Treatment discontinuation for toxicity	25%	24%	0.96

Conclusions: Performing CGA helps to prevent high-grade toxicity in elderly pts with digestive tract tumors by adapting CT treatment and reduces CT dose reductions related to toxicities.

2115P Pre-cachexia incidence in patients with solid cancer: A cross-sectional study

L. Gottmann[1], L. Berchtold[1], M. Mair[1], A.M. Starzer[1], J.H. Fürst[1], J.M. Berger[1], C. Englisch[2], M. Kleinberger[1], M. Korpan[1], E. Hütterer[1], E.S. Bergen[1], M. Preusser[1], A.S. Berghoff[1]

[1]Division of Oncology, Department of Medicine I, Medical University of Vienna, Vienna, Austria; [2]Division of Hematology, Department of Medicine I, Medical University of Vienna, Vienna, Austria

Background: Cancer-associated cachexia (CAC) is an ongoing loss of skeletal muscle which cannot be fully abolished by nutritional interventions. While ESMO suggests precise CAC definitions, pre-cachexia definition is vague.

Methods: Patients with solid cancers and lack of CAC at baseline, enrolled in the *TRU Biobanking Program* of the *Medical University of Vienna* between March 2019 and February 2022, were analyzed. At inclusion and each restaging, the prevalence of modified Glasgow Prognostic Score ≥1 (mGPS), weight loss ≥2% (WL), physical functioning <80 (PF2) and fatigue >30 (FA) was assessed clinically and with the EORTC QLQ-C30 questionnaire. In addition, we evaluated the burden of nutritional risk symptoms (diarrhea, nausea, vomiting, lack of appetite, constipation) with a score (NR) of 1-34. Pre-cachexia criteria were correlated with clinical parameters (age, gender, therapy status). Occurrence of CAC was evaluated using ESMO definitions.

Results: For analysis, 391 patients (47% female, 53% male, median age 59 years) were available. Median observation time was 4 months (range 0-46) with a median of 2 observations (range 1-13). Within the observed period 12% of patients developed CAC. Pre-cachexia as defined by mGPS was found in 52% of patients, by WL in 53%, by PF2 in 69%, by FA in 84%, and by NR ≥7 in 51% of patients. Pre-cachexia by WL was found less often in female (43%) than in male patients (62%; OR 2.14, 95% CI 1.43-3.23; p<0.001) and more often in treatment-naive patients (60%) than in those with prior systemic therapy (48%; OR 1.62, 95% CI 1.08-2.43, p=0.019). Patients with pre-cachexia by NR were younger (median 58, IQR 50-65) compared to the other patients (median 60, IQR 53-70; p=0.018). All other pre-cachexia definitions did not correlate with clinical characteristics (p>0.05). All five pre-cachexia definitions were fulfilled by 15% of patients, four by 27%, three by 29%, two by 14%, and one by 14%. No pre-cachexia definition was fulfilled by 2.3%. None of the investigated pre-cachexia definitions reliably identified patients with subsequent CAC development (p>0.05).

Conclusions: Further research on pre-cachexia-defining parameters is needed for the development of standardized screening methods as current definitions fail to identify patients with high CAC risk.

2116P Preoperative body mass index, waist circumference, and mortality after major cancer surgery: A nationwide cohort study in South Korea

J. Yoon, I. Park

Department of Anaesthesiology and Pain Medicine, Seoul National University Bundang Hospital, Seongnam, Republic of Korea

Background: Body mass index (BMI) and waist circumference (WC) were used to evaluate nutritional status and obesity.We aimed to examine whether preoperative BMI or WC was associated with mortality after cancer surgery.

Methods: As a population-based cohort study, this study used data extracted from the National Health Insurance Service database of South Korea.We included 87,220 adult patients who underwent major cancer surgery with curative intent between January 1, 2016, and December 31, 2020.

Results: A total of 87,220 patients were included in the final analysis, and 1,374 (1.6%) died within 90 days after cancer surgery. In the multivariable logistic regression model, the BMI <18.5/kg/m^2 and >35 kg/m^2 groups showed 1.98-fold (odds ratio [OR]: 1.98, 95% confidence interval [CI]: 1.58, 2.49; P<0.001) and 2.62-fold (OR: 2.62, 95% CI: 1.26, 5.45; P<0.001) higher 90-day mortality after cancer surgery than did the BMI 18.5−24.9 kg/m^2 group. The 25.0−29.9 kg/m^2 (P=0.143) and 30.0−34.9 kg/m^2 (P=0.109) BMI groups did not show significant differences compared to the BMI 18.5−24.9 kg/m^2 group. Compared with the normal WC group, the high (P=0.052) and very high (P=0.236) WC groups also did not show significant differences in terms of 90-day mortality.

Table: 2116P Subgroup analyses for 90-day mortality according to cancer surgery type

Surgery	OR (95% CI)	*P*-value
Lung cancer		
BMI: <18.5	1.89 (1.08, 3.29)	0.025
BMI: 25.0−29.9	0.82 (0.59, 1.14)	0.235
BMI: 30.0−34.9	0.97 (0.37, 2.59)	0.954
BMI: >35.0	5.91 (1.19, 29.312)	0.030
Gastric cancer		
BMI: <18.5	2.47 (1.49, 4.10)	<0.001
BMI: 18.5−24.9	1	
BMI: 25.0−29.9	0.99 (0.70, 1.39)	0.944
BMI: 30.0−34.9	0.32 (0.09, 1.11)	0.072
BMI: >35.0	1.62 (0.20, 13.26)	0.654
Colorectal cancer		
BMI: <18.5	2.36 (1.53, 3.65)	<0.001
BMI: 25.0−29.9	0.91 (0.68, 1.24)	0.556
BMI: 30.0−34.9	1.01 (0.47, 2.19)	0.979
BMI: >35.0	4.67 (1.23, 17.73)	0.024
Liver cancer		
BMI: <18.5	2.22 (1.11, 4.43)	0.024
BMI: 25.0−29.9	0.78 (0.52, 1.17)	0.227
BMI: 30.0−34.9	0.62 (0.20, 1.94)	0.409
BMI: >35.0	1.09 (0.12, 9.88)	0.941

OR, Odds ratio; CI, confidence interval; BMI, body mass index; WC, waist circumference

Conclusions: Preoperative BMI <18.5 kg/m^2 and >35 kg/m^2 are associated with an elevated risk of 90-day mortality after major cancer surgery. However, preoperative WC was not significantly associated with 90-day mortality after cancer surgery.

2117P Dietary patterns and clinical outcomes in patients with lung cancer: What needs to change

I. Borchardt[1], C. Augusto[1], E. Vieira[1], S. Chek[1], G. Farias[2], G.F. Moreira[3], F.C. Dias[4], F.T. Taveira[4], T.C. Montella[5], A.C. de Melo[6], W. Peres[1], C.G.M. Ferreira[7]

[1]Nutrition, UFRJ - Universidade Federal do Rio de Janeiro, Rio de Janeiro, Brazil; [2]Nurse, Grupo Oncoclínicas, Rio de Janeiro, Brazil; [3]Clinical Pharmacy, Grupo Oncoclinicas Botafogo, Rio de Janeiro, Brazil; [4]Oncology, Grupo Oncoclínicas Botafogo, Rio de Janeiro, Brazil; [5]Oncologist, Grupo Oncoclínicas, Rio de Janeiro, Brazil; [6]Clinical Research Division, Grupo Oncoclínicas, Rio de Janeiro, Brazil; [7]Education and Research, Grupo Oncoclinicas Botafogo, Rio de Janeiro, Brazil

Background: The provision of nutrients in adequate quantity and quality is essential for the treatment of low muscle mass, which is highly found in patients with lung cancer (LC). Identifying an early deficit in food consumption is recommended as a strategy to preserve muscle and weight compartments that directly impact treatment tolerance, functionality and quality of life. This study aimed to investigate whether caloric and protein intake at diagnosis are predictive of outcomes in patients with LC.

Methods: This is a prospective, observational study. Data were collected at the first nutritional consultation between January and December 2019 and consisted of nutritional risk screening for cancer patients, height, body weight, weight loss, calf circumference, handgrip strength measured using a dynamometer and 24-hour recall to estimate average food and macronutrient intake. Survival curves were generated by Kaplan-Meier analysis to assess the association between caloric and protein intake and 3-year mortality.

Results: A total of 50 patients with LC were included, 62% were female, 94% elderly, 88% with non-small cell lung cancer, 88% were diagnosed with disease stages III and IV, and 64% were smokers. Weight-adjusted mean daily intake of energy was 18.6 kcal/kg/day and protein 0.94g/kg/day, and 86% and 60% had lower energy and protein intakes, respectively, than the recommended for patients with cancer. Individuals with consumption greater than 1g/kg/day had significantly longer overall survival with 35,2 versus 21,9 months than those with consumption lower than the recommendation for patients with cancer (p=0.03). There was no statistical difference according to the caloric intake (>25kcal/kg/day versus <25kcal/kg/day) (p=0.20).

Conclusions: Caloric and protein intake at diagnosis is low in patients with LC, and a lower protein intake was a predictor of negative results. Nutritional interventions are low-cost and can be easily implemented as a strategy to modify these results and improve care for these individuals.

2118P Refeeding syndrome: A prospective analysis in adults admitted to an oncology hospital

F. Gonçalves[1], S. Cabral[2], P. Alves[2], F. Coelho[3]

[1]Faculty of Health Sciences, University of A Coruña, A Coruña, Spain; [2]Department of Nutrition & Dietetics, Instituto Portugues de Oncologia do Porto Francisco Gentil, EPE (IPO-Porto), Porto, Portugal; [3]Intensive Care Unit, Instituto Portugues de Oncologia do Porto Francisco Gentil, EPE (IPO-Porto), Porto, Portugal

Background: The refeeding syndrome is a potentially lethal condition, associated with metabolic alterations after food reintroduction, and subsequent increase in nutritional intake. It occurs especially in malnourished patients, or in a hyper-catabolic stage. Particularly oncological diseases represent an increased risk factor for the manifestation of the syndrome. Data related to the oncological population is rarely reported, except for the various case series/case studies published to date.This study aims to determine the prevalence of refeeding syndrome in oncological patients according to their risk and to develop a clinical pathway to address and monitor this syndrome.

Methods: A prospective longitudinal study was carried out on 124 patients who started exclusive support via parenteral or enteral nutrition, in 4 units of the oncology hospital: intensive care, intermediate care, medical and surgical inpatient units. Risk for refeeding syndrome was determined as follows: low risk, moderate, high. Biochemistry available (ionogram) before feeding, and its evolution over the first 5 days after initiation was evaluated.

Results: In 64% of patients, serum phosphate, potassium, and magnesium measurements were available prior to nutritional support. There was no information on serum phosphate in 29.7% of patients, with no significant differences between surgical and medical patients. After 48 hours, serum concentration variations were especially pronounced in patients without electrolyte supplementation prior to feeding (-18.2%) versus previously supplemented (10.3%) (p=0.035). After 72 hours, 31.8% of patients experienced reductions superior to 30% in the ionogram, compatible with refeeding syndrome. A positive Spearman's correlation (0.69, p=0.017) was identified between the initially assessed risk (moderate and high) and the decrease in phosphate (>20%) observed at the end of 48 hours in non-supplemented patients.

Conclusions: There is a high prevalence of refeeding syndrome in cancer patients. Monitoring should be continuous, including hypophosphatemia. By providing a multidisciplinary intervention and allowing the provision of micronutrients at the appropriate time, complications of the syndrome can be avoided.

2119P The prognostic impact of nutritional assessment and scores in advanced gastric cancer

S. Torresan[1], M. De Scordilli[1], G. Bortolus[1], M. Bortolot[1], G. Zapelloni[1], R. Mazzeo[1], F. Totaro[1], G. De Pieri[1], C. Zanchetta[1], A. Michelotti[1], M. Casagrande[2], V. Fanotto[2], S.K. Garattini[3], G.G. Cardellino[2], N. Pella[2], D. Iacono[2], F. Puglisi[4], G. Fasola[2]

[1]Department of Medicine (DAME), University of Udine, Udine, Italy; [2]Department of Medical Oncology, ASU Friuli Centrale - Ospedale S. Maria della Misericordia, Udine, Italy; [3]Department of Medical Oncology, ASU Friuli Centrale - Ospedale S. Maria della Misericordia, Udine, Italy; [4]Unit of Medical Oncology and Cancer Prevention and Department of Medicine (DAME), IRCCS CRO and University of Udine, Udine, Italy

Background: Malnutrition and weight loss have renowned prognostic value in patients (pts) with localised gastric cancer (GC). We analysed the association of weight loss and early nutritional intervention with outcomes in pts with advanced GC.

Methods: A retrospective cohort of non-resected metastatic GC pts treated with first-line chemotherapy (CT) at the Academic Hospital of Udine (2012-2022) was analysed. Biometric and nutritional parameters were evaluated at diagnosis and during treatment. The prognostic value of >10% weight loss 3 months (mo) after nutritional intervention was assessed. Nutritional interventions and scores (Prognostic Nutritional Index [PNI], neutrophil-lymphocyte ratio [NLR], platelet-lymphocyte ratio [PLR]), dichotomized as high/low per literature-derived cut-offs, were evaluated as predictors of overall survival (OS) and progression-free survival (PFS) with Cox regression model.

Results: 100 pts were included (65 male), median age was 69 years. At CT start, 87.8% of pts had lost weight (>10% in 49.4%), with a median loss of 8 Kg. 55.7% of pts had low PNI, more than 60% high NLR and PLR. 71 pts underwent nutritional assessment (NA), 53.5% before CT start; median time from diagnosis to NA was 40 days. 51 pts had >1 NA, 31 pts >2 NA. At first NA, nutritional interventions consisted in oral supplements (53.4%), parenteral nutrition (28.2%) and counselling (59.2%). Overall, 49% of pts gained weight 3 mo after NA; 88.9% of pts' PNI improved, >50% of NLR and PLR lowered. At disease progression, recorded in 96 pts, PLR and NLR increased significantly (60% vs 48% at 3 mo after NA and 70% vs 34%, respectively). In our cohort, median PFS was 5 mo and median OS was 9 mo. Low PNI (HR 2.05, p = 0.008), high NLR (HR 2.51, p <0.001) and PLR (HR 2.63, p <0.001) at CT start and a >10% weight loss (HR 3.05, p = 0.020) 3 mo after first NA were associated with worse OS. PLR improvement at 3 mo after first NA was associated with better OS (HR 0.46, p = 0.018).

Conclusions: These results underline the importance of early and efficient nutritional assessment and support in cancer pts. The prognostic value of PNI, NLR and PLR reinforces the importance of the interplay between immune system and weight loss for advanced GC.

2120P Nutritional deficiency post gastric cancer surgery

A. Makishev, A. Bekisheva

Department of Oncology, Astana Medical University, Astana, Kazakhstan

Background: Malnutrition is frequent, but underdiagnosed consequence of gastrectomy. Nutritional status is an important factor influencing optimal recovery after treatment. The aim of the present study was to assess the prevalence of micronutrient deficiencies post gastrectomies.

Methods: Between January 2022 and January 2023, 115 patients post gastrectomy had micronutrient screening including vitamin B12, vitamin D, folate, ferritin and albumin. Patients with any micronutrients deficiency were invited for a follow-up and rehabilitation (nutrient rich diet, supplements). Descriptive statistics and t-tests.

Results: Patients' characteristics were as follow: 64.3% women and 35.6% men; median age 58 [30-81]; median follow-up period 19 months [2-24]; proportion of patients with deficiency in vitamin B12, vitamin D, folate, ferritin and albumin were 5.2%,40%,10.4%, 23.4% and 20.9%, respectively. We observed significant improvement in several indicators (vitamin B12 156→357mmol/l, vitamin D 24.6→69.4mmol/l, folate 2.7→9.6mmol/l, ferritin 16.4→92.2mmol/l, albumin 2.2→3.0mmol/l, p=0.01).

Conclusions: This study defined the prevalence of micronutrient deficiencies post gastrectomy. Appropriate nutritional intervention based on findings micronutrients deficiency led to improve quality of life.

2121P Association between nutritional status and adverse events in gastrointestinal cancer patients undergoing outpatient chemotherapy in Japan

N. Sato[1], F. Motoi[2], H. Imai[3], H. Shirota[4], C. Ishioka[5], M. Unno[6]

[1]Department of Oncology Nursing, Fukushima Medical University, Fukushima, Japan; [2]Department of Surgery I, Yamagata University Graduate School of Medical Science, Yamagata, Japan; [3]Department of Clinical Oncology, Institute of Development, Aging and Cancer, Tohoku University, Sendai, Japan; [4]Department of Clinical Oncology, Tohoku University Hospital, Sendai, Japan; [5]Department of Clinical Oncology, Tohoku University Hospital, Sendai, Japan; [6]Department of Surgery, Tohoku University School of Medicine, Sendai, Japan

Background: Recently, the development of anticancer drug administration methods and advances in supportive care for side effects have made it possible to safely perform chemotherapy through outpatient visits. Outpatient chemotherapy is important for maintaining the patient's quality of life (QOL). Side effects of chemotherapy include anorexia, nausea, dysgeusia, and oral mucosal disorders, which affect diet, and weight loss affecting the effectiveness and prognosis. In particular, patients with gastrointestinal cancer are considered to have a high nutritional risk status. We assessed the nutritional status of patients with gastrointestinal cancer during outpatient chemotherapy and found an association with adverse events symptoms.

