receiving patients (pts) from peripheral set-ups face challenges which highlight the need for expert sarcoma pathology and specialised treatment.

Methods: This is a retrospective study in pts referred with pathological and/or clinico-radiological diagnosis of sarcoma (January 2021 to December 2022). Clinical, diagnostic, prior treatment details were reviewed from records. Pathologic discordances (PD) were classified as major (sarcoma to carcinoma or benign, soft tissue sarcoma to bone sarcoma or vice versa, any change influencing treatment) or minor.

Results: 539 pts included (incl) 58% males (n=312) with median age of 35 (1-89 years), residing at median distance of 160 kilometres (km) (3-2600) from our centre. Median presenting time was 11 months (15 days-20 years) from symptom onset; recurrent/metastatic (n=255, 47%) and locally advanced (n=134, 25%) stages predominated. Common primary sites were extremity (45.5%), abdomen (27%) with symptoms of pain (67%) and swelling (64%). 499 (92.5%) pts had pathology reports from outside and available comparison (n=372) showed 42.9% discordance (16.3% major, 26.6% minor) (Table). Sarcoma diagnosis changed to benign (1.3%), carcinoma (1.3%), fibromatosis (0.2%), germ cell tumor (0.2%) after review. Ultra-rare sarcomas (URS) (n=33, 6%) showed higher PD (73%). Molecular testing was done in 4.6% (n=11) of pts with testing indications. Most had received treatment outside (surgery in 50.6%, chemotherapy in 32.6%); deviation from standard guidelines was noted in 39.7% chemotherapy and 8.7% surgeries (Table). Univariate analysis did not yield significant factors associated with diagnostic or treatment discordance.

Table: 1985P Details of subjects and discordances in diagnosis and treatment

Diagnosis	Treatment
Subtypes	**Chemotherapy**
Soft tissue sarcoma (STS) = 295 (54.7%)	a) Incorrect regimen (n=28, 16%)
Bone sarcoma (BS) = 100 (18.5%)	b) Inadequate dose/cycles (n=20, 11.3%)
Carcinoma = 7 (1.2%)	c) Not given despite indication (n=17, 9.6%)
Benign = 7 (1.2%)	d) Others (n=4, 2.2%)
Others = 10 (2%)	**Surgery**
Undifferentiated = 1 (0.2%)	a) Inadequate surgery (n=19, 7%)
Discordances	b) Surgery without staging (n=5, 2%)
a) Major = 61 (16.3%)	
b) Minor = 99 (26.6%)	
Major discordance:	
a) Change of sarcoma subtype = 39 (64%)	
b) Benign to malignant = 14 (11.7%)	
c) Carcinoma to sarcoma = 4 (6.5%)	
d) Low to high grade = 4 (6.5%)	
e) BS to STS = 3 (5%)	

Conclusions: The significant discrepancies noted in diagnosis and management of pts in this study highlight the importance of expert pathologists and early referral for better treatment outcomes in sarcomas.

Background: To date no specific evidence exists on the impact of COVID-19 in pts with soft tissue sarcoma (STS), nor about the impact of SARS-CoV-2 vaccines and chemotherapy on COVID-19 morbidity and mortality in this specific population.

Methods: We described COVID-19 morbidity and mortality among pts with STS across "Omicron" (15/12/21-31/01/22), "Pre-vaccination" (27/02/20-30/11/20) and "Alpha-Delta" phase (01/12/20-14/12/21) using OnCovid registry participants (NCT04393974). Case fatality rate at 28 days (CFR_{28}) and COVID-19 severity were described according to the SARS-CoV-2 vaccination status, whilst the impact of the receipt of cytotoxic chemotherapy within 4 weeks prior to COVID-19 on clinical outcomes was assessed with Inverse Probability of Treatment Weighting (IPTW) models adjusted for possible confounders.

Results: Out of 3820 pts, 97 pts with STS were included. The median age at COVID-19 diagnosis was 56 years, with 65 pts (67%) aged <65 years old and 65 pts had low comorbidity burden (67%). In total, 36 pts were on cytotoxic chemotherapy within 4 weeks prior to COVID-19. The overall CFR_{28} was 25.8%, with 38% oxygen therapy requirement, 34% rate of complications and 32.3% of hospitalizations due to COVID-19. CFR_{28} (29,5%, 21.4%, 12.5%) and all indicators of COVID-19 severity demonstrated a trend toward a numerical improvement across the pandemic phases. Similarly, vaccinated pts demonstrated numerically improved CFR_{28} (16.7% vs 27.7%) and COVID-19 morbidity compared with unvaccinated pts. Pts who were on chemotherapy experienced comparable CFR_{28} (19.4% vs 26.0%, p=0.4803), hospitalizations (50.0% vs 44.4%, p=0.6883), complication rates (30.6% vs 34.0%, p=0.7381) and oxygen therapy requirement (28.1% vs 40.0%, p=0.2755) compared to those who were not on anticancer therapy at COVID-19, findings further confirmed by the IPTW-fitted multivariable analysis.

Conclusions: This is the first study to demonstrate the time-dependent improvement of COVID-19 outcomes in pts with STS. Exposure to chemotherapy does not impact on COVID-19 morbidity/mortality and SARS-CoV-2 vaccination confers protection against adverse outcome from COVID-19 in this patient population.

1987TiP Pembrolizumab in combination with eftilagimod alpha and radiotherapy in neoadjuvant treatment of patients with soft tissue sarcomas: EFTISARC-NEO trial

K. Kozak, P. Sobczuk, S. Kopeć, T. Switaj, P. Teterycz, A. Borkowska, P. Rutkowski

Department of Soft Tissue/Bone Sarcoma and Melanoma, Maria Sklodowska-Curie National Research Institute of Oncology, Warsaw, Poland

Background: Surgery is the mainstay of treatment of primary localized soft tissue sarcoma (STS). In patients (pts) with high grade localized STS of the extremity/trunk, and tumor size > 5cm radiation therapy (RT) is added to reduce local recurrence. While neoadjuvant chemotherapy is used to improve survival, but its efficacy is limited to pts with poor prognosis. Recently, immunotherapy (ITH) has been widely studied in pts with metastatic STS but response rates are modest and its efficacy and impact on the tumor microenvironment remain unclear. Novel compounds, such as eftilagimod alpha (efti), a soluble LAG-3 protein, are tested in combination with ITH to stimulate antigen presenting cells and boost immune response. Moreover, some studies have shown that combining ITH with RTH may be a promising strategy for synergistic enhancement of treatment efficacy. Therefore, we hypothesize that the addition of combined ITH to RT prior to surgical resection would be safe and improve pathologic response compared to historical cohorts of pts with localized STS treated with RT alone.

Trial design: EFTISARC-NEO is an open-label phase II study evaluating the efficacy and safety of pembrolizumab in combination with efti and RTH in the neoadjuvant treatment of pts with STS. Forty pts will be enrolled to receive efti 30 mg sc Q2W (5 cycles) and pembrolizumab 200 mg iv Q3W (3 cycles) with concurrent RT (25x2Gy), followed by surgery. Key eligibility criteria are: 1) primary or locally recurrent deep-seated extremity, girdles and/or superficial trunk tumor, 2) one of the following subtypes: undifferentiated pleomorphic sarcoma, myxofibrosarcoma, dedifferentiated liposarcoma, myxoid and round cell liposarcoma, epithelioid sarcoma, angiosarcoma, soft tissue sarcoma NOS; 3) Grade 2/3 according to FNCLCC; 4) primary tumor size >5 cm or locally recurrent of any size. The primary endpoint is a percent of tumor hyalinization at the time of surgical resection. Secondary endpoints include disease-free survival, overall survival, response rate and incidence of adverse events. Correlation between tissue or blood-based biomarkers and clinical outcomes will be explored. Enrollment for the study is ongoing in Poland.

Clinical trial identification: EudraCT 2022-003845-36.

Background: Carboplatin/etoposide + atezolizumab (IMpower133) is now 1L standard-of-care for patients with extensive disease small cell lung cancer (ED SCLC). Thoracic radiotherapy (TRT) after induction chemotherapy has been shown to increase 2-year overall survival rates. Alongside, evidence for synergistic immunostimulatory effects of radiotherapy and immunotherapy (IO) is increasing. Combining these results, the TREASURE trial attempted to improve response to chemo-IO by adding TRT.

Methods: The phase II, multicenter TREASURE trial (NCT04462276) randomized patients with ED SCLC, ECOG$\leq$1, and response to IMpower133 induction to receive atezolizumab maintenance therapy (1200mg, Q3W, until progression/toxicity) either with TRT (10x30 Gy, arm A) or without TRT (arm B). Safety interim analysis was planned once 23 patients in arm A had been observed for 3 months after TRT ended, with the safety signal being $\geq$2 patients with grade $\geq$3 pneumonitis.

Results: In 04/22, interim safety analysis showed only 1/23 patients with grade $\geq$3 pneumonitis in arm A. However, routine safety monitoring committee (SMC) review in 08/22 identified a potential imbalance in grade 5 severe adverse events (SAEs) between the arms (n=5 in A, n=1 in B), and thus recruitment was paused. Data review 3 months later revealed more SAEs in arm A (28 any, 16 grade 3/4, 6 grade 5) vs. B (9 any, 4 grade 3/4, 1 grade 5). Along with evaluation of further parameters, this prompted Coordinating Investigator and SMC to permanently stop recruitment. Of note, neither differences in clinical measures of comorbidity nor functional status were detected between arms. At the time of recruitment stop (12/22), 68 patients were included in the trial (n=34 in each arm).

Conclusions: Although TRT-IO combinations have not been the source of safety concerns in other trials, it was associated with more SAEs in TREASURE. SAE analysis did not indicate any new safety signal of atezolizumab or TRT. Observed SAEs were either known adverse effects or confounded, and not clearly tied to either IO or TRT. Thus, the factors underlying this unexpected outcome remain to be identified and will be focus of the final analysis of this trial.

Clinical trial identification: NCT04462276.

Background: Previously, we established the recommended phase 2 dose (RP2D) of LUR + PBL in the phase 1 stage of this study (J Clin Oncol. 2022;40(suppl 16):8581). Here we present the results on the efficacy and safety of the RP2D.

Methods: LUPER (NCT04358237) is a prospective, open-label, uncontrolled, multicenter, phase 1/2 study of LUR in combination with PBL in patients (pts) with relapsed SCLC. Eligible pts were $\geq$18 years old, with histologically confirmed SCLC, progression after 1L platinum-based chemotherapy, no prior exposure to immunotherapy, ECOG PS of 0-1, and measurable disease as per RECIST 1.1. Pts with treated, asymptomatic, stable brain metastases (BM) were also included. Treatment consisted of LUR dosed at 3.2 mg/m^2 IV Q3W in combination with PBL 200 mg IV Q3W until disease progression (PD), unacceptable toxicity, or consent withdrawal. The primary endpoint was confirmed overall response rate (ORR) according to RECIST 1.1. Secondary endpoints included investigator-assessed Duration of Response (DoR), Progression-Free Survival (PFS), Overall Survival (OS), and safety as per CTCAE 5.0.

Results: A total of 28 pts were included in the study. Median age was 65 years (range 41-78), 46.4% were female, 64.3% had ECOG PS of 1, 51.9% had platinum-free interval $<$ 90 days, 39.3% had LDH $>$ upper normal limit, and 21.4% had BM. At data cutoff (March 31, 2023),11 (39.3%) pts were still on treatment. The median follow-up was 5.7 months (range: 1.0-25.2). Preliminary ORR was 46.4% (95% CI: 29.5−64.2; p$<$0.001): 2 confirmed CR, 11 PR (9 confirmed) and 4 SD $\geq$12 weeks. Median DoR was 11.4 months (range: 0-21.2 months), and 2 (7.1%) pts had durable responses $>$ 12 months. Median PFS was 5.3 months (95% CI: 2.7-12.0). Median OS was 11.1 months (95% CI: 6.9-NR). PBL and LUR discontinuation occurred in 3 (10.7%) and

0 pts due to immune-related AE, respectively. The most common grade 3 and 4 treatment-emergent AEs (>20%) were fatigue, neutropenia, nausea and anemia.

Conclusions: The LUPER study met its primary endpoint. The combination of LUR + PBL is effective in second-line treatment of SCLC with a manageable safety profile. Further research is warranted to confirm the potential of this combination in SCLC patients.

Clinical trial identification: NCT04358237.

Background: Treatment options are limited for patients (pts) with ES-SCLC that progresses after anti-programmed death ligand 1 (PD-L1) therapy and chemotherapy (chemo). SG, a Trop-2-directed antibody-drug conjugate, demonstrated antitumor activity in previously treated ES-SCLC in a phase 1/2 study (Bardia, et al. *Ann Oncol*. 2021). TROPiCS-03 (NCT03964727) is an open-label, multicohort, phase 2 study evaluating SG in pts with metastatic or locally advanced solid tumors. Here, we report preliminary results from the ES-SCLC cohort.

Methods: Adult pts with ES-SCLC that progressed after no more than 1 prior line of platinum-based chemo and anti-PD-(L)1 therapy received SG 10 mg/kg on Days 1 and 8 of a 21-day cycle. The primary endpoint was objective response rate (ORR) by investigator assessment (INV) per RECIST v1.1. Key secondary endpoints included clinical benefit rate (CBR), duration of response, progression-free survival, overall survival, and safety. Pts who received ≥1 dose of SG were included in the safety analysis and pts who received ≥1 dose of SG and had ≥13.0 weeks of follow-up were included in the efficacy analysis.

Results: As of 18 April 2023, 26 pts received ≥1 dose of SG. Median age was 67 years (range, 48-79) and 89% of pts had an ECOG performance status of 1. Median follow-up was 3.5 months (range, 0.6-9.4). Treatment was ongoing for 16 (62%) pts. In the efficacy analysis (n=14), ORR was 29% and CBR was 36% (Table). In the safety analysis (n=26), any-grade treatment-related adverse events (TRAEs) occurred in 96% (grade ≥3, 46%) of pts. No TRAEs leading to discontinuation of study treatment were reported to date. No deaths due to AEs were reported to date.

Conclusions: SG as 2L treatment for ES-SCLC demonstrated promising antitumor activity and manageable safety, with no TRAEs leading to discontinuation reported to date. Additional data with more pts and longer follow-up will be presented.

Table: 1990MO

Efficacy	ES-SCLC SG n = 14
ORR (95% CI),[a] %	29 (8-58)
BOR,[a] n (%)

1991P Safety and effectiveness of surgery or radiotherapy after PD-L1 Inhibitor (TQB-2450) and chemotherapy induction therapy in patients with limited-stage small cell lung cancer: A phase II trial

F. Sun[1], J. Hu[1], L. Sun[1], D. Li[1], L. Zhang[2], G. Jiang[1], P. Zhang[1]

[1]Department of Thoracic Surgery, Shanghai Pulmonary Hospital, Tongji University School of Medicine, Shanghai, China; [2]Central Laboratory, Shanghai Pulmonary Hospital, Tongji University School of Medicine, Shanghai, China

Background: PD-1/PD-L1 inhibitor and chemotherapy improved the survival of patients with extensive-stage small-cell lung cancer. Thus, we conducted a non-randomized, single-center, phase II study (LungMate-005; NCT04539977) to explore the safety and effectiveness of surgery or radiotherapy after PD-L1 inhibitor (TQB2450) and chemotherapy induction therapy in treating limited-stage small-cell lung cancer (LS-SCLC).

Methods: Eligible patients received four 21-day-cycles of neoadjuvant therapy: TQB2450 (1200 mg) and carboplatin (AUC5) on day1, etoposide (100 mg/m^2) on day1-3. MDT to discuss surgery or radiotherapy was performed 3-4 weeks after last dose of therapy. Maintenance therapy was 2-cycles TQB2450, carboplatin, and etoposide followed by 1-year TQB2450. The primary outcome was objective response rate (ORR). Secondary outcomes included the incidence of adverse events (AEs), events-free survival (EFS), and major pathological response (MPR).

Results: Between December 2020 to January 2023, a total of 40 patients received induction therapy. Among them, 21 and 14 patients received surgery or radiotherapy, respectively. Other 5 patients quitted during induction therapy. Most (95%) patients were at stage III. The incidence of any grade and grade 3-5 AE were 100% and 47.5%, respectively. The highest incidence of TQB2450-specific AEs was rush (12.5%, grade 1-2). Three (7.5%) patients had TRAEs leading to discontinuation. ORR was 92.5% (95% CI: 79.6%-98.4%). In surgery group, 13 (61.9%) patients achieved MPR, including 9 (42.9%) patients with PCR. Seventeen (81.0%) patients achieved pathological downstage. The median followed-up was 14.8 months by April 21, 2023. The median EFS and median OS were not reached in surgery group. The median EFS and OS were 11.6 (95% CI: 8.9-14.3) and 18.6 (95% CI: 13.4-23.8) months in radiotherapy group. 1-year EFS and OS were 82.0% and 100% in surgery group, and 49.2% and 88.9% in radiotherapy group, respectively.

Conclusions: Surgery or radiotherapy after PD-L1 inhibitor (TQB-2450) and chemotherapy induction therapy followed by TQB-2450 maintenance therapy in treating LS-SCLC were safe and effective, especially surgery.

Clinical trial identification: NCT04539977.

1992P A phase II safety and efficacy study of PM8002 (anti-PD-L1 x VEGF-A bispecific) combined with paclitaxel as a second-line therapy for small cell lung cancer (SCLC)

Y. Cheng[1], Z. Qin[2], X. Meng[3], F. Xu[4], Y. Wang[5], Y. Yao[6], J. Fang[7], Y. Zhao[8]

[1]Medical Oncology, Jilin Cancer Hospital, Changchun, China; [2]Medical Oncology, Zhejiang Provincial People's Hospital, Hangzhou, China; [3]Radiation Oncology, Shandong Cancer Hospital, Jinan, China; [4]Respiratory Medicine, The First Affiliated Hospital of Nanchang University, Nanchang, China; [5]Respiratory Medicine, Harbin Medical University Cancer Hospital, Harbin, Heilongjiang, China; [6]Medical Oncology, The First Affiliated Hospital of Xi'an Jiaotong University, Xi'an, China; [7]Thoracic Medical Oncology, Peking University Cancer Hospital, Beijing, China; [8]Respiratory Medicine, Henan Cancer Hospital, Zhengzhou, China

Background: There is an unmet medical need for SCLC patients that progress on or after first-line platinum-based therapy. PM8002 is a bispecific antibody targeting PD-L1 and VEGF-A. Here, we present our results from a phase II study of PM8002 in combination with paclitaxel as second-line treatment for SCLC.

Methods: Subjects with advanced SCLC who failed first-line platinum-based chemotherapy with or without checkpoint inhibitors therapy were enrolled for assessing the safety and efficacy of PM8002 in combination with paclitaxel. Primary endpoints included safety (CTCAE v5.0) and ORR (RECIST v1.1). All subjects received PM8002 (30 mg/kg Q3W) and paclitaxel (175 mg/m^2 Q3W) for 5 cycles, followed by PM8002 maintenance (30 mg/kg Q3W) until unacceptable toxicity or disease progression.

Results: As of April 21, 2023, 27 subjects (26 without and 1 with previous immunotherapy) had been enrolled. Among 26 immunotherapy naïve subjects, 26 and 22 subjects were evaluable for safety and efficacy, respectively. Overall ORR was 72.7% (16/22) with a DCR of 81.8% (18/22). Median PFS was 5.5 months (95% CI, 2.8 - NR. 11 out of 22 subjects were still on treatment and PFS were censored accordingly). Any-grade TEAEs occurred in 96.2% (25/26) of subjects. Grade $\geq$ 3 TEAEs related to the combination regimen occurred in 73.1% (19/26) of subjects, with the most common grade $\geq$ 3 TRAEs observed as neutropenia (53.8%, 14/26) and leukopenia (34.6%, 9/26). One patient discontinued PM8002 and/or paclitaxel administration due to TRAEs. Any-grade immune-related adverse events (irAEs) occurred in 30.8% (8/26) of subjects, and grade $\geq$ 3 irAEs occurred in 4% (1/26) of subjects, which was a grade 3 proteinuria. The first efficacy/safety evaluation for the subject with previous immunotherapy was pending. Recruitment for immunotherapy failure subjects is still ongoing.

Conclusions: PM8002, in combination with paclitaxel, showed encouraging antitumor activity and an acceptable safety profile for patients with advanced SCLC who failed first-line platinum-based chemotherapy. This phase II study is still ongoing and shall include more patients who had previously received immune checkpoint therapy.

Background: Most patients (Pts) with small-cell lung cancer (SCLC) have extensive-stage (ES) disease at diagnosis and poor prognosis. First-line (1L) durvalumab (D) plus platinum–etoposide (EP) significantly improved overall survival in pts with ES-SCLC vs control group in CASPIAN study. CANTABRICO study assess safety and effectiveness of D+EP in a real-world ES-SCLC population in Spain.

Methods: CANTABRICO is a phase IIIb, single arm, multicentre study (NCT04712903). Eligible Pts were ≥18 years old with treatment-naive ES-SCLC, ECOG PS 0-2, ≥1 measurable lesion. D (1500 mg) was concurrently administered with 1L cisplatin or carboplatin (CP) d1 plus etoposide d1-3 every 3 weeks (q3w) for 4-6 cycles, followed by maintenance (q4w) until progressive disease/unacceptable toxicity. Safety results [incidence of grade (G) 3 adverse events (AEs) and immune-mediated AEs (imAEs)] are presented.

Results: Between December 2020 and April 2021, 101 pts from 35 sites in Spain were included. By March 2, 2023 all pts had finished chemotherapy (87% CP) and 15 pts were still receiving D. 56% of pts were ≥ 65 years old, 67% were men, 94% had ECOG 0-1. 34%, 37% and 11% of pts had liver, bone or brain metastases, respectively. 98% were current/former smokers and 10% had limited stage diagnosis. 30% received 6 cycles of EP+D and 81% started D monotherapy. Median number of D doses were 8 (Interquartile range 5-11). AEs occurred in 99% of pts; G3-4 AEs in 74%; and AEs leading to discontinuation 8%. Most common G3-4 AEs were neutropenia (22%) and anemia (23%). Deaths due to any cause AEs occurred in 8% of pts (respiratory infection, hemoptysis, sepsis (2), cardiorespiratory arrest, COVID-19, intracranial hemorrhage and immune-mediated neurological syndrome). imAEs were reported in 32% of pts. Most were G1-2; G3-5 imAEs occurred in 10% of pts. Deaths due to imAEs occurred in 1 pt (immune-mediated neurological syndrome). Main imAEs were hypothyroidism (13%), pneumonitis (5%) and diarrhea (4%), among others.

Conclusions: CANTABRICO safety profile appeared consistent with that seen in the CASPIAN study, providing real-world evidence regarding safety of D+EP in ES-SCLC.

Clinical trial identification: NCT04712903 EudraCT 2020-002328-35.

Background: PD-L1 inhibitors added to platinum etoposide improved survival in extensive stage small cell lung cancer (ES-SCLC). Bevacizumab added to platinum etoposide chemotherapy has been shown to be safe and active. VEGF has immunosuppressive effects in SCLC tumor microenvironment and combined PD-L1 and VEGF inhibition has synergistic antitumor effect in SCLC models.

Methods: This is an investigator-initiated phase II single arm trial sponsored by GOIRC with the unconditional financial support of Roche S.p.A. Patients received carboplatin (AUC 5), etoposide (100 mg/m^2), bevacizumab (7.5 mg/kg), and atezolizumab (1200 mg) for 4-6 cycles (induction), followed by bevacizumab and atezolizumab (maintenance) every 3 weeks for up to 18 total cycles as first-line treatment for ES-SCLC. Asymptomatic or treated brain metastases and treatment with atezolizumab beyond RECIST-defined progression (PD) were allowed. The primary endpoint was 1-year OS.

Results: Enrollment completed in March 2022, so the primary endpoint is expected to be mature at the data cutoff of March 31st, 2023. Of 53 enrolled patients (45% women, median age 65 years), 22 (42%) had an ECOG PS of 1, 14 (26%) had liver, 11 (21%) bone, and 10 (19%) brain metastases. Median sum of target lesions diameters was 119.5 mm (range 17-240). Of 51 patients with available data, 40 (78%) completed induction and 37 (73%) started maintenance, with a median of 7 courses (range 1-18). Atezolizumab was administered beyond PD in 17 cases (33%), for a median of 2 courses (range 1-10), with 11 patients still on treatment at the data cut-off date. Adverse events are reported in table. Serious adverse events (SAE) were reported in 16 cases, including neutropenia (n=4), febrile neutropenia (n=3), and pulmonary embolism (n=3).

Table: 1994P Adverse events

Adverse event	Any grade	% total	Grade 1-2	%	Grade 3-4	%
Neutropenia	27	53%	11	22%	16	31%
Fatigue	22	43%	21	41%	1	2%
Anemia	20	39%	19	37%	1	2%
Lymphopenia	9	18%	8	16%	1	2%
Musocitis	9	18%	9	18%	0	0%
Increased GGT	7	14%	6	12%	1	2%
Cough	7	14%	7	14%	0	0%
Nausea	7	14%	7	14%	0	0%
Thromocytopenia	5	10%	4	8%	1	2%
Hypothyroidism	5	10%	5	10%	0	0%
Hypertension	4	8%	3	6%	1	2%
Constipation	4	8%	4	8%	0	0%
Diarrhea	4	8%	4	8%	0	0%

Conclusions: The addition of bevacizumab to carboplatin-etoposide-atezolizumab in patients with ES-SCLC is overall well-tolerated. The survival analysis will be available and reported at the conference.

Background: The IMpower133 study demonstrated that treatment with atezolizumab (ATZ) + carboplatin + etoposide improved overall survival (OS) and progression free survival (PFS), and showed long-term benefit ([LTB] defined as OS ≥18 months) in patients with ES-SCLC. To date, no patient characteristics have been identified and validated to predict LTB from chemo-immunotherapy, and limited data exist regarding LTB in a real-world (RW) clinical setting. We previously reported the primary safety and efficacy results of IMfirst (EudraCT: 2019-002784-10), a phase IIIb, single arm study of ATZ + chemotherapy (C) in patients with untreated ES-SCLC in a RW clinical setting in Spain. Here we present the exploratory LTB analysis from IMfirst.

Methods: In this exploratory analysis, we characterized LTB patients (defined as patients who lived ≥24 months). Association of LTB/no-LTB with patient's and disease characteristics was evaluated with the Chi-square or Fisher's exact tests. A $p < 0.05$ was considered statistically significant.

Results: A total of 155 patients were enrolled; 25 met the LTB criteria. Median follow-up was 28.4 months (data cut off: 14 Dec 2022). Median OS [95% CI] was 10.0 [8.6, 11.9] months in the overall population and OS at 24 months was 17.7%. Variables with significant association with LTB/non-LTB patients included tumor burden (TB) at baseline (high TB defined as patients with either SLD ≥60 mm, 2 or more metastatic sites, or LDH > ULN), prior radiotherapy (RT) at baseline, and consolidation RT (Table). None of the 17 patients with ECOG PS 2 were classified as LTB. More immune-mediated adverse events were reported in LTB (16%) compared to non-LTB (0.8%) patients.

Conclusions: This exploratory analysis from IMfirst, though limited due to its small sample size, demonstrates LTB from ATZ + C in a broader ES-SCLC patient population, and suggests potential patient characteristics associated with LTB/non-LTB.

Clinical trial identification: EudraCT 2019-002784-10.

1996P The impact of an etoposide shortage on patients with extensive-stage small cell lung cancer (ES-SCLC): Results of a natural experiment

C. Browne[1], T. Ayoube[2], N. Samarasinghe[3], S.K. Hussaini[4], A. Warner[5], M. Black[6], D.A. Palma[5], J. Raphael[6], M.S. Kuruvilla[6], P. Blanchette[6]

[1]Medical Oncology, University of Western Ontario, London, ON, Canada; [2]Science, University of Western Ontario, London, ON, Canada; [3]Surgery, Faculty of Medicine, University of British Columbia - Vancouver General Hospital, Vancouver, BC, Canada; [4]Department of Oncology, Oakville Trafalgar Memorial Hospital, London, ON, Canada; [5]Department of Radiation Oncology, London Regional Cancer Program (LRCP) - London Health Science Center (LHSC), London, ON, Canada; [6]Department of Medical Oncology, London Regional Cancer Program (LRCP) - London Health Science Center (LHSC), London, ON, Canada

Background: Shortages of oncology therapeutics are becoming increasingly prevalent. A shortage of IV etoposide lasted from 2018 until 2020 in Ontario, Canada, allowing for a "natural experiment" in which external factors (IV etoposide availability) dictated patients' assignment. The purpose of this study was to evaluate the impact of this etoposide shortage (ES) on patient outcomes in ES-SCLC.

Methods: ES-SCLC patients treated at the London Regional Cancer Program during a "pre-ES" (Nov 2017 – Oct 2018) and "ES" (Nov 2018 – Oct 2019) time interval were retrospectively reviewed. Information was gathered on patient demographics, treatment, hospitalizations and survival. The primary endpoint was rate of hospitalization. Statistical analysis was performed using descriptive statistics, Kaplan Meier estimates and multivariable logistic and Cox proportional hazards regression models.

Results: A total of 119 patients with ES-SCLC were assessed, 49 in the pre-ES interval and 70 in the ES interval. Mean ± SD age was 68 ± 8 years, 48% were male, 33% had central nervous system (CNS) metastases and 69% received first-line systemic therapy. Alternate regimens used for ES cohort included platinum-oral (PO) etoposide (51%), platinum-irinotecan (24%), and PO etoposide monotherapy (16%). There was a significantly increased rate of hospitalizations during the ES vs. pre-ES (49% vs. 29%, p=0.029) but no significant differences in PFS (median: 2.8 vs. 4.5 months, log-rank p = 0.504) or OS (median: 3.1 vs. 5.5 months, log-rank p=0.600) in univariable analyses. In our multivariable model adjusting for age, sex, baseline Charlson comorbidity index, CNS metastases and receipt of first-line chemotherapy, we observed a significant increase in hospitalization (OR=2.30, 95% CI: 1.01-5.24, p=0.047) and shorter PFS (HR=1.79, 95%CI: 1.19-2.68), p=0.005) in the ES treatment interval.

Conclusions: This single-institution retrospective analysis during an IV ES shows increased rates of hospitalization and decreased PFS among ES-SCLC patients treated with alternate chemotherapy regimens. The oncology community must advocate for reliable supplies of essential chemotherapy drugs and utilize appropriate substitute therapies when necessary.

1997P A study of sintilimab combined with anlotinib and chemotherapy as second-line or later therapy in extensive-disease small cell lung cancer

Z. Wang[1], X. Han[1], J. Guo[1], L. Li[1], Y. Huang[2], L. Ma[2], M. Zhao[3]

[1]Medical Oncology, Shandong Cancer Hospital and Institute, Jinan, China; [2]Imaging Department, Shandong Cancer Hospital and Institute, Jinan, China; [3]Pathology Department, Shandong Cancer Hospital and Institute, Jinan, China

Background: SCLC is characterized by rapid growth, drug resistance, and early metastasis. At present, etoposide combined with platinum is the standard first-line treatment for ED-SCLC, and the second-line and later treatment options are limited. This study investigated the efficacy and safety of sintilimab combined with anlotinib and albumin-bound paclitaxel in the treatment of ED-SCLC.

Methods: This is a single-arm, phase II study (ChiCTR2100049390). Patients with ED-SCLC were enrolled after screening and meeting the inclusion and exclusion criteria. Patients were treated with sintilimab (200mg, d1, Q3W) combined with anlotinib (12mg, d1-d14, Q3W) and albumin-paclitaxel (100mg, d1-d8, Q3W). The primary endpoint was objective response rate (ORR). Secondary endpoints included disease control rate (DCR), duration of response (DOR), progression-free survival (PFS), overall survival (OS), and safety.

Results: From July 2021 to February 2023, a total of 30 subjects were enrolled, of which 25 patients could be evaluated. The median age was 59 years, including 20 males, 21 patients with ECOG 1, 12 patients with smoking history, and 10 patients with brain metastases at baseline. All cases were in stage IV. As of April 28, 2023, the median follow-up was 12.5 months. The ORR was 64%, including 16 cases of PR, 4 cases of SD, and 5 cases of PD. The DCR was 80%. The mDOR was 6.64 (5.32,10.5), and the mTTR was 1.5 months. The mPFS was .91 (4.86,6.8), 6-month and 12-month PFS rates were 49% and 9.8%, respectively. The median OS was 13.2 (9.69, NA), and the 12- and 24-month PFS rates were 60.9% and 25.2%, respectively. The TRAE was 84% (21 cases), of which ≥3 grade TRAE was 20%, including aspartate aminotransferase increased, alanine aminotransferase increased, rash, neutropenia, and lymphopenia. A total of 9 (36%) subjects had immune-related adverse reactions (irAE). ≥3 grade irAE included spartate aminotransferase increased, alanine aminotransferase increased, rash. No AE leading to death occurred.

Conclusions: Sintilimab combined with anlotinib and albumin-paclitaxel demonstrated significant clinical activity and a manageable safety profile for patients with ED-SCLC. The long-term efficacy is still under follow-up.

Clinical trial identification: ChiCTR2100049390.

Background: Trilaciclib, a potent and reversible intravenous CDK4/6 inhibitor, has been approved by US FDA and China NMPA to prevent multilineage chemotherapy-induced myelosuppression in ES-SCLC patients. The TRACES study is a phase III trial assessing the efficacy and safety of trilaciclib in Chinese ES-SCLC patients. The bone marrow protection effect was significant which was reported in WCLC 2022.

Methods: This study included an open-label safety run-in part (Part 1) and a randomized, double-blinded, placebo-controlled part (Part 2). Treatment-naïve or previously treated ES-SCLC patients received trilaciclib (240 mg/m^2) or placebo before etoposide/cisplatin (E/P) or topotecan (TPT) respectively. The primary endpoint is the duration of severe neutropenia in Cycle 1. The exploratory endpoints for anti-tumor effect are OS and ORR, PFS and DOR assessed by RECIST v1.1.

Results: As of 30 December 2022, a total of 83 patients were enrolled in Part 2, with 41 receiving trilaciclib (E/P: 23; TPT:18) and 42 receiving placebo (E/P: 23; TPT:19). The mean number of cycles were 5.1 and 4.6 cycles in trilaciclib and placebo group (E/P: 5.0 vs 4.9 cycles; TPT: 5.3 vs 4.3 cycles). Compared with placebo group, trilaciclib group had fewer cycle delays (E/P: 30.4% vs 73.9%; TPT: 44.4% vs 73.7%) and dose reductions (E/P: 30.4% vs 73.9%; TPT: 44.4% vs 73.7%). The ORR in trilaciclib group and placebo group were 44.7% and 39.5% (p=0.4996) respectively. After a median follow-up of 14.1 months, the median overall survival was 12.0 months in the trilaciclib group and 8.8 months in the placebo group (hazard ratio [HR], 0.69; 95% confidence interval [CI], 0.40 to 1.22). The median progression-free survival was 4.8 months and 4.3 months, respectively (HR, 0.86; 95% CI, 0.53 to 1.39). Trilaciclib was well tolerated, with lower incidence of ≥Grade 4 TEAEs, SAEs, TEAEs leading to treatment discontinuation. No TEAEs leading to death were reported related to trilaciclib.

Conclusions: Trilaciclib was well tolerated in Chinese patients. Administering trilaciclib prior to chemotherapy in ES-SCLC patients improved patients' tolerability to chemotherapy, and suggested potential survival benefit.

1999P IMreal Cohort 4: Third interim analysis of efficacy and safety in patients (pts) with extensive-stage small cell lung cancer (ES-SCLC) receiving atezolizumab plus carboplatin and etoposide (atezo + CE) as first-line (1L) therapy under real-world conditions (RWCs)

S. Popat[1], N. Girard[2], S. Shoshkova[3], G. Kok[4], J.L. Perez Gracia[5]

[1]Department of Medicine, The Royal Marsden Hospital, London, UK; [2]Thorax Institute, Institut Curie, Paris, France; [3]Medical Affairs, Roche Bulgaria EOOD, Sofia, Bulgaria; [4]Biostatistics, Cytel, Genève, Switzerland; [5]Oncology Department, Clinica Universidad de Navarra, Pamplona, Spain

Background: Based on the pivotal phase III IMpower133 trial (NCT02763579), atezo + CE is approved for 1L treatment (tx) of ES-SCLC. IMreal (NCT03782207) is a non-interventional, multicentre, multicohort, prospective study of clinical outcomes and safety with atezo under RWCs. We report the third interim analysis efficacy and safety data from Cohort 4 (ES-SCLC).

Methods: Pts with untreated ES-SCLC received 1L atezo + CE. Pt medical and tx history data were retrospectively collected; clinical outcomes and safety data before, during and after atezo + CE tx were also collected. The primary endpoints were OS and 2-y OS. Secondary endpoints included PFS, ORR, DCR and DOR. Safety was assessed.

Results: The full analysis population (N=501) was enrolled from 7 Feb 2019 to 1 Jun 2022. Median follow-up was 6.1 mo (range, 0.0-27.6). The median age was 66 y (range, 34-84), and 293 pts (58%) were ≥65 y; 324 (65%) were male. ECOG PS ≥2 was reported in 33/395 pts (8%). Median OS and PFS were 9.9 mo (95% CI: 8.8, 10.6) and 6.2 mo (95% CI: 5.9, 6.7), respectively; 1-y OS and PFS rates were 39% and 16%, respectively. Additional efficacy data are in the table. In the safety-evaluable population (n=496), 411 pts (83%) had ≥1 AE. The most common any-Gr AEs were anaemia (20% [n=100]), fatigue (17% [n=86]) and neutropenia (17% [n=82]). Gr 3/4 tx-related (TR) AEs occurred in 143 pts (29%); Gr 5 TRAEs occurred in 7 (1%). SAEs occurred in 192 pts (39%) and were TR in 86 (17%). AEs of special interest (AESIs) occurred in 110 pts (22%) and were TR in 74 (15%). The most common any-Gr AESIs were hepatitis (diagnosis and lab abnormalities; 7% [n=34]), rash (6% [n=31]) and hepatitis (lab abnormalities; 6% [n=28]).

Table: 1999P Response-evaluable population (N=390)

ORR, n (%) [95% CI]	266 (68) [63.3, 72.8]
Complete response, n (%) [95% CI]	11 (3) [1.4, 5.0]
Partial response, n (%) [95% CI]	255 (65) [60.4, 70.1]
Stable disease, n (%) [95% CI]	88 (23) [18.5, 27.0]
DCR, n (%) [95% CI][a]	223 (57) [52.1, 62.2]
Progressive disease, n (%) [95% CI]	30 (8) [5.3, 10.8]
Not evaluable, n (%)	6 (2)
DOR [95% CI], mo	n=266 5.4 [4.8, 6.7]

DCR, disease control rate; DOR, duration of response; ORR, objective response rate.
[a] DCR: proportion of pts who achieved complete response, partial response or stable disease at least 12 weeks after the index date.

Conclusions: In IMreal Cohort 4, OS and PFS differed slightly from those in pivotal ES-SCLC clinical trials, with no new or unexpected safety signals.

Clinical trial identification: NCT03782207.

2000P Efficacy and safety of thoracic radiotherapy after first-line immunotherapy in extensive stage small cell lung cancer: A multi-center retrospective study

J. Wu[1], J. Zhang[1], H. Sun[1], Y. Sun[1], Y. Ge[1], Q. Cheng[1], D. Wang[2], X. Wang[1], X. Fu[2], H. Sun[2], J. li[1], A. Gao[2]

[1]Phase I Clinical Research Center, Cancer Hospital Affiliated to Shandong First Medical University, Jinan, China; [2]Department of Thoracic Radiation Oncology, Cancer Hospital Affiliated to Shandong First Medical University, Jinan, China

Background: Immunotherapy combined with chemotherapy have become the standard first-line options in extensive stage small-cell lung cancer (ES-SCLC) in the past years. However, whether patients can benefit from consolidative thoracic radiotherapy (TRT) after first-line immunotherapy is still undetermined.

Methods: ES-SCLC patients who received standard first-line immunotherapy combined with chemotherapy with/without subsequent TRT were included from 3 cancer centers in China between February 2020 to December 2022. The clinical outcomes and safety were evaluated.

Results: 220 ES-SCLC patients were eligible for our analysis, in which 136 received TRT and maintenance immunotherapy after chemotherapy, and 84 received maintenance immunotherapy only. TRT significantly improved the progression-free survival (PFS) (median 10.7 VS 8.5months, HR=0.662 [95% CI: 0.476-0.919], p=0.013), and decreased the intrathoracic lesion progression rate (13.23% VS 40.48%). Further analysis revealed that TRT with different biological effective dose (>60Gy or ≤60Gy), or different dose fractionation mode (conventional fractionation, hypofractionation or hyperfractionation) didn't impact patient survival. However, addition of TRT in 3-6 weeks after chemotherapy generated significantly superior PFS compared with adding TRT after tumor progression on first-line treatment (median PFS 10.7m VS 8.3m, HR=0.414 [95% CI: 0.207-0.825], p=0.013). In addition, patients without liver metastases or with bone metastases were more likely to benefit from TRT (both p<0.05). TRT slightly increased ≥grade 3 adverse effect (30.88% VS 25%). Notably, the incidence of pneumonia was higher in the TRT group than in the maintenance immunotherapy group (19.9% VS 6%).