Methods: The Tohoku University School of Medicine IRB approved this study (2018-1-176); patients provided written informed consent. Patients undergoing outpatient chemotherapy were enrolled, nutritional status, self-assessment of adverse events and depression by The Depression Scale Epidemiological Research Center (CES-D) were assessed. Responses were analyzed by Chi-squared test, ANOVA, Spearman's correlation coefficient, and multiple regression analysis. $p<0.05$ was considered significant. All statistical analyses were performed using SPSS (ver. 21).

Results: Valid responses were obtained from 120 patients with gastrointestinal cancers including pancreatic, colorectal, gastric, and esophageal cancers. The mean age was 65.2 (±9.6) years. Side effects of chemotherapy were fatigue in 99 (83.9%), neuropathy in 88 (73.3%), and dysgeusia in 85 (70.8%). Subjects were classified into 70 normal persons, 32 malnourished, 6 pre-cachexia, and 12 cachexia according to the nutrition assessment classification by Glasgow prognostic score (GPS). Although GPS classification did not show a significant relationship with the basic attributes, there was a significant relationship between anorexia ($r=0.26$, $p=0.004$), taste change ($r=0.26$, $p=0.005$), dry mouth ($r=0.18$, $p=0.049$), and edema ($r=0.22$, $p=0.018$).

Conclusions: Adverse events during chemotherapy including anorexia, dysgeusia, dry mouth and edema would have negative impact on nutritional status.

2122P Clinical significance of oncology patients' nutritional status assessment

E.P. Kostaridis[1], A. Michas[1], K. Gkikas[1], E. Arvanitou[1], A. Pouliakis[1], A. Tsitsimpis[1], M. Chantzipavlou[1], P. Xantzaridis[1], E. Panagou[2], X. Kagaras[1], I. Binas[1], M. Gkiaouraki[1], E. Stamatogianni[3], K. Ballasis[1], C. Christofyllakis[1], N.G. Tsoukalas[1]

[1]Oncology Deptartment, 401 General Military Hospital of Athens, Athens, Greece; [2]Oncology-Hematology Department, 401 General Army Hospital, Athens, Greece; [3]Pathology Department, 401 General Military Hospital of Athens, Athens, Greece

Background: The catabolic activity of cancer combined with various side effects of cancer treatment, lead to decreased food intake, weight loss and muscle wasting, compromising patients' clinical outcome and quality of life. As a result, the incidence of prolonged hospital stays is increasing. Thus, maintaining the nutrition balance is critical for health care services.

Methods: 136 patients participated in this prospective observational study. Nutritional status was accessed via the patient generated-subjenctive global assessment (PG-SGA).

Results: Patients characteristics are depicted in the table. During a six-month period, 45 patients (33.1%) had no weight loss, 48 (35.3%) had lost up to 10% of their initial weight and 43 (31.6%) over 10%. 61 patients (44.9%) had decreased their food intake compared to a month ago. According to PS-SGA questionnaire, 57 patients (42%) had score up to 8, while 79 patients (58%) had score 9 or more, which is the limit for initiation of urgent nutrition intervention. Statistical analysis showed that age, chemotherapy or radiotherapy had no effect in body weight or food consumption change, neither in PG-SGA score ($p>0.05$ in all cases). Gender was related to BW change during the last two weeks, specifically more women had stable weight (54% compared to 32% of the men, $p=0.037$) and more men had reduced weight (45% vs 32% in women). Metastasis had significant role in the number of patients with PG-SGA, 66% of metastatic patients vs 34% of non-metastatic had score ≥9, (OR:3.8, 95% CI: 1.7-8.5, $p=0.0009$). Moreover PG-SGA score was highly dependent of cancer site.

Table: 2122P Characteristics of the study population

Characteristic	Measure
Number of patients	136
PG-SGA score	10.41±5.6
BW change during the last six months (in 3 scales)	
Loss	91 (66.91%)
Same	15 (11.03%)
Gain	30 (22.06%)
PG-SGA score with cut off ≥9 (need for food intervention)	
<9	57 (41.91%)
≥9	79 (58.09%)

Conclusions: The results highlight the importance of early assessment of the nutritional status of cancer patients receiving oncology treatment according to patient and disease characteristics. A timely intervention for nutritional support of the patients being at risk for malnutrition and cachexia is crucial.

2123P Value of immuno-nutritional scores in the prognosis of hospitalised patients with lung cancer

J.P. López[1], D. Jiménez Bou[1], I. Ruiz-Gutiérrez[1], L. Gutierrez Sainz[1], C. Navas-Jiménez[1], J.I. Alonso-Eiras[1], Á. García-Zamarriego[1], D. Sanchez Cabrero[1], L. Ruiz Jimenez Ubeda[1], A. Pertejo[1], J.P. Perez Wert[1], A. Alonso-Babarro[2], P. Cruz Castellanos[1], O. Higuera Gomez[1], J. de Castro Carpeño[1]

[1]Medical Oncology Department, Hospital Universitario La Paz, Madrid, Spain; [2]Palliative Care Unit, Hospital Universitario La Paz, Madrid, Spain

Background: Immuno-nutritional scores like neutrophil-lymphocyte ratio (NLR), prognostic nutritional index (PNI), modified Glasgow prognostic score (mGPS) and controlling nutritional status (CONUT) have been developed to reflect the chronic inflammatory state and malnutrition induced by cancer, and to predict clinical outcomes. This study aims to investigate the prognostic value of these scores in hospitalized patients with lung cancer as we know that unscheduled admission in patients with cancer may imply organ fragility.

Methods: In this retrospective study, we examined patients with lung cancer and unscheduled hospitalizations that took place between June 2021 and May 2022 within the Medical Oncology Service of La Paz University Hospital in Madrid, Spain.

The optimal cutoff for continuous variables was evaluated with Youden index. Survival since admission was estimated with the Kaplan-Meier method. Univariate and multivariate analyses were performed by Cox regression model to determine independent prognostic factors. Areas under the curve (AUCs) or ROCs were calculated to evaluate the discriminatory ability.

Results: We admitted 158 patients with a median age of 68 years, majority of male (66.5%) and stage IV predominance (84.8%). The median follow-up was 14.9 months. The median overall survival since admission was 3.3 months (95%CI: 1.86-7.74). The optimal cut-off value for NLR was calculated to be 6 (Youden index=0.2) and for PNI was 40 (Youden index=0.1). In univariate analysis, poorer survival was associated with NLR>6 (1.87 vs 7.40 months, $p=0.006$, HR 1.67, 95%CI 1.16-2.42) and PNI<40 (1.67 vs 4.97 months, $p=0.044$, HR 1.49, 95%CI 1.01-2.20) and was not associated with CONUT ($p=0.70$) or mGPS ($p=0.067$). In the multivariate analysis only NLR>6 was an independent prognostic factor ($p=0.042$, HR 1.61, 95%CI 1.02-2.57). The ROC curve to evaluate the discriminatory ability of 30-day mortality was only significant in the case of NLR>6 ($p=0.035$, AUC 0.599, 95%CI 0.51-0.69).

Conclusions: In our setting, NLR was the most robust score for estimating prognosis in hospitalized patients with lung cancer.

Background: Malnutrition affects up to 75% of cancer pts and results from a combination of anorexia and metabolic dysregulation. Metabolic and nutritional abnormalities in cancer pts can lead to cachexia, a multifactorial syndrome characterized by involuntary loss of skeletal muscle mass, systemic inflammation and increased protein catabolism. Cancer cachexia negatively affects patients' outcomes, compliance to anticancer treatments, quality of life and survival. However, risk of malnutrition and cachexia are still under recognized in cancer pts. The Prevalence of Malnutrition in Oncology (PreMiO) study revealed that 51% of pts had nutritional impairment already at the first medical oncology visit.

Methods: The retrospective, observational NUTRIONCO study included a subpopulation (n=571 pts) of the prospective, observational PREMiO study (n=1952 pts) for whom follow-up data were collected from August 2019 to October 2021 and made available in electronic case report forms at ten medical oncology sites in Italy. The clinical outcomes that were considered for the association analysis with the baseline clinical and nutritional variables were: patient's rehospitalization, onset of treatment-related toxicity, patient's death and disease progression.

Results: We highlighted a statistically significant association between baseline variables and patients' death, rehospitalization, treatment toxicity and disease progression at follow-up. We found a higher overall survival probability in well-nourished general study population vs. malnourished pts ($p<0.001$). Patients' stratification revealed that malnutrition decreased the survival probability in non-metastatic pts, but not in metastatic pts ($p<0.001$). Multivariate analysis confirmed that baseline malnutrition ($p=0.004$) and VAS score for appetite loss ($p=0.0104$), in addition to albumin <35 g/L ($p<0.0001$) and neutrophil/lymphocyte ratio >3 ($p=0.0007$), were independently associated with death of non-metastatic pts at follow-up.

Conclusions: These findings support the importance of a proactive, early management of malnutrition and cachexia in cancer pts, and in particular in non-metastatic pts, in the perspective of a substantial improvement of their clinical outcomes.

Background: Hypovitaminosis D can have a negative impact in patients (pts) with cancer. We hypothesized that systematic vitamin D repletion could improve outcomes in pts receiving immune-checkpoint inhibitors (ICIs).

Methods: We planned a prospective observational study (PROVIDENCE) to investigate vitamin D levels in pts with advanced cancer receiving ICIs (cohort 1 at treatment initiation, cohort 2 during treatment) and the impact of systematic repletion in the case of hypovitaminosis on survival and toxicity outcomes. In an exploratory analysis, we compared clinical outcomes of cohort 1 with a control cohort of pts followed at the participating centers who did not receive systematic vitamin D repletion.

Results: Overall, 164 pts were prospectively recruited. In cohort 1, consisting of 101 pts with 94.1% hypovitaminosis (≤30 ng/ml) at baseline, adequate repletion with cholecalciferol was obtained in 70.1% at the three months re-assessment. Cohort 2 consisted of 63 pts assessed for vitamin D at a median time of 3.7 months since immunotherapy initiation, with no pts having adequate levels (>30 ng/ml). Even in cohort 2, systematic supplementation led to adequate levels in 77.8% of pts at the three months re-assessment. Compared to a retrospective control group of 238 pts without systematic vitamin D repletion, PROVIDENCE cohort 1 showed longer OS and time to treatment failure (TTF), $p=0.013$ and $p=0.017$. The IPTW-fitted multivariable Cox regression confirmed the significantly decreased risk of death (HR 0.55, 95%CI: 0.34-0.90) and treatment discontinuation (HR 0.61, 95%CI: 0.40-0.91) for pts from PROVIDENCE cohort 1 in comparison to the control cohort. In the context of longer treatment exposure, the cumulative incidence of any grade irAEs was higher in the PROVIDENCE cohort 1 compared to the control cohort. Nevertheless, pts from cohort 1 experienced a significantly decreased risk of all grade thyroid irAEs than the control cohort (OR 0.16, 95%CI: 0.03-0.85).

Conclusions: The PROVIDENCE study suggests the potential positive impact of early systematic vitamin D supplementation on outcome of pts with advanced cancer receiving ICIs and support adequate repletion as a possible prophylaxis for thyroid irAEs.

2126P Exercise implementation into a clinic setting with 1.660 cancer patients: Real-world data from eight years oncological exercise therapy in Cologne (OTT)

T. Niels[1], D. Zubac[2], S. Siebert[2], F.T. Baumann[2]

[1]Department I of Internal Medicine, Center of Integrated Oncology Aachen Bonn Cologne Düsseldorf, University Hospital of Cologne, Cologne, Germany; [2]Department I of Internal Medicine, Center of Integrated Oncology Aachen Bonn Cologne Düsseldorf, University Hospital Cologne, Cologne, Germany

Background: The beneficial effects of exercise for cancer patients are well recognized but implemented exercise programs remain scarce, especially for patients during medical treatment. For that reason, we developed a supervised, personalized exercise concept for cancer patients, implemented into a clinical, oncological setting.

Methods: Cancer patients before, during or eventually after their medical treatment with an identified need for exercise could participate in a free of charge exercise intervention for at least three months at the University Hospital Cologne, Germany. We recorded demographic and medical data at enrolment and exercise adherence up to one year.

Results: A sample of n=1.660 patients attended the exercise program. The majority of patients were female (70%), under medical treatment (65%), diagnosed with breast cancer (40%), without metastasis or severe comorbidities (>70%) and on average 54 years old. The median time between diagnosis and exercise participation differed in patients during medical treatment (4 months), patients with metastasis (7 months) and cancer survivors (11 months). Almost one third (31%) discontinued exercise within the first two weeks of participation. Prolonged exercise (median: 19 weeks) was achieved by one third (32%) of the patients. The average exercise adherence was ~1 session a week with <3% of patients reaching ≥2 sessions a week

Conclusions: To our knowledge, this is the worlds-first report of a professional, supervised exercise program tailored for cancer patients under medical treatment implemented into a clinical setting with >1.600 patients. We described the population that was referred to an exercise program, identified barriers to exercise participation and observed an important mismatch between recommendations and real-world exercise data. Exercise participation was engaged ≥4months after diagnosis and only a third of the patients exercised longer than three months. Almost all patients undercut the well-established exercise recommendations of ≥2 sessions a week. Future implementation concepts should optimize exercise initiation timely after diagnosis and adherence levels due to innovative exercise approaches.

2127P Long-term yoga reduces the side effects of systemic therapies and improves arm symptoms in the breast cancer patients

M. Jain[1], A. Mishra[1], S. Kumar[1], V. Yadav[2], A. Rai[1]

[1]Department of Thoracic Surgery, KGMU - King George's Medical University, Lucknow, India; [2]Department of Physical Education, University of Lucknow, Lucknow, India

Background: Yoga has gained more attention worldwide in the last decade and shown the potential to improve physiological and psychological health in various disease conditions. Studies on breast cancer (BC) survivors showed mild to moderate effects within one-month to six-month on various parameters. Cancer treatment-related side effects are often related with functional as well as symptomatic scales. Therefore, we have conducted a randomized control study to find out the effect of long-term yogic intervention on symptom and functional scale in patients undergoing treatment.

Methods: This study was approved by the institutional ethics committee. The current study consisted of 96 BC stage II/III patients receiving cancer treatments who were randomly divided into two groups: Group-I (non-yoga) and Group-II (yoga). Group-II was advised to perform yoga 5 days per week for 48 weeks and was monitored regularly by video or phone calls. At different time points (T0 (baseline), T1 (16th week), T2 (32nd week), and T3 (48th week), we collected the breast cancer specific questionnaire (EORTC-BR23), which consisted of various functional scales (body image, sexual functioning, sexual enjoyment, future perspective) and symptomatic scales (systemic therapy side effects, breast symptoms, arm symptoms, upset by hair loss), and compared them between groups as well as within group.

Results: Out of 96 total patients, 82 were analyzed for T0-T3 (40 in group-I and 42 in group-II). In groups I and II, the mean age was 47.67±11.68 and 43.11±9.39, respectively. Yogic intervention resulted in a significant improvement in arm symptoms and side effects from T0 to T3 ($p<0.001$) and T1 to T3 ($p<0.01$) in group II, while group I also improved from T0 to T3 ($p<0.05$). The most significant difference was observed in Group-I (T0) vs. Group-II (T3). There was no significant difference observed in upset by hair loss, body image, breast symptoms, or future perspective.

Conclusions: The duration of yoga positively correlated with the systematic therapy side effects and improved their arm symptoms. This suggested that yogic intervention during therapy could be an effective complementary therapy.

Background: Exercise (EX) is associated with a reduction in mortality and recurrence risk in patients (pts) with cancer and may help pts cope with treatment side effects and improve their quality of life. This study aims to explore the role of oncologists in promoting exercise in the oncological context.

Methods: A self-administered, anonymous questionnaire was proposed to pts visiting the outpatients' facilities at the Oncology Unit of Verona Hospital. The questionnaire assessed demographic, health, and EX parameters. EX variables, drawn from a prior study, included: the level evaluated with Godin's Leisure Time Exercise Questionnaire and information regarding: whether EX was discussed; whether oncologists assess, advise, reinforce, and refer (AARR process) pts effort to exercising; and whether pts preferred that EX be discussed. Descriptive statistic, presented as mean, frequencies, and percentages, was applied.

Results: Overall, 202 pts completed the survey (76% response rate). The most frequent tumor types were upper gastrointestinal (45%) and breast (19%). Only 9% of pts were sufficiently active. Regarding the actual EX discussion, 29% of pts reported that their oncologist started a discussion about EX, 12% initiated the discussion themselves, and 60% referred that the issue was not considered. Concerning the AARR process, 26% of pts declared that their oncologists assessed their EX level, 14% and 33% received advice or reinforcement to increase their EX, respectively, and 9% were referred to an appropriate EX service. On the other hand, the items related to the preferred modality of EX discussion showed that 69% of pts thought that oncologists should initiate an EX-discussion, 3% that only pts should start the discussion, and 23% thought that EX should not be discussed.

Conclusions: Our preliminary results show that most pts are insufficiently active, and the majority stated that they did not discuss EX. Nevertheless, most pts would prefer that oncologists initiate a discussion about EX. According to these findings, strategies to support clinicians in promoting EX to their pts should be developed. Further pts' enrollment is currently ongoing and a more updated analysis will be available for presentation at the ESMO Congress.

2129P Feasibility of a virtual exercise program to mitigate decline in physical function for advanced lung cancer patients

Y. Wang[1], S. Yeo[2], R. Fujita[3], P. Camp[3], K. Mackenzie[3], J. Laskin[4], K. Campbell[3]

[1]Medicine, BC Cancer - Vancouver, Vancouver, BC, Canada; [2]Medicine, UBC - The University of British Columbia, Vancouver, BC, Canada; [3]Physical Therapy, UBC - The University of British Columbia, Vancouver, BC, Canada; [4]Medical Oncology, BC Cancer Agency - Vancouver, Vancouver, BC, Canada

Background: Exercise in cancer patients can mitigate declines in physical and psychosocial function. However, low recruitment and retention for in-person exercise programs limit evidence-based program development for patients with advanced lung cancer. The study of a virtual intervention, that leverages on the emerging acceptance of virtual healthcare delivery, has the potential to overcome barriers of prior exercise studies.

Methods: Mitigation of decline with Virtual Exercise with Lung Cancer is an ongoing prospective single-arm feasibility study. Individuals with advanced lung cancer on systemic therapy were recruited to a 12-week virtual group exercise program, including aerobic and functional strength exercises, delivered twice weekly over Zoom by an exercise physiologist. Feasibility measures included accrual, attendance, exercise adherence, attrition, and adverse events. Efficacy measures and quality of life (QoL) were assessed at start and end of program. Patient demographics, treatment, and outcomes were collected via electronic medical records.

Results: Of 44 patients referred, 30 were eligible and enrolled, of which, 3 were lost to follow up, 1 withdrew, 16 completed and 10 continue to participate in the program. Baseline demographics of 26 active participants: median age 65.5 years old (range 39 − 88), female (n=12), ECOG 0/1 (n=24), adenocarcinoma (n=21), metastasis to brain (n=9), liver (n=4), bone (n=7), and on targeted therapy (n=19). Total attendance is 87% and adherence is 96%. Of those who completed the program, statistically significant changes in physical function were identified by the 6 minute walk test (median improvement of 147 meters $p = 0.046$), gait speed ($p = 0.030$), sit to stand ($p = 0.004$), and biceps curl repetitions ($p = 0.001$). No significant difference was found in QoL using the Functional Assessment of Chronic Illness Therapy-Lung (FACT-L) and -Fatigue (FACT-F) questionnaires. Participants found the program to be accessible and were very likely to recommend this program to a friend.

Conclusions: Preliminary results suggest that a virtual exercise program for patients with advanced lung cancer is feasible, with high attendance and adherence, and significant improvements in physical function.

2130P ATTITUDE - ATTrition In longiTUDinal studiEs of cancer survivors (CS): Can we improve the experience of patients (pts)?

C.K. Chiodi[1], E. Martin[2], M.A. Franzoi[2], M. Pagliuca[2], D. Soldato[2], P. Lapidari[2], A. Barbier[2], J. Havas[2], J. Arvis[2], D. Boinon[3], G. Menvielle[2], L. Golli[4], R. Desjardin[5], G. Jacob[6], I.V. Vaz Luis[7], A. Di Meglio[7]

[1]Breast Cancer Survivorship Research Group, Institut Gustave Roussy - INSERM UMR 981, Villejuif, France; [2]INSERM U981, Institut Gustave Roussy, Villejuif, France; [3]Unité de Psycho-Oncologie, Institute Gustave Roussy, Paris, France; [4]Unicancer, Paris, France; [5]INSERM 1296, Université Lyon 2, Lyon, France; [6]Seintinelles, Paris, France; [7]Breast Cancer Survivorship Research Group, Institut Gustave Roussy, Villejuif, France

Background: Dropout is common in longitudinal studies and generates attrition bias. ATTITUDE uses a mixed, multistep methodology to reduce attrition, building on the CANTO cohort (NCT01993498, collecting clinical and patient-reported outcome measures [PROMs] for 5 years post breast cancer [BC] treatment). In Step 1, we had found that 16.2% of pts who were still on study at year-4 did not attend at all the CANTO visit and 33.1% did not respond to any PROMs. Here we present results of Step 2, gathering key stakeholders' input about participation to longitudinal studies.

Methods: A multidisciplinary group of oncologists, sociologists, patient engagement experts and advocates co-developed a 28-item survey. The survey addressed CS and citizens within the Seintinelles platform for collaborative cancer research and was open to completion for 4 weeks. Descriptive analyses were performed.

Results: There were 1834 respondents, 733 CS (84.0% of BC) and 1101 citizens without history of cancer: 95.3% were female, 58.2% were 40-65 years old, 87.4% had $\geq$ high school degree. Among CS, 58.4% had previously participated in a longitudinal study: 85.0% felt to have received adequate information prior to enrollment and 99.5% would participate again in the same or a similar study. Overall, motivation for participation included desire to support the research team (92.8%), to help (other) pts (49.8%), and to improve one's own cancer management (20.1%). Facilitators to participation included option to use digital platforms (96.1%), home-based data collection (95.0%), flexible study visit schedule (77.5%), obtaining individual explanations regarding study procedures by phone (56.6%), and receiving reminders to complete PROMs (56.9%). Responses were consistent between CS and citizens.

Conclusions: Actionable interventional components to reduce attrition in longitudinal studies that emerged from this survey include implementation of decentralized, digital data collection tools such as e-PROMs, flexible study visit schedule, and study navigators. The present survey, complemented with additional input from ongoing qualitative explorations, will inform the co-design and piloting of tailored interventions to minimize attrition in Step 3 of ATTITUDE.

2131P Real-life experiences from a late effects clinic: An investigation of health-related quality of life in Danish cancer survivors

L.K. Tolstrup, K.B. Dieperink, L.H. Clausen, L. Fechner, T. Mattsson

Department of Oncology, OUH - Odense University Hospital, Odense, Denmark

Background: Three out of four cancer survivors experience one or more late effects; many report unmet needs. Consequently, the Region of Southern Denmark has established late effects clinics (LEC) for patients with complex late effects to help cancer survivors regain their physical and mental functioning and improve their Health-Related Quality of Life (HRQoL). By the use of the newly developed EORTC QLQ-SURV100 questionnaire, this study elucidates the most predominant late effects occurring in Danish cancer survivors referred to a LEC and compares the patients' HRQoL to that of newly diagnosed cancer patients and the general Danish population.

Methods: Primo 2022 , a LEC opened at Odense University Hospital. Prior to the first consultation, patients complete the EORTC QLQ-SURV100 questionnaire to capture the full range of physical, mental, and social HRQoL issues relevant to cancer survivors. Moreover, we collect data on demography, disease, treatment, and type of intervention following the first consultation in the LEC.

Results: One hundred and forty-nine patients have been included in the clinic's first year. Inclusion is ongoing. Age; median 58 [26-82] years. Women 75%. The most common diagnosis is breast cancer. 50% are referred by general practitioner. Over 90% report multiple late effects. Fatigue, sleep disturbance, pain, cognitive impairment and fear of recurrence are most commonly reported. QLQ-SURV100 mean scores on Global Health 51.4, Role functioning 51.4, Emotional functioning 60.0, Cognitive functioning 49.4, and Physical functioning 52.3. Compared to the HRQoL of patients at the time of diagnosis and the general population, these numbers are significantly lower. The number of recruited patients will reach app. 220 in October 2023. However, this is not expected to influence the mean scores as they have been constant throughout the clinic's lifetime.

Conclusions: Cancer survivors referred to the LEC suffer from multiple and complex late effects after cancer and its cancer treatment and report a significantly lower HRQoL compared to patients at the time of diagnosis and the general Danish population.

2132P Unmet needs, quality of life, and financial toxicity in survivors of lung cancer

J. Feliciano[1], M. Boulanger[2], S. Olson[3], L. Prichett[3], M. Guo[4], M. Miller[4], M. Turner[5], M.L. Hsu[6]

[1]Sidney Kimmel Cancer Center, Johns Hopkins Hospital, Baltimore, MD, USA; [2]Oncology, Massachusetts General Hospital Cancer Center, Harvard Medical School, Boston, MA, USA; [3]Biostatistics, Johns Hopkins Hospital, Baltimore, MD, USA; [4]Johns Hopkins Hospital, Baltimore, MD, USA; [5]Oncology, Johns Hopkins Hospital, Baltimore, MD, USA; [6]Medical Oncology, Case Western Reserve University / University Hospitals, Cleveland, OH, USA

Background: Survivors of lung cancer (LCS) have unmet emotional, social, and physical needs regardless of stage at diagnosis or treatment types, experience decreased quality of life (QOL) and high financial toxicity (FT). The relationship between unmet needs, QOL, and FT is yet to be reported in LCS and may provide insight into potentially modifiable needs to address to improve patient reported outcomes.

Methods: We performed a cross-sectional survey to assess the physical, social, emotional, and medical needs, QOL, and FT in patients with histologically confirmed non-small cell lung cancer alive $>$ 1 year from diagnosis. The survey consisted of an adapted needs survey, the Comprehensive Score for FT (COST), and the lung cancer specific QOL questionnaires EORTC-QLQ and EORTC-QLQ-LC13. Demographic and clinical information was obtained retrospectively by chart review. Separate multiple linear regression models, treating QOL and FT as dependent variables, were performed to assess the adjusted relationship between total number of unmet needs and type of unmet need (physical, emotional, social or medical) with QOL and FT.

Results: Of 360 LCS approached, 232 surveys were completed. The median age was 69, most were female (62%), married (71%), Caucasian (74%), and had stage III/IV lung cancer (60%). Previous/current smoking history ($p=0.042$) and ECOG performance status of 1 or $\geq$ 2 (compared to 0) ($p<0.0001$) were each independently associated with decreased QOL. Income $<$ \$30,000 or \$30,000-75,000 (compared to $>$\$75,000) ($p<0.0001$), and history of radiation therapy ($p=0.023$) were independently associated with increased FT. Higher total unmet needs was associated with lower QOL ($p<0.0001$) and increased FT ($p=0.0003$). Greater unmet physical ($p=0.023$), social ($p=0.008$), and medical needs ($p=0.007$) were associated with decreased QOL. Greater social needs were associated with increased FT ($p<0.0001$).

Conclusions: Unmet needs across multiple domains are associated with worse QOL and FT in LCS. Identifying specific modifiable unmet needs, such as patient symptoms, care coordination, or tobacco cessation, are needed to help identify interventions. Future studies with targeted inventions to address these unmet needs may improve QOL and FT in LCS.

2133P Sleep disorders: Evolution in time in early breast cancer (EBC)

B. Cantos[1], J.C. Sanchez Gonzalez[1], M. Mendez Garcia[1], B. Nunez Garcia[2], M. Blanco Clemente[1], C. Parejo[3], M. Campos[4], B. Rodriguez Morilla[5], P.F. Almaida Pagan[4], S.C. González González[1], C. Traseira Puchol[1], M. Martinez Cutillas[2], R. Aguado[1], Y. Garitaonaindía Díaz[1], A. González Sánchez[1], D.I. Ruiz de Domingo[1], M.M. Sánchez del Corral[1], I. Redondo[1], M. Torrente[1], M. Provencio Pulla[1]

[1]Medical Oncology Department, University Hospital Puerta de Hierro Majadahonda, Majadahonda, Spain; [2]Oncology Department, University Hospital Puerta de Hierro Majadahonda, Majadahonda, Spain; [3]Medical Oncology Department, Fundacion para la Investigacion Biomedica del Hospital Universitario Puerta de Hierro Majadahonda, Majadahonda, Spain; [4]Computer Science, UM - University of Murcia, Murcia, Spain; [5]Psychology, UM - University of Murcia, Murcia, Spain

Background: Sleep disorders are common in the general population and among all cancer patients, but it has been shown that they are particularly prevalent among patients diagnosed with breast cancer, both during and after treatment. These disruptions produce a significant deterioration in functional status and clearly reduce the quality of life of the patients.

Methods: 126 women diagnosed with EBC at Puerta de Hierro Hospital have been analyzed, divided into 3 groups. The first group were women with a recently breast cancer diagnosis reciving chemotherapy, the second group were women at early follow up (first two years post-diagnosis), and the third group were women at late follow up (more than 2 years after diagnosis). The control group was selected from a sample of healthy individuals matched with our patients in terms of age, weight, and physical condition (digital twin). Sleep parameters were obtained using a wearable device for 7 consecutive days (Kronowise®-Kronohealth S.L).

Results: The patients undergoing active chemotherapy treatment exhibited more disrupted sleep patterns than controls, with a delay in their circadian rhythms and more aged rhythms. 25% of them slept less than 6 hours, and the average nocturnal sleep duration in this population was 6.73 hours. They frequently resorted to napping, with 55% of them taking naps longer than 30 minutes, with a sleep efficiency of less than 80%. As time passed from the diagnosis, the sleep patterns began to resemble those of the control group, and no differences with controls were found in the third group of patients. The sleep efficiency improved in the late follow-up group, with an efficiency rate exceeding 85%.

Conclusions: The administration of chemotherapy in patients with early breast cancer produces significant disruptions in sleep, with a clear impact on their quality of life, which can be recovered with long-term follow-up (more than 2 years since diagnosis). We must make an effort to detect these problems and instruct our patients in healthy sleep habits.

2134P Self-reported late effects, need for information and follow-up in long-term Hodgkin lymphoma survivors

L.H. Willumsen[1], K.B. Smeland[2], S.A. Eikeland[2], A. Fossa[2], H. Bersvendsen[3], U-M. Fagerli[4], R.S. Falk[5], H.C. Lie[6], C.E. Kiserud[1]

[1]National Advisory Unit for Late Effects after Cancer Treatment, Department of Oncology, Oslo University Hospital - The Norwegian Radium Hospital, Oslo, Norway; [2]Oncology Department, Oslo University Hospital - The Norwegian Radium Hospital, Oslo, Norway; [3]Oncology Department, UiT The Arctic University of Norway, Tromso, Norway; [4]Oncology Department, NTNU - Norwegian University of Science and Technology - Faculty of Medicine and Health Sciences, Trondheim, Norway; [5]Oslo Center for Biostatistics and Epidemiology, Oslo University Hospital - Rikshospitalet, Oslo, Norway; [6]Department of Behavioural Medicine, University of Oslo, Oslo, Norway

Background: Hodgkin's lymphoma survivors (HLSs) are at risk for late effects due to their early age at diagnosis, multimodal therapy and long life expectancy. Among HLSs, we explored self-reported late effects, and assessed their information needs regarding lifestyle (diet and physical activity) and rehabilitation, in addition to need for long-term follow-up and factors associated with these needs.

Methods: HLSs treated 1997-2006 and aged 18-49 years at diagnosis were identified by the Norwegian Cancer Registry and invited to participate in this population-based, cross-sectional study consisting of a questionnaire, blood tests, clinical examination and echocardiography. Information regarding histology, stage and treatment was retrieved from medical records. Descriptive statistics and logistic regression models were used.

Results: Among the participants (n=304, 59% response rate), median age at diagnosis was 29 years (range 8-49), median age at survey 45 years (21-70), median observation time 16 years (10-22) and 48 % were females. Ninety percent had classical HL, 62% had stage I-IIA disease, 94% received chemotherapy and 77% radiotherapy. Seventy-four percent reported to have experienced $\geq$1 late effects; concentration/memory problems (29%), numbness/nerve pain (32%) and dental problems (27%) were the most common. Forty-one percent reported chronic fatigue (CF). One third reported to have received follow-up for late effects. A total of 64% wanted information about lifestyle and/or rehabilitation, and 58% wanted regularly follow-up for late effects. In the multivariable models, CF (OR 2.2, 95%CI 1.2-4.1), short education (2.2, 1.2-4.0), being physical inactive (2.0, 1.1-3.5) were associated with increased likelihood of need for information about lifestyle and/or rehabilitation. CF was associated with increased likelihood of need for follow-up for late effects (2.1, 1.3-3.6).

Conclusions: HLSs report a high level of late effects and only a small proportion receive follow-up for these problems. Chronic fatigue is associated with need for information and follow-up, indicating that these patients could benefit from a more structured model for long-term follow-up than what is currently available.

2135P Impact of geriatric assessment (GA) and geriatric 8(G8)-based targeted interventions on the quality of life (QoL) in older Asian adults with cancer

J.L. Low[1], J. Cheng[2], A. Ng[2], M. Chun[3], Y.S. Lim[3], C.E. Chee[3], J. Tey[4], F. Ho[5], M.Z. Chen[6], S.L.A. Pang[7], N.K. Barr[8]

[1]Cancer Institute, NUH - National University Hospital, Singapore; [2]Medicine, NUS - National University of Singapore, Singapore; [3]Medical Oncology, NCIS - National University Cancer Institute Singapore, Singapore; [4]Radiation Oncology, Singapore Society of Oncology, Singapore; [5]Radiation Oncology, National University Hospital, Singapore; [6]Geriatrics, NCIS - National University Cancer Institute Singapore, Singapore; [7]Medical Oncology, OncoCare Cancer Centre - Orchard, Singapore; [8]NUHS, NUS - National University of Singapore, Singapore

Background: G8 and GA assessments to screen for frailty and facilitate appropriate interventions have been recommended by the International Society for Geriatric Oncology in older adults with cancer. The main objective of this study is to evaluate the impact of G8 and GA-based interventions on the QoL of older Asian adults with cancer.

Methods: This is a prospective study of cancer patients aged $\geq$70 treated at the National University Cancer Institute, Singapore. The G8, CGA, and EORTC QLQ 30 questionnaires were administered at study entry. Targeted interventions were offered by the multi-disciplinary geriatric oncology (GO) service. After three months, a follow-up EORTC QLQ 30 was repeated for those who required geriatric interventions. Primary outcome measure was comparison of pre/post- EORTC QLQ 30 scores.