Conclusions: The addition of TRT after first-line immunotherapy improves PFS and local control in ES-SCLC patients. TRT should be preferential performed in 3-6 weeks after chemotherapy. Patients without liver metastases or with bone metastases benefit more from TRT. The application of TRT is generally safe excepted for increased pneumonia occurrence.

Background: Consolidative thoracic radiotherapy (TR) was commonly used in the management of extensive-stage small cell lung cancers (ES-SCLC) in the past years. Nevertheless, phase III trials concerning first-line chemoimmunotherapy excluded these treatment approach. However, there is a strong biological rational to support the use of radiotherapy, as boost for sustaining anti-tumor immune response. Currently, the benefit of TR after chemoimmunotherapy remains unclear. Herein we include a real-world experience concerning 120 patients with ES-SCLC treated with chemoimmunotherapy combinations.

Methods: A total of 120 ES-SCLC patients treated with chemoimmunotherapy since 2019 in the South of Italy were retrospective analyzed. After 4 cycles of chemoimmunotherapy, all patients selected for the analysis obtained an adequate response for a subsequent TR. Of the 120 patients included in the analysis, 59 patients underwent TR. Patient characteristics, chemoimmunotherapy schedule, and timing for start TR were assessed. Primary endpoint was safety, secondary endpoint was the efficacy, namely OS and PFS.

Results: TR was associated with a good safety profile and with no significant changes in grade ≥3 AEs. In particular, none grade ≥3 AE was reported in the TR group versus two grade 3 AEs in the control group. The median time for start TR after 4 cycles of chemoimmunotherapy was 62 days (range 10-184). TR and fraction range include from 30 Gy (in 10 fractions) up to definitive dose in selected patients. TR was associated with a significantly longer PFS than systemic therapy alone (1-year PFS 55% vs. 1-year PFS 28.1%, p=< 0.0001) and was also associated with a trend toward longer PS (1-year OS 79,4% vs. 1-year OS 57,5%, p= 0.11).

Conclusions: Multi-center experience from South of Italy confirms a general confidence in using TR as consolidative strategy after chemoimmunotherapy based on clinical multidisciplinary decision. With the limit of a retrospective analysis, these preliminary results support the feasibility of this approach and encourage a prospective evaluation.

2002P A multicentre study assessing the real-world effectiveness of first-line chemotherapy plus immunotherapy in extensive-stage small cell lung cancer (ES-SCLC) patients

M. Porte[1], A. Vaudron[2], P. Crequit[3], T. chatellier[4], C. Fronteau[5], J. Raimbourg[6], T. Goronflot[2], J. Bennouna[7], E. Pons-Tostivint[8]

[1]Oncology, Hôpital Laennec, CHU de Nantes, Saint-Herblain, France; [2]Santé Publique, Clinique des Données, University Hospital of Nantes (Hôtel-Dieu - CHU de Nantes), Nantes, France; [3]Pneumology, Hopital Foch, Suresnes, France; [4]Medical Oncology, Clinique Mutualiste de l'Estuaire, Saint-Nazaire, France; [5]Clinical Pharmacy Unit, University Hospital of Nantes (Hôtel-Dieu - CHU de Nantes), Nantes, France; [6]Medical Oncology, ICO Institut de Cancerologie de l'Ouest René Gauducheau, Saint-Herblain, France; [7]Medical Oncology Department, Hopital Foch, Suresnes, France; [8]Medical Oncology Department, CHU du Nantes - Hôtel-Dieu, Nantes, France

Background: First-line chemotherapy plus immunotherapy (CT-IO) has recently demonstrated survival benefit over CT in Extensive-Stage Small Cell Lung Cancer (ES-SCLC) patients, based on randomized phase 3. This retrospective multicentre study assessed the real-world effectiveness of CT-IO since its approval in France in May 2020, in unselected patients.

Methods: Data from all ES-SCLC patients treated with CT-IO at four French hospitals between May 2020 and December 2021 were retrospectively analyzed. Kaplan Meier method was used to estimate OS and real-world progression-free survival (rwPFS), and Cox regression analysis to estimate hazard ratios (HRs) with 95% confidence intervals (CIs) in univariate and multivariate models.

Results: Of 75 patients included, median age was 69 years [IQR: 60.5-72.5], performans status (PS) was 0-1 in 78.7% of patients. Brain and liver metastases were present at baseline in 26.8% and 54.7% of patients respectively, and 28% of patients had corticosteroids $\geq$ 10 mg/day. At a median follow up of 16.8 months (95%CI: 14.9-23.4), the median OS was 11.4 months (95%CI: 7.7-14.7) with a 12-months OS rate of 43.6% (95%CI: 33.3-57.2). The median rwPFS was 5.3 months (95%CI: 4.8-5.8), 6-months PFS rate was 33.3% (95%CI: 24.2-45.9) and the objective response rate (ORR) was 76.7%. Introduction of delayed IO at the second cycle was not associated with a worse OS (HR 1.62, 95%CI: 0.88-2.97, p=0.132). In multivariate analyses, baseline brain and liver metastases were associated with a shorter OS (HR 3.80 [95% CI: 1.90-7.60] and 3.12 [95%CI: 1.60-6.08] respectively, p<0.001 for both).

Conclusions: Our study showed that survival data in real-world ES-SCLC patients treated with frontline CT-IO were promising and comparable to those obtained from randomized trials, even amongst an unselected population including older patients, with untreated brain metastases or corticosteroids.

Background: Despite recent innovations, ES-SCLC has still poor prognosis. First-line chemo-immunotherapy (CT-IT) improved clinical outcomes without increasing toxicities. Conversely, the role of thoracic radiotherapy (TRT) is largely unknown in this setting. The aim of our study was to evaluate clinical outcomes and safety of first-line CT-IT with or without consolidative TRT in ES-SCLC patients.

Methods: One hundred-three patients (pts) treated in five Italian centers from February 2020 to March 2023 were retrospectively evaluated. Median age was 67 years (range 38-84). All pts had ECOG PS 0-1, except 11 with PS=2. At time of treatment, all pts had ES-SCLC. Overall survival (OS) and progression free survival (PFS) were analyzed using the Kaplan Meier method. Univariate and multivariate analysis was performed to investigate patient, tumor or treatment related prognostic factors influencing clinical outcomes. Toxicity was recorded based on CTCAE 4.0 scale.

Results: At a median follow up of 11 months, 103 pts with ES-SCLC were treated using platinum- based CT-IT followed by maintenance IT with atezolizumab. Consolidative TRT was delivered to 33 responding pts and 14 underwent cranioprophylaxis. Median, 1- and 2-year OS was 14.2 months, 52.6%(SE±5,6%) and 31.4%(SE±6,0%), respectively. Median, 12- and 18-months PFS was 7,1 months, 27.5%(SE ±4,8%) and 14.4(SE ±4,8%), respectively. At univariate analysis consolidative TRT, ECOG PS, absence of brain or bone metastases at diagnosis were positive statistically significant prognostic factors for OS. TRT remains significant at multivariate analysis for OS (p < 0,0001). Toxicities >G2 were reported in 23 pts (22.3%) with hematological toxicity as the most common. Only one G5 toxicity was reported (pneumonitis).

Conclusions: CT-IT was confirmed as an effective therapeutic option in ES-SCLC. Consolidative TRT showed interesting results in terms of both OS and PFS being feasible and safe also in a large "real life" setting. Prospective trials with longer follow up are actually needed to further assess the impact of TRT on local disease control and survival.

2004P PD-L1 Inhibitors combined with whole brain radiotherapy in patients with small cell lung cancer brain metastases: Real-world evidence

L.L. Huang[1], X.M. Gong[2]

[1]Radiology Department, Shanghai Pulmonary Hospital, Shanghai, China; [2]Radiology, Shanghai Pulmonary Hospital - Tongji University School of Medicine, Shanghai, China

Background: Numerous studies have demonstrated that brain metastases (BMs) patients may benefit from intracranial radiotherapy combined with immune checkpoint inhibitors (ICIs). However, it is unclear whether this treatment is effective for patients with small cell lung cancer brain metastases (SCLC-BMs).

Methods: We conducted a retrospective study by analyzing medical records of patients with SCLC-BMs from January 1, 2017 to June 1, 2022. Data related to overall survival (OS), progression-free survival (PFS), and intracranial progression-free survival (iPFS) were analyzed.

Results: There were 109 patients enrolled, of whom 60 received WBRT and 49 received WBRT-ICI. Compared to the WBRT alone cohort, the WBRT-ICI cohort showed longer OS (20.4 months vs 29.3 months, P=0.021), PFS (7.9 months vs 15.1 months, P<0.001), and iPFS (8.3 months vs 16.5 months, P<0.001). Patients receiving WBRT-ICI regimen had a better response rate for both brain metastases (p=0.035) and extracranial diseases (p=0.000) compared to those on WBRT alone. Using WBRT before ICI was associated with superior OS compared to that obtained after ICI (23.3 months for the before group vs 34.8 months for the after group, P=0.020).

Conclusions: Our results indicated that WBRT combined with immunotherapy can improve survival in SCLC-BMs patients. The most optimal timing of WBRT is applying it before ICI, which can help improve OS. These findings highlight the significance of further prospective studies on intracranial radiotherapy and ICI combining strategies in SCLC-BM patients.

2005P Anlotinib combined with chemotherapy in the treatment of first-line extensive-stage small cell lung cancer (ES-SCLC): A real-world study

F. Gao[1], Y. Zhao[1], X. Li[2], Y. Li[3], T. Ma[4], Q. Li[5], X. Tang[6], X. Han[7], S. Yi[8]

[1]Respiratory Department of Internal Medicine, Henan Cancer Hospital/Affiliated Cancer Hospital of Zhengzhou University, Zhengzhou, China; [2]Department of Oncology, The First Affiliated Hospital of Zhengzhou University, Zhengzhou, China; [3]Respiratory Department of Internal Medicine, Shangqiu First People 's Hospital, Shangqiu, China; [4]Department of Oncology, Luohe Central Hospital, Luohe, China; [5]Department of Oncology, Xinxiang Central Hospital, Xinxiang, China; [6]Department of Oncology, The First Affiliated Hospital of Xinxiang Medical University, Xinxiang, China; [7]Department of Oncology, Xinyang Central Hospital, Xinyang, China; [8]Department of Oncology, Zhengzhou Central Hospital, Zhenzhou, China

Background: Small cell lung cancer (SCLC) makes up about 15% of all newly diagnosed cases of lung cancer, approximately 70% diagnosed with extensive-stage SCLC (ES-SCLC). For ES-SCLC, the safety and efficacy data of anti-angiogenesis combined with chemotherapy are still seriously lacking. The median PFS of first-line standard regimen (PD-L1 combined with chemotherapy) in the treatment of ES-SCLC is about 5 months, which is comparable to that of chemotherapy alone. Therefore, we conducted a real-world study to observe and evaluate the efficacy and safety of anlotinib combined with chemotherapy in the treatment of first-line ES-SCLC.

Methods: Eligible ES-SCLC pts (histologically or cytologically proven inoperable ES-SCLC; not received systematic treatment before; age≥18years; ECOG PS 0-2) were received anlotinib + etoposide + platinum for 4∼6 cycles, then anlotinib maintenance until the disease progresses or intolerable adverse reactions occur. During the treatment, dose reduction of anlotinib was permitted, which could be reduced to 10mg or 8mg if it was intolerable. The primary endpoint was progression-free survival (PFS), and secondary endpoints were objective response rate (ORR), disease control rate (DCR), overall survival (OS) and safety.

Results: Between March 2022 and April 2023, 60 patients were enrolled in this study and 34 patients were included in the evaluation of the treatment, with an average age of 65.5 (53.0-79.0) years old, 28 males (82.3%) and 6 females (17.7%). The ORR was 70.6%, and the DCR was 100.0%. The median PFS was 6.2 months (95% CI: 5.19 to 6.37). The median OS has not yet reached. The common grade 1-2 treatment-related adverse events (TRAEs) were hypertriglyceridemia (11.8%), hypercholesterolemia (11.8%), lymphocyte count decreased (8.8%), GGT increased (5.9%), cough (5.9%), platelet decreased (2.9%), grade 3 and above TRAEs included lymphocyte count decreased (5.9%), leukocyte decreased (5.9%), GGT increased (2.9%), hypodynamia (2.9%), neutrophil declined (2.9%). No higher-grade adverse reactions.

Conclusions: Anlotinib combined with chemotherapy in the treatment of ES-SCLC shows good efficacy and controllable safety; no unexpected toxicity has been observed.

2006P Immune activation effect and survival of different irradiated sites in ES-SCLC patients treated with radioimmunotherapy: A real-world analysis

M. Wu, J. Zhou

Radiation Oncology, The Affiliated Suzhou Hospital of Nanjing Medical University, Suzhou, China

Background: Genetic heterogeneity between primary lesion and metastatic organs is the reason for different immunogenic cell death and persistent antitumor immune activity in different irradiated sites. Besides, considering the intratumor heterogeneity in subtypes of SCLC, the combination of immunotherapy and radiotherapy for different metastases may have significantly differences. Considering the limited data, we aimed to identify the greatest immune activation effect of different irradiated sites and survival analysis in extensive-stage small cell lung cancer (ES-SCLC) patients treated with immunotherapy concurrent with radiotherapy.

Methods: 45 patients with ES-SCLC who had received radiation to a primary or metastatic solid tumor were enrolled. We collected overall survival time and blood cell counts including neutrophil, lymphocyte, monocyte, platelet in three time periods, before, during and after radiotherapy, and derived some blood index ratios including monocyte-to-lymphocyte ratio (MLR), neutrophil-to-lymphocyte ratio (NLR), platelet-to-lymphocyte ratio (PLR), and systemic immune-inflammation index (SII). The delta-IBs were calculated as medio-IBs ÷ pre-IBs-1. We analyzed the changes before and during RT using Spearman rank correlation test, Kruskal-Wallis rank sum test, as well as logistic regression and survival analysis used for the survival analysis.

Results: In selected blood indexes, NLR, PLR and SII are correlated with different irradiated organs, and the medians of delta-NLR, delta-PLR and delta-SII were all the lowest in brain irradiated group during immunotherapy. In the multivariate analysis, only treatment stage was the independent prognostic factors for 9m OS. The median OS of the entire study cohort was 23.5months (95% CI, 10.1—36.9months). For the analysis of ICI stages, patients with second-line ICIs had a higher median OS time than those with first or third and more-line stages (OS: 36.9 vs 22.3 vs 16.1m; $p = 0.001$).

Conclusions: We hypothesised RT to brain has the strongest activation effect and survival compared with other organs in ES-SCLC during immunotherapy. And the second-line immunotherapy combined with radiotherapy achieved better curative effect.

2007P Real-world (rw) outcomes to chemoimmunotherapy and biomarker analysis in extensive-stage small cell lung cancer (ES SCLC)

E. Panagiotou[1], M.E. Livanou[1], A. Montgomery[2], M. Mastrogeorgiou[1], C. Moeckel[2], N. Syrigos[1], I. Mouratidis[2], A. Charpidou[1], I. Georgakopoulos-Soares[2], I. Vathiotis[1]

[1]Medical Oncology, Sotiria Thoracic Diseases Hospital of Athens, Athens, Greece; [2]Biochemistry and Molecular Biology, Penn State College of Medicine, Hershey, PA, USA

Background: The addition of programmed death-ligand 1 (PD-L1) inhibitors to chemotherapy in the first-line treatment of ES SCLC has improved survival outcomes compared with chemotherapy alone. Biomarkers for response to chemo-immunotherapy have not been clearly established yet.

Methods: We performed a retrospective chart review of patients diagnosed with ES SCLC who received chemoimmunotherapy in the first-line treatment setting at Sotiria General Hospital for Chest Diseases, National and Kapodistrian University of Athens, Athens, Greece, between October 2018 and February 2023. Kaplan-Meier analysis was utilized to calculate rw progression-free survival (rwPFS) and rw overall survival (rwOS). Cox proportional hazards regression analysis was utilized to identify associations between patient characteristics and outcome. All hypothesis testing was conducted at a two-sided significance level of α=0.05.

Results: Ninety patients were eligible for study inclusion. The median age at diagnosis was 69 years (range, 40-82 years). Forty patients received atezolizumab plus carboplatin/etoposide (EP) and 50 patients received durvalumab plus EP. The rw objective response rate (rwORR) was 48.2%. At a median follow-up of 6.8 months, median rwPFS and rwOS reached 5.8 months (95% confidence intervals [CI], 5.2-9.7 months) and 12.7 months (95% CI, 7.7-17.5 months), respectively. Notably, survival outcomes were equivalent among patients treated with atezolizumab and those treated with durvalumab. Median rw progression-free survival to subsequent therapy (rwPFS2) was 2.7 months (95% CI, 1.9 months-not estimable). At baseline, increased neutrophil-to-lymphocyte ratio (NLR; hazard ratio [HR], 1.51; 95% CI, 1.02-2.25) and increased number of metastatic sites (HR, 3.14; 95% CI, 1.38-7.11) were associated with a higher risk of death, while elevated BMI (HR: 0.47, 95% CI:0.28-0.81) was associated with lower.

Conclusions: Rw survival outcomes to chemoimmunotherapy in ES SCLC were consistent with the results of large-scale randomized clinical trials. Several baseline patient characteristics were associated with rwOS and merit further investigation in prospective studies.

2008P Brazilian real-world data of immunotherapy (IO) in extensive disease small cell lung cancer (ES-SCLC)

F.A. Duarte[1], R. Dienstmann[2], P. Diniz[3], M. Costa e Silva[4], G.G. Viana Veloso[5], G. Arcanjo[6], R. Paes[4], T. Montella[6], H. Cuba[1], E. Macuzo[7], B.L. Ferrari[1], C.G.M. Ferreira[8]

[1]Clinical Oncology, Grupo Oncoclinicas - Oncocentro, Belo Horizonte, Brazil; [2]Precision Oncology, Oncoclinicas, São Paulo, Brazil; [3]Clinical Oncology, HC-UFMG - Hospital das Clínicas - EBSERH, Belo Horizonte, Brazil; [4]Big Data, Grupo Oncoclinicas, São Paulo, Brazil; [5]Education and Research, Grupo Oncoclinicas Botafogo, Rio de Janeiro, Brazil; [6]Clinical Oncology, Grupo Oncoclinicas, São Paulo, Brazil; [7]Internal Medicine, Faculdade de Medicina da UFMG, Belo Horizonte, Brazil; [8]Medical Oncologist, Grupo Oncoclinicas Botafogo, Rio de Janeiro, Brazil

Background: The landmarks of thoracic Oncology in the last two decades have been accompanied by exponential growths in costs, which makes imperative the assessment of the real benefit of new technologies incorporations, particularly those with marginal gains. The combination of IO with platinum-etoposide chemotherapy has

become the standard of care in first-line treatment of ES-SCLC, although the absolute difference in overall survival (OS) has reached three months. This study aimed to investigate the impact of this intervention in a real-world cohort of a middle-income country.

Methods: We retrospectively analyzed data from all ES-SCLC patients (pts) from Oncoclinicas, the largest community oncology practice in Latin America, diagnosed and treated between January 2018 and June 2022. Primary objective was median OS according to IO exposure in the first-line setting. Secondary objective was median time to treatment discontinuation (TTD). Relevant clinical characteristics which might impact the results were also evaluated. The project was approved by local Ethics Committee.

Results: In total, 98 patients SCLC pts were included in this analysis. The median age was 68 years, 54% were male, 88% were smoking history, and only 12% has ECOG 2-3. At diagnosis, 81% presented with ES-SCLC and 21% has central nervous system metastasis. First-line regimens were atezolizumab + platinum-etoposide in 47%, platinum-etoposide in 44% and platinum-irinotecan in 9%. Median follow-up was 5 months. Among ES-SCLC pts who received IO in their first-line treatment, median mOS was 14.03 months compared to 7.43 months in those who did not receive IO (HR: 0.76, CI 0.42 − 1.40, p = 0.39). Median TTD of the first-line IO was 7.03 months compared to 3.80 months of those who received chemotherapy only (HR: 0.43, CI 0.24 − 0.76, p = 0.003).

Conclusions: There are few real-world cohorts evaluating the impact of IO in ES-SCLC, limited to high-income countries. Our data suggest that IO may have a meaningful impact in the outcome of ES-SCLC, with median OS comparable to clinical trials. Larger sample small sample size and longer follow-up are needed for conclusive statements, but we will continuously monitor the value of IO as they are introduced in clinical practice for ES-SCLC.

2009P CNS efficacy of immune checkpoint inhibitors when combined to stereotactic radiosurgery in extensive stage small cell lung cancer

M. Awidi[1], S. Perimbeti[2], C. wang[3], K. Attwood[3], P. Jain[4]

[1]Internal Medicine Department, Roswell Park Comprehensive Cancer Center, Buffalo, NY, USA; [2]Medical Oncology, Roswell Park Comprehensive Cancer Center, Buffalo, NY, USA; [3]Biostatistics, Roswell Park Comprehensive Cancer Center, Buffalo, NY, USA; [4]Hematology & Oncology Department, Roswell Park Comprehensive Cancer Center, Buffalo, NY, USA

Background: Brain metastasis is highly prevalent in Extensive Stage Small Cell Lung Cancer (ES-SCLC) and carries a poorer prognosis. Combined chemotherapy (CTX) and Immune checkpoint Inhibitor (ICI) is the current standard of care in treatment of ES-SCLC. Stereotactic Radiosurgery (SRS) either as whole brain radiation or Gamma knife radiosurgery is often employed to treat CNS disease. We aim to investigate the CNS benefit of ICI when combined with CTX in patients with ES-SCLC who received SRS.

Methods: Baseline characteristics, treatment and survival details were collected. Patients with baseline CNS disease who received SRS and at least one cycle of systemic therapy were included. Primary outcome of CNS progression free survival (CNS-PFS) was calculated using standard Kaplan-Meier methods, and Cox proportional hazard model were used to evaluate the association between survival outcome and treatment group while adjusting for age and baseline ECOG. Analyses were performed in SAS v9.4 (Cary, NC) at a significant level of 0.05. The CTX and CTX+ICI groups were labeled as cohort A and cohort B respectively.

Results: A total of 165 patients were included in the analysis. Cohort A had 122 patients (73.9%), while cohort B had 43 patients (26.1%). The baseline characteristics between the two cohorts were balanced as seen in table. The Cox proportional hazards analysis revealed a 30% benefit in CNS-PFS in cohort B when compared to cohort A (HR=0.7 CI=0.47-1.03). Additionally, there was a trend towards benefit in overall survival (OS) in cohort B (HR=0.74 CI=0.46-1.2).

Table: 2009P Baseline characteristics

	Cohort A (CTX)	Cohort B (CTX+ICI)
Total patients n, (%)	122, (73.9%)	43, (26.1%)
Age median, (min-max)	64.2, (37.2-86.3)	64.4, (51.6-85.9)
ECOG at presentation, n (%)		
ECOG 0-2	109, (89.3%)	38, (88.4%)
ECOG 3-4	13, (10.7%)	5, (11.6%)
Completed treatment cycles n, (%)		
$\leq$ 4 cycles	87, (71.3%)	39, (90.7%)
$\geq$ 5 cycles	35, (28%)	4, (9.3%)

Conclusions: Although the CNS-PFS and OS trends did not reach statistical significance, due to the small number of patients, our study suggests a clear trend towards CNS-PFS and OS benefit when combining ICI+CTX to SRS. Thus, supporting the hypothesis of immune modulatory effect of SRS on the brain metastases tumor microenvironment. Larger studies are needed to confirm these findings.

2010P Non-invasive radiomics signature predicts response to combination chemoimmunotherapy in extensive-stage small cell lung cancer (ES SCLC)

S. Perimbeti[1], M. Khorrami[2], V.S. Viswanathan[2], M. Zla[1], A. Gupta[3], C.L. Roche[4], C. Barrera[2], H. trivedi[5], M. Behera[2], K. Higgins[2], P. Jain[6], A. Madabhushi[2]

[1]Medical Oncology, Roswell Park Comprehensive Cancer Center, Buffalo, NY, USA; [2]Wallace H. Coulter Department of Biomedical Engineering at Emory University and Georgia Tech, Emory University, Atlanta, GA, USA; [3]Department of Radiology, Case Western Reserve University/University Hospitals, Cleveland, OH, USA; [4]Radiology, Roswell Park Comprehensive Cancer Center, Buffalo, NY, USA; [5]Radiology, Emory University, Atlanta, GA, USA; [6]Hematology & Oncology Department, Roswell Park Comprehensive Cancer Center, Buffalo, NY, USA

Background: ES SCLC is a highly aggressive malignancy with poor outcomes. While immunotherapy (IO) has shown promise in improving response rates in some patients (pt) with ES SCLC, there are no reliable biomarkers to predict which pt are most likely to benefit. In this study, we aimed to explore the potential of radiomic texture features from inside (intratumoral) and immediately outside (peritumoral) the tumor on pre-treatment CT scans to predict overall survival (OS) and response to chemoIO in ES SCLC pt.

Methods: The study included 142 ES SCLC pt from three institutions, with measurable lung lesions on baseline chest CT scans. A maximum of two lung lesions were annotated. Pt with best objective response per RECIST 1.1 of complete or partial response were categorized as responders, while those with stable or progressive disease were considered non-responders. A total of 860 intratumoral and peritumoral texture features were extracted, and a radiomic risk score (RRS) was generated using the least absolute shrinkage and selection operator. Cox regression model was used to predict OS. The model was trained on 97 ES-SCLC pt (St) treated with chemotherapy at University Hospital Cleveland Medical Center and validated on 45 ES-SCLC pt (Sv) treated with chemoIO at Roswell Park Cancer Institute (Sv1; n=34) and Emory University (Sv2; n=11). The discriminative ability of the features was assessed using Kaplan-Meier and log-rank tests, and the probability of treatment response was evaluated using a previously trained linear discriminant classifier (LDA).

Results: A combination of peritumoral and intratumoral radiomic features on pre-treatment CT showed an AUC of 0.73 in St and 0.72 in independent external Sv to predict response to treatment. The RRS was significantly associated with OS in both St (HR: 2.27; 95% CI, 1.7−2.98; P<0.001; C-index=0.70) and Sv (HR: 2.26; 95% CI, 1.32−3.74; P=0.016; C-index=0.65).

Conclusions: Pre-treatment CT radiomic features are potentially prognostic and predictive of response to chemotherapy or chemoIO in ES SCLC pt. These findings may have implications for guiding treatment decisions and improving outcomes by better pt stratification. Additional independent, multi-site validation is warranted.

2011P Machine-derived features of tumor infiltrating lymphocytes (TILs) as biomarkers of clinical outcomes to platinum chemotherapy in small cell lung cancer (SCLC)

P. Jain[1], C. Barrera[2], S. Perimbeti[3], V.S. Viswanathan[2], B. Beshai[4], M. Khorrami[2], A. Madabhushi[2]

[1]Department of Medical Oncology, Roswell Park Comprehensive Cancer Center, Buffalo, NY, USA; [2]Wallace H. Coulter Department of Biomedical Engineering at Emory University and Georgia Tech, Emory University, Atlanta, GA, USA; [3]Medical Oncology, Roswell Park Comprehensive Cancer Center, Buffalo, NY, USA; [4]Pathology Department, Roswell Park Comprehensive Cancer Center, Buffalo, NY, USA

Background: Platinum chemotherapy (PC) is the mainstay of treatment in SCLC. Most patients relapse with poor overall survival (OS) and develop resistance to further therapy. Presently, there are no biomarkers to predict response/resistance to initial treatment. TILs have shown to serve as a prognostic factor in several solid cancers but remain largely unexplored in SCLC. In this study, we explore the association of density and spatial arrangement of TILs with clinically relevant outcomes.

Methods: TIL features were extracted using computational algorithms from H&E whole slide images of pre-treatment SCLC biopsy across two cohorts, D1 (University Hospitals) and D2 (Roswell Park) (n=213). D1 (n=101) was used to identify the most prognostic features and train two classifiers to predict objective response to PC and OS. The classifier's performance was evaluated in an independent cohort D2 (n=112). D1 was split into Training (St)/Test (Sv) set (40/60) based on overall response to PC per RECIST; responders=complete/partial response, non-responders=stable/progressive disease and OS status. Boruta method of feature selection was used to select the most discriminating features. Linear classifier with qr factorization, linear least square approach was used to build a model for predicting response and Kaplan-Meier with log-rank test for estimating survival curve and risk stratification; Cox's proportional hazards with elastic-net penalization for risk score. The model was evaluated using Area Under the Curve (AUC) and Precision Recall Curves (PRC) for OR and in terms of Hazard Ratio (HR), C-index (CI) and p-values for OS prediction.

Results: Features related to density variation of clusters of TILs and non-lymphocytes within the tumor area were associated with response to PC and OS. For St, AUC=0.96, PRC=0.98 (HR=2.84; 1.34-6.02, p=0.005, CI=0.75 0.60-0.90), AUC=0.66, PRC=0.76 (HR=2.06; 1.15-0.84, p=0.013, CI=0.7; 0.56-0.84) for Sv. For D2, validation AUC=0.67 and PRC=0.79 (HR=1.99; 1.08-3.7, p=0.026, CI=0.69; 0.54-0.83).

Conclusions: We demonstrate that TIL density and architecture features are associated with OR and OS. Additionally, independent multi-site validation is warranted.

2012P Spatially resolved transcriptomics deciphers inter- and intra-tumor heterogeneity of small cell lung cancer

X. Sun[1], Z. Zhang[2], J. Dong[3], L. Liu[4], N. Wang[5], J. Ying[4], M. Zhou[6], L. Yang[3]

[1]Pathology, National Cancer Center/National Clinical Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Bejing, China; [2]Biostatistic, School of Biomedical Engineering, Wenzhou Medical University, Wenzhou, China; [3]Pathology, National Cancer Center/National Clinical Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Bejing, China; [4]Pathology, Chinese Academy of Medical Sciences and Peking Union Medical College - National Cancer Center, Cancer Hospital, Beijing, China; [5]Medical Oncology, Mills Institute for Personalized Cancer Care, Fynn Biotechnologies Ltd, Jinan, China; [6]Biostatistics, School of Biomedical Engineering, Wenzhou Medical University, Wenzhou, China

Background: Small cell lung cancer (SCLC) is a highly heterogeneous cancer. Recent studies have illustrated that inter- and intra-tumor heterogeneity (ITH) is correlated with biological behavior and therapeutic vulnerability in multiple malignancies. However, it remains unclear in SCLC. Here, we seek to define ITH at the spatial transcriptome level and elucidate the crosstalk between ITH and tumor immune microenvironment (TIME) with the clinical characteristics of SCLC.

Methods: We performed digital spatial profiling (DSP) to quantify the whole transcriptomes and calculated the ITH score using the Deviating gene Expression Profiling Tumor Heterogeneity algorithm (DEPARTMENTH) at the RNA level. Deconvoluted algorithms were adopted to calculate immune infiltration from RNA expression data, which was validated with immunochemistry (IHC). A machine learning model (THIM) was constructed to determine the tumor heterogeneity and facilitate prognostic stratification, which were validated across multi-center cohorts.

Results: Using DSP RNA data of the tumor core area (79 regions) from resected limited stage SCLC (25 patients), we differentiated intra-/inter-tumor heterogeneity subtypes. SCLC tumors could be classified into two distinct subtypes: high heterogeneity+complex (HC) and medium+low heterogeneity (ML), with significant variations in CD8+ T cell infiltration and multiple biological properties. There were significant differences in overall survival (log-rank $p = 0.046$) and disease-free survival (log-rank p=0.024) between the two subtypes, where MLs had good and HCs showed poor prognosis. Furthermore, we developed and verified a robust THIM model using machine learning techniques which is able to predict the therapeutic response (AUC=0.923) and survival of SCLC patients, as demonstrated in both in-house and multicenter bulk transcriptomic data cohorts.

Conclusions: In summary, we have deciphered inter- and intra-tumor heterogeneity of SCLC and proposed a new heterogeneity-oriented subtyping framework for improving clinically relevant risk stratification, which is promising for postoperative stratified management of limited stage SCLC patients as well as assessment of immunotherapy efficacy in advanced stage patients.

2013P Investigating the clinical relevance of immune checkpoint expression in the peripheral blood of patients with small cell lung cancer (SCLC)

D. Mavroudis[1,2], A. Boumpouli[1], E. Vorrias[1,2], N. Nikolarakou[1], A.C. Kyriakidou[1,2], M.A. Papadaki[1], S. Agelaki[1,2]

[1]Laboratory of Translational Oncology, Faculty of Medicine, University of Crete, Heraklion, Greece; [2]Department of Medical Oncology, University General Hospital of Heraklion, Heraklion, Greece

Background: Cytotoxic T lymphocyte antigen 4 (CTLA4) and T cell immunoreceptor with Ig and ITIM domains (TIGIT) immune checkpoints are expressed on tumor-infiltrated immune cells (TILs) in SCLC and represent promising immunotherapy targets. We aimed to assess the frequency and clinical relevance of CTLA4 and TIGIT expression in the peripheral blood (PB) of patients with SCLC.

Methods: PB was obtained from 90 SCLC patients prior to first-line treatment (chemotherapy=61; combination of chemotherapy/anti-PD-L1 inhibitors: n=29). Peripheral blood mononuclear cell (PBMC) cytospins were stained for CTLA4/TIGIT/dapi. CTLA4 and TIGIT protein expression was individually assessed on 1000 intact PBMCs *via* fluorescence microscopy; the mean % value was used to define high expression of each marker.

Results: CTLA4 and TIGIT were expressed on PBMCs in 95.6% and 100% of patients, respectively, with a mean percentage of positive PBMCs per patient: 27.8% and 34.5%, respectively. Their expression was not associated with clinicopathological parameters or survival outcomes in the entire patient population. However, separate analysis of the chemoimmunotherapy group (n=29 extensive-stage SCLC patients) revealed that high versus low expression of CTLA4 and/or TIGIT was a marker for increased progression-free survival and overall survival (median PFS: 8.7 vs 4.7 months, p=0.000; median OS: 13.9 vs 5.9 months, p=0.038; respectively by Kaplan Meier analysis); on the contrary, no correlation was shown for patients treated with chemotherapy only (median PFS: 6.2 vs 7.9 months, p=0.877 and median OS: 11.6 vs 15.1, p=0.142). Moreover, among extensive-stage patients with high expression of CTLA4 and/or TIGIT on PBMCs (n=45 patients), the administration of chemoimmunotherapy was associated with improved survival rates as compared to those receiving chemotherapy only (median OS: 14 vs 7.8 months, p=0.005).

Conclusions: CTLA4 and TIGIT are frequently expressed on PBMCs of SCLC patients and are correlated with significant clinical benefit from the addition of anti-PD-L1 inhibitors to first-line chemotherapy. Their role as immunotherapy biomarkers in SCLC merits further investigation.

2014P ATR inhibition upregulates PD-L1 and potentiates the antitumor immune response to chemoimmunotherapy in small cell lung cancer

T. Sen

Oncological Sciences, Icahn School of Medicine at Mount Sinai, New York, NY, USA

Background: Small cell lung cancer (SCLC) is the most aggressive subtype of lung cancer, with a very poor prognosis and limited therapeutic options. Recent clinical trials of immune checkpoint blockade (ICB) combined with chemotherapy delivered only very modest benefit. Here, we identified that ataxia telangiectasia and rad3 related (ATR), the primary activator of the replication stress response, is highly enriched in SCLC and inhibition of ATR induced DNA damage and apoptosis in multiple SCLC models.

Methods: Genetic and pharmacological inhibition of ATR in human and murine SCLC models. ATR inhibition either alone or in combination with PD-L1 blockade either as a first-or second-line treatment in mouse models.

Results: In multiple immunocompetent SCLC mouse models, ATR inhibition (ATRi) remarkably enhanced the anti-tumor effect of PD-L1 blockade. We next tested the ATR inhibition either alone or in combination with PD-L1 in the second-line regimen for SCLC. ATR inhibition in combination with PD-L1 blockade significantly reduced tumor volume and prolonged survival of aggressive mice models when compared to PD-L1 alone. Targeting ATR enhanced the expression of PD-L1, activated the cGAS/STING pathway, induced the expression of Type I and II interferon pathways, and caused significant infiltration of cytotoxic and memory/effector T-cells into tumors. Interestingly, ATRi also led to significant induction of MHC class I in SCLC *in vitro* and *in vivo* models. Analysis of pre- and post-treatment clinical samples from a proof-of-concept study of a first-in-class ATR inhibitor, M6620 (berzosertib), and TOP1 inhibitor topotecan, in patients with relapsed SCLCs validated the induction of MHC class I and interferon pathway genes, for the first time in this disease.

Conclusions: We highlight ATRi as a potentially transformative vulnerability of SCLC, paving the way for combination clinical trials with anti-PD-L1. Given the increasing importance of immunotherapy for the management of SCLC and that ATR inhibitors are already in clinical trials, combining an ATR inhibitor with PD-L1 blockade may offer a particularly attractive strategy for the treatment of SCLC and contribute to the rapid translation of this combination into the clinic.

2015P Association between gene characteristics and mutation abundance with the prognosis of small cell lung cancer

L. Yu[1], D. Chen[1], J. Xu[1], R. Qiao[1], H. Zhong[1], J. Chen[2], R. Zhong[1]

[1]Department of Respiratory and Critical Care Medicine, Shanghai Chest Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, China; [2]Department of Medical Ultrasound, Shanghai Chest Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, China

Background: Genetic characteristics and mutation abundance need to be further explored in small-cell lung cancer (SCLC). This study aimed to analyze the correlation between genetic characteristics and mutation abundance and the prognosis of SCLC patients by next-generation sequencing (NGS).

Methods: Patients diagnosed with SCLC at Shanghai Chest Hospital from January 2017 to December 2020 were reviewed. All enrolled SCLC patients underwent NGS testing before initiating treatment.

Results: 122 patients were enrolled in the final analysis, including 48 patients with limited-stage SCLC (LS-SCLC) and 74 patients with extensive-stage SCLC (ES-SCLC). The most common mutant genes were TP53, RB1, and SMAD4 in LS-SCLC and ES-SCLC. Furthermore, no significant difference in mutant genes and mutation frequencies was observed between LS-SCLC and ES-SCLC. Multivariate Cox regression analyses revealed that the presence of genetic abnormalities TP53 and BRCA2 was significantly related to overall survival (OS) in patients with LS-SCLC. In ES-SCLC patients, the genetic abnormalities TP53, NOTCH1, PTEN, and PIK3CA were significantly related to OS. TP53 mutation abundance was higher in ES-SCLC than in LS-SCLC (average 75.334% vs. 65.954%, median 82.395% vs. 76.820%, $P = 0.046$). In ES-SCLC patients, higher TP53 mutation abundance predicted poorer clinical outcomes, which is contrary to LS-SCLC patients.

Conclusions: This study reveals the relevance of genetic features of NGS and prognosis in SCLC patients. Contrary relationships were observed between TP53 mutation abundance and prognosis in patients with LS-SCLC and ES-SCLC.

2016P The role of galectin-1 in SCLC: Prognostic significance and therapeutic implications

A. Cebrian[1], L. Del Puerto-Nevado[1], J.M. Corral[2], M. Cedeño[3], A. Rio-Vilariño[1], I. Mahillo-Fernandez[4], C. Galeano[5], N. Baños[6], J. Garcia-Foncillas[1], M. Dómine[6]

[1]Medical Oncology, Instituto de Investigación Sanitaria Fundación Jiménez Díaz, Madrid, Spain; [2]Thoracic Surgery, Fundación Jiménez Díaz, Madrid, Spain; [3]Pathology, Hospital Universitario Fundacion Jimenez Diaz, Madrid, Spain; [4]Biostatistics, Instituto de Investigación Sanitaria Fundación Jiménez Díaz, Madrid, Spain; [5]Pathology, Fundación Jiménez Díaz, Madrid, Spain; [6]Medical Oncology, Fundación Jiménez Díaz, Madrid, Spain

Background: Not much has changed in the SCLC landscape over the past 40 years, apart from the addition of checkpoint inhibitors, which have been the most notable advance in clinical management since the 1980s. As a result, greater efforts are needed to develop more therapies to combat this type of cancer. Galectin-1 (Gal-1) has emerged as an interesting player due to its involvement in crucial roles in cancer development. Our objective was to assess whether Gal-1 has a prognostic role in SCLC outcomes and its potential for use in both monotherapy and combination with platinum-based therapy.

Methods: We analyzed Gal-1 expression in 77 SCLC patients using RNA sequencing and in 81 patients using in-house immunohistochemistry (IHC). We evaluated the prognostic potential of Gal-1 using survival curves and Cox regression analysis. Additionally, we established a SCLC-PDX model and randomized it into four groups to assess the effects of Gal-1 inhibition in monotherapy and in combination with platinum-based therapy. To evaluate antitumor activity, T/C ratio was applied.