Results: N=230 patients were accrued. Median age was 74 (range:70-90). Majority were male (56%), diagnosed with gastrointestinal cancers (35%) and receiving palliative intent treatment (60%). Based on GA, 11% were classified as frail, 58% as pre-frail and 31% as fit. 79% had G8 scores $\leq$14. Pre-frail, frail and those with G8 $\leq$14 had lower baseline EORTC QOL function scores and higher EORTC QOL symptom scores ($p<0.05$). They also had significantly shorter overall survival (OS) compared to fit or with patients G8$>$14. (HR=2.54 95% CI 1.46-4.43, p=0.001 for frail vs fit patients; HR=1.72 95% CI 1.18-2.53, p=0.005 for pre-frail vs fit patients; HR=1.51 95% CI 1.05-2.18, p=0.027 for G8 $\leq$14 vs $>$14). GO interventions were suggested for 144 patients with 104 patients completing a 2nd EORTC QOL questionnaire. These patients reported significant improvements in the EORTC emotional and social functioning domains (mean difference +4.6, $p<0.001$ and +12.3 $p<0.001$, respectively), a significant reduction in the EORTC symptom scale of pain, insomnia, constipation, and financial difficulties (mean difference -5.8 p=0.003, -8.3 $p<0.001$, -9.0 $p<0.001$, and -6 p=0.01), with no significant deterioration in other QOL domains.

Conclusions: Geriatric assessment-based targeted interventions delivered by a multidisciplinary GO service significantly improved multiple QOL domains in older Asian adults undergoing cancer treatment.

2136P Prostate cancer supportive care (PCSC) program for patients and partners: A model for meeting an unmet need for PC patients

C.S. Higano[1], M. Sundar[2], C. Zarowski[2], M. Lui[2], N. Pratap[2], J. Egilson[2], A. Holmes[2], N. Ivanov[2], M. Dayan[2], A. Hudon-Kaide[2], P. Griggs[2], C. Maurice-Dror[2], R. Ho[2], D. Sare[2], A. Hwang[2], W. Eugenia[2], J. Bentley[2], R. Flannigan[1]

[1]Department of Urologic Sciences, University of British Columbia, Vancouver, BC, Canada; [2]Prostate Cancer Supportive Care Program, Vancouver Prostate Centre, Vancouver, BC, Canada

Background: Prostate cancer (PC) patients face treatment-related sequelae that affect their health and quality of life. The PCSC Program was created in 2013 and is located in the Vancouver Prostate Centre's urology clinic. It is a clinical, educational, and research-based program that addresses challenges experienced by PC patients from the time of diagnosis onward. The program consists of 8 "modules" listed in the table.

Methods: We describe the operational details of the PCSC Program and its metrics.

Results: A Medical Director and Program Manager set the mission, oversee the day-to-day operations, and hire and manage the allied health clinicians and support staff. Office/clinic space is rotated during the week to accommodate a sexual health RN (1.4 FTE), 2 pelvic floor physiotherapists, a nurse practitioner, a registered dietitian, a clinical exercise physiologist (all 0.2 FTE), and a clinical counsellor (0.4 FTE). As of 05/2023, 3351 pts have registered for this no-cost program (Table). In 4/2020, the real-time group education sessions and clinic appointments transitioned from in-person to a hybrid with virtual options enabling the participation of patients from throughout British Columbia.

Table: 2136P Attendance at PCSC modules for 3351 registrants from 2013 to May 2023

Modules	Attendees, n	Group education*, n (# sessions)	Clinic appointments, n (# appointments)
Introduction to PC and primary treatment options	945	955 (159)	not applicable
Managing sexual function and intimacy	1745	844 (122)	1519 (6109)
Management of side effects of ADT	443	376 (25)	212 (313)
Pelvic floor physiotherapy for incontinence	1304	910 (97)	594 (2382)
Counselling	444	not applicable	444 (1629)
Metastatic disease management	85	87 (30)	not applicable
Nutrition	742	195 (31)	361 (593)
Exercise	826	455 (70)	674 (2167)

*Some attendees attended the group education sessions more than once.

Conclusions: The need for PC supportive care is well recognized but may be challenging to offer when the services are fragmented and time-consuming for clinicians or staff to arrange. All modules offered by the PCSC Program can be accessed with one registration. It is convenient for patients because it is housed in one location, which also facilitates communication across disciplines. We attribute the success of our program to this model and our team approach to the individual patient's needs.

2137P Impact of supportive care on the quality of life (QoL) of hospitalized cancer patients (pts)

J. Sanz Beltran[1], O. Mirallas[2], F. Bosma[1], M.A. Molina Pérez[1], C. Salva[2], K.S. Vega Cano[2], D.A. Gomez Puerto[2], D.E. López Valbuena[2], J.M. Ucha Hermida[2], G. Molina Lores[2], M. Roca Herrera[2], C. Sola Sahun[1], D. Romero Montenegro[1], S. Serradell[2], D. Paez[1], J. Carles Galceran[2], B. Martin Cullell[1]

[1]Medical Oncology Department, Hospital de la Santa Creu i Sant Pau, Barcelona, Spain; [2]Medical Oncology Department, Vall d'Hebron University Hospital, Barcelona, Spain

Background: Performance ECOG status and staging are described as prognostic factors in oncologic outpatients while nutritional assessment can impact survival in both outpatients and inpatients. The aim of this study was to describe the Charslon Comorbidity Index (CCI), the nutritional status, the impact of opioid therapy and psycho-oncology and palliative care unit intervention for hospitalized cancer patients (pts).

Methods: A prospective multicentric study of pts hospitalized between January 2020 February 2022 at Vall d'Hebron and Sant Pau Hospitals [Plantology database] in Spain. Demographic and clinical variables such as CCI, laboratory results and nutritional status were collected at admission. Prognostic Nutritional Index (PNI) was calculated at admission. Quality of life (QoL) was collected through the EORTC-QLQ30 v.3 questionnaire. Statistical analysis was performed with SPSS v.29 (Log rank, Chi-square, Student's t-test were used).

Results: A total of 1.431 patients (median age 66 years, 53.2% males) were included with a median of 9 days hospitalized. With a follow-up of 15 months, the median survival was 4.67 months after admission. Most pts (91.6%) had severe comorbidity (CCI $\geq$ 5 points) related to a lower survival (4.5 vs 12.8 months, $p<0.001$). A positive chair stand test for sarcopenia (12.2%) was associated with reduced survival (3.5 vs 9.1 months, $p<0.001$). Pts with hypoalbuminemia (65.3%) presented lower survival (3.5 vs 8.4 months, $p<0.001$). In addition, the PNI stratified 59.5% pts with serious malnutrition (PNI <40) linked to reduced survival (3.6 vs 7.9 months, $p<0.001$). Regarding supportive care, pts under opioid therapy (39.6%) had a higher QoL (mean EORTC QLQ-30 score of 73.4 vs 64.3, $p<0.001$). Palliative care team assessment and psycho-oncology intervention positively impacted in pts QoL (EORTC QLQ-30 of 74 vs 67.3, $p<0.001$, and 74.3 vs 65.2, $p<0.001$, respectively).

Conclusions: In hospitalized cancer pts, severe comorbidity, malnutrition and sarcopenia were associated with a reduced survival. Opioid therapy and psycho-oncological and palliative care unit intervention had a positive impact on the QoL of pts. Early supportive care interventions are key to improve symptomatology and preserve QoL of hospitalized cancer pts.

2138P Time toxicity of palliative chemotherapy in a geriatric oncology population

C. Cronin, D.T. O'Sullivan, K. Ronan, M. Hannan, A.M. Horgan

Medical Oncology, University Hospital Waterford, Waterford, Ireland

Background: Older adults with cancer undergoing cytotoxic chemotherapy (CTx) are at increased risk of treatment-associated toxicity. Data supporting the efficacy of systemic anticancer therapy (SACT) in this patient population are sometimes limited. The concept of time toxicity has emerged to describe the time commitments and opportunity cost involved in undertaking SACT, particularly when the magnitude of clinical benefit is expected to be modest.

Methods: We conducted a retrospective review of patients attending the multidisciplinary Geriatric Oncology Assessment and Liaison (GOAL) clinic of University Hospital Waterford, Ireland over a 3.5-year period. We included patients for whom an initial or subsequent line of palliative CTx was commenced in the last 6 months of life. We recorded ambulatory physical healthcare contact days related to the delivery of CTx as well as treatment-related inpatient admissions as a measure of time toxicity.

Results: Of 304 patients assessed, 64 patients commenced SACT with palliative intent. A total of 26 patients met inclusion criteria for the study. The median age of patients was 78 (67-86). At initial GOAL clinic review, 15 patients (58%) had an ECOG performance status of 1, and 10 patients (38%) had a performance status of 2. Most patients received single agent cytotoxic CTx (17/26; 65%) and 85% of patients received only 1 line of treatment. 23 patients (88%) required hospital admission during treatment and 11 patients (42%) required more than one admission. 5 patients (19%) were admitted due to treatment-associated toxicity. The median number of physical healthcare contact days related to CTx (including hospital admissions directly due to treatment toxicity) was 14 (5-37). Median survival from initiation of CTx was 119 days (15-170). 9 patients (35%) received treatment in the last month of life.

Conclusions: High rates of hospitalisation were noted in our study, reflecting the challenges in delivering CTx to an older adult population. Physical healthcare contact days represented a substantial proportion of days alive from commencing systemic treatment. Consideration of the time toxicity of CTx in this population may help to better align palliative-intent treatment with patient goals.

2139P Quality of life in adult cancer survivors (QLACS) in Spain: Study of its clinical characteristics and use of social media for oncological information

M. Cornide Santos[1], M. Vargas Aragon[2], P. Lambert de Diesbach[3], R. Vidal Tocino[4], D. Herrero Rivera[5]

[1]Oncology Department, Hospital General Segovia, Madrid, Spain; [2]Pschiatry, University of Valladolid - Faculty of Medicine, Valladolid, Spain; [3]Bussines, ISG, Paris, France; [4]Medical Oncology Dept., IBSAL - Instituto de Investigación Biomédica de Salamanca, Salamanca, Spain; [5]Medical Oncology Department, HLA Moncloa Universitary Hospital, Madrid, Spain

Background: Long-term cancer survivors (*LS),* patients over 5 years free of disease, are a population on the rise due to oncological advances. Our aim is to explore QLACS in long-term cancer survival patients in Spain. As a secondary objective is to study their clinical and sociodemographic characteristics and their preference for social media or face-to-face meetings to obtain oncological information.

Methods: We carried out a transversal study in a sample of *LS* patients from several Spanish hospitals. They completed QLACS, FERREL, SPF12 and social media data. Different types of tumor were included. Psychometric properties of the QLACS were evaluated. Principal component analysis with Varimax rotation was applied to explore the dimensional structure. Pearson's correlation (Pc) was used to study associations of QLACS with temporal variables. Student's t test was used to study differences between them.

Results: N= 257, women=59,9 %, < 65 years=55%. Types Tumor: 33% breast, 27% colorectal, 8,9% urothelial, 7,4% other digestive tumors, 7% orl-lung. Factor analysis showed a 12-component solution accounts for 71.03 % of the variance, showing a similar comparable dimensional structure with QLACS. Alfa Cronbach=0,9. Appearance concern, distress over recurrence, pain, negative feelings and distress familiar are statistically higher in female ($p<0,05$). We found negative correlation between age and use of social networks for oncological information (Facebook: $p = 0.01$, Pc: -248; Twitter: $p<0.04$, Pc:- 200; Instagram: $p <0.007$, Pc: -259 except; Youtube: $p = 0.17$; Pc: -134). No differences by sex were observed in the use of social networks There were no differences by age in attending face-to-face meetings: $p< 0.94$, Pc: -196. Breast cancer patients are more willing to attend face-to-face meetings to help other patients than those with colon cancer ($p< 0.036$).

Conclusions: QLACS is a valid and reliable instrument for measuring quality of life in long-term cancer survivors in Spain. Younger patients are more likely to use social media for oncology information. Older people tend to prefer face-to-face meetings. We found differences between men and women in different factors for measuring quality of life.

Background: Metastases-directed stereotactic body radiotherapy (SBRT) in addition to standard of care systemic therapy is supported by randomized phase II trials and international practice guidelines for patients with an oligometastatic disease (OMD). However, little is known about quality of life (QoL) following SBRT, which would be valuable to better inform patient and clinicians in their decision-making process about the optimal multimodality treatment strategy.

Methods: OligoCare is a pragmatic prospective cohort study of E^2-RADIatE, a collaboration between ESTRO and EORTC, which aims to identify patient, tumour, and treatment characteristics influencing overall survival after ablative radiotherapy for oligometastatic breast, colorectal, lung and prostate cancer. Patients are eligible irrespective of oligometastatic state (de-novo, repeat or induced), without restrictions to local or systemic therapy. Radical radiotherapy must be a component of treatment, irrespective of maximum number of metastases, as long as all cancer lesions are treated with radical intent. Assessment of QoL using the EORTC QLQ-C30 is optional. This analysis reports QoL at baseline and first FU (3-12 months) on the first 1600 enrolled patients.

Results: 530 patients completed baseline QoL and 399 completed follow-up (median time after SBRT: 6 months). 71% of patients were male, with oligometastatic prostate cancer the most frequent primary (45%), followed by NSCLC (24%), breast (17%) and colorectal cancer (14%). WHO performance status was 0 or 1 in 87% of patients, median age was 69 years and median one single oligometastasis was treated with SBRT (range 1-8). Average global health status at baseline was 72 (SD 19.5), with higher baseline QoL in prostate cancer (average 78) as compared to NSCLC (average 65) or breast cancer (average 68) patients. Global health status remained stable during follow-up (average 72; SD 20), without differences between primary diseases. A more detailed assessment of QoL subdomains is underway.

Conclusions: Collection of QoL data was feasible in this prospective registry and early QoL remained stable following metastases-directed SBRT in oligometastatic breast, colorectal, lung and prostate cancer.

Clinical trial identification: NCT03818503.

2141P Symptom burden and health-related quality of life (HRQoL) in platinum-resistant or -refractory ovarian cancer (PROC): A systematic literature review (SLR)

N. Indukuri[1], Z. Chen[2], M. Payer[3]

[1]Global Value, Novocure Inc., New York, NY, USA; [2]HEOR, Cytel, Inc., Waltham, MA, USA; [3]Global Market Access, Novocure Inc., Portsmouth, NH, USA

Background: PROC is characterized by a cumulative burden of progressive disease and prior treatments. The goals of treatment are symptom reduction, HRQoL improvement or stabilization, and providing survival benefits with limited toxicity. We aimed to comprehensively characterize HRQoL in patients with PROC.

Methods: An SLR was conducted per Preferred Reporting Items for Systematic Reviews and Meta-Analyses guidelines. MEDLINE®, Embase®, EconLit, Cochrane, and relevant conference proceedings were searched for randomized and non-randomized studies reporting HRQoL in patients with advanced ovarian cancer and disease recurrence within 6 months of platinum-based chemotherapy published January 2010—March 2, 2023.

Results: Of 13,043 records identified in the SLR, 39 were included. The most common HRQoL measures were European Organization for the Research and Treatment of Cancer Quality of Life Questionnaire (EORTC QLQ)-C30 (n=28), EORTC QLQ-Ovarian Cancer Module (OV28) (n=23), Functional Assessment of Cancer Therapy (FACT)-Ovarian (n=10), and FACT Ovarian Symptom Index (FOSI) (n=6). Gastrointestinal (GI) problems, fatigue, sleep disturbances, pain, anxiety, and depression were commonly reported at baseline. HRQoL scores and outcomes were heterogeneous, however, across studies and treatments, the majority of patients experienced stable or worsening HRQoL. Few studies reported clinically meaningful improvements in HRQoL in abdominal/GI symptoms, pain, insomnia, global health, function (physical, emotional, role, social), and these occurred in less than half of patients. Worsening of dyspnea, GI symptoms, chemotherapy side effects, and peripheral neuropathy were noted with some treatments including pegylated liposomal doxorubicin.

Conclusions: Disease-specific and generic HRQoL instruments demonstrated a substantial burden including GI disturbances, pain, fatigue, emotional distress, and poor functioning in PROC. Existing treatments provided no HRQoL improvement for the majority of patients. A substantial unmet need remains for tolerable treatments that reduce symptoms and improve HRQoL among patients with PROC.

2142P Criteria for the choice of therapeutic ceiling in the hospitalized oncology patient: Healthcare impact of the multidisciplinary committee with the Intensive Care Unit (ICU)

M.E. Guirao García[1], M. Sanchez Canovas[2], A. Sanchez Saura[1], S. Montenegro Luis[1], M.A. Ivars[1], N. Blaya Boluda[2], N. Alonso Fernández[3], E. Martínez Quintana[3], M. Cerón García[3], L. López García[3], P.S. Bayoumy Delis[3], A. Carrillo Alcaraz[3], F. Ayala de la Pena[4]

[1]Oncology, Hospital General Universitario Morales Meseguer, Murcia, Spain; [2]Dept. Oncologia Medica, Hospital General Universitario Morales Meseguer, Murcia, Spain; [3]Intensive Medicine, Hospital General Universitario Morales Meseguer, Murcia, Spain; [4]Hematology and Medical Oncology Department, Hospital General Universitario Morales Meseguer, Murcia, Spain

Background: The improvement in cancer survival, allows for higher ICU admission ratios. A pilot program in our center instituted weekly meetings between ICU and Oncology aimed at determining the appropriate level of care for patients admitted in Oncology. Objective: establish which factors predict decision-making regarding the level of care and admission to the ICU and benefit of intensive care.

Methods: Single-center prospective observational study. Recruitment between September-2021 and July-2022. Statistical analysis: descriptive study, multivariate logistic regression for decision of admission in ICU. We performed a second subsequent analysis with the paired propensity score matching technique. Survival analysis: Kaplan-Meier (KM) curves and log-Rank test. Significance level: $p \leq 0.05$.

Results: 411 patients. 60.3% male; median age: 64 years. Most prevalent tumor: lung (26.3%). Stage IV: 72.5%. The most common reason for admission in Oncology: infectious pathology (33.8%). 54.7% were considered ICU candidates, while only 17 patients (4.1%) finally required intensive care. In a multivariate logistic regression model, ECOG 0-1 (OR 2.7; IC95%: 1.6-4.5), absence of peritoneal carcinomatosis (OR 4.5; IC95%: 2.0-9.9), and intentionality of treatment (adjuvant, neoadjuvant or first-line) (OR 5.4; IC 95%: 3.1-9.5) predicted decision of admission to the ICU. Age > 65 years (OR 0.35; IC 95%: 0.2-0.6) and poor symptom control as cause of admission in Oncology (OR 0.16; 95%: 0.03-0.93) were negative factors for ICU admission. By means of paired propensity analysis (Nearest-neighbor model), the sample was reduced to 172 patients and there was only statistical significance in the univariate analysis for intentionality of treatment and for treatment with immunotherapy (IT). After a median follow-up of 4 months, median survival was significantly different ($p < 0.05$) for patients who were not ICU candidates (2.5 months), patients who were admitted to the ICU (10 months) and patients who were ICU candidates but did not require admission (12.5 months).

Conclusions: Multidisciplinary decision-making may contribute to individualize the level of intensive care for Oncology patients.

2143P Mortality within 30 days after last dose of intravenous systemic anti-cancer therapy: Single-center, one-year, retrospective analysis

O. Sutcuoglu[1], T.E. Çetin[2], A. Uner[1], N. Günel[1], G. Savaş[1], A. Özet[1], N. Ozdemir[1], O. Yazici[1]

[1]Medical Oncology, Gazi University - Faculty of Medicine, Ankara, Turkey; [2]Internal Medicine, Gazi University - Faculty of Medicine, Ankara, Turkey

Background: Mortality within 30 days of systemic anti-cancer therapy may be a useful indicator of the preventable harm to patients from systemic anti-cancer therapy, but data on this indicator are limited. Identifying the characteristics of patients who develop mortality within 30 days after treatment will contribute to improving the quality of patient care and reducing financial toxicity. In this study, we aimed to screen the patients who received systemic treatment in our center in 2022 and to determine the 30-day mortality rate after the last treatment dose.

Methods: The data of all patients who received intravenous systemic anti-cancer therapy in our center in 2022 were reviewed retrospectively. Diagnoses, disease stages, chemotherapy regimens, and patient characteristics were recorded. 30-day mortality was defined as death within the first 30 days after receiving the last treatment dose.

Results: A total of 1937 patients were included in the study. The majority of the patients (n = 595, 30.7%) had gastrointestinal system cancers, followed by breast cancer (n = 369, 19.1%) and lung cancer (n = 357, 18.5%). When the patients' last treatments were reviewed, chemotherapy was the most common (n = 1514, 78.1%), followed by chemotherapy-monoclonal antibody combination (n = 241, 12.4%), and immunotherapy monotherapy (n = 91, 4.7%). The 30-day mortality rate after systemic anticancer treatment was 7.0% (n = 136) in the entire patient group. While the 30-day mortality rate for patients who received chemotherapy was 7.2% (110/1514), the mortality rate for patients who received immunotherapy (combined with chemotherapy or monotherapy) was 14.4% (15/104).

Conclusions: Our findings show that the 30-day mortality rate is high, especially in certain cancer types and after immunotherapy. In this patient group, it is necessary to review the treatment decision-making process before giving treatments with unclear clinical benefits. In addition, it is necessary to repeat our results in groups where disease types, disease stages, and treatment lines are homogeneous.

Oncology, Hospital de la Santa Creu i Sant Pau, Barcelona, Spain; [3]Oncology Data Science (ODySey) Group, Vall d'Hebron Institute of Oncology (VHIO)-Cellex Center, Barcelona, Spain; [4]Vall d'Hebron University Hospital, Barcelona, Spain; [5]Oncology Department, Hospital del Mar - Parc de Salut Mar, Barcelona, Spain; [6]Oncology Department, Vall d'Hebron University Hospital, Barcelona, Spain; [7]Medical Oncology Department, Hospital de la Santa Creu i Sant Pau, Barcelona, Spain; [8]Medical Oncology Department, Hospital del Mar - Parc de Salut Mar, Barcelona, Spain; [9]Dept. Medical Oncology, Hospital de la Santa Creu i Sant Pau, Barcelona, Spain; [10]Oncology Data Science Department, Grupo Oncoclinicas, São Paulo, Brazil

Background: Prognostic factors for oncologic outpatients have been described, including ECOG PS, tumor staging and malnutrition. However, there is no solid evidence on which variables best predict mortality for inpatients under active systemic treatment; here we present an optimized model validated externally to predict mortality in this population together with a website tool for better clinical applicability.

Methods: A prospective multicentric study of patients (pts) hospitalized between 2020-2022 at Vall d'Hebron (VH), Sant Pau (SP) and Mar Hospitals [PLANTOLOGY database] in Spain. Clinical factors and laboratory results were collected at admission. A logistic model has been trained in VH cohort with the variables selected by the LASSO method to predict 30-day mortality after discharge. As an interval validation in VH cohort a bootstrap with 1000 iterations was used. As an external validation (EV) SP and Mar cohorts were used.

Results: Out of 1,750 pts collected, 1006 had advanced disease and were under oncologic treatment during the 6 months before unplanned admission, our target population for model development (n=746) and EV (n=260). 30-day mortality was 30.6% (CI95% 27.4-34.1) and 23.3% (CI95% 18.3-29.1) in VH and EV cohort, respectively. Median age was 65 yrs, 43% had an ECOG >1, median Charlson comorbidity index was 8, and 42% were treated in a clinical trial. The most frequent tumor types were lung (23%) and colorectal (15%). The factors selected by LASSO were neutrophil count, LDH, ECOG PS, albumin, lung metastases, and treatment response at admission. The original c-index was 0.79, corrected c-index after bootstrap validation was 0.76 and c-index of external validation was 0.73 with perfect calibration. Negative predictive value and accuracy was 0.85/0.75 in VH and 0.86/0.74 in EV cohort. A website tool was created (odyssey.shinyapps.io/PROP) to facilitate the clinical implementation of our model.

Conclusions: Our model, which includes clinical and laboratory variables, accurately predicts the 30-day mortality risk (%) of cancer patients on active systemic treatment after admission. The PROP website tool may help clinicians make decisions and adjust medical interventions for hospitalized cancer patients.

Clinical trial identification: NCT05534178.

Background: The risk of venous and arterial thromboembolic events (VTE/AT) secondary to cyclin-dependent kinase inhibitors (CDKI) is not clearly defined. The objective is to characterize VTE/AT in patients with breast cancer (BC) treated with CDKI.

Methods: Retrospective, multicenter study promoted by the Thrombosis and Cancer Section of the Spanish Society of Medical Oncology (SEOM). Individuals with BC who initiated CDKI between 2015 and 2021 were recruited. We performed a descriptive analysis, analyzed the impact of VTE/AT on survival using Kaplan-Meier models and determined predictor variables using multivariate logistic regression.

Results: 849 patients were enrolled, with a median follow-up of 24 months. The incidence of VTE/AT during follow-up was 5.5% (n=47), with 34% pulmonary embolism (PE), 27.7% deep vein thrombosis (DVT), 14.9% simultaneous PE and DVT, 12.8% other forms of venous thrombosis, 8.5% arterial thrombosis and 2.1% mixed event (venous and arterial). Median time to VTE/AT was 6.9 months (interquartile range: 2.7-15.8). 31.9% of the events were diagnosed incidentally and 85.1% in an outpatient setting. One patient (2.1%) had recurrence and two (4.7%) had major bleeding. A higher proportion of thrombotic events was observed with abemaciclib (9%) compared to palbociclib (4.6%) and ribociclib (5.4%), but the differences were not significant (p=0.119). We found an association (p=0,036) between the type of CDKI and the form of VTE/AT: the most frequent with palbociclib was DVT (40.9%), with ribociclib arterial thrombosis (33.3%) and with abemaciclib PE (46.2%). Median overall survival was 49 months (95% CI 43-55.5) in the subgroup without VTE/AT, while in patients with VTE/AT it was not possible to calculate due to the low number of events. There were no significant differences (log-rank test = 0.427). Multivariate analysis revealed that the presence of metastases in the central nervous system (CNS) was associated with an increased risk of VTE/AT (OR 3.289, 95% CI 1.06-10.2).

Conclusions: CDKI-associated VTE/AT in patients with BC does not impact on survival. The type of CDKI is related to the form of presentation of VTE/AT. The presence of CNS metastases may predict these events.

[1]Medical Oncology Department, Hospital General Universitario Gregorio Maranon, Madrid, Spain; [2]Medical Oncology Dept, Hospital General Universitario Gregorio Marañon - Fundación Investigación Biomedica, Madrid, Spain

Background: Venous thromboembolism (VTE) in cancer patients is a common complication that requires a multidisciplinary management. In April 2021 we established in the Medical Oncology Department of our hospital a "Cancer-associated thrombosis (CAT) clinic" in order to provide immediate support in prevention and management of VTE to physicians involved in cancer patients' treatment. The aim of this analysis is to describe the characteristics of patients evaluated, the decisions taken and their results.

Methods: Between May 2021 and April 2023, 124 patients have been evaluated in the "CAT clinic" of the Medical Oncology Department of the Hospital General Universitario Gregorio Marañón (Madrid, Spain) with a mean follow-up of 4.25 months (standard deviation +/- 5.47 months).

Results: The main reason for referral to clinic was VTE treatment (n=120; 96.8%) and the most frequent thrombotic event was pulmonary thromboembolism (n=56; 46.7%). The most common tumors were breast (n=29; 23.4%), lung (n=21; 16.9%) and colon cancer (n=16; 12.9%). Most patients had metastatic disease (n=85; 72.0%), active cancer (n=101; 81.5%) or are receiving antineoplastic therapies (n=95; 76.6%). A modification of anticoagulation therapy was conducted in 99 patients (80.5%): change of anticoagulant drug in 77 patients (most of them from low molecular weight heparins to direct-acting oral anticoagulants [n=51;66.2%]) or change of anticoagulant dose in 49 patients (most of them from therapeutic dose to prophylactic dose in patients with low risk of recurrence and/or high risk of bleeding [n=27;55.1%]). Recurrence of VTE was observed in 8 patients (6.7%) and major bleeding (MB) in 4 patients (3.3%). In particular, 63 patients (52.5%) have received or are receiving apixaban for VTE treatment. No differences were observed between patients receiving apixaban and general population in tumor type, stage, antineoplastic treatment, or thrombotic event. VTE recurrence was seen in 2 patients (3.2%) and MB in 1 patient (1.6%) during apixaban treatment.

Conclusions: The "CAT clinic" has allowed us to adapt the anticoagulant treatment in most of patients, obtaining low complication rates (recurrence/bleeding).

Background: VTE management in cancer patients, particularly those with NSCLC, poses unique challenges due to increased bleeding and recurrence risk during anticoagulation. This study is investigating the characteristics of NSCLC patients who experience thrombotic event while assessing thrombotic recurrence, bleeding pattern, and their association with prognosis.

Methods: From the international, multicenter, prospective TESEO registry of the Spanish Society of Medical Oncology (SEOM), we selected consecutive patients diagnosed with NSCLC and VTE between June 2018 and April 2023. Demographic, thrombotic event and anticoagulant treatment were analyzed.

Results: A total of 562 patients with NSCLC and VTE were assessed (Table, clinical characteristics). Deep vein thrombosis (DVT) occurred in 22.2% (n=125), pulmonary embolism (PE) in 69.5% (n=391), and catheter-associated thrombosis (CAT) in 2.1% (n=12). Most events (59.7%, n=336) were symptomatic, 46.2% (n=260) occurring within three months of cancer diagnosis. Post-anticoagulant treatment, arterial thrombosis appeared in 0.8% (n=5) and VTE recurrence in 6.0% (n=34), with 52.9% (n=18) being PE, 20.5% (n=7) DVT and 2.9% (n=1) CAT. Bleeding complications included clinically relevant bleeding in 3.3% (n=19), minor bleeding in the same percentage, and major bleeding in 1.4% (n=8). Thrombotic recurrence (p=0.24) and bleeding (p=0.12) were not associated with worse prognosis. Males had a higher risk of thrombotic recurrence (RR 1.05, 95% CI 1.01-1.09, p=0.024). Platinum analogs and KRAS mutation were also associated with a higher recurrence risk (p=0.019 and p=0.004, respectively).

Table 2147P Baseline characteristics

	N=562 (100%)
Sex	
Male	363 (64.5)
Age	
> 65	304 (54)
ECOG	
0-1	383 (68.1)
Comorbidities	
Hypertension	231 (41.1)
Dislipemia	233 (41.4)
Smoking habit	455 (80.9)
COPD	126 (22.4)
Previous VTE	38 (6.7)
TNM Stage	
Resectable	23 (4.0)
Locally advanced	91 (16.1)
Metastatic	448 (79.9)
Histology	
Adenocarcinoma	442 (78.6)
Squamous cell carcinoma	98 (17.4)
Neuroendocrine	3 (0.5)
Other	19 (3.3)
Antineoplastic treatment at the moment of VTE	
Surgery	76 (13.5)
Radiotherapy	187 (33.2)
Quimiotherapy	224 (39.8)
Inmunotherapy	120 (21.3)

Conclusions: Our study confirms a higher incidence of thrombotic recurrence than bleeding in patients with NSCLC. Thrombotic recurrence and bleeding complications were not associated with worse prognosis. Male patients, platinum analogs, and KRAS mutation were associated with higher risk of thrombotic recurrence.

2148P Venous thromboembolism (VTE) in patients with advanced high grade ovarian carcinoma (aHGOC) receiving PARP inhibitors

L. Gervaso[1], C. Valenza[2], M. Mongillo[3], L. Boldrini[4], L. Boscolo Bielo[5], G. Castellano[6], L. Guidi[5], J. Katrini[5], E. Nicolo[7], G. Pellizzari[5], D. Trapani[5], C.A. Cella[1], I.T. Lorenzetti[8], S. Derio[8], M.T. La Presa[8], G. Parma[8], N. Fazio[1], G. Curigliano[5], A.A. Khorana[9], N. Colombo[8]

[1]Gastrointestinal Medical Oncology and Neuroendocrine Tumors, IEO - Istituto Europeo di Oncologia IRCCS, Milan, Italy; [2]Dipartimento Oncologia Clinica, IEO - Istituto Europeo di Oncologia IRCCS, Milan, Italy; [3]Division of Gynecologic Oncology, IEO - Istituto Europeo di Oncologia IRCCS, Milan, Italy; [4]Medical Oncology Department, IEO - Istituto Europeo di Oncologia IRCCS, Milan, Italy; [5]Department of Oncology and Hemato-Oncology, University of Milan; European Institute of Oncology IRCCS, Division of New Drugs and Early Drug Development for Innovative Therapies, Milan, Italy; [6]Department of New Drugs, IEO - Istituto Europeo di Oncologia IRCCS, Milan, Italy; [7]Early Drug Development for Innovative Therapies Division, Istituto Europeo di Oncologia, Milan, Italy; [8]Division of Gynecologic Oncology, European Institute of Oncology IRCCS, Milan, Italy; [9]Taussig Cancer Center, Cleveland Clinic, Cleveland, OH, USA

Background: VTE is a leading cause of death in pts with cancer, regardless of type. aHGOC is burdened by an VTE incidence of 20% and is listed as a high-risk malignancy for VTE. Treatment of aHGOC includes chemotherapy, bevacizumab and PARPi. Preclinical studies showed that the inhibition of PARP-1 could reduce endothelial dysfunction. Therefore, therapy with PARPi may potentially reduce the risk of VTE.

Methods: We conducted a retrospective single-centre observational study to describe rates, patterns and prognostic role of VTE events in patients with aHGOC receiving PARPi without bevacizumab. Pts included had received any PARPi for at least 8 weeks in any line of therapy, from Feb 2017 to Dec 2022. VTE events were identified by electronic medical record review and classified per CTCAE v5.0. Descriptive statistical analyses were performed for association with clinical outcomes (significance at p-value<0.05)

Results: Overall 166 pts were included. Baseline patients' characteristics and outcomes are reported in the table. The baseline risk of VTE event was low, according to ONKOTEV and Khorana score. After a median follow-up of 38.5 months, only 5 (3%) pts experienced a VTE event on PARPi: 1 superficial thrombosis (G1), 1 deep venous thrombosis (G2) and 3 asymptomatic pulmonary embolisms (G3). No treatment discontinuation due to VTE occurred and all the events were treated with low-molecular-weight heparins. The median time to VTE was 5.5 months (95% CI, 1.6-9.4) and median time from VTE to disease progression was 1.8 months (95% CI, 1.3-2.4).