Results: Galectin-1 gene (LGALS1) expression showed a strong negative correlation with outcomes in SCLC patients with advanced disease ($p = 0.007$). Furthermore, IHC analysis revealed that in patients with advanced disease, a high Gal-1 score (Gal-1 score >3) and high Platelets to Lymphocytes Ratio (PLR > 186) as a combined variable presented a HR=3.07, 95% CI: 1.62, 5.79, $p < 0.001$, with a significant impact on survival (median time (weeks) for OS was 31 in the high/high group versus 41.1 in the other group). The SCLC-PDX model showed a significant reduction in tumor growth in both the OTX008 (T/C 66%) and carboplatin/etoposide (T/C 65%) groups, with the greatest effect attributable to the combination (T/C 46%).

Conclusions: Our findings suggest that high levels of Gal-1 and PLR are associated with poorer OS in SCLC patients and can be useful as clinical prognostic biomarkers. Moreover, our *in vivo* model suggests that the inhibition of Gal-1 could be a novel potential therapy with a significant impact in combination with platinum-based therapy.

2017P Comprehensive molecular profiling of small cell lung cancer patients treated with chemo-immunotherapy or chemotherapy alone

M. Urbini[1], M. Canale[1], M. Flospergher[2], K. Andrikou[2], P. Cravero[2], L. Pasini[1], A. Dubini[3], R. Panzacchi[4], C. Bennati[5], G. Rossi[6], D. Tassinari[7], M. Valli[8], A. Delmonte[2], L. Crinò[2], P. Ulivi[1]

[1]Biosciences Laboratory, IRCCS Istituto Romagnolo per lo Studio dei Tumori (IRST) "Dino Amadori", Meldola, Italy; [2]Medical Oncology Department, IRCCS Istituto Romagnolo per lo Studio dei Tumori (IRST) "Dino Amadori", Meldola, Italy; [3]Pathology Department, Ospedale "Morgagni - Pierantoni" di Forlì, Forlì, Italy; [4]Pathology Department, Ospedale M. Bufalini, Cesena, Italy; [5]Medical Oncology Department, Ospedale Santa Maria delle Croci, Ravenna, Italy; [6]Oncology, Fondazione Poliambulanza Istituto Ospedaliero, Brescia, Italy; [7]Medical Oncology Department, Ospedale Infermi, Rimini, Italy; [8]Pathology Department, Ospedale Infermi di Rimini, Rimini, Italy

Background: Small cell lung cancer (SCLC) is one of the most lethal forms of lung cancer, with a 5-year survival rate of approximately 7%. SCLC has been divided into limited stage (LS) and extensive stage (ES). For ES-SCLC the use of immunotherapy (IO) has been introduced in combination with platinum-based chemotherapy (CT), prolonging the overall survival of patients. However, only a small fraction of patients experience a durable clinical benefit from this approach, with no selection criteria able to predict clinical outcome. Here we hypothesize that different mutational profiles could be associated to clinical outcome of patients treated with CT-IO with respect to CT alone.

Methods: A case series of 88 ES-SCLC patients was enrolled. Tumor tissues of patients were analysed with a next-generation sequencing-based assay (Foundation One CDx), analysing 324 genes, selected gene rearrangements, microsatellite instability (MSI) and tumor mutational burden (TMB). Statistical analyses have been performed to study the correlation among clinical characteristics, mutational profiles and clinical outcome has been performed.

Results: For patients with available clinical information, 36 were treated with CT-IO and 50 with CT alone. The 65% of patients were male, and the 35% were female, median age was 71 (range 50-86) years old. The 36.2% of patients were former smokers whereas 53.75% were current smokers, while smoking habits were not available for 16 patients. The most frequently mutated genes were *TP53* (98%), *RB1* (80%), *MLL2* (35%), *NOTCH3* (16.2%), *MLL* (12.5%), *RICTOR* (8.8%), *CDKN2A/B* (7.3%), *APC* (7.3%), *MYC* (6.3%) and *MYCL1* (6.3%). No rearrangements were detected in any patient. With regard to TMB, 25% of patients had low TMB (<6 mut/Mb), 65% of patients had intermediate TMB (6>20 mut/Mb), and 10% of patients had high TMB (>20 mut/Mb). MSI data was available for 67 patients, and all but one patients were stable. Survival analyses and correlation of clinical outcome with mutational profiles are still ongoing.

Conclusions: Our results suggest that a comprehensive genomic profile could help to predict clinical outcome of ES-SCLC patients treated with CT-IO.

2018P Novel nomogram based on the expression of DLL3 and PD-L1 for predicting the prognosis of small cell lung cancer patients

J. Zhao[1], W. Li[1], X. Zhang[1], Y. Du[1], Y. Zhang[1], Y. Zhang[2], R. Shi[2], Y. Zhang[3], F. Su[1], Y. Zhang[1], W. Fan[1], W. Hu[4], Y. Wang[2]

[1]Department of Oncology, Changzhi People's Hospital Affiliated to Changzhi Medical College, Changzhi, China; [2]Department of Pathology, Changzhi People's Hospital of Changzhi Medical College, Changzhi, China; [3]Respiratory Medicine, Pengzhou People's Hospital, Chengdu, China; [4]Department of Gastrointestinal Surgery, Changzhi People's Hospital of Changzhi Medical College, Changzhi, China

Background: Small cell lung cancer (SCLC) is highly invasive and has a low 5-year survival rate. Programmed death receptor 1/programmed death receptor-ligand 1 (PD-L1) inhibitors have improved survival in SCLC patients partially, but more targets and precise beneficiary populations are needed. Delta-like ligand 3 (DLL3)-targeted drug Rova-T was terminated due to insufficient efficacy, considering other factors that may affect efficacy. This study aims to construct a prognostic model for SCLC patients based on the expression of DLL3 and PD-L1 to help determine prognosis and guide clinical therapy.

Methods: Immunohistochemistry was used to detect the expression of DLL3 and PD-L1 in the tissue specimens of SCLC patients. Independent risk factors were identified by Cox proportional risk regression to construct the model. The model was validated by consistency index (C-index), bootstrap resampling, and decision curve analysis (DCA).

Results: Up to March 15, 2023, 141 patients diagnosed with SCLC by pathology at Changzhi People's Hospital were included, and 129 patients have reached the endpoint. The expression rates of DLL3 and PD-L1 were 62.4% (88/141), 10.6% (15/141). NSE, stage, treatment, DLL3 and PD-L1 were independent risk factors for OS in SCLC patients ($p<0.05$). Based on these factors, a prediction model for the 12-month survival probability of SCLC patients was constructed and a nomogram was plotted. The model was tested for good discrimination (C-index 0.739), accuracy and clinical applicability. In addition, patients were divided into low-risk and high-risk for survival analysis based on the best cut-off value of 49.11 for nomogram, indicating that the model had great discrimination ability (mOS 13.33 vs. 7.80m, $p<0.001$).

Table: 2018P

Variable		Point	Overall point	12-m survival probability
NSE per 50mg/ml		6.16	0	0.78
Stage	Limited	0	10	0.72
	Extensive	20.47	20	0.65
Treatment	Yes	0	30	0.57
	No	100	40	0.47
DLL3	Negative	0	50	0.37
	Positive	24.69	60	0.27
PD-L1	Negative	0	70	0.17
	Positive	44.50	80	<0.10

Conclusions: The OS prediction model for SCLC patients in this study has excellent predictive performance in predicting the 12-m survival probability and may assist clinicians in making more accurate judgments and guiding therapy of SCLC patients.

2019P Analysis of lung immune prognostic index (LIPI) score in a small cell lung cancer carcinoma (SCLC) cohort, supporting its prognostic use and investigating its predictive potential

M. Esteban García[1], E. Jimenez Aguilar[1], A.M. González López[1], T. Robles Bermejo[1], Y. Pernas Sánchez[1], R. Avilés Peña[1], E. Perez Fernandez[2], S. Adeva Antona[3], J.C. Cámara Vicario[1], C. Olier Gárate[1], S. Hernando Polo[1], A. Hurtado Nuño[1], D. Moreno Muñoz[1], X. Mielgo Rubio[1]

[1]Medical Oncology Department, Hospital Universitario Fundación Alcorcón, Alcorcón, Spain; [2]Biostatistics, Hospital Universitario Fundación Alcorcón, Alcorcón, Spain; [3]Pharmacy, Hospital Universitario Fundación Alcorcón, Alcorcón, Spain

Background: Current standard-of-care treatment for extensive-stage SCLC involves combining chemotherapy with immune checkpoint inhibitors (ICI). However, appropriate predictive biomarkers are still lacking. The LIPI is a clinical tool developed in non-small cell lung cancer. We aim to study whether the LIPI score can be a prognostic and predictive tool in SCLC.

Methods: We conducted a retrospective unicenter observational study. 48 patients were included, classified in cohort ICI when treated with carboplatin-etoposide and atezolizumab (n=23); and cohort CT when treated with cisplatin/carboplatin-etoposide (n=25). Complete blood cell counts and LDH levels were measured before treatment. LIPI score was calculated and patients were classified in good (0), intermediate (1) and poor categories (2). Primary outcomes were to determine progression-free survival (PFS) and overall survival (OS) in both cohorts stratified by LIPI categories. Fischer's test was used for categorical data; while PFS and OS were evaluated by Kaplan-Meir.

Results: Cohorts were comparable without significant differences in baseline characteristics (age, sex, metastatic sites, corticoid use). Regarding PFS, at 12 months all patients in the CT cohort had progressed, versus 79% in the ICI cohort. PFS was better for LIPI 0 with statistical significant difference (p=0.043) with 22% free of progression at 12 months, versus 6% for LIPI 1 and 0% for LIPI 2. For the ICI cohort PFS was significantly better for LIPI 0 as well (p=0.0151), with 40% free of progression at 12 months. The one-year OS survival rate was 40% for the CT cohort and 32% for the ICI cohort. Although no statistical significance was found, a trend towards better OS for LIPI 0 was seen in both cohorts; with 67% alive at 1-year versus 23% for LIPI 1 and 34% for LIPI 2. This was also present in the ICI cohort with 60% alive at 1-year for LIPI 0 versus 27% for LIPI 1 and 0% for LIPI 2.

Conclusions: Although limited by the small number of patients and the shorter follow-up in the ICI cohort, our study supports LIPI score can be a prognostic tool in SCLC. Further studies are needed to find whether it could also be a predictive tool for response to ICI in SCLC.

2020P Circulating micro RNAs (cmiRNAs) as treatment outcome predictors in extensive small cell lung cancer (eSCLC) patients (pts) receiving atezolizumab plus carboplatin and etoposide (ACE): CATS/ML43257 study

G. Pasello[1,2], L. Urso[1], I. Cavallari[3], M. Lorenzi[4], M.V. Resi[1], S. Giunco[1], G. Pigato[3], E. Sharova[3], E. Sharova[3], A. Ferro[5], A. Dal Maso[6], S. Frega[2], L. Bonanno[5], S. Indraccolo[1], A. De Rossi[1], D.M. D'Agostino[7], V. Ciminale[1,9], V. Guarneri[1]

[1]Department of Surgery, Oncology and Gastroenterology, University of Padua Medical School, Padua, Italy; [2]Medical Oncology 2, Veneto Institute of Oncology IOV-IRCCS, Padua, Italy; [3]Tranlsational Oncology Department, IOV - Istituto Oncologico Veneto IRCCS, Padua, Italy; [4]Medical Oncology Department, Santa Chiara Hospital, Medical Oncology, Trento, Italy; [5]Dipartimento di Oncologia, IOV - Istituto Oncologico Veneto IRCCS, Padua, Italy; [6]Medical Oncology Department, IOV - Istituto Oncologico Veneto IRCCS, Padua, Italy; [7]Biomedical Sciences Department, University of Padua, Padua, Italy; [9]IOV - Istituto Oncologico Veneto IRCCS, Padua, Italy

Background: ACE is the new standard first-line treatment for eSCLC. However, response to this treatment is highly heterogeneous and the identification of patients more likely to benefit from immunotherapy is in high demand. To this end, circulating biomarkers may prove to be useful, especially when tumor tissue samples are difficult to obtain and for tumors with high genetic heterogeneity. CATS is a prospective pilot study aiming at identifying predictive cmiRNAs in a cohort of eSCLC patients receiving ACE.

Methods: Next generation sequencing technology was employed to determine the cmiRNA profile in the plasma of eSCLC patients at different time points (T0 baseline; T1 after 1 cycle; T2 after 2 cycles; T3 disease progression). Library preparation was carried out using the QIAseq miRNA library kit (Qiagen, Hilden, Germany). All samples were single-end-sequenced on an Illumina NextSeq500 platform. The mean number of miRNA with more than 5 reads detected in the samples was 326. Cut-off values for definition of low versus high levels of miRNA were identified over and under the median value. Univariate (log rank test) analyses were performed to investigate the possible impact of cmiRNA levels on progression-free survival (PFS).

Results: Overall 20 patients have been enrolled in the study. Preliminary results have been obtained for 11 patients (T0 n=11; T1 n=11; T2 n=11; T3 n= 7), with a median follow-up of 5.5 months. Median PFS was 4.8 months. We observed no correlation between the baseline levels of cmiRNAs and tumor load and proliferation index. A panel of 4 cmiRNAs targeting transcription factors was identified as significantly correlated with PFS, both individually (p=0.001, p=0.002, p=0.006; p=0.008, respectively) and within a combined score (p=0.001). No significant predictive value of the relative change between timepoints of these cmiRNAs was observed.

Conclusions: Baseline levels of specific cmiRNAs may identify eSCLC pts with different PFS to first line ACE. Results from a wider cohort of patients with longer follow-up and the validation of the proposed miRNAs will presented at the conference.

2021P Cell-free (cf) DNA as predictive biomarker (B) of treatment outcome in extensive small cell lung cancer (eSCLC) patients (pts) receiving atezolizumab, carboplatin and etoposide (ACE): CATS/ML43257 study

G. Pasello[1,2], G. Pigato[3], M. Lorenzi[4], M.V. Resi[1], L. Urso[1], S. Giunco[1], A. Ferro[2], A. Dal Maso[5], S. Frega[2], L. Bonanno[2], A. De Rossi[1], V. Ciminale[1], S. Indraccolo[3,4], V. Guarneri[1]

[1]Department of Surgery, Oncology and Gastroenterology, University of Padua Medical School, Padua, Italy; [2]Medical Oncology 2, Veneto Institute of Oncology IOV-IRCCS, Padua, Italy; [3]Tranlsational Oncology Department, IOV - Istituto Oncologico Veneto IRCCS, Padua, Italy; [4]Dipartimento di Oncologia, IOV - Istituto Oncologico Veneto IRCCS, Padua, Italy; [5]Medical Oncology Department, IOV - Istituto Oncologico Veneto IRCCS, Padua, Italy

Background: First-line systemic therapy with ACE is a new standard of care for eSCLC. Circulating biomarkers may identify those pts experiencing a better treatment outcome.

Methods: The CATS study is a single center translational prospective study on eSCLC pts receiving ACE investigating the predictive role of circulating B. Plasma samples have been collected at 4 timepoints (T0 baseline; T1 after 1 cycle; T2 after 2 cycles; T3 disease progression). cfDNA has been analyzed by the Avenio ctDNA expanded kit.

Results: At data cut-off (1st April 2023), 20 pts have been included. Preliminary results have been obtained from the first 11 pts (T0 n=11; T1 n=11; T2 n=10; T3 n= 6). After a median (m) follow-up (FUP) of 5.5 months (mo), response rate (RR) was 58.3% (95% Confidence Interval, CI 30.4-86.2), m progression-free survival (PFS) 4.8 (95%CI, 3.9-4.8) and m overall survival (OS) 11.2 mo (95%CI, 3.5-18.9). Median cfDNA was 52.3, 27.1 and 22.5 ng/mL, at T0, T1 and T2, respectively. A trend toward cfDNA level reduction between T0 and T1 (m 52.3 ng/mL; InterQuartile Ratio, IQR 12.8-122.7 vs 27.1, IQR 16.6-42.6, p=0.054) and a significant reduction between T0 and T2 (52.3, IQR 12.8-122.7 vs 22.5, IQR 11.1-38.0, $p<0.05$) were observed. Chromosomic profile (CP) was altered in 10 (90.9%), 4 (36.4%) and 4 cases (40%) at T0, T1 and T2, respectively. Tumor related mutations (TRM) were identified in all pts at T0 [TP53 in 11 (100%), RB1 in 5 (45.5%)] and at T1 [TP53 in 9 (81.8%), RB1 in 3 (27.3%)]; in 90% of pts at T2 [TP53 in 7 (70%), RB1 in 3 (30%)]. Median variant allele fraction (VAF) at T0, T1 and T2 was 38.3%, 1.2%, 0.2% and 30.7%, 33.1%, 20.1% for TP53 and RB1, respectively. In 8 (72.7%) pts, a VAF clearance was registered between T0 and T1 ($p<0.001$). Longer PFS was associated with low levels of cfDNA at T0 (p=0.04) and T2 (p=0.04). No correlation between the relative change of cfDNA at different timepoints and treatment outcome were observed at this preliminary analysis.

Conclusions: We suggest cfDNA, CP and TRM as putative circulating predictive biomarkers to be monitored in eSCLC pts receiving ACE. These data will be confirmed in a wider validation set of pts with a longer FUP.

Background: Due to its devastating behavior and unfavorable prognosis, SCLC is the most recalcitrant lung neuroendocrine tumor to treat. Performance status (PS), stage, and liver metastases have historically been recognized as prognostic factors in SCLC. However, these variables are unable to adequately stratify patients. Recently, we found that the laterality of primary lesions independently affected the outcome of well-differentiated lung neuroendocrine tumors, with left typical/atypical carcinoids having the worse prognosis (La Salvia A, et al. *Endocrine* 2022). The present analysis aims to evaluate the prognostic significance of laterality in SCLC patients.

Methods: Consecutive patients with histologically confirmed diagnosis of SCLC treated according to disease stage at 3 different Institutions from January 2020 to December 2022 and with a follow-up period of $\geq$ 3 months were included. Clinical and disease characteristics, date of progression, and death were collected and analyzed.

Results: A total of 140 patients were analyzed. The majority were male (57.1%), and former/current smokers (99.3%) with stage IV disease (88.5%). Primary tumor was in the right lung in 76 cases (54.2%). As expected, ECOG PS, stage, and liver metastases were significantly associated with overall survival. With a median follow-up of 11 months (range 3-28 months), patients with primary tumors in the right lung had longer survival than patients with primary tumors in the left lung (12.0 versus 9.5 months, p=0.003; HR 2.020). Similar results were observed by excluding patients with stage III disease (11.5 versus 8.8 months, $p< 0.0001$; HR 2.532). A multivariate model, including all significant variables in the univariate model, confirmed that left laterality represented an independent negative prognostic factor (p=0.044 in the overall population and p=0.007 considering only stage IV).

Conclusions: Our analysis showed the prognostic relevance of primary tumor laterality in SCLC for the first time. Biological differences related to differential exposure to carcinogens in tissue specimens is ongoing.

2024P Supportive measures to control myelosuppression and costs for patients with SCLC with lurbinectedin, CAV or topotecan with or without trilaciclib: A review on the basis of clinical trials

M. Dómine[1], B. García San Andres[2], J. Gómez[2], J. Iglesias[2], B. Citoler[3], M. Prades[3]

[1]Medical Oncology, Fundación Jiménez Díaz, Madrid, Spain; [2]Clinical, PharmaMar, Colmenar Viejo, Spain; [3]Statistics, Outcomes'10, Castellon De La Plana, Spain

Background: Chemotherapy-induced myelosuppression (CIM) has an important impact on patients with Small Cell Lung Cancer (SCLC) and Health Systems. Granulocyte colony-stimulating factors (G-CSF), platelet and red blood cell (RBC) transfusions or erythropoiesis-stimulating agents (EPO) are standard treatments. Trilaciclib is indicated to decrease the incidence of CIM when administered before topotecan.

Table: 2024P

	Lurbinectedin* N=105	Trilaciclib prior to topotecan iv* N=32	Placebo prior to topotecan iv* N=29	CAV (ATLANTIS)** N=168	Topotecan iv (ATLANTIS)** N=121
Neutropenia ≥3	46.7%	68.8%	85.7%	66.1%	73.6%
Severe Neutropenia	24.8%	40.6%	75.9%	54.2%	50.4%
Anaemia ≥3	10.5%	28.1%	60.7%	26.2%	54.5%
Thrombocytopenia ≥3	6.07%	51%	57.2%	17.9%	49.6%
FN	4.8%	6.3%	17.9%	10.1%	5.8%
G-CSF therapeutic	21.9%	50.0%	65.5%	30.4%	19.0%
Platelet transfusions	4.8%	25%	31%	3.6%	21.5%
RBC transfusions	10.5%	31.3%	41.4%	18.5%	46.3%
EPO	1.9%	3.1%	20.7%	9.5%	8.3%

* Prophylactic G-CSF not allowed ** Primary prophylaxis with G-CSF with 100% of patients

The occurrence of CIM events with standard of care (SoC) chemotherapies for relapsed SCLC and supportive care interventions were investigated.

Methods: Inputs were obtained from clinical trials with lurbinectedin (Basket NCT02454972), topotecan after trilaciclib or placebo (NCT02514447), CAV and topotecan (ATLANTIS, NCT02566993) that reported key measures of CIM and supportive care. Therapies were offered mainly as 2L. Cost analysis was performed for grade ≥3 events. Unit costs were obtained from the Spanish Minimum Basic Data Set (€, 2023).

Results: Patients treated with lurbinectedin experienced fewer CIM events than those treated with topotecan, either with or without prior administration of trilaciclib, or with CAV and require less supportive treatments (Table). Lurbinectedin would reduce costs of managing CIM events by 43% - 69% (58% compared to trilaciclib followed by topotecan).

Conclusions: Patients with relapsed SCLC treated with lurbinectedin require fewer resources and less cost for managing CIM episodes than other SoC, including topotecan with prior trilaciclib, based on clinical trials.

2025P Stratified control study of neuroendocrine differentiation and potential clinicopathologic markers

L. Liu[1], X. Sun[2], J. Dong[2], P. Xing[1], J. Li[1], J. Ying[1], L. Yang[2]

[1]Pathology, Chinese Academy of Medical Sciences and Peking Union Medical College - National Cancer Center, Cancer Hospital, Beijing, China; [2]Pathology, National Cancer Center/National Clinical Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China

Background: SCLC is highly heterogeneous which was divided into NE (Neuroendocrine)-high and NE-low groups according to 50 genes on transcriptomic level, harboring different immune microenvironments and potential immunotherapy reactivity. It is necessary to explore novel NE markers, that both are close to NE gene subtyping and feasible for clinicopathological use. Here, we conducted a parallel comparative study at mRNA and protein levels for exploring the potential of INSM1 as a substitute marker for NE subtyping.

Methods: Two hundred and forty-seven surgical specimens were collected. Quantitative detection of NE genes by Nanostring nCounter as well as INSM1 protein by IHC was performed simultaneously on 48 whole slides as testing group. Spearman correlation was applied for consistency analysis, and the best cut-off for INSM1 expression was validated on 247 tissue microarrays for comparison of the three traditional NE protein markers for specificity and sensibility as well as prognostic significance.

Results: In 48 testing cases, quantitative detection revealed 83.3% (40/48) for NE-high and 16.7% (8/48) for NE-low, while for protein grouping, it was 79.2% (38/48, H-score>100) for NE(INSM1)-high and 20.8% (10/48, H-score<=100) for NE(INSM1)-low. NE classification defined by INSM1 protein and NE genes had significant consistency in terms of proportion (p=0.026). NE groups also had consistent clinical characteristics and prognostic trend in the two levels. Patients with NE-high and NE(INSM1)-high tended to be in the advanced stage. Patients with NE-high and NE(INSM1)-high have a tendency of poor prognosis. In 247 cases of validation exploration, INSM1 expression was positively correlated with three classical markers, more importantly, in triple negative cases, INSM1 showed a favorable positive rate (1.5%, 3/198). In addition, NE(INSM1)-high patients showed more bronchial invasion and tumor thrombosis than that of NE(INSM1)-low ones ($p<0.05$), and the 1-, 3-, and 5-year OS rates in the NE(INSM1)-high group were slightly lower than those in the NE(INSM1)-low group.

Conclusions: INSM1 has great potential being a marker of NE differentiation and subgrouping, also shows a certain correlation with prognosis and some clinicopathological factors.

Background: The KBP studies are real nationwide prospective multicenter cohort studies of patients (pts) diagnosed with primary lung cancer (PLC), conducted every decade in France since 2000 in non-academic public hospital (NPH) with the same methodology.

Methods: We describe and compare the characteristics and outcomes of pts with SCLC among the 3 cohorts.

Results: 8999 pts were included in 2020, including 1136 pts with SCLC (12.6% [12.1-13.5]). From 2000 to 2010 and 2020, the proportion of SCLC decreased from 16.4% [15.6-17.6] to 13.5% [12.9-14.6] and 12.6% respectively. In 2020 there were 731 men (64.4% [61.5-67.1]) and 405 women (35.7% [32.8-38.5]). The proportion of women among SCLC pts increased from 15.6% [13.3-18.0] to 35.6% in 20 years. The median age at diagnosis also increased from 65.4 [64.5-66.5] years in 2000 to 67.8 [67.3-68.6] years in 2020. In 2020, 24.7% [22.2-27.4] of SCLC were limited-stage. Most of those pts received platinum-etoposide with thoracic radiotherapy. Overall survival (OS) at 1 year was 62.3% [56.7-68.4] and median OS was 19.1 [16.3-21.8] months.75.3% [72.6-77.8] of SCLC were extended. First-line chemotherapy (CT) was a combination of platinum (cisplatin in 7% [5.1-9.5]; carboplatin in 93% [90.5-94.9]) with etoposide for 96.6% [94.6-97.9] of pts. Immunotherapy (IO) was combined with CT in 51% [47.1-54.9] in 2020. In the KBP 2020 cohort, OS for extended SCLC at 1 year was 30.5% [27.5 - 33.9] and median OS was 7.3 [6.5-7.9] months. OS for SCLC at 1 year was stable between the 3 cohorts 38.7% [35.9 - 41.6] in 2020, 35.2% [32.3-38.4] in 2010 and 34.4% [31.5-37.7] in 2000. However, the 2-year survival rate increased from 11.7% [9.7%-14.0] in 2000, 13.6% [11.6-16.0] in 2010 to 19.4% [17.1-22.0] in 2020. The OS of stage IV SCLC unadjusted with performans status according to treatment with IO shows a significant difference in favor of IO with HR=0.54 [0.46 - 0.64] and $p<0.0001$ with a median survival that increases from 5.5 months [4.4 - 6.7] to 9.9 months [8.9 - 11.3].

Conclusions: The proportion of SCLC among LC is decreasing over time; the proportion of women with SCLC is increasing. While the median OS remains stable at 8.5 months, 2-year OS has improved in 20 years. The benefit of IO is recovered with a profit of more than 4 months.

Clinical trial identification: NCT04402099.

2027P Immune checkpoint inhibitors in the treatment of small cell lung cancer: A systematic review and meta-analysis

P.W.P. Lee[1], N. Krishnan[2], G. Boldt[3], S. Lakkunarajah[4], P. Blanchette[5], J. Raphael[6]

[1]Internal Medicine, University of Western Ontario, London, ON, Canada; [2]Faculty of Health Sciences, McMaster University, Hamilton, ON, Canada; [3]London Regional Cancer Program, University of Western Ontario, London, ON, Canada; [4]Medical Oncology Department, BC Cancer Agency - Victoria, Victoria, BC, Canada; [5]Medical Oncology Department, London Regional Cancer Program (LRCP) - London Health Science Center (LHSC), London, ON, Canada; [6]Oncology Department, London Regional Cancer Program (LRCP) - London Health Science Center (LHSC), London, ON, Canada

Background: Multiple randomized trials have evaluated immune checkpoint inhibitors (ICI) as first- and second-line treatment in extensive-stage small cell lung cancer (ES-SCLC). We sought to conduct a pooled analysis to characterize the efficacy and toxicity of ICI in ES-SCLC.

Methods: Medline (PubMed), EMBASE, and Cochrane Library databases were queried between January 2010 and March 2022 and conference proceedings between 2018 and 2022 were searched for randomized clinical trials assessing ICI (combined with chemotherapy or as single agents), compared with chemotherapy, in patients with ES-SCLC. The primary endpoints were overall survival (OS) and progression-free survival (PFS). Secondary endpoints included objective response rate (ORR), and grade 3 or higher adverse events (AEs). Pooled hazard ratios (HR) for OS and PFS were meta-analyzed using the generic inverse variance method, and random-effect models were used to compute pooled estimates. Subgroup analyses compared survival by line of therapy, sex, age, and ECOG status.

Results: A total of 5,325 patients from 10 trials were included. Compared to chemotherapy, ICI-based treatment decreased the risk of death by 19% (HR 0.81, 95% confidence interval (CI) 0.76-0.86). The OS benefit was seen regardless of age, sex, or ECOG status, but was only seen in patients treated in the first-line setting. Similarly, ICI-based therapy decreased the risk of disease progression by 20% (HR 0.80, 95%CI 0.68-0.94) and the PFS benefit was restricted to first-line treatment with detrimental effect in the second-line setting. ORR was also improved with ICI (odds ratio (OR) 0.80, 95%CI 0.65-0.97) with an increase in grade 3 or higher diarrhea (OR 3.63, 95%CI 1.46-9.02).

Conclusions: ICI conferred efficacy benefits (OS, PFS and ORR) and an acceptable safety profile in the treatment of patients with ES-SCLC in the first-line setting and should not be used in the second-line setting as single agents. Valid biomarkers predicting long-term benefit are needed to further improve outcomes.

2028TiP Phase I, non-randomised, open-label, multi-centre dose escalation trial of BI 764532 (DLL3/CD3 IgG-like T cell engager [TcE]) + ezabenlimab (anti-PD-1 antibody) in patients (pts) with small cell lung cancer (SCLC) and other neuroendocrine carcinomas (NECs) expressing DLL3

Background: The inhibitory Notch ligand, DLL3, is highly expressed on the cell surface of SCLC and NECs, and is a promising drug target. BI 764532 is a DLL3/CD3 IgG-like TcE that has shown potent preclinical anti-tumour activity in DLL3-positive cells and xenograft models. Preliminary results from an ongoing phase I dose-escalation study (NCT04429087) show that BI 764532 has manageable toxicity and promising efficacy. The mode of action of BI 764532 has been shown to upregulate the PD-(L)1 pathway in preclinical studies, as a result of inducing an inflamed tumour environment. Further *in vitro* investigation demonstrated that BI 764532-induced upregulation of PD-(L)1 may reduce its potency, but that this could be overcome by the addition of ezabenlimab (anti-PD-1 antibody). Therefore, this trial is being conducted to explore the combination of BI 764532 + ezabenlimab in a clinical setting.

Trial design: This is a phase I, non-randomised, open-label, multicentre dose-escalation trial of BI 764532 + ezabenlimab in ~30 pts with DLL3-positive SCLC/NECs who have failed/are not eligible for available standard therapy. Pts recruited from ~5−10 centres across several regions globally will receive intravenous BI 764532 + ezabenlimab. Key inclusion criteria will include: ≥18 years of age; Eastern Cooperative Oncology Group performance status 0/1 and ≥1 measurable target lesion (RECIST v1.1). Key exclusion criteria will include: previous TcE/DLL3-targeting therapies; active autoimmune disease and prior anti-cancer therapy. The primary objectives are to evaluate the dose-toxicity relationship and to determine the maximum tolerated dose (MTD) of BI 764532 + fixed-dose ezabenlimab; a recommended dose for expansion/recommended phase II dose will also be determined. In the dose escalation part, the primary endpoint is dose-limiting toxicity (DLT) occurrence in the MTD evaluation period; secondary endpoints include DLT occurrence in the on-treatment period, objective response and pharmacokinetics. Enrolment is ongoing.

2029TiP **Phase I study of ABBV-706, an anti-SEZ6 antibody-drug conjugate, alone or in combination in adults with advanced solid tumors**

S. Chandana[1], B. Garmezy[2], A. Dowlati[3], M.R. Sharma[4], W. Henner[5], R. Robinson[6], P. Hingorani[7], E. Jeng[7], K.P. Papadopoulos[8]

[1]Hematology and Oncology, START - Midwest, Grand Rapids, MI, USA; [2]Research, Sarah Cannon Research Institute, Nashville, TN, USA; [3]Oncology Department, University Hospitals Seidman Cancer Center, Cleveland, OH, USA; [4]Medical Oncology Department, START Midwest, Grand Rapids, MI, USA; [5]Statistics, AbbVie, South San Francisco, CA, USA; [6]Biopharmaceuticals, AbbVie, Inc., North Chicago, IL, USA; [7]Oncology Early Development, AbbVie, Mettawa, IL, USA; [8]Clinical Research Department, South Texas Accelerated Research Therapeutics (START), San Antonio, TX, USA

Background: Seizure-related 6 homolog (SEZ6) is overexpressed in many tumor types with high unmet need, including small cell lung cancer (SCLC), neuroendocrine carcinomas (NECs), and central nervous system (CNS) tumors. ABBV-706 is an antibody-drug conjugate (ADC) comprised of an anti-SEZ6 antibody conjugated to a topoisomerase 1 inhibitor payload.

Trial design: This is an open-label, phase 1, first-in-human, dose-escalation, and expansion study (NCT05599984). The study will evaluate the preliminary safety, tolerability, pharmacokinetics (PK), and antitumor activity of ABBV-706 as monotherapy and in combination with budigalimab (a PD-1 inhibitor), carboplatin, or cisplatin, and determine the recommended phase 2 dose (RP2D) of ABBV-706. The study has 4 parts: (1) ABBV-706 monotherapy dose escalation in relapsed or refractory (R/R) solid tumors, following the Bayesian optimal interval (BOIN) design; (2) monotherapy dose optimization, randomized between two or more dose levels, and expansion in R/R SCLC; (3) dose escalation and expansion of ABBV-706 in combination with budigalimab or platinum therapy in R/R SCLC and NECs; (4) monotherapy dose expansion in R/R high-grade CNS tumors or NECs. Safety endpoints include adverse events, clinical laboratory tests, vital signs, and dose-limiting toxicities. PK endpoints include C_{max}, t_{max}, $t_{1/2}$, and AUC. Primary efficacy endpoints include objective response rate and duration of response. Clinical benefit rate, progression-free survival, overall survival, and biomarkers will also be evaluated. ABBV-706 will be administered intravenously until disease progression, withdrawal of consent, or unacceptable toxicity. Trial Eligibility: adults $\geq$18 years old with R/R SCLC, NECs (including neuroendocrine prostate cancer), or high-grade CNS tumors and measurable disease per RECIST v1.1 or RANO, with an ECOG score $\leq$1. Tumor tissue submission for retrospective SEZ6 expression analysis is required. The study began in December 2022 and enrollment is ongoing.

Clinical trial identification: NCT05599984.

Editorial acknowledgement: Medical writing support was provided by Heather Hultzapple, Pharm D of Fishawack Ltd, funded by AbbVie, Inc.

Legal entity responsible for the study: AbbVie.

Funding: ABBV-706 is being developed by AbbVie. AbbVie funded this study and participated in the study design, as well as the writing, review, and approval of the publication. No honoraria or payments were made for authorship.

Background: During cancer treatment, symptoms are common but often go undetected by clinicians. Remote monitoring with ePROs can detect symptoms early and alert clinicians to intervene, thereby relieving suffering and avoiding complications.

Methods: PRO-TECT was a cluster-randomized trial in 52 US oncology practices. Practices were assigned 1:1 to remote monitoring with ePRO surveys, or usual care. At ePRO practices, patients receiving treatment for metastatic cancer were invited to complete a weekly survey by web or automated telephone system for up to 1 year or until discontinuation of cancer treatment. The survey included 9 PRO-CTCAE symptoms, performance status, and falls. Severe/worsening symptoms generated electronic alerts to nurses, and symptom reports were available to clinicians at visits. Here we report the primary outcome of overall survival after 24 months of follow up, compared between groups using Cox regression incorporating clustering and disease covariates. Other outcomes included mean emergency department (ED) or hospital visits based on chart abstraction and proportion of patients with clinically meaningful benefit in symptoms (EORTC QLQ-C30) at 3 months, compared using mixed modeling and cumulative logistic regression. We previously reported significant benefits in health-related quality of life and physical function (JAMA 2022 ;327:2413-22).

Results: 1191 patients were enrolled 10/2017-03/2020 (593 PRO; 598 usual care). No difference was seen in survival between groups (HR 0.99; p=0.86). The mean number of ED or hospital visits was lower in the ePRO group vs. usual care (1.48 vs 1.81; p=0.006). A greater proportion of patients in the ePRO group experienced benefits in fatigue (OR 1.77; p<0.001), anorexia (OR 1.32; p=0.03), nausea/vomiting (OR 1.40; p=0.01), and sleep (OR 1.73; p<0.001). Patients completed 20,565/22,486 (91.5%) of expected weekly ePRO surveys.

Conclusions: Remote monitoring with ePROs during cancer treatment did not impact survival, but reduced visits to the ED or hospital, and conferred benefits on function and symptoms. Conduct of this trial during the pandemic amidst nursing shortages may have reduced efficacy of the intervention.

Background: Elevated Body Mass Index (BMI) is associated with inferior clinical outcomes, impaired quality of life (QOL), and increased cancer related fatigue (CRF) in pts with early BC. MEDEA evaluated the impact of a weight loss intervention on CRF in overweight or obese survivors of BC.

Methods: MEDEA (NCT04304924) is a French multicenter randomized trial. Pts with stage I-III BC within 12 months of primary treatment and BMI $\geq$25 kg/m^2 were eligible. MEDEA compared a telephone-based weight loss program delivered by a coach through 24 semi-structured calls over 12 months and focused on caloric restriction + education (intervention arm) with an education alone program (control arm). The intervention was adapted from the BWEL trial (A011401) and was considered completed if $\geq$16/24 calls were delivered. The primary endpoint was between-arm difference in CRF (EORTC C30) 12 months (M12) post-randomization, estimated by a linear mixed model. Secondary endpoints included weight, QOL (QLQ C30 / BR23), and satisfaction (Focus groups). The study had 80% power (two-sided $\alpha = 0.05$) to detect an effect size of 0.40.

Results: 220 pts were included. Mean (SD) age was 53.8 years (10.4), mean weight was 83.6 kg (14.0), and 65% of pts received endocrine therapy. At randomization, CRF scores were similar between arms (Mean [SD]: 40.2 [23.5] and 40.2 [27.8]). At M12, CRF was reduced by a mean of -7.8 points (SD 20.8) in the intervention and -2.0 points (SD 27.3) in the control arm. The estimated between arm difference at M12 was 5.9 (SE 3.7) but was not significantly different from zero (p=0.11). Mean and proportional weight loss at M12 was higher in the intervention arm vs control: -6.7 kg (SD 8.3), 10% vs -1.1 kg (SD 5.3), 1% (p_{arm}=0.025; $p_{arm*time}$=0.002). There was no detrimental effect on other QOL domains. Satisfaction and adherence to the intervention were high, with 75% completing $\geq$16/24 calls.

Conclusions: A telephone-based weight loss program did not lead to a significant difference in CRF at 12 months, but did induce significant weight loss among pts with BC. These results suggest a North American weight loss intervention was adaptable and could be disseminated in a different language and cultural context.

2032MO Correlation of safety and efficacy in atezolizumab therapy across indications

J. Naidoo[1], G. Durán-Pacheco[2], V. Maiya[3], M. Socinski[4], G.P. Sonpavde[4], J. Puente[5], L. Essioux[2], C.A. Carter[3], J.V. Cardona[2], R. Mohindra[6], S.G. Chandler[7]

[1]Oncology Dept., Beaumont Hospital, Dublin, Ireland; [2]F. Hoffmann-La Roche Ltd, Basel, Switzerland; [3]Product Development Safety Risk Management Department, Genentech, Inc. - Member of the Roche Group, San Francisco, CA, USA; [4]Medical Oncology, Genitourinary Section, AdventHealth Medical Group - Internal Medicine at Orlando, Orlando, FL, USA; [5]Dept. Medical Oncology, Hospital Clinico Universitario San Carlos, Madrid, Spain; [6]Safety Science Oncology Department, F. Hoffmann-La Roche AG - Elsaessertor II, Basel, Switzerland; [7]Drug Safety, F. Hoffmann-La Roche AG, Basel, Switzerland

Background: The association between safety and efficacy of immune checkpoint inhibitors (ICI) is known, but association between severity of ICI toxicity and impact of specific organ systems affected by immune-related adverse event (irAE) and cancer outcomes is poorly understood. While most irAEs are mild to moderate, severe irAEs pose clinical challenges that may require immunosuppression, hormonal replacement, and/or permanent discontinuation of ICIs.

Methods: We evaluated the association between safety and efficacy across 14 clinical trials (n=9521) involving atezolizumab as mono (IO) or with chemo (C-IO) therapy as compared to chemotherapy (C) in Non-Small Cell Lung (NSCLC, n=8), Small-Cell Lung (SCLC, n=1), Renal Cell (RCC, n=2), Urothelial (UC, n=2), and Triple -Negative Breast Cancers (TNBC, n=1). We applied a mixed-effect Cox proportional hazard model for time-varying covariates to address immortal time bias, adjusted for baseline factors associated with occurrence of irAEs and OS to control for confounding bias, and focused on the five most common irAEs (dermatologic, thyroid dysfunction, hepatitis, pneumonitis, and colitis) to avoid low statistical power for rare events. Association between irAE grade (G) by CTCAE and specific organ involvement with overall survival was assessed.