Table: 2148P

	VTE N=5	Non-VTE N=161	p
Age at baseline, mean (SD)	63.8 (11.8)	57.9 (9.4)	.17
Previous VTE, %	20%	11%	.46
Baseline Khorana score, median (IQR)	1 (1-1)	1 (1-1)	.97
Baseline ONKOTEV, median (IQR)	1 (1-2)	1 (1-1)	.06
Anticoagulant prophylaxis at baseline, %	0%	8%	1.00
Bevacizumab within 6 months, %	0%	5%	1.00
Line of PARPi, median (IQR)	2 (2-4)	2 (1-3)	.26
Type of PARPi			.12
Olaparib, %	100%	53%	
Niraparib, %	0%	39%	
Rucaparib, %	0%	7%	
Number of cycles of therapy with PARPi, median (IQR)	7 (5-8)	12 (7-22)	.21
PARPi exposure, median (mo) (95% CI)	7.8 (6.1-8.7)	13.0 (8.9-17.1)	.72
PARPi-PFS, median (mo) (95% CI)	7.4 (6.1-8.6)	13.6 (9.5-17.7)	.38

Conclusions: Among pts with aHGOC receiving PARPi, VTE events were substantially low, suggesting a possible protective role of PARPi leading to reduced VTE risk. Conceivably, VTE occurrence may anticipate radiological disease progression.

Background: Catheter-related thrombosis (CRT) is the most frequent non-infectious complication regarding central venous devices (CVC). Its incidence has been reported 13% and 66% in symptomatic and asymptomatic patients, respectively, with several factors influencing its development.

Methods: CRT events recorded at TESEO between 2018 and 2023 were assessed. Descriptive and association analysis for rethrombosis and bleeding regarding location of thromboembolic event (TE) was conducted.

Results: A total of 245 patients developed CRT. Mean age was 60.5 years (SD 12.3). Ninety-one percent were ECOG ≤1. Most prevalent comorbidities were HTA (28.6%) and dyslipidemia (28.2%), with other TE-associated risk factors being ≤10%. PICC was present in 42.1%, PAC in 40.9% while 17% were missing. Previous VTE was present in 9.8% of patients, while 4.5% and 4.4% were on antiplatelet and anticoagulation therapy, respectively. Colorectal and breast cancers were the primary locations in 26.9% and 21.2%. Metastatic disease was observed in 54.3%. Cytotoxic chemotherapy was used in 80.4%, radiotherapy in 22.9% and 53.9% had the primary tumor resected. PE was present in 6.5%, being clinically suspected in 56.2% of cases. The diagnosis was mainly unilateral (81.3%) and 50% were central. VTE — related symptoms occurred in 70.2% of cases at presentation. LMWH was used in 91% and hospital admission was advised in 20.8% of cases. VTE — related complications were observed in 2%, being PE and superior vena cava syndrome the most frequent (40%). Arterial and venous rethrombosis were present in 0.8% and 4.9%. Minor bleeding episodes occurred in 2.5% of cases, while major/clinically relevant episodes were present in 3.6%. There was no association between rethrombosis and TE location (pulmonary embolism (PE) vs deep vein thrombosis (DVT), OR 2.57 (95% CI 0.52 — 12.6; p = 0.245)). An increased risk for major and minor bleeding was observed for PE compared to DVT (OR 6.58 (95% CI 1.8 — 23.7)).

Conclusions: Usual TE — associated risk factors were infrequent. CRT was symptomatic in most cases, with reduced complication rates after treatment. A probable association of bleeding risk and no differences for rethrombosis were observed for PE events.

2150P Clinical and molecular characterisation of cancer-associated venous thromboembolism (VTE)

P. Mascaró Baselga, J.G. Yaringaño, P.B. Buch, P. Martínez-Albaladejo, A. de Torner, O. Mirallas, S. Eremiev, S. Serradell, J. Hernando, M. Roca Herrera

Medical Oncology Department, Vall d'Hebron University Hospital, Barcelona, Spain

Background: VTE is a major, preventable complication in cancer patients (pts) and the second cause of mortality. Our aim is to describe clinical and pathological features of cancer pts with VTE and compare them to pts without VTE.

Methods: A retrospective case-control study of cancer pts with VTE diagnosed in 2022 at Vall Hebron Hospital (cases) and cancer pts without VTE treated at same centre (controls) was conducted. Clinical features including cancer site, stage, pathological/molecular profile, and therapy were registered; univariate analysis was performed.

Results: 85 cases and 100 controls were analysed. Cases characteristics: 53% females, mean age 61. Most common cancers shown in the table. Cancer was locally advanced/metastatic in 78.8%. According to Khorana score, 75.3% had intermediate/high risk for VTE. Most common histology in lung was adenocarcinoma (ADK) (72.7%); 14.3% *EGFR* mutated. In breast, 93.3% were invasive ductal carcinomas (IDC), 93.3% expressed hormone receptors (HR), 40% HER2 positive, 6.7% germline *BRCA* mutation. All CRC were ADKs, 40% *RAS* mutations and 13% microsatellite instability (MSI). 82.4% of pts received chemotherapy (CT), 16.5% immunotherapy (IO), 15.3% hormone therapy (HT), 12.9% antiangiogenics, 10.6% tyrosine kinase inhibitors. Comparative analysis (Table): female sex was associated with VTE (Odds Ratio [OR], 2; 95%CI, 1.1-3.6). As to cancer type, only breast was associated with VTE (OR, 2.6; 95% CI, 1.01-6.8). Conversely, head and neck cancers had negative association with VTE (OR, 0.2; 95%CI, 0.04-0.9). No differences were observed regarding cancer stage. CT (OR, 6.72; 95%CI, 3.4-13.3), HT (OR, 3.4; 95%CI, 1.2-10.1) and targeted therapies (OR, 3.06; 95%CI 1.43-6.56) were associated with VTE; IO was not.

Table: 2150P Characteristics of cases and controls

Characteristic	VTE cases (N=85)	Controls (N=100)	P value
Tumour site – no. (%)			
Lung	18 (21,3%)	30 (30%)	0.172
Breast	14 (16,47%)	7 (7%)	0.043*
CRC	12 (14,21%)	13 (13%)	0.825
Pancreas	9 (10,59%)	4 (4%)	0.081
Gynaecological	9 (10,59%)	8 (8%)	0.544
Gastroesophageal	4 (4,71%)	6 (6%)	0.726
Genitourinary	3 (3,53%)	6 (6%)	0.436
Head and neck	2 (2,35%)	11 (11%)	0.022*
Stage – no. (%)			
I	3 (3,53%)	6 (6%)	0.436
II	13 (15,29%)	10 (10%)	0.277
III	21 (24,71%)	21 (21%)	0.549
IV	46 (54,12%)	59 (59%)	0.504
Systemic therapies – no. (%)			
CT	70 (82,35%)	41 (41%)	<0.001*
Targeted therapy	25 (29,41%)	12 (12%)	0.003*
IO	14 (16,47%)	11 (11%)	0.278
HT	13 (15,29%)	5 (5%)	0.019*

Conclusions: Most common cancers in pts with VTE were lung (14% *EGFR* mutated), breast (HR positive 93%; HER2 positive 40%) and CRC (40% *RAS* mutated). Female sex and breast cancer were associated to VTE. CT, HT and targeted therapies were all associated with VTE.

2151P Incidence patterns and clinical implications of venous thromboembolism (VTE) in patients (pts) with neuroendocrine tumors (NET)

J. Hernando[1], M. Roca Herrera[1], A. Garcia Alvarez[1], S. Serradell[1], A. Garcia-Burillo[2], M.T. Salcedo[3], X. Molero[4], I. Navales[2], I. Diez[5], S. Landolfi[3], S. Castro[6], L. Blanco[6], X. Merino[5], G. Molina Lores[1], S. Vega[1], S. Bueno Salazar[1], J. Yaringaño[1], A. Carmona[1], S. Eremiev[1], J. Capdevila Castillon[1]

[1]Medical Oncology Department, Vall d'Hebron University Hospital, Barcelona, Spain; [2]Nuclear Medicine, Vall d'Hebron University Hospital, Barcelona, Spain; [3]Pathology Department, Vall d'Hebron University Hospital, Barcelona, Spain; [4]Gastroenterology, Vall d'Hebron University Hospital, Barcelona, Spain; [5]Radiology Department, Vall d'Hebron University Hospital, Barcelona, Spain; [6]Surgery Department, Vall d'Hebron University Hospital, Barcelona, Spain

Background: VTE is a significant complication in oncology and one of the primary causes of cancer-related mortality. Few studies have addressed VTE in pts with NET, with an estimated incidence of 7.5%. Nevertheless, there is no evidence from large datasets. In the present study, we analyzed the incidence and treatment of VTE in NET.

Methods: Consecutive pts with gastroenteropancreatic (GEP) and thoracic NET treated in our institution between 2017 and 2018 were selected to study the incidence of VTE including deep vein thrombosis (DVT), pulmonary embolisms (PE) and splanchnic venous thrombosis (SVT). Information regarding clinical characteristics, follow up and VTE treatment were collected.

Results: 320 pts (55% female) were included in the analysis (40.6% pancreatic, 27.1% small intestine, 9.3% lung). 65 pts presented any thrombotic event (20.3%), and 23 were directly related to TNE (7.1%). Characteristics of patients with TNE-related VTE are enlisted in the table. The leading cause of SVT was splenic vein thrombosis (SPLVT). All cases that started anticoagulant therapy were treated with low-molecular-weight heparin (100%) and most of them indefinitely (53.8%). All cases that did not receive anticoagulant therapy were splenic vein thrombosis, due to physician decision. Any complication related to anticoagulant therapy was described in 3 pts (13%). No cases of VTE-related death were found.

Table 2151P Clinical characteristics of patients with NET-related VTE

NET-related VTE	N=23
Sex	Female 9 (39.1%) Male 14 (60.9%)
Age (median)	76
Primary tumor location	Pancreas 16 (69.5%) Small Intestine 5 (21.7%) Lung 1 (4.4%) Other 1 (4.4%)
Tumor grade	G1 7 (30.4%) G2 9 (39.2%) G3 7 (30.4%)
Tumor stage	I-III 3 (13%) IV 20 (87%)
VTE location	SVT 14 (60.9%) PE 7 (30.4%) DVT 2 (8.7%)
Anticoagulant therapy	Yes 13 (56.5%) No 10 (43.5%)

Conclusions: NET-related VTE appears in 7.1% of pts with NET. Most common profile is a male with advanced pancreatic neuroendocrine neoplasm and SPLVT. Impact on prognosis and the need for anticoagulant therapy remains controversial.

2152P Prognostic importance of GRIM score on sorafenib side effects, hospitalization and survival in hepatocellular cancer patients

D. Ercan Uzundal, O. Yazici, B. Ulas Kahya, A. Uner, A. Özet, N. Ozdemir

Medical Oncology Department, Gazi University - Faculty of Medicine, Ankara, Turkey

Background: The Gustave Roussy Immune Score (GRIm-Score) was first used in 2017 as a prognostic index. Since the immune pathways in the pathogenesis of HCC has been demonstrated, it was aimed to examine the relationship between GRIm-score and patient survival, treatment side effects and the frequency of hospitalization in HCC patients.

Methods: In between 2010-2021, 108 patients with metastatic or unresectable HCC in our center were screened. Patients receiving sorafenib therapy and ecog 0-1 were included. Clinicopathological data, GRIm scores prior to the sorafenib treatment, previous treatment modalities of patients, hematological side effects of sorafenib, and hospitalizations to the oncology inpatient ward, excluding hospitalizations for planned procedure or chemotherapy, were recorded retrospectively. For the GRIM-Score, patients with NLR > 4.8, LDH > upper limit of normal, or albumin < 3.5 g/dL were given 1 point. Patients were divided in two groups according to the GRIM-Score as low and high.

Results: Sixty four patients were included in the study. Median age was 65 and 95.3% of the patients were male. 79.7% of them had chronic hepatitis. Most of the patients (68%) performed previous local ablative therapy. Low GRIM score (0-1) was demonstrated 60.9% of patients, whereas 39.1% of them had high score(2-3). Hematological side effects and/or AST elevation were observed in 32% of the patients. Hematological side effects were seen in 23% of all patients. During the follow-up period, 75.2% of the patients were hospitalized at least once. 72% of hospitalizations were for supportive treatment. The median number of hospitalizations was 1. The median OS was 5 months. The median survival in the low and high GRIm-score group was 8.8 and 2.7 months respectively ($p<0.0001$). Hospitalization requirement was found to be significantly higher in the high-GRIm score group compared to low GRIm-score group (p: 0.017). There was no significant difference between the presence of side effects and the GRIm-score group (p: 0.664).

Conclusions: The GRIm-score at the beginning of sorafenib therapy can be used as a significant marker both to determine survival and to predict the need for supportive care in metastatic/unresectable HCC patients.

2153P Circulating biomarkers to predict severe complications in cancer patients with low-risk chemotherapy-associated febrile neutropenia

S. Wikström Fernandez[1], A. Murillo Herrera[1], P. Garrido Ortega[1], L. García de Guadiana−Romualdo[2], P. Torrella Esteban[2], E. Feliciangeli[1]

[1]Oncology Department, Hospital General Universitario Santa Lucía de Cartagena, Cartagena, Spain; [2]Laboratory Medicine Department, Hospital General Universitario Santa Lucía de Cartagena, Cartagena, Spain

Background: Febrile neutropenia (FN) is one of the most frequent and life-threatening complications in cancer patients. The most widely used model to identify low-risk FN episodes, candidates for outpatient management, is the Multinational Association for Supportive Care in Cancer (MASCC). However, its ability to predict serious complications is not optimal, occurring in up to 15% of episodes classified as low risk. The identification of circulating biomarkers may refine these indexes. We aimed to evaluate the role of C-reactive protein (CRP) and procalcitonin (PCT) in predicting the development of serious complications in low-risk FN episodes.

Methods: A retrospective study including FN episodes in patients with solid tumors presenting to the Emergency Department (ED), classified as low risk (MASCC score $\geq$ 21). In all episodes, a blood sample was collected on admission to the ED for analysis, including CRP and PCT. Outcome was defined as Intensive Care Unit (ICU) admission and/or death and/or other serious complications. To evaluate the discriminatory ability of biomarkers for outcome, Receiver Operating Characteristic (ROC) curve analysis was used and optimal cutoffs were calculated through Youden index.

Results: During the study period, 132 low-risk episodes were included (mean age: 58.4; SD: 11.5 years; 83 (62.9%) female). Serious complications were developed in 52 (39.4%) episodes. Median CRP and PCT levels were significantly higher in patients developing complications: 11.8 mg/dL (IQR: 5.21-19.6) vs 5.3 mg/dL (IQR: 2.2-9.0), $p < 0.001$; 0.42 ng/mL (IQR: 0.14-1.09) vs 0.12 ng/mL (0.06-0.23), $p < 0.001$, respectively. In ROC AUC analysis, both biomarkers achieved a similar predictive accuracy (CRP: 0.733 and PCT: 0.744). Optimal cutoffs were 9.8 mg/dL for CRP (Sensitivity (S): 61.5%, Specificity (Sp): 80%, positive predictive value (PPV): 66.7% and negative (NPV): 76.2%) and 0.27 ng/mL for PCT (S: 61.5%, Sp: 81.3%, PPV: 68.1%, NPV: 76.5%).

Conclusions: In chemotherapy-associated FN patients, circulating CRP and PCT levels might be useful to improve the risk stratification of low-risk episodes, contributing to decision making in the management of these patients.

2154P Total cholesterol as an independent prognostic factor in cancer patient survival: A single institution experience

M. Alameda-Guijarro, D. Sanchez Cabrero, A. Rueda-Lara, G. Martin-Montalvo Perez, R. Marcano, A. Garcia Leal, P. Zwisler Contreras, J.P. López, L. Ruiz Jimenez Ubeda

Medical Oncology Department, Hospital Universitario La Paz, Madrid, Spain

Background: The role of lipid levels in the development and outcomes of cancer patients remains unclear in the literature. In this study, we aimed to analyze whether there is a relationship between total cholesterol levels and the survival of hospitalized cancer patients.

Methods: This retrospective observational study included patients admitted to the Medical Oncology Hospitalization Unit at La Paz University Hospital between September 2018 and January 2020. Total cholesterol levels, tumor type, treatment received, and mortality were analyzed.

Results: A total of 839 patients were included, with no differences in gender distribution. The most frequent tumor was lung (20.7%), followed by digestive tumors, including colorectal, esophagogastric, pancreatobiliary, or hepatic (33.4%), and breast (11.4%). The majority of patients were receiving active cancer-specific treatment, with chemotherapy (51.5%) or targeted treatments (18.6%) at the time of admission. At the end of the median follow-up period (31,8 months), 615 deaths had occurred (78.9%). The median overall survival (OS), regardless of tumor type, was 199 days. Having low total cholesterol values (less than 150 mg/dL) increased the risk of mortality by 25.9% compared to having physiological levels (150-200 mg/dL) ($p=0.016$, CI95% 1.045, 1.518)) with a Hazard Ratio of 1.259. Having high total cholesterol values (above 200 mg/dL) increased the risk of mortality by 30.6% compared to having physiological levels ($p=0.036$, CI95%(1.017, 1.677)) with an HR of 1.306.