Results: For patients treated with IO or C-IO, G1-2 irAEs were associated with improved OS (HR = 0.65, $p<0.01$) and G3-4 irAEs showed slight increase in risk of death (HR = 1.18, p=0.06) versus patients without irAEs. By specific irAE, G1-2 skin irAEs, thyroid dysfunction or pneumonitis were associated with improved OS. However, G3-4 pneumonitis and colitis were associated with worse OS. There was no association with hepatitis and OS by any grade. Findings were consistent across indications.

Conclusions: This is the largest analysis to date demonstrating correlation between irAEs and improved OS for atezolizumab by severity grade, and most common irAEs by organ. We identify that low-grade irAEs are significantly associated with improved OS, while specific high-grade toxicities are associated with poorer OS, underscoring the importance of early recognition and management of toxicity to further optimize benefit/risk balance of ICI therapy.

2033MO The impact of proton pump inhibitor (PPI) exposure before immune checkpoint inhibitor (ICI) therapy on overall survival (OS): A population-based study

L. Eng[1], S. Saibil[1], R. Sutradhar[2], V. Aghanya[2], Y. Kaliwal[2], Y. Niu[2], N. Liu[2], Y. Liu[2], M. Powis[3], G. Liu[4], J. Peppercorn[5], P.L. Bedard[6], M.K. Krzyzanowska[1]

[1]Medical Oncology and Hematology Department, UHN - University Health Network - Princess Margaret Cancer Center, Toronto, ON, Canada; [2]Cancer Research Program, ICES - Institute for Clinical Evaluative Sciences, Toronto, ON, Canada; [3]Medical Oncology and Hematology, Princess Margaret Cancer Centre, Toronto, ON, Canada; [4]Medical Oncology Department, UHN - University Health Network - Princess Margaret Cancer Center, Toronto, ON, Canada; [5]Cancer Care Delivery Research, Massachusetts General Hospital, Boston, MA, USA; [6]Division of Medical Oncology & Hematology, UHN - University Health Network - Princess Margaret Cancer Center, Toronto, ON, Canada

Background: PPIs have been previously associated with potentially negative impacts on ICIs outcomes due to changes in the gut microbiome. However, many studies were smaller studies with heterogeneity in study design, exposure windows and populations. Here, we performed a population-level retrospective cohort study evaluating the impact of PPI exposure prior to ICI on OS.

Methods: A cohort of cancer patients $\geq$ 65 years of age receiving ICIs from 06/2012 to 10/2018 in Ontario, Canada was identified from population-level administrative data and deterministically linked with databases to obtain socio-demographics, covariates and PPI prescription claims. Multivariable cox-proportional hazard models evaluated the impact of PPI exposure both within 1 year and 60 days prior to starting ICI on OS, adjusted for age, gender, body mass index, comorbidities, autoimmune history, hospitalization in the past year and treatment facility level at start of ICI therapy.

Results: Among 2737 patients, median age 73; 43% received Nivolumab, 41% Pembrolizumab and 13% Ipilimumab; 53% had lung cancer, 34% melanoma. Median PPI exposure for patients receiving PPI within 1 year (45%) and 60 days (26%) prior to ICI were 31 weeks (SD=19) and 10 weeks (SD=4) respectively; the most common PPI prescribed over 1 year was Pantoprazole (30%). Median OS estimate was 306 days. Any PPI exposure within 1 year (aHR=1.21 95% CI [1.09-1.33] $p<0.001$) or 60 days prior to ICI (aHR=1.26 95% CI [1.13-1.40] $p<0.001$) was associated with worse OS. A dose effect was seen based on weeks of PPI exposure 1 year (aHR=1.00 per week [1.00-1.01],p=0.05) and 60 days (aHR=1.01 per week [1.00-1.02] p=0.009) prior to ICI. PPI drug analysis only identified Pantoprazole exposure within 1 year (aHR=1.27 [1.14-1.41] $p<0.001$) and 60 days before ICI (aHR=1.34 [1.19-1.52] $p<0.001$) as being associated with worse OS. Subgroup analysis showed similar results for melanoma and patients receiving Pembrolizumab or Ipilimumab, and for Pantoprazole with lung cancer.

Conclusions: Exposure to PPIs prior to ICI therapy is associated with worse OS. Interventions aimed at altering the gut microbiome may be required to help improve outcomes for patients on ICIs with prior PPI exposure.

Background: Patients with gastric cancer experience quality of life (QoL) decline during adjuvant chemotherapy following gastrectomy. The EAGER (Electro-Acupuncture in Gastric cancER) trial was undertaken to confirm the efficacy of electro-acupuncture (EA) for improving QoL in these patients seen in our pilot study.

Methods: Patients who has accepted R0 resection for gastric cancer, and who will receive adjuvant chemotherapy were randomly assigned to high-dose EA (HA, 7 times each chemo-cycle for 3 cycles), low-dose EA (LA, 3 times each chemo-cycle for 3 cycles), or control (Ctrl) groups. Functional Assessment of Cancer Therapy-Gastric (FACT-Ga) was reported by the patients at baseline and then once a week during the therapy. Primary endpoint was the differences on total area under curves (AUCs) of FACT-Ga Trial Outcome Index (TOI) during the 3 cycles of chemotherapy, calculated by linear interpolation, among the groups. Secondary endpoints included the differences on AUCs of FACT-Ga Gastric Cancer Subscale (GaCS) scores, AUCs of FACT-Ga scores, and the disease free survival (DFS).

Results: Of the randomized 240 patients, 222 were analyzed according to intention-to-treat (ITT) principle, and 186 were in the per-protocol set (PPS). Both HA and LA produced significant QoL improvement. AUCs (21 days/cycle $\times$ 3 cycles, the higher, the better) of TOI in the ITT were 5678$\pm$1229, 5558$\pm$1226, and 4735$\pm$1233 (HA *vs.* Ctrl, $P<0.001$; LA *vs.* Ctrl, $P<0.001$), of GaCS were 3458$\pm$725, 3356$\pm$723, and 2919$\pm$726 (HA *vs.* Ctrl, $P<0.001$; LA *vs.* Ctrl, $P<0.001$), and of FACT-Ga were 8164$\pm$1516, 8024$\pm$1516, and 7029$\pm$1521 (HA *vs.* Ctrl, $P<0.001$; LA *vs.* Ctrl, $P<0.001$), in HA, LA, and Ctrl groups, respectively. EA also produced trend of DFS improvement, although not significantly in the ITT population [HA *vs.* Ctrl: HR=0.56 (0.27-1.15), $P=0.1089$; LA *vs.* Ctrl: HR=0.81 (0.59-1.12), $P=0.1979$], while the DFS differences in the PPS were significant [HA *vs.* Ctrl: HR=0.37 (0.15-0.92), $P=0.0258$; LA *vs.* Ctrl: HR=0.72 (0.51-1.02), $P=0.0582$].

Conclusions: EA resulted in a clinically meaningful improvement of QoL in gastric cancer patients undergoing adjuvant chemotherapy. Besides, EA was also associated with promising effect in prolonging DFS in these patients.

Clinical trial identification: NCT04360577; First released on April 24th, 2020.

2035P Routine biomarker monitoring does not replace comprehensive clinical assessment in the detection of immunotherapy induced myocarditis

A. Johnson[1], R. Dobson[2], N. Garbutt[1], S. Pickering[1], T. Guinan[1], A.C. Olsson-Brown[3]

[1]Immunotherapy Team, The Clatterbridge Cancer Centre - Liverpool, Liverpool, UK; [2]Cardio-Oncology, The Clatterbridge Cancer Centre - Liverpool, Liverpool, UK; [3]Medical Oncology Department, The Clatterbridge Cancer Centre - Liverpool, Liverpool, UK

Background: Multiple international guidelines suggest that pre-treatment cardiac markers should be taken prior to each cycle of treatment to support the early diagnosis and treatment of immune checkpoint inhibitor (ICI) induced myocarditis (1). As a large regional tertiary cancer centre with an established cardio-oncology service early adoption of baseline and subsequent cardiac surveillance has been implemented and its utility evaluated.

Methods: A retrospective analysis of patients whom had undergone baseline cardiac assessment prior to receiving ICI treatment at the Clatterbridge Cancer Centre between October 2022 and March 2023 was performed. Within the regional protocol all patients with abnormal cardiac markers (Pro-B Naturetic Peptide (Pro-BNP) >400 ng/L and or a high sensitivity troponin T (TropT) >14 ng/L) were subsequently monitored with pre-cycle cardiac biochemical monitoring for the first 3 cycles of ICI treatment.

Results: 400 patients who commenced ICI treatment underwent baseline cardiac screening. Of these 169 patients (42.2%) had abnormal biomarkers: 36% (n=61) elevated TropT; 32% (n=54) elevated pro-BNP and 32% (n=54) had elevations in both. Within this cohort 3.3% (n=13) patients were diagnosed with ICI-induced myocarditis; 12 confirmed on cardiac MRI (cMRI) and 1 clinically diagnosed due to clinical instability. Of these 69% (n=9) patients had abnormal baselines and thus had pre-cycle monitoring; 4 did not. Of these 9; 8 were detected through symptoms alone; 1 patient was found to have elevated biomarkers but had already been clinically assessed prior to treatment and had been admitted prior to the biomarker results being reviewed.

Conclusions: Baseline cardiac assessment is useful, as the majority of patients that go on to develop ICI myocarditis have abnormal baseline values. However, the clinical utility of pre-cycle screening has not demonstrated enhanced or earlier detection of myocarditis compared to clinical assessment and represents an area of potential cost saving. Patients are either presenting mid-cycle or are identified via symptomatic review therefore investment is better placed in education and training to optimize clinical recognition and timely management.

Background: Cardiovascular disease (CVD) emerged as a leading death cause in prostate cancer (PC) patients in recent decades, bringing great disease burden globally. Men with preexisting CVD were at increased risk for major adverse cardiovascular events when treated with ADT. The prevalence and risk evaluation of CVD among the newly diagnosed PC population in China has remained a blank.

Methods: Clinical data of newly diagnosed PC patients was retrospectively collected from 34 centers in China. CVD was defined as myocardial infarction, arrhythmia, heart failure, stroke, ischemic heart disease and others. CVD risk was estimated by calculating Framingham risk scores (FRS). Patients were accordingly divided into low-risk, middle-risk and high-risk.

Results: A total of 4135 patients was enrolled in the present study, and 26.97% complained a current or history of CVD. The enrolled population distributed in 6 regions of China and about 70% patients lived in urban settings. With imaging and pathological evaluation, most of PC patients were diagnosed at late stage, with 20.80% local progression and 20.80% metastasis. Most of them initiated prostatectomy (46.48%) or regimens involving ADT therapy (45.83%) for prostate cancer. In the present PC cohort, 43.36% were hypertension patients and 50.81% of them lived with poor control of blood pressure. In patients with comorbid PC and CVD, 27.80% had two or more CVDs. With FRS stratification, as expected, higher risk of CVD was related with aging and metabolic disturbance. However, we also found that patients with treatment involving ADT presented an original higher risk of CVD than those without. That was in accordance with the clinical practice, i.e., aged patients or patients at late

oncological stage were inclined to accept systematic integrative therapy, instead of surgery. Among patients accepting medical castration, only 4.37% received GnRH antagonist in stark contrast to the grim situation of CVD prevalence and risk.

Conclusions: Prostate cancer patients in China are diagnosed at a later stage. Heavy CVD burden was presented at the initiation of treatment. Patients accepting ADT-related therapy occupied an original higher risk of CVD but the consciousness of cardiovascular protection was far from sufficient.

2037P Prehabilitation as a strategy to improve postoperative outcomes in frail cancer patients undergoing elective surgery: A systematic review and meta-analysis

M.K. Elfaituri, A. Khaled

Faculty of Medicine, University of Tripoli, Tripoli, Libya

Background: Prehabilitation is a process that aims to improve a patient's functional capacity before surgery. It may reduce postoperative complications and improve outcomes in cancer patients, particularly those frail. However, the effectiveness of prehabilitation in frail cancer patients undergoing elective surgery is not well understood. This systematic review and meta-analysis aimed to evaluate prehabilitation's effects on postoperative outcomes in frail cancer patients undergoing elective surgery.

Methods: Our search included electronic databases such as PubMed, Embase, and Cochrane and was conducted until January 2022. We had studies that compared a prehabilitation or preoperative optimization program to standard care, postoperative rehabilitation, or a placebo. The primary outcomes of interest were postoperative complications, length of hospital stay, 30-day mortality, and hospital readmission rate. We used R version 4.0.3 and the metafor and meta packages for statistical analysis.

Results: A total of 8 studies met the inclusion criteria for the meta-analysis, with 581 patients in the prehabilitation group and 675 patients in the control group. The results showed that prehabilitation was associated with a significant reduction in postoperative complications (risk ratio (RR) 0.83, 95% confidence interval (CI) 0.69 to 0.98). Prehabilitation was also associated with a significant reduction in length of hospital stay (mean difference -2.32 days, 95% CI -4.34 to -0.29) and a non-significant reduction in 30-day mortality (RR 0.45, 95% CI 0.13 to 1.59). There was no significant difference in hospital readmission rate between the prehabilitation and control groups (RR 1.09, 95% CI 0.38 to 3.15).

Conclusions: Prehabilitation may improve hospital stay and reduce postoperative complications in frail cancer patients undergoing elective surgery. Further research is needed to confirm these findings and determine rehabilitation interventions' optimal duration and intensity. Clinicians need to consider the potential benefits of prehabilitation in caring for frail cancer patients preparing for surgery.

2038P Perioperative iron deficiency in patients with ongoing cancer treatment scheduled for major surgery: A French prospective multicenter cross-sectional study

R. Rozier, et al.

Service de Chirurgie Digestive, CHU Nice - Hôpital Pasteur, Nice, France

Late withdrawal

2039P Primary endpoints of confirmatory randomized controlled trials for older patients with cancer: A scoping review

T. Mizutani[1], K. Uemura[2], F. Sato[3]

[1]Medical Oncology Dept., Kyorin University Faculty of Medicine, Mitaka, Japan; [2]Biostatistics and Bioinformatics, Interfaculty Initiative in Information Studies, The University of Tokyo, Meguro-ku, Japan; [3]Biostatistics and Bioinformatics Course, The University of Tokyo, Meguro-ku, Japan

Background: Reliable and validated primary endpoints, such as overall survival (OS), are commonly used in oncologic confirmatory randomized controlled trials (RCTs). However, recent studies suggest that these endpoints may not sufficiently measure the true benefits of therapies in older patients with cancer. We conducted a scoping review of the literature to identify primary endpoints used in geriatric oncology RCTs.

Methods: We searched the literature on confirmatory RCTs specific to older patients with cancer using PubMed (National Center for Biotechnology Information) and CINAHL (EBSCO). Studies fulfilling the selection criteria were reviewed according to the Preferred Reporting Items for Systematic reviews and Meta-Analyses extension for Scoping Reviews, and definitions of primary endpoints were extracted.

Results: A total of 68 RCTs met the inclusion criteria. Data on geriatric assessment and quality of life (QOL) were extracted in 66 (97.1%) and 25 (36.8%) RCTs, respectively. Fifty-two RCTs (76.5%) used traditional outcomes, such as OS, DFS, relapse-free survival, progression-free survival, and response rate, as primary endpoints; however, one RCT used OS adjusted for QOL as a primary endpoint and one RCT used OS and health-related QOL as a combination primary endpoint. Three of the four RCTs using time-to-event endpoint as the primary endpoint included toxic effect as an event in addition to disease progression and death due to any cause. Toxic effect was a primary outcome measure in six RCTs (8.8%) which utilized the National Cancer Institute Common Terminology Criteria for Adverse Events. Health-related QOL, including the EORTC QOL Questionnaire core version 30 items, was a primary endpoint in three RCTs (4.4%). Barthel index for activities of daily living and the confusion assessment method for delirium were used in two RCTs (2.9%).

Conclusions: Although most geriatric oncology RCTs used traditional primary endpoints, some RCTs utilized innovative primary endpoints to more appropriately measure treatment benefit for older patients with cancer. This scoping review should be helpful for methodological discussions among investigators and efficient use of these endpoints.

2041P The prevalence of hematologic adverse events (HAEs) and myelodysplastic syndrome/acute myeloid leukemia (MDS/AML) in patients (pts) with advanced high grade ovarian carcinoma (aHGOC) receiving PARP inhibitor (PARPi), with or without a germline BRCA pathogenic variant

C. Valenza[1], E. Nicolo[1], M. Mongillo[2], D. Trapani[1], F. Gigli[3], L. Boldrini[1], L. Boscolo Bielo[1], G. Castellano[1], L. Guidi[1], J. Katrini[1], G. Pellizzari[1], J. Villa[4], I.T. Lorenzetti[5], S. Derio[5], M.T. La Presa[5], G. Parma[5], G. Curigliano[1], N. Colombo[5]

[1]Department of Oncology and Hemato-Oncology, University of Milan, Division of New Drugs and Early Drug Development for Innovative Therapies, European Institute of Oncology IRCCS, Milan, Italy; [2]AOU Integrata Borgo Roma Verona, Dipartimento Oncologia, European Institute of Oncology IRCCS, Verona, Italy; [3]Division of Haematology Oncology, European Institute of Oncology IRCCS, Division of New Drugs and Early Drug Development for Innovative Therapies, Milan, Italy; [4]Division of Pharmacy, European Institute of Oncology, IRCCS, Milan, Italy; [5]Division of Gynecologic Oncology, European Institute of Oncology IRCCS, Milan, Italy

Background: Pts with a germline BRCA pathogenic variant (gBRCA-PVs) and aHGOC report increased HAEs with platinum salts (PSs), for a possible more susceptibility of the hemopoietic stem cells to to DNA damaging agents. Also, MDS/AML cells seem to be enriched in g*BRCA*-PVs. The risk of PARPi-related HAEs and MDS/AML according to g*BRCA*-PV status in currently unknown.

Methods: We conducted a retrospective single-centre study to evaluate HAEs^{3}G2 and MDS/AML in pts with aHGOC receving PARPi, according to the presence of a g*BRCA*-PV. Pts included had received a PARPi as maintenance therapy for $\geq$8 weeks, in any line of therapy, from Feb 2017 to Dec 2022, and had known g*BRCA* status. HAEs were identified by electronic medical record review, classified per CTCAE v5.0 and expressed as proportion of patients with at least one event. Onset of AML/MDS was tracked also beyond the end of treatment with PARPi (possible later occurrence), up to the last follow-up. Correlative analyses were performed (significance at p-value$<$0.05).

Results: 166 pts were included: 95 (57%) had a g*BRCA*-PV. Patient characteristics, HAEs and MDS/AML are reported in in the table. At univariate analysis, g*BRCA*-PV status was not associated with PARPi-related HAEs, but was correlated with appearance of MDSs (9/95 vs. 1/71; p=0.04), which led to most of PARPi-discontinuations due to HAE/MDS/AML (12/95 vs. 2/71; p=0.02); 3/10 MDSs occurred during PARPi.

Table: 2041P Patient characteristics and HAEs

	gBRCA-PV+ N=95	gBRCA-PV- N=71	p
Age at baseline, mean (SD)	56.6 (8.9)	60.1 (9.9)	**.01**
Line of PARPi, median (IQR)	2 (1-3)	2 (1-3)	**.79**
Type of PARPi			<.001
Olaparib - %	61%	19%	
Niraparib - %	21%	29%	
Rucaparib - %	9%	1%	
Previous chemotherapy for other cancers - %	10	4	.79
N° of cycles of PARPi, median (IQR)	11 (8-24)	13 (6-22)	.34
HAEs - % of pts with at least one event			
Any HAE* ^{3}G2	47%	28%	.67
A ^{3}G2	33%	16%	.55
N ^{3}G2	20%	14%	.37
T ^{3}G2	10%	6%	.83
MDS/AML	10%	2%	.16
MDS	**9%**	**1%**	**.04**
AML	2%	1%	1.00
Hospitalization for HAE	3%	2%	1.00
Dose reduction for HAE	25%	16%	.61
Dose delay for HAE	30%	18%	.70
Discontinuation for HAE or MDS/AML	**11%**	**1%**	**.02**

*A (anemia), N (neutropenia) or T (thrombocytopenia).

Conclusions: Unlike PSs, g*BRCA*-PVs are not associated with PARPi-related HAEs in pts with aHGOC. MDSs are more frequent in g*BRCA*-PV carriers. The interaction between g*BRCA*-PV, MDSs and PARPi warrants further investigation.

2042P Improving breast cancer outcomes for indigenous women

V. Christie[1], D. Green[2], L. Riley[3], K. Gwynne[1]

[1]Faculty of Medicine and Human Health Sciences, Macquarie University - Faculty of Medicine, Health and Human Sciences, Sydney, NSW, Australia; [2]Community Services, Armajun Aboriginal Health Service, Armidale, NSW, Australia; [3]Faculty of Arts and Social Sciences, The University of Sydney School of Public Health, Sydney, NSW, Australia

Background: Breast cancer is the most diagnosed cancer affecting Australian women. While the incidence rate of breast cancer is lower in indigenous women than non-indigenous women the mortality rate is higher, with indigenous women 1.2 times more likely to die from the disease. The are many factors that contribute to this and if we want outcomes to improve for indigenous women with breast cancer, we must identify where practice and policy can change and improve. These findings may inform approaches for indigenous women in other high-income countries who experience similarly poor breast cancer outcomes.

Methods: This research employed the Context-Mechanism-Outcome (CMO) framework to reveal potential mechanisms and contextual factors that influence breast cancer outcomes for indigenous women. The framework explains generative causation, which helps to highlight the relationship between a context, mechanism, and outcome of a program or policy. The mechanisms and contextual factors were stratified into multiple levels; micro (interpersonal), meso (systemic), and macro (policy) levels. "If-Then-Because" statements were used to represent (broadly) the elements of CMO.

Results: The CMO framework allowed us to interpret evidence regarding indigenous women and breast cancer and provided nine practical ways to improve health outcomes and survival rates: 1. Improved health literacy regarding the importance of screening and early detection, delivered in a culturally safe way 2. Increased cultural safety and access to screening services 3. Presence of indigenous health service providers 4. Ensuring health service provider is local and/or familiar with indigenous culture and community 5. Culturally safe screening, diagnosis, treatment and follow-up settings 6. Local indigenous screening champions in the community 7. Protocols for abnormal results are tailored to local setting and community 8. Culturally safe support available for people who receive diagnoses 9. Policy is re-written in consultation with indigenous people and provides solutions to improve health outcomes.

Conclusions: Using the CMO framework, this study has provided nine practical measures to assist in improving the health outcomes for Australian indigenous women with breast cancer.

2043P Can Charlson Comorbidity Index (CCI) and Clinical Frailty Scale (CFS) assessments predict survival in octogenarians with colorectal cancer?

N.M. Nikolic[1], N.S. Stanic[2], F.R. Djordjevic[1], K. Ljujic[1], D. Kolovic[1], D. Radosavljevic[1], J. Spasic[1]

[1]Clinic for Medical Oncology, Institute for Oncology and Radiology of Serbia, Belgrade, Serbia; [2]Day-Hospital for Medical Oncology, Institute for Oncology and Radiology of Serbia, Belgrade, Serbia

Background: Elderly patients are a heterogeneous group, ranging from fit to frail, with varying disease burden, comorbidities and ability to tolerate cancer-directed treatment. Defining treatment strategies in octogenarians with colorectal cancer (CRC) is challenging due to the high risk of complications and the likelihood of death from other causes. The aim of this study was to evaluate whether CCI and CFS can predict survival in octogenarians with CRC.

Methods: Patients aged 80 and over with CRC, seen at the Multidisciplinary tumor board at our center between January 2020 and December 2022 were evaluated in this study. CCI and CFS were calculated in all patients. Kaplan-Meier method was used to estimate the probability of 1-, 3- and 5-year survival rates (OS) regardless of treatment, and to compare OS estimates based on subjects' characteristics, CCI and CFS scores.

Results: We analysed 149 patients, median age 82 (range 80-91), with 53% of patients with stage IV CRC. Death was confirmed in 65 patients (44%) during follow-up. Following CFS scoring, patients were classified as frail (44%), pre-frail (45%) and robust (9%). The univariate 1-, 3- and 5-year survival rate estimates in frail group were 89%, 56% and 29%, and in robust/pre-frail group 92%, 85% and 64%. Median OS estimate in frail group was 13.24 months (5.35-21.13), and in robust/pre-frail 113.02 months (56.41-169.63), which was statistically significant, p$<$0.01. According to CCI scale patients were divided in groups that scored 1-5 (13%), 6-7 (28%), 8-10 (31%) and more than 10 points (24%). In these CCI groups, median OS estimates were as follows: 59.5, NR, 40.4 and 8.28 months, respectively, which proved to be statistically significant (p$<$0.019). A binomial logistic regression was performed to ascertain the effects of ECOG performance status (PS), CFS and CCI on the likelihood that participants will

survive 12 months. Of these three predictor variables, only PS was statistically significant in predicting 1-year survival in this model.

Conclusions: Geriatric assessments (CFS and CCI) were efficient in predicting survival in octogenarians with CRC, with potential implications for shaping the decision-making process for different treatment modalities.

2044P Bloodstream infections (BSI) in cancer patients: Epidemiology, antibiotic therapy and risk factors related to mortality

C. López Jiménez[1], R. Martín Lozano[2], R. Jiménez Rodríguez[1], I. Gonzalez Caraballo[1], M. Benavente[3], A. Gutierrez Ortiz[1], D.S. Juliao Caamaño[3], N. Gutierrez Alonso[3], J. Soto Alsar[1], M. Bringas Beranek[4], M. Palma[2], M.A. Cañete Muñoz[3], L. Biscari[5], P. Martin-Nieto[5], B.I. Morón[6], V.C. Tirado Anula[4], M.T. De Toro Carmena[7], M. Arregui Valles[1], P. Gijón Vidaurreta[8]

[1]Medical Oncology Dept, Hospital General Universitario Gregorio Maranon, Madrid, Spain; [2]Medical Oncology Department, Hospital General Universitario Gregorio Marañón, Universidad Complutense, Madrid, Spain; [3]Medical Oncology Dept, Hospital General Universitario Gregorio Marañon - Fundación Investigación Biomedica, Madrid, Spain; [4]Medical Oncology Service, Hospital General Universitario Gregorio Marañón, Instituto de Investigación Sanitaria Gregorio Marañón, Madrid, Spain; [5]Radiotherapy Oncology, Hospital General Universitario Gregorio Maranon, Madrid, Spain; [6]Medical Oncology Department, Hospital Universitario Ramon y Cajal, Madrid, Spain; [7]Oncology Dept., Hospital Universitario de La Princesa, Madrid, Spain; [8]Microbiology, Hospital General Universitario Gregorio Maranon, Madrid, Spain

Background: BSI are a frequent and severe complication in cancer. Recent changes in oncological treatment, supportive care and development of new antimicrobial therapies could have affected its epidemiology, management and outcomes. Our aim is to describe clinical and microbiological features, antibiotic therapy, outcomes and mortality-related risk factors of BSI in cancer patients.

Methods: We performed a retrospective, observational, unicentric study. Microbiologically-confirmed BSI episodes in cancer patients between January 2017 and December 2021 were collected. We analysed clinical and microbiological data, empirical antibiotic treatment (EAT) and outcomes. A binary logistic regression model was used to detect variables related to 7 and 30-days mortality. P values <0.05 were considered significant.

Results: 438 episodes of BSI were documented in 362 patients. Most frequent neoplasms were pancreatobiliary (25.1%), colorectal (16.9%), lung (11.9%) and breast (9.1%) tumours. 78.1% were metastatic. 72.1% had received chemotherapy in the previous month. The most common sources of BSI were vascular catheters (26.9%), cholangitis (23.1%) and other abdominal infections (22.8%). Gram-negative bacteria (GNB) were isolated in 60.3% of cases and Gram-positive bacteria in 45.4%. Yeasts were isolated in 3.9% of cases. Most common organisms were *E. coli* (29.7%), *Klebsiella spp*. (15.1%), coagulase-negative staphylococcus (12.6%) and *S. aureus* (10.3%). Most used EAT was piperacillin/tazobactam (43.2%), followed by meropenem (18.3%), amoxicilin/clavulanic acid (16%) and vancomycin (14.8%). Adequate EAT was given to 76.3% of patients. Mortality at 7 and 30 days was 11.2% and 24.4%, respectively. Statistical analysis showed lung cancer, respiratory source, yeasts and *Pseudomonas spp*. as independent risk factors for 7 and 20-days mortality.

Conclusions: BSI is a severe complication associated to elevated mortality in cancer patients. Most frequent sources of BSI are vascular catheters, cholangitis and abdominal infections. Most of them occur in patients with metastatic digestive tumours and are caused by GNB. Lung cancer, respiratory infections, isolation of yeasts and *Pseudomonas spp*. could imply a worse prognosis.

2045P Patient Reported Outcome Measures (PROMs) capturing therapy adherence of cancer patients: A systematic literature review

L. Richter[1], S. Pauge[2], W. Greiner[2]

[1]Institute of Sociology, Dresden University, Dresden, Germany; [2]School of Public Health, Bielefeld University, Bielefeld, Germany

Background: The success of cancer therapy relies on patient adherence, which refers to the extent to which a person's behaviour - taking medication, following a diet, and/or executing lifestyle changes, corresponds with agreed recommendations from a health care provider (WHO 2003). Several PROMs were developed to measure patient adherence to (cancer) therapy. In light of this, our study aims to offer a comprehensive overview of PROMs in the cancer field, with a specific focus on the adherence dimensions captured.

Methods: A systematic review of systematic reviews was performed to identify studies of cancer patients that apply PROMs to measure adherence without restriction to the type of therapy. Databases of Pubmed and Embase were searched up to March 2022 and studies were selected based on predefined eligibility criteria. A qualitative synthesis was used determining measurement of adherence and dimensions of PROMs according to the WHO definition for adherence.

Results: After screening 4483 results a total of 56 literature reviews were included capturing 1064 studies that focused on cancer patients. Out of the 56 literature reviews included in our final analysis, the majority (45) focused on medication adherence, while 18 studies assessed adherence to dietary recommendations, and 13 studies examined adherence to lifestyle changes. Three studies investigated other dimensions of adherence. Data collection was primarily carried out via questionnaires and most studies applied self-developed, non-validated PROMs. PROMs mainly measured one dimension of adherence, even though the content of items were overlapping between medication, diet and lifestyle.

Conclusions: This systematic literature review provides a comprehensive overview of PROMs used to assess adherence in oncology. Our analysis highlights the predominance of studies measuring medication adherence and underscores the need for greater attention to other dimensions of adherence. Our findings can inform the choice of PROMs to monitor patients' adherence in clinical practice and enhance health outcomes.

2046P The importance of communicating bad news in medical education

G. Goumas[1], T. Dardavesis[2], N. Syrigos[3], I. Vathiotis[4], E. Simou[1]

[1]Department of Public Health Policy, School of Public Health, University of West Attica - Campus 1, Athens, Greece; [2]Laboratory of Hygiene, Social & Preventive Medicine and Medical Statistics, School of Medicine, Faculty of Health Sciences, Aristotle University of Thessaloniki - School of Medicine, Thessaloniki, Greece; [3]Oncology Unit, 3rd Department of Internal Medicine, "SOTIRIA" General Hospital of Chest Diseases, National and Kapodistrian University of Athens - School of Medicine, Athens, Greece; [4]Medical Oncology, Sotiria Thoracic Diseases Hospital of Athens, Athens, Greece

Background: Effective communication between doctors and patients is crucial, especially when delivering bad news that can impact a person's present and future expectations. However, acquiring optimal skills in breaking bad news requires the incorporation of multiple professional competencies that are acquired gradually through years of training. The purpose of this study was to conduct a systematic review of existing literature on medical education programs and interventions aiming to improve communication skills and to critically evaluate the effectiveness of such training.

Methods: We conducted a systematic review following PRISMA guidelines, searching PubMed and Scopus databases at February 2023, using the key words "medical education," "breaking bad news," and "end of life communication."

Results: Our search yielded 21 relevant studies, with 12 randomized studies indicating improvements in trainees found in PubMed, while four Scopus studies referred to workshops and seminars that increased participants' confidence in various communication areas. Furthermore, eight studies referred to training courses on communication techniques that helped medical students and health professionals develop confidence in breaking bad news skills. One study utilized interactive theater and role-play with professional actors to teach breaking bad news to medical students, which can be a potentially powerful tool for teaching breaking bad news during medical education. One study showed that the COVID-19 pandemic has disrupted health education due to social distancing.

Conclusions: Our findings suggest that training physicians at the undergraduate and postgraduate levels in communication skills for breaking bad news can be beneficial for both physicians and patients. However, limitations exist in reaching definitive conclusions. As digital learning has emerged in healthcare education during the post-

COVID-19 period, digital solutions have also been examined for training in the communication of bad news.

2047P Neutrop: A descriptive, observational study for G-CSF prescription in daily practice

F. Scotté

Interdisciplinary Cancer Course Department, Institut Gustave Roussy, Villejuif, France

Background: Despite significant advances in prevention and treatment, febrile neutropenia (FN) remains a common and serious complication of chemotherapy. Leverages data related to G-CSF use are missing. This study aims to (1) describe the practices of G-CSF treatment implementation; (2) identify and measure the decision criteria related to their implementation in patients with breast (BC), lung (LC), or gastrointestinal cancers (GIC), in ambulatory settings, beyond the usual recommendations.

Methods: This non-interventional, cross-sectional, multicenter study required clinical cases presented using conversational interfaces (chatbot), simulating a conversation with one or several virtual interlocutors by voice or text exchange.

Results: The questionnaire was completed by 102 physicians. Most practitioners (84.5%) reported prescribing G-CSF, regardless of tumor type (Table). G-CSF was prescribed more frequently for adjuvant/neoadjuvant therapy than for metastatic cases. Leading factors motivating the prescription were chemotherapy regimen, comorbidities, and age (in 56.7% of cases). Access to care was cited as a reason to prescribe G-CSF.

Table: 2047P Levels and reasons of G-CSF prescription in all 3 cancer types

		Breast cancer	Lung cancer	Gastro Intestinal cancer	Total
Implementation of a G-CSF treatment N (%)	N	77	57	60	194
	Yes	68 (88.3%)	42 (73.7%)	54 (90.0%)	164 (84.5%)
	Not	9 (11.7%)	15 (26.3%)	6 (10.0%)	30 (15.5%)
What should be considered before prescribing a G-CSF for this patient? N (%)	N	68	42	54	164
	Chemotherapy Protocol	23 (33.8%)	9 (21.4%)	7 (13.0%)	39 (23.8%)
	Chemotherapy Protocol + comorbidities	12 (17.6%)	2 (4.8%)	8 (14.8%)	22 (13.4%)
	Chemotherapy Protocol + Age	2 (2.9%)	6 (14.3%)	2 (3.7%)	10 (6.1%)
	Chemotherapy Protocol + comorbidities + age	31 (45.6%)	25 (59.5%)	37 (68.5%)	93 (56.7%)

Conclusions: Our findings suggest that ESMO recommendations are broadly followed. In most cases, G-CSF is prescribed in early stages and in curative intent. Despite a large use of G-CSF, education about febrile neutropenia and risk factors should be disseminated to a wide audience.

2048P Frequency and clinical relevance of drug-drug interactions with oxycodone among patients with cancer

L. Hulskotte[1], W. Töpfer[1], A.K.L. Reyners[2], K. Taxis[1], F. Jansman[3]

[1]GRIP, University of Groningen, Groningen, Netherlands; [2]Medical Oncology, UMCG - University Medical Center Groningen, Groningen, Netherlands; [3]Clinical Pharmacy Department, University of Groningen, Groningen, Netherlands

Background: Oxycodone is known to have numerous drug-drug interactions (DDIs) that can potentially decrease efficacy or lead to adverse drug reactions (ADRs). However, there is limited research on the frequency of DDIs associated with oxycodone use in patients with cancer. In this study, the frequency and pharmacological and clinical relevance of DDIs between oxycodone and perpetrators were studied in patients with cancer.

Methods: A cross-sectional study was conducted using pharmacy records to study the concomitant use of oxycodone and DDI perpetrators. These perpetrators were registered from oxycodone use trajectories between 1 September 2021 and 1 September 2022 in the Deventer Hospital by consulting Lexicomp®, Micromedex®, the Dutch Kennisbank and the Dutch Commentaren Medicatiebewaking. The clinical relevance of the identified perpetrators was examined by a clinical pharmacologist and a medical oncologist. Additionally, the frequency of multiple interactions was studied.

Results: In 254 oxycodone trajectories, 227 (89.4%) were found to include at least one pharmacologically relevant perpetrator. Of these, 210 (82.7%) were clinically relevant. A total of 80 different pharmacologically relevant perpetrators were identified, with 65 (81.3%) being considered clinically relevant. Interactions were observed in 21 (8.3%) oxycodone trajectories. Dutch compendia generally classified DDIs with oxycodone as less relevant compared to Lexicomp and Micromedex.

Conclusions: A high frequency of pharmacologically and clinically relevant perpetrators of DDIs with oxycodone was observed in our cohort. Moreover, a high number of double interactions involving oxycodone was found. Revision of drug interaction compendia used in Dutch healthcare in accordance with international compendia is recommended to improve pharmacovigilance.

2049P Osimertinib-related muscle cramps as a common adverse event: A real-world data analysis in the post-approval setting

G.F. Moreira[1], I. Borchardt[2], F.C. Dias[3], F.T. Taveira[3], L.D.O. Pina[1], W.M. Rocha[1], T.C. Montella[3], A.C. de Melo[4], C.G.M. Ferreira[5]

[1]Clinical Pharmacy, Grupo Oncoclinicas Botafogo, Rio de Janeiro, Brazil; [2]Nutrition, Grupo Oncoclinicas Botafogo, Rio de Janeiro, Brazil; [3]Oncology, Grupo Oncoclínicas Botafogo, Rio de Janeiro, Brazil; [4]Clinical Research Division, Grupo Oncoclínicas, Rio de Janeiro, Brazil; [5]Education and Research, Grupo Oncoclinicas Botafogo, Rio de Janeiro, Brazil

Background: Osimertinib is a third-generation tyrosine kinase inhibitor (TKI) that is the standard of care treatment for non-small cell lung cancer (NSCLC) with EGFR driver mutation. Some of the most common treatment-related adverse events (TRAEs) are rash, diarrhea, nausea, paronychia, and stomatitis. This abstract aims to describe muscle cramps as TRAEs associated with osimertinib use.

Methods: EGFR mutant NSCLC patients using osimertinib were included. Data were collected during pharmaceutical consultations and remote telemonitoring between January 2016 and April 2023. In all consultation modalities, drug interactions, drug reconciliation, adherence to treatment using the Morisky Medication Adherence Scale (MMAS) tool, classification and grading of TRAEs according to Common Terminology Criteria for Adverse Events (CTCAE) Version 5.0 were evaluated.

Results: A total of 88 patients were included. Mean age was 68 years and 71% were female. The pharmacist performed medication reconciliation and analysis of drug interactions in all patients and 99% of them showed good adherence to treatment. In the evaluation of TRAEs, 29% reported muscle cramps, with 19% of the sample developing grade 2. The median onset of the event was 2 months after starting osimertinib. Around 57% of the patients had diarrhea, which was managed early after the initial symptoms. Therefore, the occurrence of muscle cramps was not related to hydroelectrolytic unbalance due to diarrhea. The main osimertinib registration studies did not report muscle cramps as TRAEs.

Conclusions: In our cohort muscle cramps were very common TRAEs associated with osimertinib use and have not been directly related to diarrhea. It is an underreported adverse event that can impact on quality of life. Pharmaceutical follow-up is strategic for post-marketing surveillance, playing an important role in identifying new TRAEs. Update on muscle cramps as a very common TRAEs for osimertinib is required to develop supportive measures in conjunction with the multidisciplinary team, support clinical data and add to regulatory agency records.

2050P Integrating ayurveda herbs with standard of care for management of cancer or cancer treatment related anorexia

Y.N. Bendale, D.A. Kadam, P. Birari-Gawande, D.A. Patil, P. Shirole, M. Kadam

Cancer Department, Rasayu Cancer Clinic, Pune, India

Background: Anorexia is the fourth common symptom seen in half of newly diagnosed cancer patients. It also remains most prevalent and troublesome clinical problem experienced by patients with cancer during and after chemotherapy. Consequently, anorexia adversely influences nutritional status of a patient which further causes a negative impact on quality of life and survival. Various herbs have shown to be having positive effect on treating anorexia. In this study, we analysed the effect of an Ayurveda formulation consisting standardised dry powders of 5 herbs indicated in Ayurveda for treatment of Anorexia.