Conclusions: To date, the majority of studies indicate that elevated cholesterol levels in patients with advanced cancer are associated with a higher risk of mortality, both due to a higher burden of comorbidity and the potential effects of cholesterol on oncogenic pathways. On the other hand, low cholesterol levels, possibly reflecting a significant metabolic dysregulation during cachexia, seem to be linked to a worse prognosis as well. Although the mechanisms by which high or low cholesterol levels increase the risk of mortality may differ, their incorporation into prognostic scores can contribute to a more accurate estimation of prognosis in advanced patients.

2156P Use of taxanes during pregnancy: A systematic review

A.S. Ferrigno Guajardo[1], B.F. Vaca Cartagena[2], A. Aranda Gutierrez[3], A. Becerril Gaitan[2], H. Azim[2], C.M. Villarreal Garza[2]

[1]Department of Medicine, Yale University School of Medicine, New Haven, CT, USA; [2]Breast Cancer Center, Hospital Zambrano Hellion, Tecnologico de Monterrey, San Pedro Garza Garcia, Mexico; [3]Departamento de Hemato-Oncología, Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Mexico City, Mexico

Background: The use of chemotherapy (CT) with taxanes after the first trimester of pregnancy is endorsed by guidelines despite limited data on their safety. This study aims to review the neonatal and obstetric outcomes after the use of taxanes during pregnancy.

Methods: A MEDLINE search was performed up to 1/1/2023. Inclusion criteria included gestational taxane use, original findings, and reporting of individual patient outcomes.

Results: A total of 69 out of 316 references identified were included. Overall, 143 cases of gestational taxane use have been reported in the literature, resulting in 145 fetuses exposed in utero. Most received paclitaxel (78%) and were diagnosed with breast (59%), cervix (23%), or ovarian (13%) malignancies. Taxanes were initiated most frequently in the 2nd (69%) or 3rd trimesters (28%) of pregnancy (n=110), at a median gestational age of 17 weeks (range 2-32; n=89). The median cumulative dose received during pregnancy was 405 mg/m2 (range: 125-1200; n=63) for paclitaxel and 320 mg/m2 (range: 160-650; n=12) for docetaxel. Out of 107 cases, 91% received other CT agents during pregnancy, including platinums (50.4%) or doxorubicin/cyclophosphamide (17.8%). No maternal adverse events or obstetric complications were reported in 54% (41/97). The most frequent adverse obstetric events were preterm contractions (12/121; 10%), pre-eclampsia (6/97; 6%), intrauterine growth restriction (7/97; 7%), oligohydramnios (5/97; 5%), and preterm premature rupture of membranes (6/120; 5%). All cases with data available resulted in live birth (n=117). Preterm birth was reported in 63% (82/131) and 29% of neonates were classified as small for gestational age (36/123). Perinatal complications were documented in 18% (20/109), including one case of neonatal death secondary to multiple congenital malformations that had been detected before CT start. A congenital malformation was reported in 4% (6/142). Information of health status after birth was available for 85 cases (median follow-up 19 months, range 1 to 160), of which 87% were reported as healthy. Two cases of pediatric malignancy were noted.

Conclusions: Data on gestational taxane use is largely limited to case reports and small case series with heterogeneous reporting of outcomes. Future studies are urgently needed to evaluate their safety.

2157P A phase II randomised controlled trial comparing the cardiotoxicity of capecitabine and S-1

S. Clive[1], A. Bularga[2], P. Henriksen[2], D.E. Newby[2], L.R. Wall[1], L. Dawson[1], E.R. Brown[1], E. Evans[3], S. Denham[4], N. Homer[4], O. Demyanov[1], S. Muir[5], G. Tapia-Rico[6], N. Peel[7], A. Christie[1]

[1]Edinburgh Cancer Centre, Western General Hospital, Edinburgh, UK; [2]Centre for Cardiovascular Science, University of Edinburgh, Edinburgh, UK; [3]Edinburgh Clinical Research Facility, Western General Hospital, University of Edinburgh, Edinburgh, UK; [4]Mass Spectrometry Core, Edinburgh Clinical Research Facility, University of Edinburgh, Edinburgh, UK; [5]Clinical Trials Unit, Beatson West of Scotland Cancer Centre, Glasgow, UK; [6]Medical Oncology, ICON Cancer Centre Adelaide (Kurralta Park), Adelaide, SA, Australia; [7]Department of Surgery, Queen Elizabeth University Hospital, Glasgow, UK

Background: Fluoropyrimidines are used widely to treat cancer but their cardiotoxicity, which remains incompletely understood, has serious consequences for some patients. The fluoropyrimidine S-1 (Teysuno®) has recently been approved for the management of colorectal cancer in patients who develop cardiovascular toxicity with other fluoropyrimidines.

Methods: This was a single-centre phase II prospective randomised open-label blinded endpoint trial that investigated the cardiotoxicity of capecitabine and S-1 in patients treated between May 2014 and March 2020. Patients were randomized 1:1 to receive oral capecitabine or S-1, alone or with oxaliplatin, for days 1-14 of a 21-day cycle. Baseline computed tomography coronary angiogram (CTCA) was performed. Myocardial ischaemia was quantified by ST-segment analysis of continuous 12-lead electrocardiography before and during days 3-5 of oral chemotherapy, by a blinded analyst. Alpha-fluoro-beta-alanine (FBAL) was measured using a validated liquid chromatography tandem mass spectrometry method.

Results: Fifty-nine patients (29 capecitabine; 30 S-1; mean age 64 years (range 40-83)) were enrolled, 56 started treatment and 72% (capecitabine) and 70% (S-1) received oxaliplatin. CTCA was performed in 53 patients, coronary artery disease (CAD) was seen in 30 (capecitabine, n=14/26; S-1, n=16/27). Duration of ST change was not significantly different between groups (p = 0.2198) but change in mean daily ischaemic burden (p=0.0442) was significantly higher for capecitabine compared to S-1. Ischaemic burden was unrelated to the presence of underlying CAD. FBAL (precursor to cardiotoxic fluoroacetate) was significantly increased with capecitabine compared to S-1 during treatment (Table).

Table: 2157P Mean FBAL (ng/mL) during fluoropyrimidine treatment

Week	Capecitabine (n=23)	S-1 (n=23)	P value
1	2507	95	<0.0001
2	2632	103	<0.0001
3	12	3	0.0083

Conclusions: In this prospective randomised trial, capecitabine was associated with significantly higher ischaemic burden and higher levels of FBAL than S-1 and this was unrelated to presence of CAD.

Clinical trial identification: NCT01845337.

2158P A self-assessment survey to identify the risk of patient's screen fail in phase I clinical trials (SCITEP trial)

K. Ouali[1], I. Deneche[2], L. Seknazi[1], R. Bahleda[1], A. Vozy[1], P. Vuagnat[1], F-X. Danlos[1], V. Goldschmidt[1], A. Bayle[1], P. Martin Romano[1], A. Hollebecque[1], J-M. Michot[1], A. Marabelle[1], S. Postel-Vinay[1], A. Gazzah[1], C. Smolenschi[1], Y. Loriot[1], S. Ponce Aix[1], S. Champiat[1], C. Baldini[1]

[1]Drug Development Department (DITEP), Gustave Roussy - Cancer Campus, Villejuif, France; [2]Department of Statistics, Gustave Roussy - Cancer Campus, Villejuif, France

Background: Screen failures (SF) in early phase clinical trial are deleterious for patients, physicians and drug companies. It is therefore crucial to identify risk factors of SF, in order to optimize drug development and maximize patient's benefit.

Methods: We created a self-assessment survey (SCITEP score) comprising 15 questions extracted from the ESAS, EQ-5D and PALLIA 10 scores, which evaluate patient's (pts) symptoms and quality of life, each item being scored from 0 to 10 (i.e total score between 0 and 150). Patients entering a phase I clinical trial (ph1T) at Gustave Roussy cancer center between January 10th and October 26th 2022 were evaluated at screening (T0), and subsequently every month (T1, T2,..) until end of treatment.

Results: 227 of 275 pts entering a Ph1T were assessed between January 10th and October 26th 2022. Most frequent tumor types were lung (18%), GI (16%), hematological (10%) and gynecological cancer (9.3%); 56% were female. At data cut off (January 15th 2023), 25 pts were considered SF. There was no difference observed between SF pts and pts who went on with the trial in terms of ECOG, RMH score, albumin and LDH levels, number of previous lines of treatments and of metastatic sites at baseline (Table). At T0, there was a significant difference in the SCITEP score between SF pts and the others (median score 41 [IQR 26-63] vs 20 [IQR 10-38], p<0.001). Internal validity of the score was good (cronbach alpha > 0.7). With a cutoff of ≥35, sensitivity of the survey to identify pts at high risk of SF was of 66.6% and specificity of 70.5%. Regarding overall survival, pts with a score ≥35 (n= 68) at T0 were at higher risk of death (survival rate at 3 months of 53% vs 65%, p<0.01).

Table: 2158P

	SF pts (n= 25)	Non SF pts (n=202)	*p-value*
ECOG (IQR)	1 (0-1)	1 (0-1)	0.3
RMH score (IQR)	1 (0-1)	1 (0-1)	0.3
LDH level (IQR)	260(185-433)	222 (185-286)	0.2
Albumin level (IQR)	43 (36-45)	43 (41-45)	0.5
Nb of metastatic sites (IQR)	2 (2-3)	2 (2-3)	0.4
Nb previous lines of treatment (IQR)	3 (3-4)	3 (2-4)	0.04
SCITEP score (IQR)	41 (26-63)	20 (10-38)	<0.001

Conclusions: Self-assessment of risk of SF by pts entering a ph1T is feasible with the SCITEP score. A score ≥35 seemed associated with a higher risk of SF and of death at 3 months. Independent cohorts are needed to revalidate this score as a tool to better detect pts at risk of SF and thereby optimize drug development.

2159P Machine learning algorithms to predict the risk of chemotherapy-related toxicity in older Asians

M. Li[1], M.S. Furqan[2], S.L.A. Pang[3], J.L. Low[3], C. Choong[3], M. Ooi[3], Y.S. Ng[3], M.Z. Chen[4], F. Ho[5], J. Tey[5], Y. Yao[6], M. Chun[7], N. Barr Kumarakulasinghe[3]

[1]Yong Loo Lin School of Medicine, NUS - National University of Singapore, Singapore; [2]AIO-Innovation Office, NUHS - National University Health System, Singapore; [3]Department of Haematology-Oncology, National University Cancer Institute (NCIS), NUHS - National University Health System, Singapore; [4]Division of Geriatric Medicine, Department of Medicine, NUH - National University Hospital, Singapore; [5]Department of Radiation Oncology, National University Cancer Institute (NCIS), NUHS - National University Health System, Singapore; [6]Department of Pharmacy, NUH - National University Hospital, Singapore; [7]Department of General Medicine, Ng Teng Fong General Hospital, Singapore

Background: The International Society for Geriatric Oncology (SIOG) recommends the use of geriatric assessments (GA) or clinical adverse event risk predictors when managing older cancer patients. However, traditional GA and risk predictors are rarely utilized in the real-world setting due to limitations in time and resources. The objective of this study was to assess the performance of machine learning algorithms in predicting the risk of post-chemotherapy grade 3-5 toxicity in older Asian patients.

Methods: This study is based on a dataset of patients from a prospective study at the National University Cancer Institute, Singapore (NCIS) that successfully validated the CARG model in older Asian patients. In this study, 200 patients aged 70 years or older of various Asian ethnicities, with a solid tumor diagnosis and undergoing chemotherapy were prospectively recruited over the period of June 1, 2017, to January 1, 2019. We trained four machine learning models — Support Vector Machine (SVM), Random Forest (RF), Extreme Gradient Boosting (Xgboost), and Light Gradient Boosting Machine (Light DBM) to predict the outcomes of grade 3-5 (CTCAE version 4.0) adverse events post-chemotherapy.

Results: The median patient age was 74 years (IQR, 71 to 78), and 110 (55.0%) were male. 137 (68.5%) patients experienced grade 3 to 5 chemotherapy toxicity. The best-performing model for predicting grade 3-5 chemotherapy toxicity in the test set was the Xgboost model which achieved an area under the ROC curve (AUC) of 0.87. By comparison, the CARG clinical model and oncologist prediction of grade 3-5 toxicity achieved an AUC of 0.61 and 0.74 respectively in the test set. The best performing Xgboost model included elements of the CARG model in addition to clinical features such as the Karnofsky Performance Scale, number of co-morbidities and medications, current treatment line, "Timed-Up and Go".

Conclusions: The Xgboost Machine Learning model was able to predict the occurrence of grade 3-5 toxicity post-chemotherapy in elderly Asian patients with a better performance compared to the CARG clinical model and oncologists' predictions. These results will be further evaluated in external, prospective patient cohorts to validate them for clinical use.

2160P Sociodemographic disparities associated with financial toxicity in stage IV non-small cell lung cancer survivors

M. Parma[1], M.L. Hsu[2], C. Eaton[3], S. Olson[3], M. Boulanger[4], M. Guo[1], M. Miller[1], R. Hu[1], J. Feliciano[1]

[1]Oncology, Johns Hopkins Hospital, Baltimore, MD, USA; [2]Medical Oncology, Case Western Reserve University/University Hospitals, Cleveland, OH, USA; [3]Biostatistics, Johns Hopkins Hospital, Baltimore, MD, USA; [4]Oncology, Massachusetts General Hospital Cancer Center, Harvard Medical School, Boston, MA, USA

Background: The dawn of immunotherapies and tyrosine kinase inhibitors (TKI) for patients with metastatic non-small cell lung cancer (NSCLC) has brought about improved survival. As a consequence, there is now a rapidly growing population of lung cancer survivors (LCS), even in the metastatic setting. Little is known about patient reported outcomes such as financial toxicity during the survivorship period. We evaluated sociodemographic and clinical factors in LCS with metastatic disease at the time of diagnosis and whether these factors are associated with financial toxicity (FT) in a survivorship period.

Methods: We performed a survey study of 176 patients with stage IV NSCLC at diagnosis from December 2020 to March 2023. Surveys with 80% or more of self-reported demographic data completed and 100% of COST tool, a validated 11-part Likert-scale-based questionnaire measuring FT, were analyzed. Final analysis included 129 surveys. Descriptive statistics were used to categorize sociodemographic and clinical features of participants. The Kruskal-Wallis one-way analysis of variance was used to identify sociodemographic or clinical factors associated with FT.

Results: Females were significantly more likely to have completed survey data (p=0.0057). 56% of participants were female, 50% were above the age of sixty-five years, 74% Caucasian, 54% current/former smokers and 91% had an ECOG 0-1. Sixty percent were more than 2 years since diagnosis, 81% on active systemic therapy at the time of the survey, 48% received immunotherapy, and 60% received targeted therapies. Additionally, 76% had private insurance, 86% employed or retired, 20% had a change in employment after the diagnosis, 60% reported annual household income >$75,000 and 82% reported some college level or higher education. We identified that lower household income (p=0.001), unemployment status (p=0.02), and lower education levels (p=0.005) were significantly associated with worsened FT.

Conclusions: Sociodemographic factors are associated with disparities in financial toxicity in LCS with metastatic disease. Future work to identify high-risk populations and potential interventions, such as financial counseling, may improve disparities in patient reported outcomes.

2161P Organization of hospital pharmaceutical consultations for cancer patients receiving oral anticancer drugs: A nationwide cross-sectional study

F. Slimano[1], S. Sanchez[2], C. Partant[3], M. Fages[4], F. Lemare[5], G. de Lambert[5], M. di Palma[6]

[1]Pharmacy Department, Hopital Robert Debré - CHU de Reims, Reims, France; [2]Public Health and Performance Department, Centre Hospitalier de Troyes, Troyes, France; [3]Pharmacy Department, Union Hospitalière de Cornouaille Hôpital Laennec Quimper, Quimper, France; [4]Public Health and Performance Department, CHU Nimes - Hopital Universitaire Carémeau, Nimes, France; [5]Territorial Strategy Department, AstraZeneca France, Courbevoie, France; [6]Medical Oncology Dept., Gustave Roussy - Cancer Campus, Villejuif, France

Background: In France, cancer patients receiving oral anticancer drug (OAD) may benefit from pharmaceutical consultations (PC) with a hospital pharmacist (HPh) along the care pathway to ensure quality and safety of care. The purpose of this study was to evaluate how these PC are implemented in clinical practice in French hospitals.

Methods: We conducted a cross-sectional study including a national based panel of HPh. These professionals were identified via a committee of experts and their personal network, and using a National Database of Hospital Pharmacists Directory of Pharmacists in Health Establishments (OPAS data — 2020).

Results: 431 HPh were contacted, 72 (17 %) from 66 different hospital (corresponding to 14 % of chemotherapy-delivering hospitals in France) responded to the survey. 53 (73 %) of the respondents declared a care pathway was implemented in their institutions, 37 (52 %) with a coordination by a dedicated oncology nurse and 62 (85%) with a PC systematically proposed to patients. PC content was relatively homogeneous: medication reconciliation, assessment of patient's autonomy and understanding of the OAD treatment, side-effects prevention and management, and coordination with the community pharmacist and the general practitioner. Communication by HPh with patients' oncologist was almost systematic (66, 92 %), directly or using the hospital electronic health record. Concerning the time needed for PC: preparation of PC required more than 15 minutes for 41 (57 %) of the survey respondents, the consultation itself lasted 20 to 30 minutes for 33 (46 %) of them while time to report PC required more than 15 minutes for 35 (49 %) of them. 44 (61 %) of the respondents mentioned improved patient compliance, 68 (95 %) improved collaboration between healthcare professionals and 63 (87 %) increased patient satisfaction.