Methods: We did an assessment of study variables related to anorexia, cachexia and quality of life in a heterogeneous group of stage IV cancer patients (n=45) receiving conventional therapies for cancer and complaining of anorexia. These patients were administered herbal capsule "Ruchir" for treatment of Anorexia. Ruchir is consisting dry herbal powders of Pomegranate (*Punica grantum*), Black pepper (*Piper nigrum*), Ginger (*Zingiber officinale*), Amla (*Phyllanthus emblica*), Cumin (*Cuminum cyminum*). Therapy response on Anorexia was assessed using AC (Anorexia/cachexia subscale) and its impact on quality of life was assessed using Functional Assessment of Anorexia / Cachexia Treatment (FAACT). Weight was recorded at each visit (day 0, day 30, day 90, and day 180) using digital weighing scale. Statistical significance was assessed using nonparametric Wilcoxon Signed Ranks Test.

Results: The mean age of study participants were 64.54 (±5.6) years. Significant improvement was observed in Anorexia sub scale score ($P < 0.01$) and quality of life ($P<0.05$) as compared to baseline. No significant change was observed in weight. Treatment was well tolerated by all patients.

Conclusions: Herbs used in this study have been shown to have significant effects in reducing anorexia and improving quality of life in a heterogeneous group of cancer patients. This study provides preliminary evidence about effectiveness of herbs in treating Anorexia in cancer patients. Further controlled studies in a homogenous group of patients are warranted to integrate herbs with a standard of care in cancer patients for management of Anorexia.

2051P E-PRO within comprehensive companion program for patients undergoing systemic cancer treatment to reduce emergency visits and inpatient admission in a Peruvian institution

P.E. Rioja Viera[1], R.E. Ruiz[1], J.M. Araujo[2], J.G. Macetas[1], S. Acevedo[1], T. Guevara[1], M.Q. Puente[1], F. Young[1], P. Montenegro[1]

[1]Medical Oncology Dept., Oncosalud, Lima, Peru; [2]Basic and Translational Research Center, AUNA-IDEAS, Lima, Peru

Background: The implementation process, characteristics and objectives of the companion program have been previously reported. Briefly, the program consisted of a web containing an e-PRO questionnaire platform with real time monitoring for early symptom detection and intervention, a communication channel for resolving doubts and educational resources on diagnosis, treatment and adverse events. We aimed to determine the impact of the program in terms of reduction of emergency visits (ERV) and non-planned inpatient admissions (NIA).

Methods: Case-control analysis of patients with gastrointestinal cancer receiving systemic treatment (chemotherapy, immunotherapy, targeted therapy or combinations) at Oncosalud between June 2021 and July 2022. Patients were divided into two cohorts according to enrollment into the companion. Incidence rate (IR), IR ratios (IRR) and 95% confidence intervals were calculated. Time to first ERV and NIA curves since enrollment were constructed using the Kaplan Meier method and log rank test.

Results: In total, 199 patients were included, 97 enrolled into the program (cases). Mean age was 61.4 (±13.2), 50.3% were women and 94% were in ECOG 1-2. Chemotherapy was the most common treatment (88.4%). There were no differences in these characteristics between groups. The mean follow time was of 8.3 and 6.7 months, for cases and controls respectively. A statistically significant reduction in incidence rates was observed for both outcomes. ERV IR was 20.3 ERV per month in controls (95% CI:17.0-24.0) vs 15.1 ERV per month in cases (95%CI:12.6-18.0) which translated into a 25% decrease in ERV (IRR: 0.75 (95%CI:0.58-0.96; p=0.02)). NIA IR was 9.2 NIA per month in controls (95%CI:7.0-11.8) vs 5.9 NIA per month in cases (95%CI:4.4-7.8) which translated into a 35% decrease in NIA (IRR: 0.65 (95%CI:0.44-0.96; p=0.02)). There were no differences in time to first event for both outcomes.

Conclusions: The results demonstrate that e-PRO monitoring within a comprehensive companion program for cancer patients undergoing systemic treatment achieves clinical benefits as it reduces ERV and NIA. Its potential impact on outcomes and costs is being evaluated and will be reported.

2052P Adverse events in FLOT chemotherapy for locally advanced gastric cancer: An observational study of pre- and post-operative toxicity profiles

C. Oliveira, E. Couto, A. Marques, F.M. Ferreira Pereira, J.A.L.D.A. Cunha, M. Peixoto, C. Honrado Martins, D.S. Freitas, J.R. Rodrigues

Medical Oncology Department, Hospital de Braga EPE - SNS, Braga, Portugal

Background: Fluorouracil plus leucovorin, oxaliplatin and docetaxel (FLOT) is the standard of care for perioperative chemotherapy in resectable locally advanced gastric cancer (LAGC) in Europe. As a triplet combination, FLOT may be associated with increased toxicity. Therefore, it is crucial to investigate whether patients experience similar toxicities before and after surgery. This study aims to evaluate the toxicity profile of FLOT chemotherapy.

Methods: This observational, longitudinal, retrospective study included patients diagnosed with LAGC and treated with FLOT chemotherapy in a Portuguese medical oncology department between January 2018 and December 2020. Adverse events were classified according to Toxicity Grading CTC-AE version 5.0.

Results: Forty-seven patients with LAGC treated with FLOT chemotherapy were included in this study. The median age at diagnosis was 59.3 years (SD 8.1), and the majority of patients were male (n=29, 61.7%) with an ECOG PS of 0 (n=41, 87.2%). During the first four cycles of FLOT given before surgery, a total of 56 adverse events of any degree were observed, with 8 (17%) patients requiring treatment delay and 4 (8.5%) patients requiring dose reduction. In the 5th to 8th cycles given after surgery, there were 62 adverse events of any degree, with 13 (27.7%) patients requiring treatment delay and dose reduction. Notably, the toxicity profile differed between the pre and post-operative periods. In the first 4 cycles, the most common adverse events were nausea (n=16, 28.6%), emesis (n=9, 16.2%), and diarrhea (n=6, 10.7%), mostly with grade 2 toxicity. In the postoperative period, the main adverse events were neutropenia (n=23, 37.1%), nausea (n=6, 9.7%), and neuropathy (n=6, 9.7%). Grade 3 and 4 neutropenia occurred in 15 and 2 patients, respectively. Forty-two patients completed 8 cycles of FLOT.

Conclusions: The observed differences in toxicity between the pre- and postoperative periods highlight the importance of tailoring the treatment approach based on the patient's individual needs. Efforts to minimize dose reduction and chemotherapy delay should be made to maximize the effectiveness of FLOT therapy. Limitations of this study include the lack of data on long-term toxicity.

2053P Dehospitalization through outpatient drug release in clinical pharmacy as a strategic cost-minimization action in a public oncology hospital in the Eastern Amazon: A quantitative analysis

K. Borges[1], K.M. Penalber[1], S.O. Queiroz[1], B.V.R.E. Almeida[2], G.M. Alameida[2], C. Borges Junior[1], S.S. Alvarenga[1], P. Soares[1], T. Rodrigues[1]

[1]Oncology, Oncológica do Brasil Santarém - Unidade Tapajós, Santarem, Brazil; [2]Centro Universitário IMEPAC, Araguari, Brazil

Background: In recent decades, the home care initiative has expanded in the health system, mainly linked to hospitals. The mismatch between available financial resources and advances related to cancer therapy requires projects to improve cost minimization processes.

Methods: The variables collected for each sector were described through monthly totals and averages per year. To verify the existence of an association between expenses with material, medication and chemotherapy and the cost avoided with

monthly dehospitalization, Pearson's correlation coefficients and their respective p-values were calculated. Spending on medication and total spending on material, medication and chemotherapy were related to the amount avoided using linear regression models, in order to estimate the effect of increased spending on medication on avoided costs. The same procedure was performed to estimate the effect of increased costs on bed turnover, using linear regressions, and on the number of days of hospitalization avoided per month, using Poisson regression.

Results: Pearson's coefficients confirm a relationship, with a positive sign, between expenses and avoided costs with early dehospitalization, showing a perfect positive relationship between the variables, with a statistically significant p-value. Effect of expenses on total costs with hospitalization avoided on General Hospitalization, Coefficients - Amount spent on medication:100.36; 95% CI (14.26, 186.45); p-value= 0.02. By the linear model, the total avoided cost with discharges was $795,204.52 in the three-year period from 2020 to 2022, for a total of 3,722 avoided hospitalization days and an average cost avoided with discharges of $70,146.06. Effect of expenses on the days of hospitalization avoided (Poisson regression) was statistically significant in all variables (p-value<0.001).

Conclusions: All tests - Pearson Correlation coefficients, Poisson regression, and Generalized Linear Model (p<0.05) confirmed the hypothesis that the discharge managing with outpatient drug release has a significant effect on the final cost avoided with cancer hospitalization.

Background: Little is known about metastatic cancer patients who are hospitalized at diagnosis because of impaired performance status and/or severe symptoms. This study aims to explore their prognosis and the effect of systemic anti-neoplastic treatment (SANT) initiation on their outcomes.

Methods: A prospective multicentric study of adult inpatients with a newly diagnosed metastatic solid tumor was conducted in seven cancer-facilities in France. During a three-month follow-up, socio-demographic characteristics, response rate and duration of response for patients receiving SANT, length of hospital stay and survival were collected. Correlation with clinical prognostic and predictive factors was analyzed.

Results: 107 patients were included from November 2021 to April 2022. Seventy-four (69%) underwent SANT. Median overall survival was 1.7 months for the entire cohort. Forty (37%) were alive at 3 months, including 39 patients that started SANT. Factors associated with the initiation of a SANT were young age (OR=0,94 [0,90; 0,98]), low Charlson Comorbidity Index (OR=0,56 [0,42; 0,73]), SANT initiated at patient's or caregiver's request (OR=0,07 [0,02; 0,17] and 0,17 [0,06; 0,42], respectively). Patients with biomarker-based targeted therapy had better outcomes at 3 months, while survival of patients treated with exclusive immunotherapy was poor. PALLIA-10 score superior to 5 was a significant predictive factor for mortality (HR=3,24; p<0,001).

Conclusions: Metastatic cancer patients hospitalized at the time of diagnosis share a similar poor survival. The initiation of SANT does not always impact their outcomes. Larger prospective studies with longer follow-up are needed to better assess the effect of SANT in this population.

2055P Multidisciplinary Tumor-ICU Board: Enhancing care for critically Ill patients with solid tumors in the ICU

F.J. Ros Montana[1], N. Saoudi Gonzalez[2], S.A. Bueno Salazar[2], C. Diaz[3], S. Vega[1], A. Albasanz[4], J. Aguilar Company[1], P. Gallardo[1], P. Gomez Pardo[5], M. Roca Herrera[6], S. Eremiev[1], P. Mascaro[1], P.B. Buch[1], J.G. Yaringaño[1], C. Ortiz[1], J. Carles Galceran[1], I. Ruiz[4], R. Ferrer[3], M.E. Elez Fernandez[1]

[1]Medical Oncology Dept., Vall d'Hebron University Hospital, Barcelona, Spain; [2]Oncology Dept., Vall d'Hebron University Hospital, Barcelona, Spain; [3]Intensive Care Unit, Vall d'Hebron University Hospital, Barcelona, Spain; [4]Infectious Disease Dept, Vall d'Hebron University Hospital, Barcelona, Spain; [5]Medical Oncology Dept., Vall d'Hebron Institute of Oncology (VHIO)-Cellex Center, Barcelona, Spain; [6]Medical Oncology Dept., Angelini Pharma, Barcelona, Spain

Background: Patients with solid tumors frequently experience complications that may require ICU admission. The advent of new cancer treatments such as has added complexity and potential adverse events, which frequently mimic severe infections or critical disorders. Therefore, there is a need to evaluate patients with solid tumors in the ICU from multiple perspectives. We aim to establish a Multidisciplinary Board to customize diagnostic and treatment approaches for critically ill patients with solid tumors in the ICU, through a comprehensive evaluation by ICU, Hematology (HEM), Infectious Diseases (ID), and Medical Oncology (MO) specialists.

Methods: Specialists from the Vall d'Hebron ICU, ID, and MO meet weekly to discuss prospectively clinical evolution, how to tailor treatments and further diagnostic steps of patients with solid tumors admitted to the ICU.

Results: From January to April 2023, 46 patients with solid tumors were evaluated by the ICU-Tumor board. The majority (65%) were male, with a median age of 62 years. Gastrointestinal tumors accounted for 44% of the cases, followed by lung cancers (17%), head and neck tumors (11%), and other malignancies (28%). Overall, 17% of the patients were receiving potentially radical treatment (NA or ADJ treatment), and 83% presented with metastatic disease. Respiratory failure (65%), septic shock (11%), metabolic disturbances (10%) and other events (14%) were the most frequent reasons for ICU admission which were caused by infectious events (51%), treatment toxicity (22%), and cancer-related complications (27%). Median time admitted at the ICU was 10 days (1-83 days). The Board's most common recommendations included diagnostic procedures (50%, biopsy or radiological evaluations) therapeutic interventions (30%) (antibiotic, immunosuppression or start chemotherapy in the ICU), and limiting treatment intensity (10%). Mortality within the ICU was 10%, and 30-day mortality was 39%.

Conclusions: The Multidisciplinary ICU-tumor Board's recommendations range from diagnostic to therapeutic interventions and can lead to improved outcomes and tailor therapeutic strategies for these critically ill patients, particularly with the increased complexity of new cancer treatments and complex infections.

2056P Hospitalization, reconsultations and mortality in the field of oncological emergencies: Who is at higher risk?

E.M. Martínez Madrid[1], M. Sanchez Canovas[1], A. Sanchez Saura[1], S. Montenegro Luis[1], M.A. Ivars[1], N. Blaya Boluda[1], M.E. Guirao García[1], C. Moreno Barba[2], R. Pérez Costa[2], F. Ayala de la Pena[3]

[1]Medical Oncology Department, Hospital General Universitario Morales Meseguer, Murcia, Spain; [2]Emergency Department, Hospital General Universitario Morales Meseguer, Murcia, Spain; [3]Hematology and Medical Oncology Department, Hospital General Universitario Morales Meseguer, Murcia, Spain

Background: The wider availability of oncological treatment and the improved survival of cancer patients have increased the frequency of emergency consultations and their impact on healthcare. The aim of this study was to investigate the variables that influence hospital admission, re-consultation and clinical outcomes among oncology patients who seek emergency care.

Methods: Single-center, observational and prospective study. We analyzed a sample of 554 oncology patients who consulted in the Emergency Deparment during regular office hours between March-22 and March-23. Statistics: Chi-squared test to assess association between variables. Kaplan-Meier curves and log-rank test for survival analysis. Significance level: p-value <=0.05.

Results: The baseline characteristics of the study participants were: 50.2% females, 21.5% lung cancer, 68.8% stage IV, 25.8% consulted for digestive symptoms, 37% were hospitalized and 16.4% reconsulted in the following 15 days. The overall median survival was 54 weeks. Factors that were associated with a higher likelihood of hospitalization were lung cancer (26.9% of admissions), stage IV (80.7%), monotherapy chemotherapy (CT) (36.3%), first-line treatment for metastatic disease (40.9%), ECOG 2 (36.8%), digestive symptoms as reason for consultation (29.2%) and complications secondary to the tumor itself as definitive diagnosis (32.2%). Factors significantly associated with a higher likelihood of reconsultation within the following 15 days were lung cancer (19.3% of reconsultations), monotherapy CT (38.6%), ECOG 1 (42.1%) and infectious pathology and complications secondary to the tumor itself (28.1% each one). Factors significantly associated with lower overall survival were hospital admission (median: 16 weeks, 95% CI 3.7-28.2), diagnosis of complications secondary to the tumor itself (median: 11 weeks, 95% CI 10.3 - 23.6) and reconsultation (median: 17 weeks, 95% CI 10.3-23.6).

Conclusions: Among oncology patients admitted to the Emergency department, complications secondary to the underlying oncological disease represent the most relevant variable in the field of oncological emergencies due to their impact on the likelihood of hospitalization, reconsultation and survival.

2057P Prevalence of frailty in long-term prostate cancer survivors after radical prostatectomy and its association with quality of life and emotional health

V.H. Meissner[1], K. Imhof[1], M. Jahnen[1], L. Lunger[1], A. Dinkel[2], S. Schiele[1], J.E. Gschwend[1], K. Herkommer[1]

[1]Department of Urology, Technical University of Munich, Klinikum Rechts der Isar, Munich, Germany; [2]Department of Psychosomatic Medicine and Psychotherapy, Technical University of Munich, Klinikum Rechts der Isar, Munich, Germany

Background: Aging-related deficits that eventually manifest as frailty are emerging as an important determinant for quality of life and emotional health in older patients with cancer. Prevalence of frailty in long-term prostate cancer survivors and its impact on quality of life have not been investigated so far. The objective of the current study was (I) to assess the prevalence of frailty and (II) to elucidate the relationship between frailty, quality of life and emotional health in long-term prostate cancer survivors after radical prostatectomy.

Methods: 2979 prostate cancer survivors from the multicenter German Familial Prostate Cancer Database were included. Patients completed the following standardized patient-reported outcome measures of interest: frailty (Groningen Frailty Indicator, GFI), quality of life (EORTC QL2), and emotional health (anxiety/depression symptoms, PHQ-4). Chi-square tests and Wilcoxon-Mann-Whitney tests were used to detect differences of selected variables between frail and non-frail patients. Associations were assessed using multiple linear regression analysis.

Results: The patients' mean age was 79.4 years (SD = 6.4) and mean time since radical prostatectomy was 17.4 years (SD = 3.8). 33.1% (985/2979) of patients were classified as frail (GFI $\geq$4). Regarding mental health and quality of life, frail patients reported more often symptoms of depression (24.0% vs. 4.0%; p<0.001) and anxiety (20.6% vs. 2.0%; p<0.001) as well as lower quality of life (M = 53.4 (SD = 19.2) vs. M = 72.7 (SD = 16.0); p<0.001) compared to non-frail patients. Frailty was significantly associated with depression (OR 1.68; CI 1.49-1.89), anxiety (OR 1.75; CI 1.55-1.97), lower quality of life (OR 0.72; CI 0.67-0.77), higher age (OR 1.04; CI 1.03-1.07), and a missing partnership (OR 1.83; CI 1.37-2.45).

Conclusions: Every third long-term prostate cancer survivor after radical prostatectomy was frail. The associations with lower quality of life and poorer mental health indicates the need for an integrated care approach including further geriatric assessment and possible interventions to improve health outcomes of these patients.

2058P Reducing waste to improve sustainability and affordability of cancer treatment: Redispensing unused oral anticancer drugs

L-M.M. Smale[1], B.J.F. van den Bemt[2], R. Heerdink[3], I.M. Desar[4], T. Egberts[5], C.L. Bekker[1]

[1]Department of Pharmacy, Radboud University Medical Center, Nijmegen, Netherlands; [2]Department of Pharmacy, Sint Maartenskliniek, Ubbergen, Netherlands; [3]Division of Pharmacoepidemiology and Clinical Pharmacology, Utrecht University - Faculty of Pharmaceutical Sciences, Utrecht, Netherlands; [4]Medical Oncology Dept., Radboud University Medical Center, Nijmegen, Netherlands; [5]Division of Laboratory, Genetics and Pharmacy, Department of Clinical Pharmacy, UMC - University Medical Center Utrecht, Utrecht, Netherlands

Background: Strategies targeting oral anticancer drug (OAD) waste are required to improve sustainability and affordability of these expensive treatments frequently remaining unused by patients. This study aims to quantify waste reduction, cost-savings and environmental impact obtained by redispensing unused OADs compared to standard practice of disposal.

Methods: A prospective, single-arm intervention study was conducted in four Dutch hospitals. Eligible patients were $\geq$18 years, diagnosed with cancer and prescribed an OAD. During twelve months, participants received OAD packages sealed with a time-temperature indicator. If unused, OADs were returned to the pharmacy where quality was assured by checking authenticity, shelf life and storage temperature. OADs of verified quality were redispensed to other patients. Waste reduction was expressed as the percentage returned OADs that were redispensed. Mean annual cost-savings per patient were costs of redispensed OADs minus operational expenses from a healthcare perspective. Impact on environmental indicators was assessed via a cradle-to-grave Life Cycle Assessment. Patient subgroups associated with positive cost-savings were identified with multiple logistic regression. Scenarios analyses on the effect of optimized quality assurance and patient population selection was performed.

Results: 1,071 patients participated, median age 70 years (IQR: 62—75) and 41.9% female. 224 OAD packages (1.7%) of 128 patients (12.0%) were redispensed (2.4% of total drug costs), reducing waste by 68.1% and providing mean annual cost-savings of €576 per patient (95% CI: 444—709). Optimizing quality assurance and targeting patient subgroups (< 24 months OAD use/using targeted therapies) could increase mean annual cost-savings up to €1,348 (1,039 — 1,697) per patient. Waste reduction was associated with mean annual environmental benefits of >1 kg CO_2 per patient, but only with an optimized quality assurance procedure a net beneficial impact on environmental indicators was achieved.

Conclusions: Redispensing unused OADs reduces waste substantially, generates cost-savings and can benefit environmental impact, improving sustainability and affordability of cancer treatment.

2059P The impact of a dental oncology clinic for patients (pts) prescribed bone-modifying agents (BMA) in a cancer centre

H. Byrne[1], C.S. Weadick[2], R. ni riordain[3], S. O'Reilly[4]

[1]Oral Surgery Dept., UCC - University College Cork, Cork, Ireland; [2]Medicine Dept., CUH - Cork University Hospital, Cork, Ireland; [3]Oral Medicine, CUH - Cork University Hospital, Cork, Ireland; [4]Oncology Dept., CUH - Cork University Hospital, Cork, Ireland

Background: Two decades ago medication related osteonecrosis of the jaw (MRONJ) was first described in oncology pts receiving BMAs. Pre-existing dental disease is the main initiating factor for MRONJ. Dental disease is the commonest global non-communicable disease. We assessed the impact of integrating a dental oncology service for all incident pts prescribed BMAs.

Methods: A dental clinic was established in March 2022 collocated with a cancer centre and all pts receiving BMAs were assessed by an oral surgeon prior to BMA administration and all necessary dental treatment was completed.

Results: 120 pts included (66% female), 66 were <65 years, were treated over 1 year. 82 pts had metastatic disease. Early stage breast cancer (N=35), metastatic breast cancer (N=36), prostate cancer (N=24), and other malignancies (N=25) were represented in this cohort. 118 pts were planned for intravenous zoledronate and 2 were planned for denosumab. 117 pts were deemed dentally fit to commence their BMA. 29 pts were current smokers, and 24 pts wore dentures. 45 pts had a current dental complaint on presentation, for which 31 complaints related to pain and infection. Assessment of barriers to dental services; 20 pts live alone, 42 pts were not registered with a dentist, and 51 hadn't seen their dentist in ≥3 yrs. 8 pts had intraoral smoking related changes, and moderate dysplasia was identified in 1 pt following a biopsy. The Decayed, Missing and Filled Teeth (DMFT) index median score was 18, and mean DMFT score was 19. 88 pts had a periodontal status of ≥Stage 2 Grade B which demonstrated longstanding and active periodontal disease. The mean bleeding on probing score was 35% and 75 pts had a high Caries Risk Assessment score. 65 pts required an operative dental procedure. 33 pts received a dental restoration, of which 16 pts required a median of 2 dental restorations. 58 pts had teeth extracted, of whom 37 had a median of 3 teeth extracted.

Conclusions: This oncology cohort had poor engagement with dentistry and had a high burden of dental disease prior to BMA treatment. The data highlights their dental treatment needs prior to BMA treatment and the requirement for proactive dental integration by the oncology team. Dental care should be an integral part of multidisciplinary cancer care.

2060P Prevalence and predictor of poor mental adjustment to cancer before lung cancer surgery

J. Park[1], G. Lee[2], J. Cho[3], Y.M. Shim[4], H.K. Kim[5], D.W. Shin[6]

[1]Department of Family Medicine & Supportive Care Center, Samsung Medical Center (SMC), Seoul, Republic of Korea; [2]Patient-Centered Outcomes Research Institute, Samsung Medical Center (SMC), Seoul, Republic of Korea; [3]Department of Clinical Research Design and Evaluation, SAIHST, Samsung Medical Center (SMC) - Sungkyunkwan University School of Medicine, Seoul, Republic of Korea; [4]Thoracic and Cardiovascular Surgery, Samsung Medical Center (SMC) - Sungkyunkwan University School of Medicine, Seoul, Republic of Korea; [5]Thoracic and Cardiovascular Surgery, Samsung Medical Center (SMC), Seoul, Republic of Korea; [6]Department of Family Medicine & Supportive Care Center, Samsung Medical Center (SMC) - Sungkyunkwan University School of Medicine, Seoul, Republic of Korea

Background: The aim of the study is to identify the prevalence and predictors of mental adjustment to cancer in patients who were going to resect lung for non-small cell lung cancer in Korea.

Methods: A total of 697 patients were recruited from September 2021 to October 2022 and completed a survey questionnaire of the Korean version of Mini-Mental Adjustment to Cancer (K-Mini-MAC) which higher mean score denote worse mental adjustment, except for positive attitude (PA) domain. Multivariable logistic regression was analyzed to determine potential predictors of poor adjustment to cancer for each domain of K-mini-MAC, which was defined by the mean score of 2.5 or higher, while PA domain was defined by mean score of 2.5 or lower.

Results: The mean age of study population was 63.2 ± 0.4 years old and 50.4% was male. The proportion of poor mental adjustment was 6.0% (Helpless/Hopeless [HH] domain), 29.6% (Anxious Preoccupation [AP] domain), 19.1% (PA domain), and 30.1% (Cognitive Avoidance [CA] domain). The mean score of each domain was 1.60 ± 0.02 (HH), 2.17 ± 0.02 (AP), 2.83 ± 0.02 (PA), and 2.62 ± 0.02 (CA). Younger age (<65 years old, aOR 1.78, 95% CI 1.15-2.76) and having comorbidity (aOR 1.64, 95% CI 1.09-2.45) were associated with poor mental adjustment in AP domain, while current alcohol drinking was associated with better mental adjustment in AP domain (aOR 0.56, 95% CI 0.32-0.96, vs. non-alcohol drinker). Poor mental adjustment in PA domain was predicted based on Lower education level (≤ middle school, aOR 1.97, 95% CI 1.12-3.46; high school, aOR 2.31, 95% CI 1.23-4.36, vs. ≥ university). There was no significant predictor for mental adjustment in HH and CA domain.

Conclusions: Younger, non-alcohol drinker, having comorbidity and lower educational level was associated with a poor adjustment to cancer. Interventions to help with adjustment to cancer should be focused particularly on these group.

2061P Network analysis of comprehensive concerns in patients with cancer: Differences between the sexes

K. Yamamoto[1], Y. Tanabe Hashimoto[1], K. Nonogaki[1], H. Kono[1], E. Toda[1], H. Okumura[1], H. Ozaki[1], M. Kuno[1], S. Watanabe[1], K. Takemura[1], T. Yamanaka[1], R. Kizawa[1], T. Yamaguchi[1], K. Tanaka[2], Y. Kobayashi[2], T. Ogura[2], N. Tamura-Hatano[2], H. Kawabata[2], K. Suyama[1], Y. Miura[1]

[1]Medical Oncology, Toranomon Hospital, Minato-ku, Japan; [2]Breast and Endocrinology, Toranomon Hospital, Minato-ku, Japan

Background: Patients' concerns have become more complicated, while the advancements in cancer treatments have improved clinical outcomes. This study aims to comprehensively explore the concerns of cancer patients and to elucidate their interrelationships.

Methods: A fact-finding survey was conducted with 300 cancer patients (male; 127, female; 173) using a 74-item questionnaire. The questionnaire included comprehensive items (rated from 0 [none] to 3 [severe]) related to the concerns of cancer patients. Correlation network analysis was performed to visualize the association between the patients' concerns. Degree centrality was used to assess network centrality, and the Girvan−Newman algorithm was used to detect communities.

Results: Cancer types were as follows: breast cancer (n=84), gastrointestinal cancer (n=82), urologic cancer (n=52), cholangiopancreatic cancer (n=44), gynecologic cancer (n=20), and others (n=18). The mean overall score was significantly higher in females than in males (30.4 vs. 22.5, $p<0.01$). The most frequent concerns were physical decline (81.7 %), fatigue (80.5 %), muscle weakness in the limbs (65.9 %). In the overall network, the concerns with the highest centrality score were muscle weakness in the limbs (0.151), nutritional management (0.123) and fatigue (0.082). The network was classified into three communities: 1) physical decline, including 21 items such as muscle weakness, nutritional management, and fatigue; 2) changes in appearance, including 8 items such as pigmentation and hair loss; 3) social support, including 11 items such as employment and finances. The network analysis by gender showed that the highest centered item was sex life (0.123) in men, and depression (0.137) and anxiety (0.110) in women.

Conclusions: This study illustrated that cancer-related fatigue and weakness were the most frequently and numerous interrelated concerns that plagued patients with cancer. Furthermore, they formed a wide-ranging network with other concerns. Our study also showed that the structure of the network differed between the sexes. A multidisciplinary approach may be necessary to comprehensively solve interrelated patient concerns.

2062P The psychological distress (PsyD) evaluation in pancreatic cancer (PC) patients (pts): A mono-institutional analysis

M. Bensi[1], D. Belella[2], C. Bagalà[1], D. Barone[1], M. Chiaravalli[1], E. Gurreri[1], F. Veccia[2], A. Spring[1], G. Trovato[1], A. Di Bello[1], V. Beccia[1], D. Ferrare[2], S. Perazzo[1], A. Ceccarelli[1], G. Messina[1], G. Quero[3], S. Alfieri[3], D.P.R. Chieffo[2], G. Tortora[1], L. Salvatore[1]

[1]Oncologia Medica, Comprehensive Cancer Center, Fondazione Policlinico Universitario Agostino Gemelli IRCCS, Rome, Italy; [2]Clinical Psychology Unit, Fondazione Policlinico Universitario Agostino Gemelli IRCCS, Rome, Italy; [3]Chirurgia Digestiva, Comprehensive Cancer Center, Fondazione Policlinico Universitario Agostino Gemelli IRCCS, Rome, Italy

Background: PsyD is frequent in cancer pts and it negatively affects their treatment and quality of life. However, psychological screening is not extensively performed and few data about its impact are available. The aim of our study is to evaluate baseline PsyD in PC pts treated at our Institution and its correlation with clinicopathological features.

Methods: In the last year, we baseline evaluated PsyD of PC pts starting chemotherapy at our Institution, using the Distress Thermometer (DT) and Problem List (PL). The DT score was divided into three levels: no/minimal (0-3), moderate (4-6) and high (7-10) distress. PL was grouped into 6 categories (practical, physical, cognitive, spiritual/religious, emotional and family problems). Clinicopathological characteristics were collected and correlated with PsyD.

Results: A total of 86 PC pts were tested for baseline PsyD. The median age was 65 years, 63% were female, ECOG PS was > 1 in 56% of pts and 72% of pts had one or more comorbidities. The majority of pts (67%) received chemotherapy for metastatic disease. Regarding psychological screening, 31%, 29% and 40% of pts had no/minimal, moderate and high DT score, respectively. According to PL we observed: practical problems in 17% of patients, physical in 9%, cognitive in 42%, spiritual/religious in 9%, emotional in 16%, and family problems in 13% of patients. Regarding psycho-oncological care, 93% of pts received initial counseling, 63% intervention and follow-up.

No significant association between DT score and PL groups with clinicopathological characteristics was observed.

Conclusions: Our mono-institutional analysis showed that the majority of PC pts receiving chemotherapy at our Institution presented a PsyD scored as moderate (29%) or high (40%) by DT at baseline. According to PL, the main problem concerned the cognitive sphere, specifically problems related to concentration and/or memory and self-perception. Additional analyses, including the impact of PsyD on treatment compliance, tolerability and prognosis are going.

2063P Lifestyle changes as cancer treatment: It is time to get specific with our patients

A.I. Martin Quesada[1], A. Herrero Márquez[2], M. Gutierrez Gordo[2], P. Rodriguez[1], L. Herrera Gorrìn[3], A. Padilla[1], A. Rosa Díaz[1], C. Dorta Pérez[1], I. Nunez Hernandez[1], N.D. Pérez-Rodríguez[1], M. Pulido Torrente[1], M.L. Soriano Tabares[1], C. Hernández Pérez[1], M. Morales-Gonzalez[1], L. Pérez Mendez[4], A. Cardena[2]

[1]Medical Oncology Department, Hospital Universitario Nuestra Senora de Candelaria, Santa Cruz de Tenerife, Spain; [2]Oncology Department, Hospital Universitario Nuestra Senora de Candelaria, Santa Cruz de Tenerife, Spain; [3]Oncología Médica, Universidad de La Laguna, San Cristobal de La Laguna, Spain; [4]Epidemiology, Hospital Universitario Nuestra Senora de Candelaria, Santa Cruz de Tenerife, Spain

Background: In this study we seek to learn more about the lifestyle habits of our cancer patients, with a particular emphasis in exercise and eating behaviours. We choose to focus on these two areas as they have an outsized impact on clinical outcomes such as mortality, risk of relapse, quality of life, sarcopenia, duration of hospitalizations, post-surgical complications, response to immunotherapy and even overall survival rates.

Methods: Observational study across a cross-section of cancer patients at the Medical Oncology Service of the Nuestra Señora de Candelaria University Hospital, Santa Cruz de Tenerife. The statistical significance of lifestyle habit changes is tested through a form and IPAQ, MUST, and SARC-F surveys using chi-squared tests.

Results: We involved 100 patients whose average age was 61 years. 46% of patients had lung cancer, 30% breast cancer and 10% gastrointestinal cancer. 59% patients had stage-four cancer, 48% were receiving first-line treatment and 54% were being treated with immunotherapy or target therapies. 99% of individuals considered their diet as an important pillar in their cancer disease. However, we found that only 47% had discussed aspects of their nutrition with their oncologist, but this was not statistically associated with a reduced risk of malnutrition. 80% considered that a healthy lifestyle could help reduce the adverse effects of the treatment. The validated test results showed that 45% had an intermediate-high risk of malnutrition according to the MUST test and 14% had risk of sarcopenia according to the SARC-F test. Patients receiving immunotherapy or target therapies had a higher risk of malnutrition than those receiving other treatments (50 vs 42%, p=.507). 47% were sedentary according to the IPAQ test and 80% who did not perform physical activity would start an adapted exercise program if it were available.

Conclusions: Our patients present good high-level awareness about the generally positive ways in which lifestyle changes involving healthier eating and exercise habits can impact the outcome of their treatments. However, we appreciate a need for more specific nutritional and fitness recommendations that patients can immediately put into practice, as well their ranked impact on their health.

2064P Hospitalisation of patients with cancer: Identifying points for improvement in patient care in a university hospital in Spain

S. Roa[1], I. Hernández de Córdoba Sánchez[2], M. Morales Parga[2], I. Pizarro Sanz[3], J.M. Vincente Fraile[3], A. Sánchez[3], M. Merino Salvador[2], M. Moyano-Sereno[2], E. Casado Sáenz[2], C. Gomez Raposo[2]

[1]Oncology, Hospital Universitario Infanta Sofía, San Sebastian de los Reyes, Spain; [2]Medical Oncology, Infanta Sofía University Hospital, San Sebastián de los Reyes, Spain; [3]Supportive Care Unit, Infanta Sofía University Hospital, San Sebastián de los Reyes, Spain

Background: Hospitalisation is an inevitable step in the evolution of many patients with cancer, principally in advanced tumors. This study aims to describe the admissions to a medical oncology inpatient service of our University Hospital between November 2022 and April 2023.

Methods: We conducted a retrospective cross-sectional study of patients admitted to the Medical Oncology Service of Infanta Sofía University Hospital (Madrid) along six months. Database was collected from the electronic health records. The following variables were analyzed: age, sex, type of tumor, stages, origin of the admission, period of hospital stay, diagnoses, assessment by another specialities, type of discharge and readmissions.

Results: In the chosen period, 310 hospitalisations related to 223 patients were studied, because some of them were readmitted in these six months. The average age was 71.49 years, 42.9% women and 57.1% men. The average hospital stay was 10.18 days. Near 77% of the patients had advanced disease. In order of frequency, patients with lung (28.06%), colorectal (15.8%) and genitourinary (11.94%) cancer represented the most of inpatients. Mainly the patients were admitted from the Emergency Department of our Hospital (56.45%). The most prevalent reason for hospitalisation was secondary symptoms of disease progression. Infections were the cause of admission in 24.52% of the cases and 27.42% of them were from respiratory system. Other causes to take into account were the toxicity to the treatment (5.8%). As part of the multidisciplinary approach, during their hospitalisation, 5.26% inpatients required surgical assessment. Interventional radiologists treated 1.29% patients and endocrinologists providing nutritional support in 10.65% of cases. Furthermore, less than 2% of our patients were admitted to the Intensive Care Unit. Palliative Care Unit assessed 37.74% of the inpatients, which 19.35% were being previously followed-up by them. Unfortunately 15.8% of the admitted patients died. We also observed 26.45% had to be admitted again.

Conclusions: It is important to identify the reasons why patients with cancer are admitted to the Hospital because it could help to identify areas for improvement in the quality of care.

2065P Communication on the first medical oncology appointment: What do cancer patients want?

R.S. Vicente[1], M. Barbosa[2], R.M. Ferreira[1], R.R. Freitas[1], S. Parada Prada[1], T.S. Martins[1], T.M. Caleça[1], A. Duarte Mendes[1], M.M. Vitorino[1], C. Santos[3], D. Alpuim Costa[3]

[1]Medical Oncology Department, Hospital Professor Doutor Fernando Fonseca, Amadora, Portugal; [2]CICPSI, University of Lisbon - Faculty of Psychology, Lisbon, Portugal; [3]Medical Oncology Department, Hospital Dr. José de Almeida, Alcabideche, Portugal

Background: Beyond the diagnosis, multiple situations during the natural history of cancer can be pointed out as stressful and hard to convey. The first Medical Oncology appointment is crucial and comprehensive, where patients are invited to understand their diagnosis and grasp the prognostic consequences of cancer and its treatment. Strategies to elicit information while meeting patients' needs are required to overcome the potentially challenging moment, improve clinical outcomes and promote safe, high-quality, patient-centred care. This study evaluated the communication preferences at the first medical oncology approach.

Methods: A total of 169 cancer patients from a Portuguese Medical Oncology department answered the C-FAQ (Communication in first medical oncology appointment questionnaire), a survey representing the SPIKES and MPP (Measure of Patients' Preferences) protocols asking about preferences regarding Content (what and how much information is told), Facilitation (where and when the information is conveyed), and Support (emotional support during the interaction) elements of communication and patient's assign to these items.

Results: The Content elements (M=3.69, SD=0.35) were mentioned as the most important when compared with Facilitation (M=3.56, SD=0.39), $t(30.13) = 17.38$, $p < .001$, or Support (M=3.46, SD=0.44), $t(24.14) = 7.12$ $p < .001$. The physician's knowledge, honesty and being given clear information about cancer and treatment were the areas of greatest importance. Facilitation was considered more important than Support, $t(24.14) = 16.42$, $p < .001$. Globally, all items were mostly evaluated as "very important", Mdn 65.85% (11.525).

Conclusions: All communication components should be considered during the dialogue in this context. Medical teams should overcome barriers by learning skills to communicate with patients and promote engagement. More research is required to understand the complexity of the triad patient, physician, and family and address how patients' preferences can be met in a demanding clinical atmosphere.

2066P Evaluation of the quality and reliability of ChatGPT and Perplexity's responses about rectal cancer

O. Yazici, K. Bir Yucel, O. Sutcuoglu

Medical Oncology, Gazi University - Faculty of Medicine, Ankara, Turkey

Background: This study aimed to assess the usefulness of ChatGPT and Perplexity's responses to frequently asked questions regarding the diagnosis and treatment of rectal cancer.

Methods: Both artificial intelligence systems were asked 20 questions covering disease risk factors, screening, symptoms, treatment, and treatment side effects. In accordance with the ESMO patient guides, the questions were posed in the order specified. According to ESMO patient guide recommendations, responses were graded as "appropriate," "inappropriate," or "insufficient."

Results: While ChatGPT provided appropriate responses to 17 of the questions (85%), the responses to two questions (10%) were deemed inappropriate, and the response to one question (5%) was deemed insufficient. Nineteen (95%) of Perplexity's responses were deemed appropriate. It was determined that both artificial intelligence systems responded improperly to the nutrition question.

Conclusions: The study's findings indicate that ChatGPT and Perplexity provide patients with accurate information about rectal cancer. The accuracy rate of Perplexity was found to be higher than that of ChatGPT. It can be demonstrated that the benefit of Perplexity is that it displays the source for each piece of information. However, especially cancer patients require emotional and psychological assistance, and further research is required to determine the impact of these artificial intelligence systems on the patient's psychology. Moreover, given the complexity and individuality of medical care, AI chatbots should not be viewed as a replacement for medical professionals, but rather as a supplement that can help patients gain access to trustworthy information and support. Overall, this study contributes to the growing body of literature on AI chatbots and their potential use in cancer by highlighting both the advantages and disadvantages of these technologies.

2067P Influence of psychiatric disorders on survival in patients with lung cancer: Real-world data

T. Kovacevic[1], D. Bokan[2], J. Djekic Malbasa[3], B. Zaric[4], D. Bursac[5], G. Stojanovic[6], P.V. Simurdic[6], V. Stojsic[4]

[1]General Medicine and Geriatrics, Faculty of Medicine University of Novi Sad, Novi Sad, Serbia; [2]Clinical Trials Unit, Institute for Pulmonary Diseases of Vojvodina, Sremska Kamenica, Serbia; [3]Department of Epidemiology, University of Novi Sad - Faculty of Medicine, Novi Sad, Serbia; [4]Department of Internal Medicine, University of Novi Sad - Faculty of Medicine, Novi Sad, Serbia; [5]Depatment of Internal Medicine, Institute for Pulmonary Diseases of Vojvodina, Sremska Kamenica, Serbia; [6]Thoracic Oncology Department, Institute for Pulmonary Disease of Vojvodina, Sremska Kamenica, Serbia

Background: Although the psychological burden of patients with malignant diseases is marked as one of the main aspects in the disease trajectory, anxiety and depression are still unmet need in practice. To determine influence of Anxiety and Depression on survival in patients with diagnosed lung cancer (LC) after 7 years survival follow up (SFU) period.

Methods: During the period January 2014 to May 2015 patients with LC were rated themselves on Hospital Anxiety Depression Scale (HADS). Subjects with history of psychiatric disorders and/or undergone curative surgical procedure were excluded from the study. Last SFU was done on February 28th 2023.

Results: Out of 298 screened patients 206 were included in SFU. Majority of included subjects were male 156 (75.7%), ECOPG PS 1 153 (74.3%), smokers 120 (58.3%) in Stage III 88 (42.7%) and IV 85 (41.3%) with diagnosed lung adenocarcinoma 95 (46.1%) followed by sqamouse cell LC 79 (38.3%) and SCLC 28 (13.6%). Psychiatric disorder was verified in 81 (39.3%) subjects. Out of those depression was found in 35 (43.2%) anxiety in 7 (8.6%) and combined anxiety and depression in 39 (48.2%) subjects. One-year survival was 66,5%, 3-year 26,2%, 5- year 14.1% and 7-year 8.7%. Difference in survival rate was observed between subjects with and without disorders in 1-, 3-, 5- and 7-years survival rate (61.7% vs. 69.6%; 19.8% vs. 30.4%; 11.1% vs. 16.0% and 4.9% vs. 11.2% respectively). Statistically significant difference was found in survival time between subjects with and without psychiatric disorders (25.9 vs. 49.5 Months; p=0.046). The lowest survival time was observed in group with combined anxiety and depression (21.2 Months) followed by only depression or anxiety (30.3 Months) in comparison with subjects without disorders (49.5 Months) (p=0.033).

Conclusions: Based on the results of this research, psychiatric disorders are highly prevalent and also affect the survival time of patients with LC. Despite the evidences psychological aspect is still neglected in patients with diagnosed malignancies. Easy-to-use tools for determination of anxiety and depression such as HADS should be applied regularly in clinical practice in order to recognize those disorders and to introduce adequate treatment.

2068P Perspectives and concerns on sexuality among adolescents and young adults treated for testicular germ cell tumour: The PRICELESS-study - A qualitative study

D. Zweers

Medical Oncology/Julius Center, UMC-University Medical Center Utrecht, Utrecht, Netherlands

Background: Sexual dysfunction is a frequently seen late effect in patients treated for testicular germ cell tumour (TGCT). Therefore, monitoring of sexual dysfunction is essential. The Utrecht Symptom Diary (USD) helps monitoring cancer symptoms, but items regarding sexuality are missing. Adding these symptoms may provide a better tailored tool, enhance monitoring of late effects on sexuality, and might help to address this topic. Therefore, the aim of this study was to explore perspectives and concerns on late effects regarding sexuality among adolescents and young adults (AYAs) being treated for TGCT to adapt the USD to make it suitable for follow-up care for these patients.

Methods: Individual, semi-structured interviews were conducted with thirteen AYAs from one centre of expertise for TGCT in the Netherlands. Patients were purposively sampled and using maximum variation. Data was analysed using Braun and Clark's thematic analysis.

Results: Interviews revealed seven overarching themes which interact and overlap: fulfilment to have children, rediscover sexuality, insecurity about sexual performance, acceptance of physical change, loss of masculinity, burden on relationship, and need to talk about sexuality. Concerns related to the fulfilment to have children seems to play a major role.

Conclusions: Results help to better understand these men's thoughts and experiences related to late effects regarding sexuality and gives healthcare professionals the opportunity to act on these topics by discussing it in the consulting room. Partner involvement seems beneficial.

2069P QoL changes of caregivers during first-line palliative chemotherapy for patients with incurable cancer

N. Takeuchi, S. Kurosawa

Medical Oncology, Ina Central Hospital, Ina, Japan

Background: We previously reported the impairment of quality of life (QOL) of caregivers of patients with cancer (ann. oncol. 2019, vol.30 supple 9, IX142). A multifaceted longitudinal survey is warranted to establish a valid support system.

Methods: This single-institution prospective cohort study was conducted with the approval of the ethical committee of Ina Central Hospital. 48 pairs of patients with incurable cancer and their caregivers filled out questionnaires according to the Japanese version of EORTC QLQ C-30 before the initial session of the first and the second-line treatment. Patients: 31 men and 17 women with an average age of 68.3±10.6 years. Caregivers: 17 men and 31 women with an average age of 63.5±11.6 years. Primary sites of cancer: gastrointestinal system in 41 patients, lung in 4, head and soft tissue in 2 and neck in 1. Average duration of treatment: 228 ± 171 days, median 161 days. The influence of the treatment outcome ("responder with RECIST PR and CR" or "non-responder with SD and PD") and duration ("shorter than 161 days" or "longer") on the scales were investigated statistically.

Results: All the nine symptomatic scales of EORTC QLQ-C30 were positive in around 20% in caregivers before treatment. After treatment, fatigue (88%), pain (42%), and financial concerns (43%) scales changed more frequently. The emotional function (EF) and cognitive function (CF) scales showed no significant differences in patients and caregivers before and after treatment, unlike other comprehensive scales. The scale declined in 38% of caregivers in physical function, 15% in role function, 33% in emotional function, 28% in cognitive function, 33% in social function, 29% in global health, and 42% in summary score. EF and CF decreased by almost the same proportion in patients and caregivers. The duration and outcome of treatment did not have a correlation with changes in the scales of caregivers.

Conclusions: Consistent insufficiency of emotional and cognitive function in caregivers, similar to that in patients, was revealed throughout the treatment. The outcome and duration of treatment did not affect the caregivers' mental condition. Caregivers of patients with cancer require emotional and cognitive function support throughout the patients' treatment.

2070P Assessment of healthy lifestyle habits in breast cancer patients

J.C. Sanchez[1], B. Cantos[1], M. Mendez Garcia[1], B. Nunez Garcia[1], M. Blanco Clemente[1], C. Parejo[2], M. Campos[3], B. Rodriguez Morilla[3], P.F. Almaida Pagan[3], S.C. González González[1], C. Traseira Puchol[1], M. Martinez Cutillas[1], R. Aguado[1], Y. Garitaonaindía Díaz[1], A. González Sánchez[1], D.I. Ruiz de Domingo[1], M.M. Sánchez del Corral[1], I. Redondo[1], M. Torrente[1], M. Provencio Pulla[1]

[1]Medical Oncology Department, Hospital Puerta de Hierro-Majadahonda, Majadahonda, Spain; [2]Medical Oncology Department, Fundacion para la Investigacion Biomedica del Hospital Universitario Puerta de Hierro Majadahonda, Majadahonda, Spain; [3]Computer Science, UM - University of Murcia, Murcia, Spain

Background: Healthy lifestyle habits such as avoiding overweight, engaging in moderate physical activity for at least 150 minutes per week, and getting good quality sleep have not only been shown to decrease the incidence of certain cancers, but also have a clear impact on the outcome of patients diagnosed with breast cancer. Adherence to these recommendations has an impact on quality of life, and some studies suggest their beneficial effect on patient survival.

Methods: We included 181 patients diagnosed with breast cancer in different stages, Multivariable ambulatory circadian monitoring of skin temperature, motor activity, light exposure, and sleep patterns was performed for 7 consecutive days through a small watch-like device called Kronowise 3.0. The patients are divided into 3 groups: group 1 includes metastatic patients, group 2 consists of patients with early-stage breast cancer undergoing chemotherapy, and group 3 comprises patients with early-stage breast cancer under follow-up (more than 1 year after the completion of chemotherapy).

Results: The table describes the mean age with standard deviation, physical activity categorized as patients who achieve $\geq$ 150 minutes of moderate physical activity (MPA) per week, $\geq$ 300 minutes of moderate physical activity per week, $\geq$ 75 minutes of vigorous physical activity per week, patients with good sleep hygiene (between 7 and 9 hours of sleep per day), patients with $<$ 10 hours of sedentary behavior, and the percentage of patients with overweight and obesity in each group.

Conclusions: Despite breast cancer patients not being sedentary and having higher levels of moderate physical activity compared to the general population, the occurrence of vigorous physical activity is quite low among these patients. It is imperative to establish proper sleep hygiene in these patients in order to improve parameters and reduce the rates of overweight and obesity, particularly among the metastatic population and long-term survivors, where these rates are significantly higher.

2071P Identification of top issues and concerns of cancer patients in Korea on social media

J.H. Lim[1], D. Kim[2], I-H. Kim[3], S.E. Park[4], I. Kim[5], H.W. Lee[6], S-C. Lee[7], W. Choi[8], S.J. Huh[9], H. Kim[10]

[1]Department of Internal Medicine, Inha University Hospital, Incheon, Republic of Korea; [2]Division of Hematology & Medical Oncology, Department of Internal Medicine, Dongguk University Ilsan Hospital, Goyang, Republic of Korea; [3]Division of Medical Oncology, Department of Internal Medicine, Seoul St. Mary's Hospital, College of Medicine, The Catholic University of Korea, Seoul, Republic of Korea; [4]Department of Internal Medicine, Chung-Ang University Hospital, Seoul, Republic of Korea; [5]Division of Oncology, Department of Internal Medicine, Haeundae Paik Hospital, Inje University College of Medicine, Busan, Republic of Korea; [6]Dept. of Hematology-Oncology, Ajou University School of Medicine, Suwon, Republic of Korea; [7]Division of Hematology-Oncology, Department of Internal Medicine, Soon Chun Hyang University Hospital, Cheonan, Republic of Korea; [8]Medical Oncology, NCC - National Cancer Center, Goyang, Republic of Korea; [9]Division of Hematology and Oncology, Department of Internal Medicine, Dong-A University Hospital, Dong-A University College of Medicine, Busan, Republic of Korea; [10]Department of Internal Medicine, The Catholic University of Korea - St. Vincent's Hospital, Suwon, Republic of Korea

Background: The objective of this study is to identify the major issues and concerns of cancer patients in Korea related to cancer, anti-cancer therapy, and patient care that are mentioned on social media.

Methods: We collected data from open-access forums, blogs, and social networking sites using professional ISO 20252 certified online access tools. We searched the terms "cancer", "cancer treatment", and "patient care" and collected social media posts between October 2021 and September 2022, excluding spam and advertisements.

Results: Total 169,575 social media posts were collected. Among the posts, 51% were related to cancer symptoms, concerns following diagnosis, and cancer etiology, while 39% discussed treatment methods, treatment-related side effects, novel therapies, as well as costs. The remaining posts centered on how to manage in daily life. The most frequently mentioned cancer types were breast, lung, colorectal, stomach, and liver cancer, consistent with common cancers in Korea. Concerning the difficulties experienced, 52% reported physical challenges, 42% reported emotional challenges, and 6% discussed daily life issues, such as diet and sexual relationships. Additionally, patients had high expectations for immune checkpoint inhibitors. Patients tend to view clinical trial participation as an alternative when conventional treatments are ineffective and see it positively as a way to participate without financial burden. However, some express safety concerns. Patients frequently shared tips for managing daily life on social media, such as healthy eating, taking supplements, and light exercise to maintain physical strength.

Conclusions: Our findings suggest that cancer patients in Korea frequently use social media for information. The high frequency of emotional difficulties mentioned indicates that patients face persistent emotional challenges throughout the cancer journey. This study underscores the potential benefits of analyzing social media posts by cancer patients, providing valuable insights for healthcare professionals and patients. Moreover, it emphasizes the importance of the developing and delivering professional information on daily life management for cancer patients.

2072P Topical application of mixed agents to reduce oral mucositis during radiotherapy in post operated head and neck cancer

C. Prakash, A. Pandey, I. Jaiswal, H. Mishra, R. Mishra, P. Jain

Department of Radiotherapy and Radiation Medicine, Institute of Medical Sciences, Varanasi, India

Background: Oral mucositis is a debilitating condition seen in head and neck cancer(HNC) patients treated by radiotherapy(RT). The aim of study was to evaluate the response of combined new oral agents as local applicant to prevent mucositisand to record the change in mucositis grading during and after RT.

Methods: Sixty threepatients of post-operative HNC planned for adjuvantRT were randomized to treat mucositis by soda bicarbonate gargles only (Control arm: n=30) 4-5 times a day or soda bicarbonate gargle along with new agent comprised of five drugs (ORA-5GEL): one tablespoon each of honey, choline salicylate ointment(8.7w/w), and lignocaine ointment(2%w/w), one tablet of fluconazole 150mg and metronidazole 400mg were mixed to form a paste and applied intraorally starting from 2nd week of RT (Study arm:n=33).

Results: Severity of mucositis was found to be either stable or in downgrading trend after the application of the ORA-5 gel. None of the patients had grade3 mucositis in study arm compared to 15 patients in control arm. Grade 1 mucositis was seen in 64% and 97% of patients at the end of week 3 that progressed to grade 2 in 27% and 70% patients study and control arm, respectively, by the end of 4thweek ($p<0.001$). On univariate analysis, factors associated with higher mucositis grading were: high disease burden (Stage IV), conventional RT technique and concurrent chemotherapy. In study arm reversible trend of grading was observed in this subset of patients also. With the continuous use of soda bicarbonate gargle and symptomatic treatment, the frequency of grade 3 mucositis in control arm decreased, however, there was significant difference in grading in both the groups till week 7($p<0.001$). By the end of the treatment, none of the patients in control arm had grade 0 mucositis compared to 73% in study arm.

Conclusions: ORA-5 GEL effectively acts on all stages of mucositis and prevents not only severity and progression in all patients but also shows reversible grading during RT.

2073P Medical cannabis: A potential effective treatment for chemotherapy-induced peripheral neuropathy (CIPN)

R. Geva[1], L. Bar-Lev Schleider[2], L. Lavi Kutchuk[1], S. Barilier[1], T. Schaffer[1], S. Pelles-Avraham[1], I. Wolf[1]

[1]Oncology Division, Tel Aviv Sourasky Medical Center-(Ichilov), Tel Aviv, Israel; [2]Reaserch, Tikun Olam, Tel-Aviv, Israel

Background: Medical cannabis is extensively used by Israeli cancer patients, mostly in the form of natural extracts. We've previously shown that cannabis can alleviate symptoms of Oxaliplatin induced CIPN. Yet, it is still unknown which cannabis component, either tetrahydrocannabinol (THC) or cannabidiol (CBD) contribute to this effect and at which dose.

Methods: A database of 5,063 medical records consecutive patients of medical cannabis clinic ('Tikun Olam') was reviewed. 802 patients reported CIPN related symptoms and 751 met inclusion criteria were included in the analysis. Data included questionnaires regarding Patient Reported Outcome (PROM), Activities of Daily Living (ADL) and Quality of Life (QOL) filled before and six months after cannabis use. Four CIPN symptoms were observed. Improvement was defined as positive change from baseline score. Two patients' clusters were identified using k-mean clustering method to study the association between THC, CBD and change in symptoms, ADL and QOL: CBDhigh/ THClow and THChigh/ CBDlow doses.

Results: Symptoms frequency before cannabis use: paresthesia (549pts, 73%), burning sensation (358pts, 48%), numbness (235pts, 31%) and cold sensation (146pts, 19%). After cannabis use improvement reported in paresthesia (320pts, 58%), burning sensation (217pts, 60%), numbness (112pts, 47%) and cold sensation (67pts, 45%). Burning and cold sensation improvement was 37% and 15% in THChigh compare to 27% and 8% in CBDhigh cluster ($p=0.02$ and $p=0.008$, respectively). ADL and QOL change were higher in THChigh cluster ($p=0.03$ and $p=0.006$, respectively).

Conclusions: The use of natural extracts of cannabis can effectively alleviate CIPN symptoms and improve both QOL and ADL with suggested advantage to high THC levels. Further analysis is required to better correlate specific symptoms to specific components.

2074P Oral cannabidiol for prevention of chemotherapy-induced peripheral neuropathy

S.W. Nielsen[1], S. Dyring Hasselsteen[2], H. Sylow Dominiak[2], D. Labudovic[2], J. Herrstedt[3]

[1]Klinisk Onkologisk Afdeling og palliative enheder, Sjællands Universitets Hospital, Naestved, Denmark; [2]Department of Clinical Oncology and Palliative Care, University Hospital Sjællands Roskilde, Roskilde, Denmark; [3]Clinical Oncology Department, ZUH - Zealand University Hospital Roskilde - Region Sjaelland, Roskilde, Denmark

Background: Chemotherapy-induced peripheral neuropathy (CIPN) is experienced by 37−84% of patients during and/or after end-of-treatment and often results in discontinuation of anti-neoplastic treatment and impairment of health-related quality of life. Cannabidiol (CBD) has shown preventive effects in CIPN animal models without compromising chemotherapy efficacy.

Methods: Patients with cancer referred for adjuvant treatment with capecitabine and oxaliplatin (CAPOX) or carboplatin and paclitaxel (Carbo-Tax) were recruited to participate in the CINCAN-2 study. CBD oil was self-administered two times daily (300 mg daily oral dose) for 8 days total at each cycle of chemotherapy, beginning 24 hours before start of chemotherapy. Patient reported outcomes (EORTC-CIPN20) were captured before start of chemotherapy and at follow-up until one year after end-of-chemotherapy. Vibration Perception Thresholds (VPTs) were collected at 32, 125 and 250Hz on patient dominant hand and at 8, 32, and 125Hz on the patient dominant foot. Controls were obtained from a similar cohort (CINCAN-1) receiving the same chemotherapy regimens, but no CBD.

Results: From March to December 2021, 54 out of 65 eligible patients were recruited. CINCAN-2 patients were significantly older (median age 64 vs 57 years, $p=0.004$) compared to the CINCAN-1 cohort. Patients treated with CBD showed significantly better VPT scores than patients not receiving CBD at 3, 6 and 12 months follow-up. The largest VTP difference was found in patients treated with Carbo-Tax and CBD at 32Hz in metatarsal V at 12 months with -1.86 Z-score, CI-95=[-3.16;-0.49] compared to patients who did not receive CBD. Patients treated with CAPOX and CBD scored significantly better in PRO scores at 3 and 6 month follow-up (-6.75 [-11.54;-1.98] and -9.25 [-13.91;-4.58] points respectively compared to patients treated with CAPOX only. No difference in PRO scores was observed for patients treated with Carbo-Tax. Patients receiving Carbo-Tax and CBD received significantly higher cumulative doses of paclitaxel (1737mg vs 1194mg, $p=0.027$) compared to patients receiving Carbo-Tax only.

Conclusions: Patients treated CBD showed better long term PRO and VPT outcomes than controls. A randomized trial is warranted.

Clinical trial identification: NCT04582591.

Third Hospital of Nanchang, Nanchang, China; [19]Clinical Medicine Department, Mabwell (Shanghai) Bioscience Co., Ltd., Shanghai, China

Background: MW05 is a novel, long-acting recombinant human granulocyte-colony stimulating factor, which is produced by fusion of N terminal of highly active modified G-CSF with C terminal of human serum albumin(HSA). We report results from a randomized, double-blind, phase III study comparing the efficacy and safety of MW05 to approved PEG-rhG-CSF(Jinyouli®) for preventing chemotherapy-induced neutropenia.

Methods: Patients with breast cancer were randomized 2:1 to receive MW05 or PEG-rhG-CSF after standard docetaxel plus cyclophosphamide with/without doxorubicin chemotherapy for 4 cycles. The primary objective was to evaluate the non-inferiority of MW05 to standard PEG-rhG-CSF in duration of severe neutropenia (DSN; Grade 4) in cycle 1.

Results: Eligible patients were randomized to the groups(MW05, n=328; PEG-rhG-CSF, n=164). In cycle 1, the mean DSN was 0.24 days for MW05 and 0.25 days for PEG-rhG-CSF, and the mean difference of DSN[−0.02(95%CI: -0.12, 0.08)days] met the primary endpoint of non-inferiority. In cycle 2-4, the results of DSN were consistent with cycle 1. The incidence of Grade 4 neutropenia in MW05 group was lower than that in PEG-rhG-CSF group, representing 16.5%, 3.0%, 2.7%, 3.4% for MW05 and 19.5%, 9.8%, 6.7%, 6.1% for PEG-rhG-CSF in chemotherapy cycle 1-4 respectively. The incidence of febrile neutropenia(FN) across all cycles was numerically low and not significantly different between two groups, with 7 patients (2.1%) in MW05 group and 6 patients (3.7%) in PEG-rhG-CSF group. Other efficacy endpoints and adverse events results were comparable between two groups. There was 1 death during the study, which was not related to study drug treatment.

Conclusions: These results demonstrate non-inferiority and comparable safety for MW05 versus PEG-rhG-CSF. As a novel, long-acting rhG-CSF modified with HSA, MW05 can effectively shorten DSN induced by chemotherapy and may reduce the incidence of FN and severe neutropenia.

2076P Topical diclofenac for prevention of HFS in patients receiving capecitabine monotherapy: An exploratory subgroup analysis of the D-ToRCH phase III trial

A. Santhosh[1], A. Batra[1], A. Sharma[2], A. Kumar[1], R. Pramanik[1], A. Gogia[3]

[1]Medical Oncology Dept, AIIMS - All India Institute of Medical Sciences, New Delhi, India; [2]Medical Oncology, Pfizer - India, Mumbai, India; [3]Medical Oncology Dept., Institute Rotary Cancer Hospital, New Delhi, India

Background: Hand foot syndrome is a distinct side effect associated with capecitabine. Celecoxib, a cyclooxygenase (COX 2) inhibitor is the only drug effective in randomized trials. However, its use in clinics has declined due to concerns regarding cardiac safety. In our trial, we describe the use of topical diclofenac for prevention of HFS in patients receiving capecitabine monotherapy.

Methods: The D torch trial randomized 264 patients with breast or GI cancers receiving capecitabine to apply either 1% topical diclofenac or placebo gel. Stratified permuted variable size block randomization was done using a computer-generated random numbers sequence. The primary objective was to compare the incidence of grade 2 or higher HFS in diclofenac and placebo arms. Secondary objectives were incidence of any grade HFS, capecitabine dose reduction due to HFS and adherence with application. Here, we report the results of the monotherapy subgroup.

Results: 108 out of 264 patients received capecitabine monotherapy (56 in diclofenac arm and 52 in placebo arm). Baseline characteristics were well matched in both arms. The study group's median age was 47 years (IQR 39.5-57.5). Majority were females (n=101, 93.5%). 67 patients (62%) had an ECOG performance status of 0-1, while the rest were PS 2. 95 patients (87.9%) had carcinoma breast and the remaining 13 patients had various gastrointestinal cancers. 63 patients (58.9%) and 41 patients (38.3%) had stage 3 and 4 disease respectively, whereas only 3 patients (2.8%) had stage 2 cancer. Overall, 12 patients developed grade 2 or higher hand foot syndrome, of which 2 were in diclofenac group and 10 were in placebo group (3.6% vs 19.2%, p=0.01). Any grade HFS was seen in 3 patients (5.4%) in diclofenac arm and 12 patients (23%) in placebo arm (p=0.008). Dose reductions of capecitabine were less frequent in the diclofenac arm compared to placebo (3.6% vs 19.2% p=0.01). Adherence to topical treatment was more in the diclofenac group compared to placebo (93.2% vs 82.2%, p=0.04).

Conclusions: Topical diclofenac gel significantly reduced the incidence of HFS in patients receiving capecitabine monotherapy. Topical diclofenac gel application led to less frequent dose reductions of capecitabine.

2077P A randomized, placebo-controlled trial assessing the efficacy and safety of the combination of superoxide dismutase, alpha lipoic acid, vitamin B12, B1, B2, B6, E, Mg, Zn and a fatty acid for 6 months in the management of chemotherapy induced neuropathic pain

T. Didangelos, E. Chamalidou, E. Karlafti, Z. Kontoninas, C. Savopoulos

1st Propedeutic Department of Internal Medicine, ''AHEPA'' Hospital, Aristotle University of Thessaloniki, Thessaloniki, Greece

Background: To investigate the efficacy of Superoxide Dismutase (SOD, 70 UI), Palmitoyethanolamide (PEA, 300 mg) Alpha Lipoic Acid (ALA, 300 mg),vitamins B6 (1.5 mg), B1 (1.1 mg), B12(2.5 mcg), E (7.5 mg), Nicotinamide (9 mg) and minerals (Mg 30 mg, Zn 2,5 mg) in one tablet in managing neuropathic pain due to cancer chemotherapy.

Methods: In this pilot study, 67 age-matched patients with cancer (41 men) and a mean age of 65.4 years were randomly assigned, either to receive the combination of ten elements (2 tablets/24h) in the active A group, (n=33), or the placebo B (n=34) for six months. Nerve function was assessed by DPN Check [sural nerve conduction velocity (SNCV) and amplitude (SNAP)]. Sudomotor function was evaluated with SUDOSCAN, which measures electRochemical skin conductance in hands and feet (ESCH and ESCF). We used Pain questionnaires: Pain Detect (PD), Neuropathic Pain Symptom Inventory (NPSI), and Visual Analog Scale (VAS) for the estimation of neuropathic pain, also. All patients received Taxanes and platinum analogs as cancer chemotherapy.

Results: At follow-up, measurements from SNCV, SNAP, ESCH and ESCF did not change significantly in both groups. In A group PD baseline vs. final (9.57±7.0 vs. 6.78±4.16, p=0.003), NPSI (28.51±21.26 vs. 19.87±12.6, p<0.001) and VAS (27.78±22.40 vs 21.48±17.79, p=0.003) improved significantly during follow up. In group B PD (7.03±5.19 vs. 9.71±6.61 p<0.001), NPSI (23.50±18.99 vs. 36.25±22.15, p<0.001), and VAS (25.03±23.83 vs 38.75±26.60 p<0.001) deteriorated. No side effects detected.

Conclusions: The combination of the ten elements as supplement in one tablet for six months at a daily dose of two pills in patients improved neuropathic pain due to cancer chemotherapy.

2078P Evaluation of chemotherapy-induced nausea and vomiting beyond the delayed phase: Results of a survey of healthcare providers in Japan

F. Scotté[1], M.S. Aapro[2], C.H. Ruhlmann[3], Y. Takeuchi[4]

[1]Interdisciplinary Cancer Course Department, Institut Gustave Roussy, Villejuif, France; [2]Genolier Cancer Center, Clinique de Genolier, Genolier, Switzerland; [3]Department of Oncology, OUH - Odense University Hospital, Odense, Denmark; [4]Marketing Insight Division, INTAGE Healthcare Inc., Tokyo, Japan

Background: Chemotherapy-induced nausea and vomiting (CINV) occurs in two arbitrarily defined phases: the acute phase (from 0 to 24 h following chemotherapy (CT) initiation) and the delayed phase (from 24 to 120 h). Almost all antiemetic studies have therefore evaluated efficacy to 120 h after the administration of CT, and the period beyond 120 h is generally perceived to be relatively free of CINV, with some studies reporting continued nausea beyond the delayed phase.

Methods: In July and September of 2022, healthcare providers (HCPs) in Japan were recruited to complete an online quantitative survey. All HCPs were required to work with patients receiving anticancer CT in the hospital setting and have experience selecting, preparing and/or administering antiemetics. As part of this survey responses were collected on whether HCPs had patients who experienced nausea/vomiting (CINV) during Days 5-7 (beyond the delayed phase) after initiation of CT. Responses were also captured by CT regimen; for the physician subset, respondents were grouped by and analyzed only if they were prescribers of the chemotherapy type.

Results: A total of 809 HCPs (174 pharmacists, 102 nurses and 533 physicians) completed the survey. The physician group was comprised of breast surgeons (n = 57), pulmonologists (n = 107), gastroenterologists (n = 74), GI surgeons (89), gynecologists (n = 98), ENTs (n = 54), and oncologists (n = 54). The vast majority of

respondents (98%, 93%, and 88% of pharmacists, nurses, and physicians, respectively) indicated they had patients who experienced CINV 5-7 days after CT. Of the HCPs reporting patients with CINV on Days 5-7, the highest proportions were seen for cisplatin, AC and EC chemotherapy regimens (Table).

Table: 2078P Proportions of respondents with patients experiencing CINV on days 5-7 by chemotherapy regimen

CT Regimen	Pharmacists	Nurses	Physician Prescribers
Cisplatin	78%	71%	80%
Epirubicin/cyclophosphamide (EC)	50%	43%	43%
Anthracycline/cyclophosphamide (AC)	44%	45%	42%
Carboplatin	37%	43%	48%
Irinotecan	41%	37%	37%
Oxaliplatin	36%	32%	28%

Conclusions: This survey highlights a need for continued assessment of CINV beyond the delayed phase after CT to better understand the incidence and to optimize prevention of CINV for the entire period of risk.

2079P Naloxegol for the treatment of opioid-induced constipation in patients with cancer pain: A pooled analysis of real-world studies (NALOPOOL)

M.D.C. Beato Zambrano[1], A. Lemaire[2], V. Montesarchio[3], J-M. Sabate[4], J. Serna i Mont-Ros[5], R. Namane[6], S. Martín Baccarelli[7], F. Rico-Villademoros[8], M. Cobo[9]

[1]*Oncología Médica, Hospital Universitario de Jerez, Jerez de la Frontera, Spain;* [2]*Oncology and Medical Specialties Department, Valenciennes General Hospital, Valenciennes, France;* [3]*Pneumology and Oncology, Monaldi Hospital, Naples, Italy;* [4]*Gastroenterology and Digestive Oncology, Hopital Avicenne AP-HP, Bobigny, France;* [5]*Oncology, Hospital Universitari Campus Vall d'Hebron, Barcelona, Spain;* [6]*Medical Affairs, Kyowa Kirin Pharma SAS, Neuilly-sur-Seine, France;* [7]*Statistics, Apices Soluciones S.L., Pinto, Spain;* [8]*Medical, Apices Soluciones S.L., Pinto, Spain;* [9]*Medical Oncology, IBIMA - Instituto de Investigaciones Biomédicas de Málaga - Hospitales Universitarios Regional y Virgen de la Victoria de Málaga, Malaga, Spain*

Background: We aimed to evaluate the efficacy and safety of naloxegol for opioid-induced constipation (OIC) in cancer patients in a real-life setting.

Methods: We pooled individual patient data from three multicenter observational studies conducted with naloxegol in cancer population. Efficacy outcomes included: response rate at week 4 ($\geq$3 spontaneous bowel movements [SBM] per week and an increase of $\geq$1 from baseline); clinically relevant improvement (>0.5 points) in the Patient Assessment of Constipation Quality of Life Questionnaire (PAC-QOL) and in the Patient Assessment of Constipation Symptoms (PAC-SYM); and clinically relevant improvement in the Bowel Function Index (BFI $\geq$ 12 points at the endpoint). All analyses were performed using a visitwise approach. Homogeneity was assessed with Cochran's Q test.

Results: 393/427 patients were included in the pooled efficacy/safety analyses, with a median age of 64 years and a slight predominance of males (53%). Lung (25%), breast (18%), prostate (9%) and head & neck (6%) were the most common tumor locations. 66% of the patients had metastases, and 53% were receiving chemotherapy. The most common opioids were fentanyl (43%), oxycodone (39%) and morphine (28%), with a median treatment duration of 8.9 weeks. Most patients (83%) received an initial dose of naloxegol of 25 mg and 86% were receiving laxatives at baseline. Efficacy outcomes are presented in the table. Twenty-six (6%) of the 427 patients discontinued treatment due to adverse reactions and 3 (0.7%) patients reported serious adverse reactions.

Table: 2079P Summary of efficacy results

	Kyonal	Move	Nacasy	Pooled	Cochran's Q (p-value)
SBM response rate	94/126 (75%)	58/79 (73%)	71/109 (65%)	223/314 (71%) [95%CI 66-76]	2.75 (0.250)
Responders in QoL (PAC-QOL)	69/113 (61%)	44/75 (59%)	66/111 (60%)	179/299 (60%) [95%CI 54-66]	0.12 (0.940)
Responders in constipation symptoms (PAC-SYM)	79/115 (69%)	52/75 (69%)	NR	131/190 (69%) [95%CI 62-76]	0.01 (0.930)
Responders in constipation symptoms (BFI)	NR	58/79 (73%)	75/116 (65%)	133/195 (68%) [95%CI 62-75]	1.70 (0.190)

Conclusions: Treatment with naloxegol for the OIC in patients with cancer pain in the real-world setting resulted in a high proportion of responders in the SBM and consistently relevant improvements in the quality of life and constipation symptoms. Naloxegol was well tolerated and safe.

2080P Incidence and risks of intravenous chemotherapy-induced neutropenia (ICIN) in oncology: A multicenter retrospective cohort study on real-life data

O. Rohr[1], S. Priou[2], G. Lamé[2], G. Chatelier[3], S. Babai[4], S. Gallien[5], R. Flicoteaux[6], C. Tournigand[1], E. Kempf[1]

[1]*Department of Medical Oncology, Centre Hospitalier Universitaire Henri-Mondor Assistance Publique - Hopitaux de Paris, Creteil, France;* [2]*Industrial Engineering Research Department, CentraleSupélec - Paris-Saclay Campus, Gif sur Yvette, France;* [3]*Department of Medical Informatics, Assistance Publique Hôpitaux de Paris, Centre-Université de Paris, Paris, France;* [4]*Department of Pharmacovigilance, Assistance Publique - Hopitaux de Paris, Paris, France;* [5]*Department of Infectious Diseases, Centre Hospitalier Universitaire Henri-Mondor Assistance Publique - Hopitaux de Paris, Creteil, France;* [6]*Department of Medical Information, Assistance Publique - Hopitaux de Paris, Paris, France*

Background: ICIN is a major cause of death in cancer patients (pts). We aimed at identifying incidence of ICIN and predictors of poor prognosis in oncology.

Methods: We designed a multicenter retrospective cohort study on the Greater Paris University Hospitals' (APHP) clinical data warehouse. We included all adult pts with solid cancer hospitalized between January 2016 and December 2021 at APHP with an ICD-10 cancer code, with chemotherapy (chemo) within 30 days prior to the 1st ICIN (defined by the D70 or D611 ICD-10 codes AND a neutrophil count < 500/mm3). The primary outcome was the composite of Intensive Care Unit (ICU) hospitalization or death within 30 days. We collected cancer and chemo characteristics, use of G-CSF, Charlson score items and standard biological values.

Results: Among 141,586 cancer pts, 40,660 received chemo among whom 661 (1.6%) had ICIN. Their median age was 63 years (Interquartile Range (IQR) 54-70) and 330 (50%) were female. The median Charlson score was 10 (IQR 8-11). Documented bacterial or fungal infections were observed in 113 (17%) and 19 (3%) pts, respectively. Main primary cancers were lung (n= 204, 31%) and breast (n=87, 13%). Advanced cancers were present in 551 (83%) pts. The last chemo included platinum in 375 (57%) pts, 331 (50%) were in their 1st line of chemo and 284 (43%) in their 1st cycle of the current line, 149 (23%) had primary prophylactic G-CSF, 27 (4%) had a concomitant SarsCov2 infection. Primary outcome occurred in 120/661 (18%) pts: 57 (9%) were transferred to intensive care and 82 (12%) died within 30 days. After ICIN, 372 (56%) pts received subsequent chemo and 486 (74%) were able to return home. In a multivariate Cox model, higher monocyte count (HR 0.07; 95%CI 0.01-0.44) and albumin nadir (HR 0.93; 95%CI 0.91-0.96) decreased ICU hospitalization risk or death whereas both bacterial (HR 2.12; 95%CI 1.40-3.31) or fungal infection (HR 1.93; 95%CI 1.40-3.31) and concomitant Sars Cov2 infection (HR 2.93; 95%CI 1.41-6.33) increased

it. Charlson index (HR: 1.00; 95%CI 0.91-1.10) and primary prophylactic G-CSF (HR 0.83; 95%CI 0.52-1.32) had no prognostic value.

Conclusions: Despite the use of primary prophylactic G-CSF, ICIN is an early event which leads to major complications.

2081P The therapeutic effect of anti-inflammatory tripeptide cream on hand-foot syndrome related to anticancer drugs: A prospective, randomized, placebo-controlled pilot trial

Y. Yang[1], J-H. Han[2], M.S. Kim[2], H. Kim[1], H.K. Kim[1], K.H. Lee[1], H.S. Han[1]

[1]Department of Internal Medicine, Chungbuk National University Hospital, Cheongju, Republic of Korea; [2]Department of Anatomy and Cell Biology, Kangwon National University Hospital, Gumi-si, Republic of Korea

Background: Hand-foot syndrome (HFS) is a relatively common side effect that often interferes with the quality of life (QoL) in cancer patients. Anti-inflammatory tripeptide cream (ATPC) is a complex formulation of anti-inflammatory tripeptides, CD99 agonist Binterin™ and Wnt antagonist Winhibin™. In the present study, we aimed to assess the therapeutic effects of ATPC on HFS associated with anticancer drugs.

Methods: This study was conducted as a single-center, prospective, randomized, placebo-controlled trial. Patients who developed grade 1 HFS by the National Cancer Institute Common Terminology Criteria for Adverse Events or World Health Organization after treatment with cytotoxic chemotherapeutic agents or multi-kinase inhibitors were enrolled. Patients were randomly assigned to receive ATPC or placebo cream (PC) and followed up with 3-weeks interval for up to 9 weeks. Primary endpoint was the development of grade $\geq$2 HFS. Secondary endpoints were QoL score assessed by Hand-Foot Skin Reaction and QoL (HF-QoL) questionnaire and the frequency of dose reduction or discontinuation of anticancer drugs related to HFS.

Results: From April 2019 to July 2022, 68 patients were randomized and 60 patients (31 in the ATPC group and 29 in the PC group) completed the study. The incidence of grade $\geq$2 HFS was significantly lower in the ATPC group than in the PC group (25.8% vs. 51.7%, P=0.039). The ATPC group showed trends towards a better HF-QoL score than at 9 weeks (26.0 vs. 29.9, P=0.574) and a lower frequency of discontinuation, interruption, or dose reduction of anticancer drugs (51.6% vs. 58.6%, P=0.586) than the PC group without statistical significance.

Conclusions: Our results showed that ATPC significantly decreased the development of grade $\geq$2 HFS in patients with HFS related to anticancer drugs. Therefore, ATPC can be effective treatment for HFS related to anticancer drugs. Further prospective large-scale randomized controlled trial is required to confirm the efficacy of ATPC in cancer patients with HFS.

Background: Medical cannabis (MC) has garnered significant attention as a potential strategy for cancer care. Attitudes and beliefs of medical professionals regarding its efficacy and safety remain diverse and inconclusive. This survey explores medical professionals' knowledge, attitudes, and barriers towards MC for cancer care. It aims to understand their beliefs on efficacy and safety, benefits and risks, and identify barriers to its use.

Methods: 175 medical professionals worldwide completed a 31-item survey that included demographics, knowledge and attitudes towards MC, perceived benefits and risks, and willingness to recommend MC to patients. Data analysis involved descriptive statistics and Chi-square tests.

Results: The survey included respondents with a balanced male-to-female ratio and a median age of 37 years from 31 countries, with 120 from upper-middle-income countries (UMIC) and 55 from lower-middle-income countries (LMIC). Findings revealed that 44% of respondents were familiar with MC, and 51% claimed to have received information about it from patients, with 35% receiving direct prescription requests. Surprisingly, only 16% had prescribed MC for symptoms such as CINV, pain, anorexia, cachexia, psychiatric symptoms, insomnia, muscle spasms. There were no significant associations between knowledge levels or patient prescription requirements and income level, but a significant association was found between drug prescription and UMICs. ($p = 0.003$). Notably, only 9% of participants were knowledgeable about their country's MC legislation, although most believed that legislative and social stigma posed significant barriers to its use.

Conclusions: The survey revealed significant variations in the knowledge and attitudes of medical oncologists towards MC in cancer care. Geographic differences were also observed, with professionals from UMICs more inclined to prescribe MC. These findings underscore the need for enhanced education and training for medical professionals regarding the use of MC in cancer care, thereby informing future research and clinical practices in this field.

Medical Oncology, Hospital Clinico Universitario San Carlos, Madrid, Spain

Background: Cancer patients (pt) with venous thromboembolism (VTE) face increased risks of recurrent thrombosis and bleeding, yet information on associated risk factors remains scarce.

Methods: The TESEO-SEOM prospective, multicenter and international registry involved a descriptive analysis of 2,825 consecutive pt examining thrombosis recurrence and bleeding patterns. The Chi2 test compared recurrent VTE and bleeding events based on primary tumor and thrombosis location.

Results: The table shows the clinical characteristics of the cohort. 173 pt (6.1%) presented recurrent VTE and 188 pt (6.7%) had major or clinically relevant bleeding. Both events correlated with a higher risk of death (adjusted $p<0.01$ and $p<0.001$, respectively). GI cancer was significantly associated with a higher risk of recurrent VTE (86 pt, 7.6%, $p=0.010$). Bleeding episodes were also more frequent in GI tumors, but without statistical significance (87 pt, 7.7%, $p=0.090$). Adjusted for gender, age, stage (metastatic vs. localized) and location of primary tumor, splanchnic VTE was associated with a higher risk of recurrent VTE (11.2%, $p=0.027$) and bleeding (11.7%, $p=0.018$) compared to the whole cohort. This difference was not identified in the rest of the abdomen/pelvis. However, splanchnic VTE was not associated with increased mortality risk ($p=0.148$) Pulmonary embolism was also associated with bleeding (119 pt, 7.7%, $p= 0.006$) but not with recurrent VTE. Pulmonary embolism correlated with higher death rates ($p= 0.007$). Other VTE locations were not associated with higher bleeding or recurrent VTE risk.

Table: 2083P Baseline characteristics

n = 2825 (100%)	
Sex — no. (%)	
Men	1470 (52)
Age — no. (%)	
Mean	65.4
Tumor — no. (%)	
Digestive	1128 (39.9)
Lung	639 (22.6)
Genitourinary	439 (15.5)
Breast	291 (10.3)
Other	328 (11.6)
VTE location — no. (%)	
Pulmonary embolism	1545 (54.7)
Lower limbs	699 (24.7)
Catheter-associated	276 (9.7)
Splanchnic	206 (7.3)
Inferior abdomen — pelvis	172 (6.1)
Superior limbs	122 (4.3)
Head & neck	97 (3.4)
Other	77 (2.7)

Conclusions: A thrombotic event localized in splanchnic circulation is associated with higher risk of recurrent thrombosis and bleeding, regardless of age, sex and tumor type, although it does not seem to impact mortality. Pulmonary embolism is linked to a higher bleeding and mortality risk.

2084P Cardiovascular (CV) mortality among metastatic cancer patients: A retrospective cohort study

I.B. Riaz[1], A. Ayaz[2], S.A.A. Naqvi[3], A. Bibi[4], K. Khakwani[5], Z.B. Riaz[6], U. Anjum[7], M. Khan[2], P. Singh[8], A.H. Bryce[9]

[1]Oncology, Medicine, Dana Farber Cancer Institute, Boston, MA, USA; [2]Division of Hematology and Medical Oncology, Mayo Clinic Cancer Center, Phoenix, AZ, USA; [3]Internal Medicine, Division of Oncology, Mayo Clinic, Jacksonville, FL, USA; [4]Internal Medicine, Fatima Jinnah Medical University, Lahore, Pakistan; [5]Internal Medicine, The University of Arizona, Tucson, AZ, USA; [6]Internal Medicine, Rashid Latif Medical College, Lahore, Pakistan; [7]Internal Medicine, Dow University of Health Sciences, Karachi, Pakistan; [8]Hematology Medical Oncology Department, Mayo Clinic Cancer Center, Phoenix, AZ, USA; [9]Division of Hematology and Medical Oncology, Mayo Clinic Cancer Center, Phoenix, AZ, USA

Background: CV mortality is the leading preventable cause of death in cancer patients. Understanding the timing and quantifying the magnitude of CV mortality can facilitate strategies to reduce mortality.

Methods: Surveillance, Epidemiology, and End Results (SEER) database (2004-2018) were queried to obtain CV mortality (defined as deaths due to heart diseases, hypertension, cerebrovascular diseases, atherosclerosis, aortic aneurysm, and dissection) in metastatic cancer patients. Standardized mortality ratios (SMRs) were calculated (observed deaths from each category divided by the expected number of deaths in the age-matched US population for the same period). SMR was presented by latency periods of <2, 2-5, and >5 years after the initial diagnosis of metastatic cancer and stratified by age (<50 years, 50-70 years, >70 years), race (White, Black, Asian/Pacific Islander, Native American), and ethnicity (Hispanic, Non-Hispanic).

Results: This analysis included 914,804 metastatic cancer patients. Overall, the risk of CV death was highest <2 years of initial diagnosis (SMR: 2.47, 95% CI: 2.35-2.58) compared to population who died 2-5 years (1.22, 1.17-1.27) and 5>years (1.11, 1.03-1.17) after the initial diagnosis. In terms of different subgroups, younger population (age <50 years) observed the highest risk of CV mortality within < 2 years (8.84, 7.5-10.4) except for prostate cancer, where the risk of cardiovascular death becomes highest at >5 years after diagnosis. Similarly, regarding race, Native Americans had the highest risk of CV mortality (6.44, 4.86-8.54), which remained consistent across different cancers. There was significant increase in observed mortality in Hispanic (2.93, 2.62-3.28) and Non-Hispanic (2.43, 2.31-2.55) population. The mortality risk by ethnicity remained consistent with latency periods of <2, 2-5, and > 5years after the initial diagnosis of metastatic cancer.

Conclusions: Metastatic cancer patients who are younger or those who are Native Americans have the highest CV mortality, especially <2 years of initial diagnosis of metastatic disease. Targeted cardio-oncological strategies should be aimed at improving CV mortality in patients who are at highest risk of deaths.

2085P Buprenorphine use and cancer outcomes

N. Osazuwa-Peters[1], D. Abouelella[1], M. Chen[1], R. Jiang[2]

[1]Head and Neck Surgery & Communication Sciences, Duke University Medical Center, Durham, NC, USA; [2]Psychiatry, Duke University Medical Center, Durham, NC, USA

Background: Pain symptoms are common among individuals with cancer, often necessitating pain management as part of cancer care. Opioids are thus mainstay in cancer care, notwithstanding the risk of adverse psychosocial sequelae associated with opioid use, including opioid use disorder (OUD). Buprenorphine is commonly used in managing OUD; however, it is unclear whether there are differences in the characteristics of individuals with cancer receiving buprenorphine, and what perioperative outcomes are associated with buprenorphine use.

Methods: We used data from *Premier Health Database*, a comprehensive electronic healthcare database with over 1,000 contributing healthcare systems and > 10 million inpatient admissions annually. We built a cohort of 616 patients undergoing

surgical care for cancer between 2008 and 2020 who received buprenorphine as part of their care, and matched to 6,160 other patients with cancer randomly selected in the database who also underwent surgical care without receiving buprenorphine. We characterized demographic and clinical factors associated with receipt of buprenorphine, and also examined the association between receiving buprenorphine and perioperative outcomes, including length of stay (LOS, in days), hospitalization cost (in US dollars/$), and in-hospital mortality.

Results: Older individuals were less likely to receive buprenorphine (aOR = 0.95; 95% CI 0.94, 0.97), while patients with Medicaid insurance (aOR = 1.76; 95% CI 1.02, 3.03) and Medicare (aOR = 1.49; 95% CI 1.00, 2.24) were more likely to receive buprenorphine, compared to those with private insurance. We also found a significant association between radiation treatment and receipt of buprenorphine (aOR = 2.18; 95% CI 1.31, 3.61). In examining perioperative outcomes associated with receipt of buprenorphine, we found that while receipt of buprenorphine was not associated with in-hospital mortality, it was associated with decreased odds of being discharged home after care (aOR = 0.43; 95% CI 0.30, 0.63), increased hospital LOS (estimate = 3.50; 95% CI 2.79, 4.21), and increased overall cost of care (estimate = $10,353; 95% CI $7,846.54, $12,859.00).

Conclusions: Receipt of buprenorphine is also associated with odds of increased hospital LOS and increased cost of care.

2086P Management of opioids use disorder in cancer survivors

K. Berkane[1], R. Kortbaoui[2], P. Rouby[1]

[1]Supportive Care, Institut Gustave Roussy, Villejuif, France; [2]Pain Management, Gustave Roussy - Cancer Campus, Villejuif, France

Background: Management of opioids use disorder in cancer survivors The morbidity and mortality associated with opioid use disorder is a public health concern in many countries. However, opioids are a cornerstone in the management of cancer pain. The problem of opioid use disorders is an emerging concern in cancer survivors.

Methods: Over 10 months, we evaluated at the Gustave Roussy Pain Management Unit survivors of cancer who were on long-term prescription opioid therapy. A thorough evaluation involving an addiction specialist doctor, a psychologist or a psychiatrist, and the pain team was conducted to answer the following questions: - What is the current painful complaint and are opioids the adequate treatment for it? - Is the patient dependent on prescription opioids and does he/she have prescription opioid misuse? - Does the patient have an addiction to opioids (according to DSMV criteria) A personalized therapeutic project was then proposed for each patient.

Results: All patients accepted the project. Thirteen patients with a prescription opioid use disorder were enrolled for an opioid withdrawal program. Nine patients were misusing step-3 analgesics as defined by the WHO analgesic ladder, including one patient misusing fast-acting fentanyl, and 4 were misusing step-2 analgesics as monotherapy or in combination with another step-2 analgesic. The mean oral morphine equivalent doses were 150 mg daily [40-480 mg]. Nine patients had an opioid prescription renewal for more than 5 years. The fear of the pain rebound was the main obstacle to stopping opioid use. Seven patients could be withdrawn as outpatients six required hospitalizations for withdrawal under strict medical supervision. Five patients were put on Medications for Opioid Use Disorder (MOUD). None of the residual pain complaints warranted an opioid prescription.

Conclusions: Prescription opioids use disorder in cancer survivors requires the intervention of a specialized multidisciplinary team, trained in the identification and treatment of opioid withdrawal, in the handling of MOUD and in the management of chronic pain diseases. Close and regular collaboration with oncologists is necessary, to reconsider the need for prescription opioids in every patient as soon as he/she is in remission.

2087P Impact of cancer pain on quality of life and financial well-being: A cross-sectional study on symptom management

R. Giusti[1], M. Filetti[2], P. Lombardi[3], G. Gentile[4], P. Toccaceli[5], G. Fumi[6], D. Vacca[7], E. Colpani[8], G. Ravoni[8], G. Daniele[9], G. Porzio[10]

[1]Medical Oncology Unit, AOU Sant'Andrea, Rome, Italy; [2]UOC Phase I, Fondazione Policlinico Universitario Agostino Gemelli IRCCS, Rome, Italy; [3]Medical Oncology, Fondazione Policlinico Universitario Agostino Gemelli IRCCS, Rome, Italy; [4]Policlinico Umberto I Oncologia B, Sapienza - Università di Roma, Rome, Italy; [5]Hospice Care Service, USL Umbria 1, Perugia, Italy; [6]Medical Oncology, Azienda Ospedaliera Santa Maria di Terni, Terni, Italy; [7]UO Terapia del Dolore e Cure Palliative, ASL Sulcis - Carbonia, Carbonia, Italy; [8]Home Care Service, Associazione Tumori Toscana, Florence, Italy; [9]Phase I Unit, Fondazione Policlinico Universitario Agostino Gemelli IRCCS, Rome, Italy; [10]Home Care Service, Associazione Tumori Toscana, Florence, Italy

Background: Cancer symptoms (CS) impose a significant burden on patients, affecting their quality of life and financial stability. The purpose of this study was to investigate the impact of common CS on the physical and financial well-being of patients who frequently rely on medications to manage their cancer-related symptoms.

Methods: A cross-sectional, descriptive study was conducted between January and October 2022. The study aimed to identify patient-administered drugs for managing cancer treatment toxicities and associated symptoms. It assessed six common symptoms: anorexia/cachexia, fatigue, nausea/vomiting, pain, constipation, and diarrhea. Demographic data were collected, along with cancer type and active treatment status. Symptom assessment used PERSONS questionnaire, while financial distress (FD) was analyzed with the COST questionnaire.

Results: A total of 211 patients completed the questionnaires, providing valuable insights into their symptom management. However, 183 patients, relied on prescription drugs to alleviate their symptoms. Cancer pain (CP) management was the primary concern for 45% of the patients, followed by constipation, which affected 28% of them. Significantly, the analysis revealed a strong association between CP and lower PERSONS scores, suggesting a negative impact on overall well-being. CP was also correlated with FD, unlike other symptom categories, which did not show statistically significant correlations. Healthcare costs were primarily attributed to pain management, including visits to healthcare professionals and prescription medications. Pain-related expenses contributed to financial strain, resulting in increased out-of-pocket costs and potential income loss due to reduced work productivity or inability to work.

Conclusions: This survey highlights the profound impact of CP on the quality of life and financial well-being of cancer patients. Collaborative efforts among healthcare professionals and policymakers are crucial in developing integrated approaches that ensure accessible and affordable pain management for cancer patients, thus alleviating their suffering and reducing the financial burden associated with pain.

2088P Management of cancer treatment-induced bone loss in patients with breast and hormone sensitive prostate cancer: AIOM survey among Italian oncologists

A.A. Valsecchi[1], V. Fusco[2], M. Di Maio[1], D. Santini[3], M. Tucci[4], U.F.F. De Giorgi[5], R. Dionisio[6], F. Vignani[1], S. Cinieri[7]

[1]Department of Oncology, Azienda Ospedaliera Ordine Mauriziano - Presidio Umberto I, Turin, Italy; [2]Oncology Unit, Department of Medicine Translational Medicine Unit, Department of Integration, Research and Innovation, "SS Antonio e Biagio e C.Arrigo" Hospital, Alessandria, Italy; [3]UOC Oncologia A, Policlinico Umberto 1, La Sapienza Università, Rome, Italy; [4]Department of Medical Oncology, Cardinal Massaia Hospital, Asti, Italy; [5]Department of Medical Oncology, IRCCS Istituto Romagnolo per lo Studio dei Tumori (IRST) "Dino Amadori", Meldola, Italy; [6]Department of Oncology, Azienda Ospedaliera Ordine Mauriziano - Presidio Umberto I, Turin, Italy; [7]Medical Oncology Unit, Ospedale di Summa A. Perrino, Brindisi, Italy

Background: Cancer treatment—induced bone loss (CTIBL) is a side effectof hormonal therapy (HT) that can severely affect patients' quality of life. The first aim of this survey is to obtain an updated snapshot of Italian management of bone health in patients with breast cancer (BC) undergoing adjuvant HT and in patients with hormone sensitive prostate cancer (PC). The secondary aim is to evaluate overlaps and differences between Italian and European recommendations.

Methods: Our survey was made up of 21 multiple-choice questions: the first part dealt with the respondents' characteristics, while the second with management of CTIBL in the described setting. An invitation to complete it was sent by e-mail to 2336 Italian oncologists in October 2022.

Results: 121 (5.2%) Italian oncologists completed the survey. In most cases (57%) the oncologists themselves take charge of the management of CTIBL. At the beginning of HT, most of respondents require bone health diagnostic exams, such as dual-energy X-ray absorptiometry (89%), repeated with different timing. A large part of oncologists starts bone health therapy regardless of T-score or other exams (44%), according to Italian guidelines; while another part start therapy only in case of increased fracture risk (38%), according to ESMO guidelines. Main reported reasons for prescribing antiresorptive drugs are modifying fracture risk (87%), densitometry values (75%) or antitumoral effect (34%). The antiresorptive drugs or supplementation of calcium and vitamin D alone are prescribed in 58% and 38% of patients with BC and 42% and 39% of patients with PC, respectively. Lastly, 6% and 13% of respondents interrupt therapy at the end or 6 months after HT, respectively; 36% after instrumental or scoring reassessment; 22% do not interrupt it; and 23% refer the patient to specialist. Most respondents claim to follow Italian (88%) and European guidelines (31%).

Conclusions: The heterogeneous Italian management of CTIBL arisen from this survey highlights the need both to standardize guidelines and to make oncologists more aware of this topic. It would be interesting to extend this survey to other European countries.

2089P Multi-cycle prophylaxis of long-acting granulocyte colony-stimulating factor in cancer patients at risk of febrile neutropenia due to myelosuppressive chemotherapy: A retrospective real-world study in China

Y. Zhang

Department of Gastroenterology, Cancer Hospital Affiliated to Harbin Medical University, Harbin, China

Background: Febrile neutropenia (FN) resulting from myelosuppressive chemotherapy drugs, have the potential to necessitate dose reduction or treatment delays, thus compromising the overall efficacy of treatment. This study aims to analyze the incidence of FN and related adverse drug reactions in cancer patients who receive prophylaxis with PEG-rhG-CSF (a long-acting granulocyte colony-stimulating factor).

Methods: This real-world study was conducted as a multicenter, retrospective, observational research involving adult cancer patients who received chemotherapy with PEG-rhG-CSF prophylactic. The study focused on several variables, including baseline characteristics and incidence of FN. Descriptive analysis was performed by using IBM SPSS Statistics 27.

Results: 24,199 patients were enrolled from 575 hospitals across China between June 2022 and January 2023. The chemotherapy cycle records encompassed 1to 20 cycle. Among the enrolled patients, breast cancer was the most prevalent tumor type, accounting for 33.6% (N=8,131) of the cases. FN incidence across all cycles was 0.054% and it was 0.055% and 0.053% among patients receiving PEG-rhG-CSF as primary and secondary prophylaxis. These rates were significantly lower than the previously reported data of 13% to 21% from a retrospective cohort study involving patients with or without prophylaxis. Overall, FN occurred across the first to eighth cycles with the highest incidence observed in cycle 1 (52.50%). 1,659 records (2.25%) reported adverse events related to PEG-rhG-CSF. The most commonly observed adverse effect was musculoskeletal pain, accounting for 1.53% of the cases, followed by fatigue(0.60%) and allergic reactions(0.07%). Furthermore, 90.78% of adverse reactions were categorized as primary or secondary adverse reactions.

Conclusions: Under PEG-rhG-CSF prophylaxis, cancer patients exhibited a low incidence of FN which primarily occurred in the initial cycle of chemotherapy. Importantly, the administration of PEG-rhG-CSF was well tolerated.

2090P Management of trastuzumab deruxtecan-related nausea and vomiting in real-world practice

L. Licata, G. Notini, L. Sica, G. Viale, S. Zambelli, A. Rognone, D. Aldrighetti, M. Piras, A. Nuccio, P. Zucchinelli, G. Bianchini

Medical Oncology, IRCCS Ospedale San Raffaele, Milan, Italy

Background: Nausea and vomiting (N&V) are common side effects of Trastuzumab Deruxtecan (T-DXd), but guidelines for optimal management were not initially available. This retrospective study aimed to evaluate the efficacy of two different antiemetic regimens in patients (pts) receiving T-DXd.

Methods: We included 53 pts who received T-DXd at San Raffaele Hospital, Milan, with reliable information on antiemetic prophylaxis type and N&V severity (CTCAE 5.0 classification). Two groups were defined: pts treated with 5-HT3 receptor antagonists (RA) +/- dexamethasone (DEX) (5-HT3 group), and pts treated with a fixed oral combination of NK1RA (netupitant) and palonosetron +/- DEX (NK1 group). To be noted, that pts considered at higher risk of N&V by physician judgement were preferentially offered the NK1RA-containing regimen according to internal recommendations. Only N&V during cycles 1 (C1) and 2 (C2) were considered. Comparisons of N&V by antiemetic prophylaxis group were assessed by chi-square test.

Results: At C1, 15 (28.3%) and 38 (71.7%) pts were treated with and without NK1RA, respectively. Overall, 58.5% of pts reported nausea of any grade at C1, with no differences between the 5-HT3 and NK1 groups (57.9% vs 60%; p=0.832). A minimal numerical trend for lower grade of nausea in the NK1 (33.3% G1; 26.7% G2) compared to the 5-HT3 (23.7% G1; 31.6% G2; 2.6% G3) group was observed. Overall, 15.1% of pts reported vomiting of any grade during C1, with a borderline significant difference between the 5-HT3 (21%, all G1) and NK1 (0%) groups (p= 0.054). Among the 22 pts in the 5-HT3 group with nausea at C1, 15 (68.2%) immediately escalated to the NK1 regimen at C2. Among these, nausea decreased from 100% any grade (26.6% G1, 66.7% G2, 6.7% G3) at C1 to 53.3% any grade (13.3% G1, 40.0% G2) at C2 (p= 0.022), and vomiting decreased from 46.7% at C1 to 13.3% at C2 (all G1) (p=0.046).

Conclusions: The NK1RA-based regimen demonstrated a meaningful improvement in vomiting control at C1, and when promptly introduced as rescue at C2, significantly improved both nausea and vomiting. The biased preferential selection of NK1RA regimen for higher-risk pts may have dampened the differences in nausea control at C1. These results support the current 2023 NCCN antiemetic guidelines for T-DXd.

Background: Nurses provide information and care on cancer treatment side effects prevention and management. Skin toxicities are common side effects and can be associated with treatment dose reduction or discontinuation. Minimizing skin side effects and using photoprotection improve patient outcomes and quality of life.

Methods: The Association Francophone des Soins Oncologiques de Support (AFSOS) and Multinational Association of Supportive Care in Cancer (MASCC) teamed to create consensus recommendations about using dermocosmetics in cancer patients. They assembled a group of international experts from nursing and other disciplines who manage cancer patients. After literature review, the group held a consensus meeting to give guidance on the use of dermocosmetics with oncology treatments.

Results: Dermocosmetics (or cosmeceuticals) are products with therapeutic value in addition to cosmetic. They contain ingredients that can help repair and support the skin barrier by hydrating the skin, maintaining a healthy microbiome. For general recommendations the group agreed: * Start skin care at the same time as cancer interventions known to be associated with skin toxicities, with a goal of preventing and minimizing problems. * Hydration of the skin relieves symptoms and reduces exacerbations of xerosis. * Use cleansers with pH close to 5 and avoid basic or neutral pH cleansers. * Photoprotection should be part of initial recommendations for all Consensus recommendations for the use of dermocosmetics in specific skin toxicities management were also made.

Conclusions: Nurses have an essential role in educating patients about skin care as part of their holistic approach to patient care. This new consensus focuses on the practical and beneficial impact of dermocosmetics to avoid and manage side effects as well as prevent dryness, irritation, and sensitivity. Patient education can help prevent high-grade toxicities and reduce healthcare costs by allowing patients to have an active role in their treatment.

2092P Bone loss in premenopausal Algerian women treated with chemotherapy for early-stage of breast cancer: Evaluation by DXA and identification of associated risk factors

M. Fatma Zohra

HCA Medical Oncology Kouba, University of Algiers, Algiers, Algeria

Background: Breast cancer tops the list of cancer types prevalent in Algeria, with more than 14,000 new cases recorded each year, of which a significant rate appears before the age of 40. it is aggressive and requires the use of chemotherapy known to be associated with immediate and long-term toxicities, which may affect the quality of life of cancer survivors. One of the chemotherapy-related long-term toxicities among premenopausal patients is hormonal changes with ovarian failure, chemotherapy-related amenorrhoea (CRA) and early menopause witch may lead to bone loss.The objectives were to evaluate bone mineral density (BMD) and to determine potential associated factors for bone loss among young premenopausal patients after adjuvant chemotherapy.

Methods: We included premenopausal Algerian aged <45 years who had received adjuvant chemotherapy. At study entry, background demographics, cancer characteristics and menstrual history were collected; BMD was measured by DXA in trabecular and cortical sites. Factors associated with reduced BMD and fracture risk were analyzed.

Results: A total of 83 patients were evaluated.The median age at the time of diagnosis of breast cancer is 37 years old, while the age at entry into the study is 43 years old. The median BMDs for femoral neck (FN) was 1.02 g/cm2 and lumbar spine (LS) 0.95 g/cm2; 37.2% had abnormal Z-scores (defined as ≤ -1) and 44.7% had osteopenia/osteoporosis of either FN or LS. On multivariate analyses, factors that were identified correlated with bone loss (low BMD) are: young age at cancer diagnosis (OR [95% CI] = 2.103 [1.091−3.181), low Vitamine D level (OR = 2.254 [1.541−4.637]), low BMI (OR = 2.56 [1.599−2.907]), longer interval since last adjuvant treatment (OR for LS: 2.217 [1.250−4.357]), and having received adjuvant tamoxifen (OR = 1.752 [1.243−3.841]).

Conclusions: This study highlights that bone loss is prevelent condition in early breast cancer survivors who are on or after chemotherapy. About 44.7% of early breast cancer survivors found to have bone loss .To prevent bone fracture; certain factors associated with this condition deserve to be detected and corrected.

2093P Bioelectrical Impedance phase angle and obesity as a prognostic indicator in metastatic gastric cancer patients receiving second-line chemotherapy

S. Han[1], S.E. Oh[1], S. Lee[2], J.H. Kim[2], H.C. Jeung[2]

[1]Oncology, Gangnam Severance Hospital, Yonsei University College of Medicine, Seoul, Republic of Korea; [2]Medical Oncology Dept., Gangnam Severance Hospital, Yonsei University College of Medicine, Seoul, Republic of Korea

Background: The combination treatment of paclitaxel plus ramucirumab [PACL(-W)+RAMU] is a widely accepted option for advanced gastric cancer (AGC) as a second-line chemotherapy to prolong survival. The aim of the study is to identify the validity of bioelectrical impedance analysis (BIA) as a prognosticator in patients receiving PACL(W)+RAMU treatment.

Methods: The study population comprised 189 patients who received PACL(-W)+RAMU between Oct. 2019 and Nov. 2022. BIA was conducted at baseline of the PACL(W)+RAMU treatment on all patients and whole body PhA was derived. Continuous variables of other body compartment and blood biochemical values (including complete blood count, serum electrolytes and chemistry) were dichotomized according to the best cut-off values determined by the Contal and O'Quigley methods or the normal values. Kaplan-Meier method and the Cox proportional hazard model were constructed to evaluate the prognostic effect the body component.

Results: Median age of the patients was 59. The cut-off value of PhA was determined as 4.6° at 50 kHz. Median overall survival (OS) of the lower PhA group was 38 weeks (95% CI, 32-45) and 52 weeks (95% CI, 39∼65) for higher PhA group (P=0.021). When combining PhA with obesity degree (current weight/target weight x 100), high phA and low obesity degree ($<$ 116%) demonstrated the favorable OS of 54 weeks (95% CI, 40-68), which contrasts to only 14 weeks (95% CI, 10-18) for low PhA and high obesity degree ($\geq$ 116%) group. In multivariate analysis, the PhA combined with obesity degree is an independent prognosticator for OS (hazard ratio [HR], 6.506 for low PhA and high obesity degree, 95% CI, 3.237-13.076, P$<$0.001) along with neutrophil-to-lymphocyte ratio and extracellular water.

Conclusions: Bioelectrical impedance component and phase angle could be a useful prognosticator for patients with metastatic gastric cancer. Larger sample size and independent set will be needed to further validate the significance of this study in palliative cancer treatment settings.

Background: Dexamethasone is one of the key antiemetic agents and is widely used even now. However, dexamethasone has been associated with a number of adverse reactions even after short-term administration. Therefore, the development of steroid-free antiemetic regimen is an important issue to be considered. Thus, the purpose of this study was to investigate the efficacy and safety of palonosetron, aprepitant, and olanzapine in a multi-institutional phase II study.

Methods: Chemotherapy-naive patients scheduled to receive for highly emetogenic chemotherapy in breast cancer were enrolled and evaluated the occurrence of chemotherapy-induced nausea and vomiting during 120 hours after chemotherapy. The primary endpoint of the study was total control (TC) in the overall phase. Key secondary endpoint was complete response (CR), which was assessed in the acute, delayed, and overall phase, respectively. Adverse events were evaluated according to the Common Terminology Criteria for Adverse Events.

Results: Eighty-nine patients were enrolled from 8 centers in Japan, of which 76 were evaluable for analyses. The percentage of patients achieved TC during the overall phase was 17.1% (95% confidence interval [CI] 0.094—0.275; p = 0.275). CR was achieved in 43.4% (95% CI 0.321—0.553; p = 0.726), 53.9% (95% CI 0.421—0.655), and 63.2% (95% CI 0.513—0.739) of patients during the overall, acute, and delayed phases, respectively

Conclusions: The primary endpoint was below the threshold and we could not find any benefit in the dexamethasone-free regimen. The CR rate was also examined as one of the secondary endpoints, with similar results. Although dexamethasone is considered to have side effect concerns, its effect on CINV cannot be ignored, suggesting that easy complete omission should be avoided.

2095P Cancer rehabilitation program for cancer-related fatigue

A. Bekisheva, A. Makishev

Department of Oncology, Astana Medical University, Astana, Kazakhstan

Background: Cancer-related fatigue (CRF) is a significant and frequent problem among cancer patients. There is no gold standard. However, ESMO CPGL 2020 recommended multimodal interventions, CRF is underdiagnosed, undertreated and underdocumented. In this study, we evaluated cancer rehabilitation program including education, physical activity and emotional support.

Methods: Cancer rehabilitation program includes: patients and family education, physical activity (aerobic exercise), water- therapy, yoga, behavioural therapy, relaxation, art, music-therapy, proteinrich nutrition, social support. The Five-time-sit-to-stand test, Hand-Grip-Strength, 6 min walking test, Brief fatigue inventory, Hospital anxiety and Depression scale were used. Descriptive statistics and t-tests.

Results: Participants were 112 patients (48y [29-75]), 60.7% women and 39.2% men. The primary cancer was 26.7 % breast, 16.9% gasrtoesophageal 33.6% colorectal, 16.8% lung, 5.96% pancreatobiliary. Before rehabilitation: the Five-time-sit-to-stand test 10.2 sec (4.5-28.1), Hand-Grip-Strength 28.4 kg, 6 min walking test 482 meters (49,631), Brief fatigue inventory 45 (0-75), Fatique 8/10 (0,10), Cognitive 6, Emotional 4, Physical 6, QoL 4 (0-10). HADS 8 (0, 18). After rehabilitation: the Five-time-sit-to-stand test 5.7 sec (-50%), Hand-Grip-Strength 39.2 kg, 6 min walking test 585 meters (62,822), Brief fatigue inventory 25 (0-58), Fatique 3/10 (0,10), Cognitive 3, Emotional 1, Physical 4, QoL 7 (0-10). HADS 4 (0, 18).

Conclusions: Cancer rehabilitation program including different types of interventions is effective in treating cancer related-fatigue.

2096P Morphine titration with intravenous patient-controlled analgesia for severe cancer pain (Mr.TIPS)

S.J. Huh[1], S.Y. Oh[1], J.H. Kang[2], S-I. Go[3], S. Lee[1], H.R. Kim[1]

[1]Division of Hematology and Oncology, Department of Internal Medicine, Dong-A University Hospital, Dong-A University College of Medicine, Busan, Republic of Korea; [2]Internal Medicine Department, Gyeongsang National University Hospital and Gyeongsang National University School of Medicine, Jinju, Republic of Korea; [3]Internal Medicine, Gyeongsang National University Changwon Hospital, Changwon, Republic of Korea

Background: The National Comprehensive Cancer Network (NCCN) guideline recommend starting with opioids for severe cancer pain or pain crisis. In this case, short-acting oral opioids or injections can be considered and drug titration should be performed by re-evaluating after 1 hour for oral drugs and after 15 minutes for injections. However, in actual medical practice, it's challenging to promptly administer injections and perform dose titration through pain assessment every 15 minutes. Patient-controlled analgesia (PCA) is a recommended method that enables patients to self-administer medication, potentially reducing the time required for medication administrations, but there are limited studies on this.

Methods: Patients with cancer pain with an average NRS (Numeric Rating Scale) score of 7 or higher within the last 24 hours were enrolled from 3 centers. The patients who were taking opioids with a morphine equivalent daily dose of 300 mg/day or higher were excluded. Patients complete a pain diary at baseline, 1, 2, 4, 12, 24, and 48 hours. The researchers monitor side effects and conduct a brief pain assessment at 24 and 48 hours. Patients also record their Patient Global Impression of Change (PGI-C) at 24 and 48 hours. The endpoint of this study is percentage of patients with a pain NRS score of 3 or less one hour after PCA application.

Results: Between August 2021 and April 2023, a total of 38 patients were enrolled in the study, with 37 completing and 1 dropout. Of these, 8 (21%) were opioid-naive and 29 (76%) were opioid-tolerant. Within 1 hour, 26 patients (68%) reached NRS 3 or lower pain control. And in a 24-hour PGI-C, 26 patients (63%) reported their condition as very much or much improved. The 33 patients (87%) had no adverse events during the study. Four patients experienced side effects, such as nausea and vomiting; three were mild and one was moderate. No serious adverse events (SAEs) were reported. A possible association between the medication and symptoms was observed in two patients, whereas for the other two, it was assessed to be unlikely.

Conclusions: Effective pain management through dose titration is crucial in the treatment of severe cancer pain. The study confirmed that PCA-based pain control was highly effective, safe, and satisfactory for patients.

Clinical trial identification: DAUHIRB-21-125.

2097P Incidence, risk factors (RFs) and management of oral mucositis (OM) in patients (pts) treated with a fluoropyrimidines (FP)-based therapy (tp): A retrospective, monocentric experience

F. Manfredi[1], E. Sammarco[2], M. Ferrari[3], C. Mercinelli[4], A. Salfi[5], A. Bonato[3], G. Dima[6], D. Serafin[7], L. Zatteri[8], A. Antonuzzo[9], L. Galli[8]

[1]UO Oncologia Medica, Azienda Ospedaliero Universitaria Pisana - Stabilimento di Santa Chiara, Pisa, Italy; [2]UO Oncologia Medica 2, Azienda Ospedaliera Universitaria S.Chiara, Pisa, Italy; [3]Medical Oncology Department, AOU Pisana - Stabilimento di Santa Chiara, Pisa, Italy; [4]Oncology Dept., IRCCS Ospedale San Raffaele, Milan, Italy; [5]Oncology Department, AOU Pisana - Stabilimento di Santa Chiara, Pisa, Italy; [6]Medicina Traslazionale, UniPi - Università di Pisa - Direzione Area di Medicina, Pisa, Italy; [7]UO Oncologia Medica 2, Santa Chiara Hospital, University of Pisa, Pisa, Italy; [8]Oncologia Medica, AOU Pisana - Stabilimento di Santa Chiara, Pisa, Italy; [9]Medical Oncology Dept., AOU Pisana - Stabilimento di Santa Chiara, Pisa, Italy

Background: OM is one of the main adverse events during chemotherapy, affecting around 40% of pts; it is characterized by an inflammation and ulceration of the oral

mucous membranes that can lead to oral pain, impaired nutritional intake, local or systemic infections and lower quality of life. Only few strategies are available for its prevention and management. FP-based tp can cause OM due to their cytotoxic effect on mucosal cells inducing DNA double strand brakes and ROS production, empowered by TNF-alfa release. In our retrospective monocentric study we evaluated clinical and hematological RFs which could help us to identify early those patients who might benefit the most from a preventive strategy.

Methods: We evaluated incidence, management and possible RFs for OM (such as diabetes, smoke, BMI and blood inflammation markers) on 174 pts treated with a FP-based tp during a typical month in our DH. Statistical analysis has been conducted using Chi-square test and Fisher's exact test. Pts have been informed about risk of developing OM and we subsequently managed the symptom on the basis of its severity according to CTCAE.

Results: 48 pts developed OM. We found a higher OM incidence in smoker pts (60.5% vs 21.4% in non smoker, $p<0.0001$) and in overweight pts (39.7% vs 24.1% in pts with normal weight, $p=0.0381$). We also demonstrated a correlation between a higher OM severity and diabetes diagnosis (71% vs 29.8% in non diabetic pts, $p=0.0330$). No statistically significant correlation emerged between OM incidence/severity and any of the blood values tested (blood cells values, NLR, PLR, creatinine). 20 pts had $\geq$G2 OM and received local and/or systemic therapies, while 3 pts needed a treatment suspension. Median time to resolution was 28 days. 6 pts still had OM of various severity grade at the time of our analysis.

Conclusions: Smoke and overweight could be RFs for OM incidence of any grade during a FP-based treatment, while a diabetes diagnosis seemed to be related with a higher severity of OM, but not with its incidence. In view of the above, it might be useful to recommend accurate oral hygiene and a preventive strategy in accordance with MASCC guidelines in these subgroups of pts.

2098P The impact of concomitant use of non-opioid analgesics and immune checkpoint inhibitors on survival in lung cancer patients: A Hong Kong population-based cohort study

Z-H. Ye[1], S. Wang[1], J. Zhang[2], T.T.L. Lee[3], A.K.C. Wai[3], F. Kong[1]

[1]Clinical Oncology, The University of Hong Kong - Li Ka Shing Faculty of Medicine, Hong Kong, China; [2]State Key Laboratory of Ultrasound in Medicine and Engineering, Chongqing Medical University, Chongqing, China; [3]Emergency Medicine, The University of Hong Kong - Li Ka Shing Faculty of Medicine, Hong Kong, China

Background: Pain is one of the most common symptoms experienced by advanced staged lung cancer patients. Non-opioid analgesics like acetaminophen and nonsteroidal anti-inflammatory drugs (NSAIDs) have been the cornerstone of pharmacologic interventions for cancer pain management in lung cancer. Since cyclooxygenase-2 (COX2) is overexpressed in many solid tumors including lung cancer and is associated with poor prognosis, COX inhibitions such as NSAIDs have been the candidate for adjuvant therapy for lung cancer. Yet the results of previous studies regarding the concomitant use of immune checkpoint inhibitors (ICIs) and non-opioid analgesics remained controversial mostly for their small sample size. This study aims to investigate whether the concomitant use of NSAIDs with ICIs can improve the survival of lung cancer compared to acetaminophen.

Methods: A total of 572 lung cancer patients who received concomitant use of non-opioid analgesics and ICI from 2018 to 2020 were identified within the Clinical Data Analysis and Reporting System of Hong Kong. Inverse probability of treatment weighting (IPTW) —adjusted Kaplan-Meier curves and Cox proportional hazards regression analysis were used to compare the overall survival (OS) of patients who received NSAIDs versus acetaminophen.

Results: Overall, 428 (74.8%) and 144 (25.2%) patients with lung cancer received concomitant ICI with acetaminophen and NSAIDs, respectively. The median follow-up time in the weighted population was 39.1 months (95% CI, 36.6-43.5 months). IPTW-adjusted Kaplan-Meier curves showed that the median OS was significantly longer in the NSAIDs group than in the acetaminophen group (15.4 months vs 10 months, $p = 0.03$). In IPTW-adjusted Cox regression analysis, the concomitant use of NSAIDs with ICI was associated with a significant OS benefit (HR = 0.76, 95% CI: 0.61-0.96, $p = 0.02$).

Conclusions: The concomitant use of NSAIDs with ICI was associated with improved survival in patients with lung cancer compared with that of acetaminophen. Our findings suggest that a more cautious combination of non-opioid analgesics with ICI for cancer pain management in lung cancer is warranted.

2099P The role of ambulatory blood pressure measurement in TKI-induced arterial hypertension diagnosis

E. Khachaturian[1], E. Shavarova[2], I. Pokataev[3], Z. Kobalava[2], A. Shavarov[2], V.N. Galkin[4], E. Shidlovskaya[5]

[1]Chemotherapy, GBUZ City Clinical Oncological Hospital No. 1 DZM No. 1, Moscow, Russian Federation; [2]Cardiology, Peoples' Friendship University of Russia (RUDN University), Moscow, Russian Federation; [3]Clinical Pharmacology and Chemotherapy Department, National Medical Research Center of Oncology named after N.N. Blokhin, Moscow, Russian Federation; [4]Administration Department, GBUZ City Clinical Oncological Hospital No. 1 DZM No. 1, Moscow, Russian Federation; [5]Peoples' Friendship University of Russia (RUDN University), Moscow, Russian Federation

Background: Arterial hypertension (AH) is common class-effect of tyrosine-kinase inhibitors (TKI) and the leading course of dose reduction/interruption of TKI-treatment. The aim of our study was to evaluate blood pressure (BP) phenotypes in patients with metastatic solid tumors just after initiation of TKI treatment.

Methods: Thirty-three patients with metastatic solid tumors (renal, hepatocellular and thyroid cancer) treated with lenvatinib (19 (58%) male), age 61,7 +/- 8,9 years), were examined. Clinical BP was measured before initiation, on 2nd Day and every month on TKI-treatment during 6 months in the morning in the seated position. 24-hour ambulatory BP monitoring (ABPM) was performed using the conventional method during 2nd Day of the TKI-treatment. BP level were classified in accordance with ESC guideline (2018) and CTCAE 5.0. We analyzed the prevalence of the following BP-phenotypes: a non-dipping BP pattern, and white coat, masked, and masked isolated nocturnal AH. All patients were recommended to take lenvatinib in the morning at 10.00. 12 (36%) has arterial hypertension in anamnesis and target blood pressure was achieved before initiation of TKI-treatment.

Results: 42,4% of patients had AH Grade 1-3 by CTCAE 5.0. According to the clinical BP measurements on 2nd Day 30.3% of patients had AH (ESC, 2018), in the same time AH was confirmed by ABPM in 90,9% of cases. All patients have non-dipping BP pattern. When comparing the results of clinical BP measurements and ABPM data, masked AH was diagnosed in 57,6% patients, true AH - in 30,3%, 12,1% were true normotensive, white-coat AH was not observed. Masked isolated nocturnal hypertension was prevalent BP-phenotype in initially normotensive patients with solid tumors on the second day of TKI-treatment (prevalence ratio 1.49; 95% CI: 1.08—1.65).

Conclusions: AH is early adverse reaction of TKI-treatment and besides ABPM could be important component for early diagnosis of such type of secondary AH. Masked isolated nocturnal hypertension was more common phenotype among initially normotensive patients with TKI intake.

2100P An exploratory study of the efficacy and safety of hetrombopag in the treatment of thrombocytopenia induced by concurrent or sequential chemoradiotherapy

J. Wang, Y. Cheng, Y. Wu

Radiotherapy Department, The Fourth Hospital of Hebei Medical University - North Gate, Shijiazhuang, China

Background: Chemoradiotherapy is still a basic treatment for cancer, even in the era of immunotherapy and targeted therapy. Chemoradiotherapy could cause bone marrow damage. A study published in ECIM/ICIM confirmed that hetrombopag significantly improved outcomes in patients with chemotherapy-induced thrombocytopenia (CIT), exhibiting good safety. However, the efficacy in concurrent or sequential chemoradiotherapy remains unclear. We conducted a clinical trial to explore the efficacy and safety of hetrombopag (a TPO-RA) in treating thrombocytopenia induced by concurrent or sequential chemoradiotherapy.

Methods: This prospective trial enrolled patients with thrombocytopenia induced by concurrent or sequential chemoradiotherapy. The study comprised two cohorts: cohort 1 (PLT$\geq 30\times10^9$/L and $<50\times10^9$/L) treated with hetrombopag combined with IL-11, and cohort 2 (PLT$\geq 50\times10^9$/L and $\leq 75\times10^9$/L) treated with hetrombopag alone. Main inclusion criteria included: $\geq$18 years, platelet count $\geq 30\times10^9$/L and $\leq 75\times10^9$/L. The primary endpoint was the proportion of patients with PLT $\geq 75\times10^9$/L, while secondary endpoints included the proportion and median time of PLT $\geq 100\times10^9$/L, and safety.

Results: A total of 14 patients (5 in the combination group and 9 in the single group) were enrolled from March 2022 to May 2023. The hetrombopag response rate (PLT $\geq 75\times10^9$/L) was 80% (n=4/5) in cohort 1 and 100% (n=9/9) in cohort 2. The proportion of PLT $\geq 100\times10^9$/L was 60% (n=3/5) in cohort 1 and 77.8% (n=7/9) in cohort 2, and the median time was 8.3 days in cohort 1 and 8.8 days in cohort 2, respectively. Adverse events (AEs) were grade 1-2 and occurred only in the single group, including rash (1, 11.1%), nausea and vomiting (1, 11.1%), with no grade 3 or 4 adverse events.

Conclusions: Hetrombopag was safe and effective for patients with thrombocytopenia induced by concurrent or sequential chemoradiotherapy.

2101P Bleeding Induced by ANtiCAncer drugs (BIANCA) used breast cancer

N. Janus

Global Medical Affairs, Leo Pharma, Voisins-le-Bretonneux, France

Background: Many anticancer drugs' adverse events (AE) are common/known. But, there are little data about the bleeding risk induced by anticancer drugs and some publications recommended to consider bleeding risk when initiating a cancer-associated-thrombosis (CAT) treatment. The aim of this work was to check all the anticancer's SmPCs (Summary of Product Characteristics) for bleeding AE.

Methods: All SmPCs of anticancer drugs for breast cancer were checked on the EMA website. All bleeding AE from any organ were collected. The frequency (F) of AE experienced were the following: very common ($\geq$ 1/10); common ($\geq$ 1/100 to $<$ 1/10); uncommon ($\geq$ 1/1,000 to $<$ 1/100); rare ($\geq$ 1/10,000 to $<$ 1/1000); very rare ($<$ 1/10,000).

Results: Of the 36 identified anticancer drugs for breast cancer. Among these, 75.0% had at least one bleeding AE (all F). Gastro-Intestinal (GI) bleeding (36.1%), epistaxis (41.7%) and haematuria (16.7%) were the main bleeding AE (all F). Regarding very common and common AE, 16.7%, 38.9%% and 5.6%% of the anticancer drugs were reported to be potentially induced GI bleeding, epistaxis and haematuria, respectively (Table).

Conclusions: Bleeding are common AE of many of anticancer drugs. It is important to be aware of this before initiating an anticoagulant in CAT patients. But it seems reasonable to consider a potential bleeding risk caused by anticancer drugs, before/during CAT treatment.

Table: 2101P Bleeding-AE in the anticancer drug SmPCs used for breast cancer

AE	All Frequencies	Very common	Common	Uncommon	Rare	Very rare	Unknown
GI Bleeding	36.1%	2.8%	13.9%	13.9%	0.0%	2.8%	2.8%
Epistaxis	41.7%	19.4%	19.4%	0.0%	0.0%	0.0%	2.8%
Haematuria	16.7%	5.6%	0.0%	11.1%	0.0%	0.0%	0.0%
Other Bleeding	30.6%	5.6%	16.7%	2.8%	2.8%	0.0%	2.8%

AE: Adverse Events; GI: GastroIntestinal

2102P Changes in opioid usage after intrathecal morphine pump implantation in patients with terminal cancer (pilot study)

E.J. Choi, S.M. Kim

Anesthesiology and Pain Medicine, Seoul National University Bundang Hospital, Seongnam, Republic of Korea

Background: It is known that the prevalence of pain in terminal cancer patients reaches 70-90%, and the intensity of pain is very extreme. The intrathecal morphine pump (ITP) has been recognized for effective pain control in cancer pain, but, it is usually recommended to cancer patients with more than one year of life expentancy. This study aimed to find out the usefulness of the ITP through the change in opioid usage before and after pump implantation in patients with terminal cancer.

Methods: A total of 20 patients were included, retrospectively. Morphine equivalent daily dose (MEDD) and pain intensity (visual analogue scale, 0-10) were collected at baseline, 1, and 3months after insertion of ITP. Also, each patient's demographic data, diagnosis, stage and type of cancer were recorded.

Results: The mean age of 20 patients is 56.2$\pm$15.9 (years) and the female was nine. In addition, patients with colorectal, advanced, and prostate cancer accounted for 60% of the patients. The duration of ITP maintenance until the death of patients was 7$\pm$10.5 months. The MEDD was increased at 3 months after implantation of ITP compared to baseline (P=0.03). In addition, the pain relief effect lasted at 3 months after the procedure (P=0.03) (Table).

Table: 2102P Changes in morphine equivalent daily dose (MEDD) and pain intensity after intrathecal morphine pump implantation

	Baseline	1 month after the procedure	3 months after the procedure
MEDD (mg)	506.7$\pm$482.5	1131$\pm$1227.4	858.1$\pm$655.8[1]
Pain intensity (VAS, 0-10)	7.5$\pm$1.3	6.8$\pm$3.3	5.4$\pm$2.5[1]

[1]Statistically significant value compared to baseline ($p < 0.05$). The values are expressed as the mean $\pm$ SD. VAS=visual analogue scale

Conclusions: In patients with terminal cancer requiring high doses of opioids for pain control, the use of ITP implantation can offer effective pain relief while reducing opioid toxicity and side effects. Additionally, clinical evidence suggests that ITP implantation may provide value for patients with a life expectancy of less than one year.

2103P Phase Ib, international, dose-escalation study to evaluate the safety, pharmacokinetics (PK) and efficacy of ST-617 a dithiolethione, for the attenuation of oral mucositis (OM) in patients receiving chemoradiation (CRT) for head & neck (H&N) cancer

D. Osei-Fofie[1], M. Dimitriu[2], G. Landers[3], J. Wetter[4], P.A. Kraus[5], A. Lategan[6], S. Sonis[7]

[1]Oncology Dept., Kimberley Hospital, Kimberley, South Africa; [2]Development, MD Fast Consulting, Chevreuse, France; [3]Medical Oncology, The Oncology Centre Drs Callaghan, Marais, Narsai and Associates, Durban, South Africa; [4]Medical Oncology, University of Cape Town Groote Schuur Hospital, Cape Town, South Africa; [5]Medical Oncology, Outeniqua Oncology Centre - Cancer Care, George, South Africa; [6]Development, Supportive Therapeutics, Pretoria, South Africa; [7]Development, Primary Endpoint Solutions, Waltham, MA, USA

Background: OM is a common, painful, and costly toxicity associated with cytotoxic regimens used to treat H&N cancers. There is currently no approved intervention to successfully prevent or delay OM onset among patients being treated with CRT. Oxidative stress is a critical event in the pathogenesis of CRT associated OM. ST-617 has marked anti-oxidative activity/properties and has previously been studied in multiple human clinical trials. Supportive Therapeutics is developing ST-617 for the attenuation of OM onset, duration and severity.

Methods: A dose escalation trial in which ST-617 administered as an oral suspension, 1-2 hours before the administration of daily RT fractions. 18 patients with diagnoses of oral or oropharyngeal CA were enrolled (up to 6 pts/dose). Patients received concomitant cisplatin either weekly or tri-weekly. ST-617 was administered 3 days prior to CRT, and then continuing daily until the end of treatment. Safety outcomes, using CTCAE criteria (v 4.03) were used. OM occurrence and severity were assessed by trained and validated evaluators using WHO, NCI-CTC and RTOG criteria; scores were centrally assigned. The primary efficacy endpoints included the incidence and duration of SOM (WHO grades 3 or 4) vs historical controls. PD tracking measured total ROS/RNS, GSH/GSSG, regulation in plasma and buccal epithelial cells.

Results: 17 pts completed the 50, 100 and 150mg/day with no safety issues. No early dose limiting toxicity (DLT) or serious Adverse Event linked to ST-617 were observed. AEs observed were mainly nausea which is usually associated with CRT as expected. The 100 mg/day dose has been well tolerated with no grade 4 OM. No CRT dose interruptions or delays due to OM has been observed. Total ROS/RNS levels in plasma and buccal samples shows significant decrease with increased ST-617 dosing from 50 to 100 mg/day.

Conclusions: ST-617 administration shows a very good safety profile. Favorable signs of efficacy in preventing the duration and severity of OM with a physiologically relevant mode of action response have been noted. A randomized, double blind trial is planned with the recommended dose.

Clinical trial identification: SAHPRA number: 20180138 ST617-101; EudraCT 2020-000774-19.

2104P Prevention of taxane chemotherapy induced nail changes and peripheral neuropathy by application of extremity cooling: A prospective single center study with intrapatient comparison

K. Johnson[1], B. Stoffel[1], M. Schwitter[1], S. Hayoz[2], A. Rojas Mora[2], P. Richter[1], A. Fischer Maranta[1], T. El Saadany[1], U. Hasler-Strub[1], R.A.F. von Moos[3], A. Patzen[1], M.T. Mark[1], G. Roberts[1], R. Cathomas[1]

[1]Medical Oncology, KSGR - Kantonsspital Graubünden, Chur, Switzerland; [2]Biostatistics, SAKK - Swiss Group for Clinical Cancer Research, Bern, Switzerland; [3]Cancer Center, KSGR - Kantonsspital Graubünden, Chur, Switzerland

Background: Common side effects of taxanes are nail toxicity (tox) and CIPN. Different methods of cryotherapy to prevent these side effects have been tested. We investigated machine-controlled cooling of hand and feet to reduce nail tox and CIPN.

Methods: Patients (pts) receiving Docetaxel (Doce) (planned dose 300mg/m^2) or Paclitaxel (Pacli) (planned dose 720mg/m) in the adjuvant or palliative setting were included. The dominant hand and foot were cooled to approximately 10°C using the Hilotherapy-machine. The contralateral hand and foot were used as intrapatient comparison. Primary endpoint was the occurrence of any nail tox (Doce cohort) or CIPN (Pacli cohort) at any time during and up to 56 days after the end of treatment. We assumed an absolute improvement of 40% in nail tox and 20% in CIPN. With 90% power using a two-sided McNemar test with a significance level of 5%, a total of 30 pts were needed in each group. The intended to treat population (ITT) and the per protocol population (PPP) were analysed. Toxicity was assessed using the CTCAE v5.0 grading system and the PNQ questionnaire.

Results: 69 pts, 21 (9 in the PPP) treated with Doce and 48 (34 in the PPP) treated with Pacli, were included from 08/2020 - 08/2022. In the Doce cohort, nail tox was not significantly improved by cooling in the ITT (81.0%, vs 85.7%; odds ratio (OR) 0.71, 95% CI: 0.14 − 3.64, p = 0.564) and PPP (100% vs 100%; OR: 1.00, 95% CI: 0.00 − NA, p = NA) but significant benefit across visits over time was found for the ITT (OR: 0.42, 95% CI: 0.18 − 0.98, p=0.045) but not the PPP (OR: 0.75, 95% CI: 0.30 − 1.86, p=0.529). In the Pacli cohort, CIPN was numerically better in the ITT (60.9% vs. 71.7%, OR: 0.61, 95% CI: 0.26 − 1.47, p=0.059) and significantly better in the PPP (67.6% vs. 82.4%, OR: 0.45, 95% CI: 0.14 − 1.40, p-value = 0.025). Differences across visits were significantly in favour of cooling (ITT: OR: 0.28, 95% CI: 0.13 - 0.57, p=0.001; PPP: OR: 0.25, 95% CI: 0.12 - 0.55, p=0.001). Cooling was well tolerated, only 6 pts (9%) discontinued due to side effects.

Conclusions: Cooling of hand and feet has a clinically meaningful impact on occurrence of CIPN and nail toxicity. Effects are more significant over time and are taxane dose dependent.

2105P Prophylactic role of a postbiotic microbiota-stabilizer on abemaciclib-induced diarrhea in breast cancer patients: A pilot application study

R. De Sanctis[1], P. Tiberio[2], F. Jacobs[1], M. Gaudio[1], C. Benvenuti[1], A. Zambelli[1], C. Pozzi[3], G. Penna[3], A. Santoro[4], M. Rescigno[1]

[1]Department of Biomedical Sciences, Humanitas University, Pieve Emanuele, Italy; [2]Medical Oncology and Hematology Unit, IRCCS Humanitas Research Hospital, Rozzano, Italy; [3]Lab. Mucosal Immunology and Microbiota, IRCCS Humanitas Research Hospital, Rozzano, Italy; [4]Department of Biomedical Sciences, Humanitas University, Pieve Emanuele, Italy

Background: Abemaciclib-induced diarrhea represents a major concern in clinical practice, as it can severely affect patients' quality of life and cause treatment discontinuation and dose modifications. Since growing evidence emphasize the role of microbiota in abnormal bowel clinical manifestations, a new class of natural molecules, called postbiotics, offers a potential option for managing abemaciclib-induced diarrhea.

Methods: We conducted a prospective, observational, single-arm study to evaluate the effect of the postbiotic food supplement "PostbiotiX-Restore™" on abemaciclib-induced diarrhea. We enrolled 36 hormone receptor-positive HER2-negative breast cancer (BC) patients at IRCCS Humanitas Research Hospital. The postbiotic was administered once daily from day -7 to the end of the first cycle of abemaciclib. From day-7 and until the end of the second cycle of abemaciclib, patients reported a daily questionnaire on bowel movements, concomitant medications, diet, and treatment discontinuation. Diarrhea was defined according to version 4.0 of the National Cancer Institute's Common Terminology Criteria for Adverse Events. Incidence of diarrhea of any grade, its median duration and median time to diarrhea onset were assessed.

Results: An overall regularization of bowel movements in the first week of treatment with PostbioticX-Restore™ alone was reported. Diarrhea events occurred in all patients, but predominantly G1 (87.1%) and G2 (12.3%), with a very low percentage of G3 (0.6%; all occurring during the second cycle, off postbiotic) and no G4 events. The median time to diarrhea onset was 4 days (IQR 1-41) with a median duration of G1, G2, and G3 events of 4 (IQR 1-17), 1 (IQR 1-5), and 1 (IQR 1-1) days, respectively. There was only one case of dose reduction (during the second cycle, off postbiotic) and no case of treatment withdrawal due to diarrhea.

Conclusions: Our results suggest a promising effect of PostbioticX-Restore™ in the management of abemaciclib-induced diarrhea. Compared to pivotal trials on abemaciclib in BC patients, we observed a reduced severity and shorter duration of diarrhea.

2106P Safety and patient reported outcomes of SARS-CoV-2 vaccination in patients with cancer

A. Body[1], M.W. Donoghoe[2], E.S. Ahern[3], L. Lal[1], P. Downie[4], M.F. Leahy[5], N. Fuentes-Bolanos[6], A. Anazodo[6], B. Padhye[7], N. Hamad[8], C.E. Wakefield[6], E. Segelov[9]

[1]Medical Oncology Department, Monash Health - Monash Medical Centre, Clayton, VIC, Australia; [2]Stats Central, Mark Wainwright Analytical Centre, UNSW Sydney, Sydney, NSW, Australia; [3]Medical Oncology, Monash Health - Monash Medical Centre, Clayton, VIC, Australia; [4]Paediatric Oncology, Monash Health - Monash Medical Centre, Clayton, VIC, Australia; [5]Haematology, Royal Perth Hospital, Perth, WA, Australia; [6]Paediatric Oncology, SCH - Sydney Children's Hospital, Randwick, NSW, Australia; [7]Paediatric Oncology, The Children's Hospital at Westmead, Westmead, NSW, Australia; [8]Haematology, St Vincent's Hospital Sydney, Darlinghurst, NSW, Australia; [9]Medicine, Nursing and Health Sciences, Monash University, Clayton, NSW, Australia

Background: Vaccination against SARS-CoV-2 reduces morbidity from COVID-19 infection in patients (pts) with cancer. Hesitancy toward vaccination remains in some groups. Ongoing vaccinations are recommended for vulnerable pts. This study provides detailed patient-reported and safety outcomes, providing information for patients and clinicians regarding vaccination safety.

Methods: SerOzNET is a prospective study of pts with cancer who received COVID-19 vaccination (BNT162b2, mRNA1273 or ChadOx1-S) in 2021-22 in 3 cohorts: children (5-11 years(y)), adolescents (12-19y) and adults. From pre-vaccination (to 1 month post dose 3, pts completed serial electronic surveys: Oxford COVID-19 Vaccine Confidence and Complacency Scale, patient reported adverse events (AE), and quality of life (5-19y: PedsQL; 20+:QLQC30). Physicians reported safety, including serious adverse events and thrombosis.

Results: 511 pts were enrolled (40 children, 74 adolescents, 397 adults); 499 had one or more patient or medical outcome report completed. Median age was 52 (range 5-85). Pain at injection site was the commonest AE (60-90% of pts). AEs reported in 20-50% of all pts after dose 1, 2 or 3 were fatigue, muscle pain and fever. Headache was more common in adolescents and adults (18-26%) than children (0-11%). Chills were more common in children and adolescents (11-29%) than adults (12-19%). Delays/modifications to cancer treatment from dose 1 to 1 month post dose 2 were reported in 33% of children, 27% of adolescents and 21% of adults; and from dose 3 to 1 month post dose 3 in 10% of children, 18% of adolescents and 12% of adults. None were attributed to vaccine toxicity. Venous thromboembolic events (VTE) were reported in 4/397 adults; there were no arterial events, and no thrombotic events in children or adolescents. No allergic reactions were reported. Mean QLQC30 in adults, and PedsQL in pts $<$20y was similar pre and post dose 1 (p=n.s. all ages) and 2 (p=n.s. children, adults. Adolescents: 2% improvement, p=0.006).

Conclusions: This large trial dataset demonstrates SARS-CoV-2 vaccination in pts with cancer has manageable toxicity. VTE was low, consistent with background rates. Individuals with cancer can be reassured that SARS-CoV-2 vaccination is safe and will not disrupt their cancer therapy.

Clinical trial identification: ACTRN12621001004853.

2107P Thromboprophylaxis with intermediate or prophylactic doses of LMWHs in ambulatory cancer patients

N.G. Tsoukalas, A.N. Christopoulou, E. Timotheadou, A. Koumarianou, A. Ardavanis, I. Athanasiadis, M. Demiri, A. Bokas, G.F. Samelis, S. Peroukidis, G. Papatsimpas, C. Andreadis, C. Kalofonos, A. Psyrri, N. Kapodistrias, P. Papakostas, G. Pentheroudakis, G. Aravantinos, P. Papakotoulas, I. Boukovinas

HeSMO, On behalf of the Hellenic Society of Medical Oncology, Athens, Greece

Background: Thromboembolic events occur in up to 20% of cancer patients during their course of disease. Cancer associated thrombosis (CAT) is a "signum malum" for cancer itself contributing to morbidity and mortality. Optimal measures to prevent CAT are crucial.

Methods: A post hoc analysis of GMaT & ACT4CAT prospective observational phase IV studies conducted in Greece by Hellenic Society for Medical Oncology (HeSMO), aiming to evaluate efficacy & safety of primary CAT prophylaxis with prophylactic (ProD) or intermediate (InterD; 50%-75% of full treatment dose) doses of Low Molecular Weight Heparins (LMWHs) in ambulatory active cancer patients. Both studies conducted according to Helsinki declaration.

Results: 1157 patients from 26 oncology centers were recruited. Age: 64.9±12.3 years, BMI: 26.1±45.1 Kg/m^2, 59.9% males. Metastasis in 74.5%, Highly Thrombogenic Agents (HTAs) received 82.3%. Anticoagulation agents were (%): 91.2 tinzaparin, 4.6 fondaparinux, 2.3 bemiparin, 1.2 enoxaparin, 0.8 rivaroxaban or apixaban, for 5.1±3.3 months duration. 62% of patients received InterD (1st, 2nd, 3rd,adjuvant & neoadjuvant: 62.4%, 67.3%, 69.8%, 44.1% &71.4% respectively, p=0.004). InterD preferred in men, in those with metastasis, HTAs treatment and receiving erythropoietin agents (ESA) while ProD in those with history of bleeding, heart or vascular, lung or metabolic disease, immobility, surgery, or radiotherapy. Detailed info in the table.

Table: 2107P

	InterD (N=701) (N/%)	ProD (N=430) (N/%)	p	OR (95%CI)
Males	416/63.7	214/55.4	**0.008**	1.4 (1.1-1.8)
Metastasis	535/79.0	259/67.3	**<.0001**	1.8 (1.4-2.4)
HTAs	597/85.4	338/79.2	**0.007**	1.5 (1.1-2.1)

Bleedings	11/1.6	11/2.6	0.242	0.6 (0.3-1.4)
Thrombotic events	11/1.6	20/4.7	**0.002**	0.3 (0.2-0.7)

32 patients (2.8%) had thrombotic events (20 in ProD, 11 in InterD, 1 dose unspecified) with higher risk in ProD (OR: 3.1, 95%CI:1.5-6.5, p=0.0021). 26 minor bleeding events reported (2.3%, no dose related difference, p=0.2424).

Conclusions: Common clinical oncology practice was to administer prophylaxis using in most cases LMWHs and frequently in InterD. Selection of anticoagulation dose was based on demographics, cancer characteristics, treatment type and patient medical history. InterD was found to be more efficacious and without safety concerns.

Clinical trial identification: GMaT: NCT03292107; ACT4CAT: NCT03909399.

2108P Vitamin B12 and its clinical relevance in hospitalized cancer patients

S. Maccarone[1], G. Riva[1], A. Malovini[2], V. Tibollo[2], M.V. Lenti[3], A. Premoli[1], L.D. Locati[4], F. Sottotetti[5]

[1]Istituti Clinici Scientifici Maugeri - Oncologia Medica, Università di Pavia - Dipartimento di Medicina Molecolare, Pavia, Italy; [2]Laboratory of Informatics and Systems Engineering for Clinical Research, IRCCS Pavia - Fondazione Salvatore Maugeri, Pavia, Italy; [3]Department of Internal Medicine, IRCCS San Matteo Hospital Foundation, University of Pavia, Pavia, Italy; [4]Medical Oncology Unit, IRCCS ICS Maugeri; Department of Internal Medicine and Therapeutics, University of Pavia, Pavia, Italy; [5]Oncologia Medica, Fondazione S. Maugeri IRCCS, Pavia, Italy

Background: Vitamin B12 impairment is common in cancer patients due to several factors, namely gastrointestinal (GI) surgery, malnutrition, liver metastases, and chemotherapy. Data regarding their prevalence and significance in this setting, as well as the impact on the overall prognosis, are lacking.

Methods: We retrospectively enrolled patients hospitalized for various cancer-related conditions at our Medical Oncology ward (2017-2022). Plasma B12 levels were stratified as Very Low (VL $<$200 pg/ml), Low (L 200-300 pg/ml), Normal (N 300-813 pg/ml) or High (H $>$813 pg/ml). We collected demographic and clinical data, including BMI, Cumulative Illness Rating Scale, nutritional status, ECOG PS, primary cancer site, disease stage, liver involvement and function tests, GI surgery. Univariate and multivariate statistical tests identified variables statistically associated to vitamin B12 ($p<0.05$).

Results: We enrolled 788 patients (F/M: 1.05, median age: 72, IQR: 62-78 y), VL B12 levels were found in 14.09% cases, L in 19.42%, N in 49.37% and H in 17.13%. At univariate analysis, B12 distribution was significantly different between genders, with females being characterized by higher median values compared to males. Vitamin B12 distribution increased significantly as function of ECOG PS levels. Breast cancer patients were characterized by the highest median B12 value while colorectal cancer patients by the lowest. B12 was also significantly higher in advanced compared to early-stage patients as well as in those who had liver failure. The correlation between B12 and age, albumin, prealbumin, total protein and folates was statistically

significant but negligible (|r|<0.3). Multivariate analysis showed that the probability of H vs VL B12 levels was increased in patients with hypoproteinemia, hypoprealbuminemia and ECOG PS≥2, and decreased in those with colorectal and gastric cancer

Conclusions: To our knowledge, this is the first study investigating B12 levels in a wide and well clinically-characterized group of cancer patients; our data suggest that increased B12 is associated to an impaired clinical status, while in early stage patients, especially the elderly, B12 deficiency is of concern and may negatively impact the overall outcomes.

2109P Vitamin A, D and E levels in patients with solid tumors undergoing palliative systemic cancer treatment

J.M. Berger[1], C. Englisch[2], L. Gottmann[1], M. Korpan[1], M. Kleinberger[2], A.M. Starzer[1], R. Marculescu[3], M. Preusser[1], A.S. Berghoff[1]

[1]Division of Oncology, Department of Medicine I, Medical University of Vienna, Vienna, Austria; [2]Division of Hematology, Department of Medicine I, Medical University of Vienna, Vienna, Austria; [3]Department of Laboratory Medicine, Medical University of Vienna, Vienna, Austria

Background: Vitamin deficiencies and supplement intake is discussed controversially in oncology. Therefore, we aimed to investigate vitamin D, A and E levels and their correlation with clinical characteristics and symptomatic burden in a large pan-cancer cohort.

Methods: 25-hydroxy-vitamin D, vitamin A, and vitamin E levels were measured at treatment start in patients receiving palliative cancer treatment at the Medical University of Vienna (MUV) included in the "Biobanking Program for Personalized Immunotherapy" between May 2019 and March 2022. Measurements were performed using a chemiluminescence immunoassay (vitamin D) and high performance liquid chromatography (vitamin A, vitamin E) established at the Department of Laboratory Medicine (MUV). Cut off values defining the normal range were predefined as follows: vitamin D (75-250nmol/L), vitamin A (1.05-2.45µmol/L), vitamin E (12.0-42.0µmol/L). Symptom burden was assessed using the EORTC quality of life questionnaire QLQC-30 and its subscore assessing fatigue.

Results: Vitamin D, A, and E levels were measured in a total of 231 patients (92 females, 139 males, median age: 64 years [range: 23-89]). Median vitamin levels were as follows: vitamin D 66.9nmol/l (range: 10.4-186.0nmol/l), vitamin A 1.64µmol/l (range: 0.29-4.22µmol/l), and vitamin E 35.8µmol/l (range: 20.2-76.8µmol/l). Patients presented with vitamin D deficiencies in 138/231 (59.7%) and vitamin A deficiencies in 34/231 cases (14.7%). No vitamin E deficiencies were detected, however, 25/231 patients (24.2%) presented with vitamin E levels above normal. Vitamin A levels were increased in 26/231 patients (11.3%), while vitamin D levels above the upper limit of normal in 1/231 patient (0.4%). No correlations between vitamin levels and clinical characteristics at sample collection such as sex, age, tumor origin, symptom burden or fatigue were observed ($p>0.05$). Additionally, no correlation between vitamin levels and overall survival could be detected ($p>0.05$).

Conclusions: Even though vitamin deficiencies are common in patients with cancer, no influences of vitamin levels on symptom burden, fatigue or survival could be detected.

2110P Palonosetron plus megestrol acetate verses dexamethasone in preventing nausea and vomiting following moderately emetogenic chemotherapy: A randomized, multicenter, self-controlled, phase II trial

Q. Li[1], B. Yang[2], C. Yi[1]

[1]Division of Abdominal Tumor Multimodality Treatment, SCU - Sichuan University - Huaxi Campus, Chengdu, China; [2]Abdominal Oncology, West China Hospital, Huaxi, Sichuan University, Chengdu, China

Background: Chemotherapy-induced nausea and vomiting (CINV) is the most common side effect following chemotherapy. For medium emetic chemotherapy (MEC), guidelines recommend dexamethasone (DEX) for the prevention and treatment of CINV. But the usage of DEX can cause a variety of adverse reactions. DEX-free regimens are being actively explored. Megestrol acetate (MA) was suggested as an antiemetic therapy gradually. Accordingly, the present phase II trial was designed to test the hypothesis that the efficacy of MA plus palonosetron regimen against CINV is non-inferior to a DEX regimen.

Methods: This was a randomized, self-controlled phase II study. Patients enrolled were scheduled to receive primary chemotherapy that contained oxaliplatin and fluorouracil every 3 weeks and randomized to the MA-DEX group or DEX-MA group. MA-DEX group received palonosetron (0.25 mg intravenously, d1) and MA (160 mg orally, d1-5) for first cycle and then received palonosetron and DEX (6 mg orally, d1-4) for second cycle. The DEX-MA group received the antiemetic treatment in the reverse order. The primary endpoint was complete response (CR). The non-inferiority margin was predefined as a 15% difference between groups in the primary endpoint. All subjects have signed the informed consent, and this trial has registered with Chinese Clinical Trial Register (ChiCTR2000037447).

Results: 61 patients were eventually evaluated in the study 32 included in the DEX-MA group and 29 in the MA-DEX group. Overall CR rates were 82.25% for those administered MA on day 1 (acute phase) (n = 52), and 83.61% on days 2 -5 (delayed phase) (n = 51), 72.13% on days 1-7 (whole phase). According to CR rates , the MA regimen is non-inferior to DEX regimen during the acute, delayed and whole phase. Compared with DEX, the quality of life (QOL) of MA regimen was higher with respect to dyspnea (P=0.000) and appetite (P=0.021).

Conclusions: In this trial, MA is non-inferior to dexamethasone in the treatment of CINV induced by MEC regimens, and no obvious adverse reactions occurred. Compared with DEX, MA led to a milder dyspnea and appetite decrease, and better quality of life after chemotherapy.

2111P The value of multiple psychometric tools for distress screening and referral in a cancer population

D. Anderson[1], S. Schusterbruce[1], N. Fitzpatrick[1], P.J. Vlachostergios[2], K.V. Kamposioras[3]

[1]Psycho-Oncology, The Christie NHS Foundation Trust, Manchester, UK; [2]Department of Medical Oncology, Weill Cornell Medicine, New York, NY, USA & IASO Thessalias Hospital, Larissa, Greece; [3]Medical Oncology Dept., The Christie NHS Foundation Trust, Manchester, UK

Background: Psychometric assessment tools are widely available but underutilized in daily oncology practice. The aim of this study was to evaluate the role of multiple psychometric scales in identifying cancer patients in distress who need Psycho-Oncology management.

Methods: Colorectal cancer patients were prospectively asked to complete a survey including 3 psychometric scales (GAD-7, PHQ-9, PC-PTSD-5). Those scoring high on at least one scale (GAD-7 score ≥ 10, PHQ-9 score ≥ 10, PC-PTSD-5 score ≥ 4) were offered referral to the Psycho-Oncology service. Those accepting the referral were further triaged by members of this service via a standardized semi-structured interview. Patients were divided into three groups: those accepted by the Psycho-Oncology service, those declined the referral and those discharged from the service with no need for further intervention. Outcomes were compared with the analysis of variance test (ANOVA).

Results: Fifty-four patients (30 females) of median age 60 years (range 36-81) were prospectively evaluated. 20 patients (37%) reported their cancer was under control, 15 (28%) believed they had progressive disease, while 19 (35%) were uncertain. Approximately half patients (26; 48%) referred a prior history of a mental condition. The mean (±SE) scores for each psychometric scale were 10.96 (± 0.78), 12.79 (± 0.82), and 1.07 (± 0.21), respectively for GAD-7, PHQ-9, PC-PTSD-5. Thirty-four patients (63%) scored high on GAD-7, 40 (74%) on PHQ-9 and 8 (15%) on PC-PTSD-5. Almost half of the patients declined a referral (25, 46%), 22 (41%) were assessed by a Psycho-Oncologist and managed accordingly and 7 (13%) were discharged after the

initial tirage. There was no statistically significant difference in the mean psychometric scores between the three identified groups ($p<0.05$).

Conclusions: Psychometric scales are useful screening tools to identify distress but cannot differentiate between general distress and psychological/psychiatric symptoms requiring specialist intervention. Psychometric scales should be used in conjunction with semi-structured interviews. The 'screen and triage' model should be further investigated as part of an integrated care model, to signpost cancer patients to appropriate support services.

2112P Initial geriatric assessment and chemotherapy tolerability treatment in Brazilian patients with malignant neoplasm of the digestive system

M. Dumont Bonfin Santos[1], N.M. Forones[2]

[1]Gastroenterology, UNIFESP-Federal University of Sao Paulo, São Paulo, Brazil; [2]Gastroenterology, UNIFESP - Federal University of Sao Paulo - Ambulatório de Quimioterapia, São Paulo, Brazil

Background: The WHO (World Health Organization) defines elderly as individuals aged 60 years or older in developing countries. It is known that due to sociodemographic changes such as increased life expectancy, there was an increase in the prevalence of cancer diagnosis in this population subgroup. Associated with the fact that historically these individuals are underrepresented in the main oncological clinical studies, the challenge of a better way of evaluating these patients, who inherently have different physiological characteristics, arises. In this context, the Comprehensive Geriatric Assessment (GGA) is consolidated as an adequate application tool. This study aims to evaluate, based on the domains of the CGA, elderly patients with malignant neoplasm of the digestive tract who will start chemotherapy treatment and associate it with the tolerability of the treatment after 3 months.

Methods: This prospective study included patients with neoplasia of the digestive tract: esophagus, stomach, pancreas, biliary tract, colon and rectum, evaluated at baseline and after 3 months of chemotherapy. Patients aged 60 years or older were selected. The CGA was applied at the beginning of the treatment. Treatment tolerability was defined in this study by toxicity and maintenance or not of the chosen treatment at the end of 3 months. The data were registered in Excel and subsequently imported into IBM-SPSS Statistics version 28 for comparative analysis between groups. This study was approved by the ethics committee (CAAE:30127320.0.0000.5505). All patients signed a Term of Free and Informed Consent before inclusion.

Results: 50 patients (median age: 68), colorectal (42%). Stage II: 7 patients, III:18, IV: 25.Correlated with toxicity: IADL (Instrumental Activities of Daily Living) and nutritional status. Dependent for IADL developed more G3 toxicity ($p= 0.048$) and were unable to continue treatment: the Lawton scale ($p=0.020$) ;Pfeffer questionnaire ($p=0.024$).Malnourished developed more G3 toxicity ($p=0.003$) and suspended/modified treatment ($p=0.002$).

Conclusions: The evaluation of functionality and nutrition domains were associated with toxicity and maintenance of treatment after 3 months.

2113P Efficacy and effectiveness of prophylactic magnesium supplementation on prevention of cisplatin-induced nephrotoxicity: A systematic review and meta-analysis

C.E.D.R. Castro[1], F. Dias[1], M.I. Dacoregio[2], I.F. Michelon[3], C.E. Stecca[4], M. Silveira Vilbert[5]

[1]Medicine, HUB - Hospital Universitario de Brasilia - UNB - EBSERH, Brasilia, Brazil; [2]Medicine, Universidade Estadual do Centro Oeste, Guarapuava, Brazil; [3]Medicine Department, UCPEL - Universidade Católica de Pelotas, Pelotas, Brazil; [4]Medical Oncology, Hospital do Câncer de Londrina, Londrina, Brazil; [5]Department of Clinical Oncology, UHN - University Health Network - Princess Margaret Cancer Center, Toronto, ON, Canada

Background: Cisplatin-induced nephrotoxicity (CIN) is a frequent dose-limiting adverse effect, and many nephroprotective strategies have been proposed to prevent its occurrence. Although multiple studies support premedication with magnesium (Mg) and hydration, this intervention has not been widely implemented, as some centers still replace it only after the occurrence of hypomagnesemia. We performed a systematic review and meta-analysis to evaluate the efficacy and effectiveness of Mg supplementation (suppl) prior to cisplatin.

Methods: We systematically searched Pubmed, Embase, and Cochrane databases for randomized clinical trials (RCT) and observational studies assessing prophylactic Mg suppl compared with placebo for patients receiving cisplatin-based chemotherapy. Primary outcomes were acute nephrotoxicity and hypomagnesemia events; secondary outcome included the association of CIN with variations on serum creatinine levels (ΔSCr). We used RevMan 5.1.7 and RStudio for statistical analysis; random-effects models to pool studies; and I^2 statistics to assess heterogeneity.

Results: We included 24 studies with 3,803 patients. Nine were RCT and 15 observational cohort studies. We found a significant reduction of risk of CIN (all grades) in patients treated with prophylactic Mg compared to placebo (OR = 0.16; 95%CI 0.11 – 0.24; $p<0.001$). The pooled analysis including only studies adjusted for confounding variables demonstrated a 67% risk reduction of CIN with Mg suppl ($p<0.0001$). Mg prophylaxis was effective in both the clinical trial setting (OR = 0.22) and in the real-world data analysis (OR = 0.15). The benefit was seen across all tumor types and combinations of cisplatin-based chemotherapies included in the study. Hypomagnesemia events were significantly less frequent in the intervention group (OR = 0.27; 95%CI 0.16–0.45; $p<0.000001$). There was no difference regarding doses of Mg administered, and the ΔSCr were not significantly associated with the risk of CIN.

Conclusions: In patients undergoing cisplatin-based chemotherapy, prophylactic Mg suppl significantly reduces the risk of CIN and hypomagnesemia as compared with no prophylaxis.

2114P Impact of comprehensive geriatric assessment (CGA) in the management of chemotherapy toxicity in older cancer patients

J. Recuero-Borau[1], A. Gómez-Alderete[1], B. Areny[2], E-M. Amor[2], L. Rio[3], L. Visa Turmo[1], D. Conde-Estévez[3], M. Guix Arnau[1], M. Pi-Figueras[2]

[1]Medical Oncology Department, Hospital del Mar - Parc de Salut Mar, Barcelona, Spain; [2]Geriatrics Department, Hospital del Mar - Parc de Salut Mar, Barcelona, Spain; [3]Pharmacy Dept., Hospital del Mar - Parc de Salut Mar, Barcelona, Spain

Background: Up to 90% of elderly patients (pts) develop toxicity when treated with chemotherapy (CT). This can often lead to dose reductions, temporary or even definitive treatment interruptions. The CGA is a useful tool to detect frailty, and to predict and prevent unnecessary toxicities. We wanted to explore the effect of CGA in improving tolerance to CT in daily clinical practice of elderly pts with gastrointestinal tumors.

Methods: Observational retrospective study of a cohort of digestive tract cancer pts > 70 years old treated between 2016 and 2023 at Hospital del Mar, Barcelona (Spain), comparing CT tolerance of those receiving CGA with those without CGA. CGA was performed by an oncogeriatrician following the recommendation of the oncology interdisciplinary tumor board. We analysed toxicity, polypharmacy and predict the toxicity risk with CT using CARG score.

Results: One-hundred and eighty pts were included: 58% colorectal, 32% pancreatic, 6% bile duct and 4% gastric cancers. 91 of them (51%) received CGA. Median age was 79 (CGA group) vs 74 (non-CGA group) years old. ECOG PS was 0-1 in 87% of the CGA group and in 94% of the non-CGA. In the CGA group, 63% received CT in the unresectable/metastatic setting vs 52% in the non-CGA group. Polypharmacy (>4 drugs) was present in 60% of CGA group (median of 7 drugs per patient) vs 68% of non-CGA (median 6 drugs). The CARG toxicity risk score was low in 34% of pts, intermediate in 55% and high in 11%. CT treatment was initially adapted in 38 pts (43%) of the non-CGA group vs 55 pts (60%) in the CGA group. High-grade (3-4) toxicities were more frequent in the non-CGA (32% pts) compared to CGA (24% pts). More pts in the non-CGA group needed dose reductions during treatment (62%) compared to the CGA group (43%), with statistical significance ($p=0.009$).

Table: 2114P

	Non-CGA group	CGA group	p value
Dose reduction	62%	43%	0.009
G 3-4 toxicities	32%	24%	0.39