Conclusions: In addition to therapeutic innovation, extensive use of OAD has changed cancer patient management. PC implemented in a systematic way represent an innovative, achievable, and efficient way to improve patient care, facilitate coordination between healthcare professionals and increase patient satisfaction.

2162P Can artificial intelligence provide accurate and reliable answers to cancer patients' questions? Comparison of chatbots based on the ESMO Patient Guide about cancer pain

K. Bir Yucel[1], O. Yazici[1], N. Ozdemir[2], A. Özet[1]

[1]*Medical Oncology Department, Gazi University - Faculty of Medicine, Ankara, Turkey;* [2]*Medical Oncology Department, Ankara Numune Education and Research Hospital, Ankara, Turkey*

Background: There is limited data on the quality of cancer information provided by ChatGPT and other artificial intelligence systems. In this study, we aimed to compare the accuracy of information about cancer pain provided by chatbots (chatGPT, perplexity, and chatsonic) based on the questions and answers contained in the the European Medical Oncology Association (ESMO) Patient Guide about cancer pain.

Methods: Twenty questions were selected from the questions available in the ESMO Patient Guide Cancer Pain. Medical oncologists with more than 10 years of experience compared responses from chatbots (ChatGPT, Perplexity, and Chatsonic) with the ESMO patient guide. The primary evaluation criteria for the quality of the responses were accuracy, patient readability, and stability of response. The accuracy of responses was evaluated using a three-point scale: 1 for accuracy, 2 for a mixture of accurate and incorrect or outdated data, and 3 for wholly inaccurate. The Flesch-Kincaid readability (FKr) grade was used to measure readability. Stability of responses was evaluated whether the model's accuracy is consistent across different answers to the same question.

Results: Chatbots were more difficult to read than the ESMO patient guideline (FKr= 9.6 vs. 12.8, p= 0.072). Among the chatbots, perplexity had the easiest readability (FKr= 11.2). In the accuracy evaluation, the percentage of overall agreement for accuracy was 100% for ESMO answers and 96% for ChatGPT outputs for questions (k= 0.03, standard error= 0.08). Among the chatbots, the most accurate information was obtained with chatGPT.

Table: 2162P Comparison of ESMO and chatbots in terms of readibility and accuracy

	ESMO	Chatbots			
		ChatGPT	Perplexity	Chatsonic	p-value
Readibility (FKr grade)	9.6 Easily understood	13.4 Difficult to read	11.2 Fairly difficult to read	13.9 Difficult to read	0.072
Accuracy	%100	%96	%86	% 90	0.037

Conclusions: The results suggest that ChatGPT provides more accurate information about cancer pain compared with other chatbots.

2163P Supportive care in French community pharmacies: OncoPharma certification

J. Sicard, H. Valque, S. Colonna, C. Vincent, R. Aim, C. Theotime, M. Djilani, M. Gauthier

TotumLab, Totum Pharmaciens, Paris, France

Background: In France, cancer is the leading cause of death among men and the second leading cause among women. Currently, supportive care provided to cancer patients in community pharmacies are heterogeneous across the country. In order to structure and standardize pharmaceuticalsupportfor all cancer patients in primary care, TotumLab foundation has created the OncoPharma certification.

Methods: The OncoPharma certification is based on a framework that covers the activities of dispensing treatments andsupportingcancer patients, caregivers and relatives, from the time of diagnosis, during and after cancer, by the entire pharmacy team. The framework presents certified characteristics, the way to implement them, as well as documentary ressources and requested internal controls to ensure compliance. The development of the certification framework is the result of a multidisciplinary collaborative effort, bringing together all healthcare professionals involved in cancer patients care. The OncoPharma certification is accessible to all community pharmacies in France.

Results: In the certification framework, patient care is structured around 14 operational characteristics that are proposed and adapted to each individual situation. Since June 2022, the OncoPharma certification framework has been accredited by the French accreditation committee (COFRAC). This document allowed for the publication of the first clinical guideline for the management of cancer patients in community pharmacies by the Francophone Association of Supportive Oncology Care (AFSOS). As of April 2023, two pharmacies have been certified under OncoPharma, and over 40 others are in the process of certification.

Conclusions: This innovative project is the result of collective and multidisciplinary work to improve the quality of life of patients living with cancer. It promotes communication and coordination among healthcare professionals, as well as training and upskilling of pharmacy teams. This project is part of the continuous improvement and value creation in healthcare. Thanks to the Oncopharma certification, the community pharmacist plays a central role in the care of people with cancer.

2164P The impact of cancer patients' face masks on oxygenation and Co2 retention during treatment

M. Sahin[1], A. Alkan[2], S. Kitaplı[2], O. Tanriverdi[2]

[1]*Internal Medicine, Mugla Sitki Kocman University - Faculty of Medicine, Mugla, Turkey;* [2]*Medical Oncology, Mugla Sitki Kocman University - Faculty of Medicine, Muğla, Turkey*

Background: After the emergence of COVID-19, face masks(FMs) have been an important of our daily lives. They are cheap and effective. However, the clinical data in healthy adults concluded that they could result in hypoxemia and hypercapnia. The impact of FM in cancer patients is not known. In this study, we aimed to evaluate the impacts of FMs on oxygenation and CO2 retention of cancer patients who are under active treatment.

Methods: The patients who were on active treatment in oncology outpatient chemotherapy unit, were included. Besides routine pretreatment evaluation; the patient, disease and treatment characteristics were recorded. Pre and Posttreatment venous blood gases, pulse oximeter, vital signs were evaluated. The patients' compliance to wear FMs during the treatment was sustained and acute toxicities were noted. The changes in parameters, and the factors effecting the changes were statistically tested.

Results: 126 patients with a median age of 60 (33-85) were evaluated. 73.8% of the had at least one comorbidity, 16.7% with a diagnosis of COPD/ Asthma. Most of them has a diagnosis of breast cancer (32.5%) and half were under palliative treatment. The median treatment time was 150 minutes (90-410). The comparison of pre-post treatment parameters showed a statistically significant changes in Ph (7.37 vs 7.35, $p<0.01$), pCO2 (44.2 vs 45.8, $p=0.049$), HCO3 (25.7 vs 25.3, $p=0.003$), SpO2 (97.0 vs 96.0, $p=0.08$), fever (36.4 vs 36.3, $p=0.023$). All the changes were clinically insignificant and in normal ranges. The analysis of the factors related with these changes didn't point out a specific group of patients that were more prone to changes. There were a few acute toxicities in 3.2% of the patients. They had more post treatment mean arterial pressure (difference; 13.3 vs 0.0 mmHg, $p=0.04$).

Conclusions: In the patients under active treatment, FMs resulted in statistically significant but clinically non- significant changes in pH, pCO2, HCO3, SpO2 and fever. The FMs are effective and safe products in cancer patients under active treatment.

2165P A French overview of electronic patient-reported outcomes use in 2022

M. Hocine[1], F. Fiteni[2], E. Coget[1], C. Cousin[1], P. Brouard[1], C. Carbasse[1]

[1]*Pharmacy Unit, CHU Nimes - Hopital Universitaire Carémeau, Nimes, France;* [2]*Medical Dept., CHU Nimes - Hopital Universitaire Carémeau, Nimes, France*

Background: Monitoring symptoms and toxicities through the use of electronic objects (electronic patient-reported outcomes, ePRO) has been shown to improve overall survival and quality of life in several clinical trials in oncology. We intended to investigate the use of ePRO in France in 2022.

Methods: An electronic form was sent to pharmacists in 416 cancer departments. Data were collected from October 2022 to December 2022. Pharmacists were asked about their use of ePRO, funding, potential improvements, and barriers to implementation.

Results: We obtained a participation rate of 25% (114/416 cancer departments, 2 were excluded due to misunderstanding). Only 13% (n=15) use ePRO.
ePRO users mentioned potential improvements in the technology : implementation of the ePRO platform directly into the patient record and a desire to improve communication between professionals (n=5). Difficulties they encountered were

mainly interoperability, which affects efficiency (n=5), and lack of human resources (n=3).
Of the 97 who do not use ePRO, 42% (n=41) are unaware of the existence of ePRO. 67% (n=65) of them would like to implement ePRO and hospital implementation is planned in 28% (n=27) of cancer departments. They describe possible difficulties due to lack of time to check patients' answers (74%, n=72), lack of human resources (67%, n=65), lack of financial resources (n=6, 6%), and digital literacy in elderly patients (5%, n=5).

Conclusions: A majority of cancer departments showed interest into ePROs. Two categories of improvements were identified : human resources to help with deployment, and better software to improve interoperability. The reimbursement of electronic monitoring starting in 2023 in France will encourage its incorporation in routine practice.

2166P Long-term consequences of SARS-CoV-2 infection in cancer patients

Y. Debie[1], Z. Palte[2], H. Salman[2], L. Verbruggen[3], G. Vanhoutte[3], S. Raats[3], E. Roelant[4], T. Vandamme[3], M. Peeters[3], P.A. van Dam[3]

[1]Center for Oncological Research (CORE), Integrated Personalized and Precision Oncology Network (IPPON), University of Antwerp, Wilrijk, Belgium; [2]Faculty of Medicine and Health Sciences, University of Antwerp, Wilrijk, Belgium; [3]Multidisciplinary Oncological Center Antwerp (MOCA), UZA - University Hospital Antwerp, Edegem, Belgium; [4]Clinical Trial Center (CTC), UZA - University Hospital Antwerp, Edegem, Belgium

Background: Long COVID is defined as the continuation of symptoms, unexplainable by alternative diagnosis, longer than four weeks after SARS-CoV-2 infection. Several studies report fatigue as the most common symptom, followed by dyspnoea, headache and myalgia. Although it is assumed that long COVID affects 10-20% of SARS-CoV-2 infected people, recent research suggests this number increases up to 60% in cancer patients. This study uncovers how long COVID is manifested in cancer patients and whether the COVID-19 pandemic impacts the quality of life (QoL) in this cohort.

Methods: A group of 96 cancer patients was followed from March 2022 till March 2023. Online questionnaires assessing symptoms associated with long COVID, anxiety and depression (HADS), quality of life (EORTC-QLQ-C30) and cognitive functioning (CFQ) were send every three months during this period. A semi-structured focus group was organised for qualitative data collection.

Results: Forty nine cancer patients (51.0%) were infected with SARS-CoV-2 over the course of the study, of which 39 (79.6%) reported persisting long COVID symptoms that were absent before infection. The most commonly reported symptoms were myalgia (46.2%), fatigue (38.5%) and disturbed sleep (35.9%). On top of this, 25.6% of the patients reported difficulty concentrating, headaches and dyspnoea, as described in other studies. Although the presence of myasthenia and persisting cough are not frequently linked to long COVID, they were frequently reported (25.6%) within our study population. We observed that the presence of long COVID symptoms is associated with increased BMI and the presence of comorbidities. Oncological patients reported a negative impact of the enforced COVID-19 restrictions on their emotional and psychological wellbeing. Independent of patients' infection status, female sex and metastatic cancer are associated with reduced QoL during the pandemic.

Conclusions: The COVID-19 pandemic negatively impacted the QoL of cancer patients, even when patients did not suffer from long COVID. While cancer patients experience similar long COVID symptoms as healthy controls, the prevalence is remarkably higher. Long COVID might be more prevalent in cancer patients because of their compromised immune system and weakened physiological reserve.

2167P Are bone targeted agents (BTAs) still useful in times of immunotherapy? The SAKK 80/19 BTA study

M.T. Mark[1], A. Rojas Mora[2], T. Winder[3], A. Stathis[4], A. Jakob[5], G. Müller[6], S. Hayoz[2], P. Reimann[7], U. Petrausch[8], R.A.F. von Moos[1]

[1]Oncology/Hematology Department, KSGR - Kantonsspital Graubünden, Chur, Switzerland; [2]Biostatistics, SAKK - Swiss Group for Clinical Cancer Research, Bern, Switzerland; [3]Innere Medizin II, Landeskrankenhaus Feldkirch, Feldkirch, Austria; [4]Medical Oncology Department, EOC - Ospedale Regionale Bellinzona e Valli - Istituto Oncologico della Svizzera Italiana (IOSI), Bellinzona, Switzerland; [5]Tumor Zentrum Aarau, Hirslanden Klinik Aarau Tumor Zentrum, Aarau, Switzerland; [6]CC, SAKK - Swiss Group for Clinical Cancer Research, Bern, Switzerland; [7]Onkologie, Landeskrankenhaus Feldkirch, Feldkirch, Austria; [8]Onkologie, OnkoZentrum Zürich, Zurich, Switzerland

Background: Patients (pts) with bone metastases (BM) from solid tumors often have additional treatment with BTAs to avoid symptomatic skeletal events (SSEs) such as clinically significant pathological fracture, radiation therapy to the bone, surgery to the bone, or spinal cord compression. The absolute value of BTA treatment in the era of immunotherapy (IO) is unknown.

Methods: Pts with BM treated with IO within the Alpine Tumor Immunology Registry who received an additional BTA (denosumab, zoledronic acid) were compared with pts who have not received a BTA. The primary endpoint was time to first SSE. Continuous data was summarized as median and range, categorical data using frequency counts and percentages. Kaplan-Meier estimates were used to describe and visualize the effect of categorical variables.

Results: In total, 197 pts with BM and treated with IO such as nivolumab (48%), pembrolizumab (40%), atezolizumab (12%), ipilimumab (9%) and other IO (5%) were included. The most frequent tumor types were lung cancer (50%), malignant melanoma (11%), renal cell cancer (10%) and bladder cancer (9%), respectively. One hundred and twenty-two pts (62%) received a BTA treatment (91% denosumab). The median treatment duration of a BTA was 178 days (min: 1 day, max: 2010 days). Out of the 197 pts, 47 pts (24%) experienced at least one SSE, 100 pts (51%) had bone pain, and 11 pts (6%) developed osteonecrosis of the jaw (ONJ). The percentage of pts without a SSE at fixed time points was numerically higher if treated with a BTA (e.g., at 6 month, 86% [95% CI: 79%-91%] versus 78% [95% CI: 66%-86%]), but no significant difference in time to first SSE (HR 0.79; 95% CI 0.44-1.42, log-rank p=0.43) or time to first bone pain (HR 1.1; 95% CI 0.73-1.69, log-rank p=0.6) between these two groups could be detected. The median OS for pts treated with a BTA was 1.7 years (95% CI: 1.1-2.0) and 1.7 years (95% CI: 1.4 -2.9) for pts not received a BTA.

Conclusions: No significant difference in time to first SSE or bone pain was observed between pts who have received a BTA or not when treated with IO. In contrast, 6% of these pts experienced an ONJ. Based on these retrospective results the indication of BTAs in cancer pts under treatment with IO must be challenged. Further prospective evaluation in a larger patient cohort is on the way.

2168P At-home infusion of immunotherapy for patients with solid tumors: First results from a single-centre program

J. Marco Hernández[1], E. Güell[2], C. Zamora[3], P. Ayora[2], V.M. Albarran Artahona[4], G. Carrera[1], C. Gallego[2], I. Grafiá[1], J. Padrosa[5], M. Viladot[1], A. Tuca[1], L. Corominas[2], A. Prat[3], F. Fernández Avilés[2]

[1]Medical Oncology Department, Hospital Clinic of Barcelona, Barcelona, Spain; [2]Home Care Unit, Institute of Oncohematological Diseases, Hospital Clinic of Barcelona, Barcelona, Spain; [3]Medical Oncology Department, Hospital Clinic y Provincial de Barcelona, Barcelona, Spain; [4]Medical Oncology / Thoracic Oncology, Hospital Clinic y Provincial de Barcelona, Barcelona, Spain; [5]Medical Oncology Ward, Hospital Clinic y Provincial de Barcelona, Barcelona, Spain

Background: The use of immunotherapy (IO) has revolutionized cancer treatment, providing a growing number of patients with substantial benefits across multiple indications. Typically, IO is administered through intravenous infusion lasting a few hours in the outpatient clinic with infrequent occurrence of infusion-related reactions (IRRs). This study aims to determine the feasibility and convenience of administering IO in a home-based setting.

Methods: Starting from July 2021, the Hospital Clinic de Barcelona has provided patients with solid organ cancers undergoing monotherapy nivolumab, pembrolizumab or atezolizumab, the option to receive treatment at home. Patient participation was voluntary and required written informed consent. The aims of this research were to 1) collect clinical data of this experience, 2) report complications, and 3) assess patient satisfaction using the SATISFAD-10 questionnaire. Descriptive statistics were used.

Results: The study enrolled 41 patients, 63% male with a mean age of 74 years. Of these, 56% had two or more comorbidities and 44% were fragile. All patients suffered from stage IV neoplasms, with non-small cell lung cancer (63%), small cell lung cancer (12%), and malignant melanoma (10%) being the most prevalent types. Pembrolizumab (49%), atezolizumab (27%), and nivolumab (24%) were the administered drugs, with peripheral line infusion (59%) and port-a-cath (39%) being the two common infusion routes. To date, 229 IO infusions have been administered (mean per patient: 5.6; range 1-24). At present, 22 patients still receive IO at home, while the others have been excluded due to changes in cancer treatment (47%), completed IO (10.5%), or death (26%). There have been no voluntary dropouts, and no IRR have occurred. Patients' satisfaction has been assessed every three months through the SATISFAD-10 questionnaire, with an average score of 29.7 points out of a maximum of 30, indicating high levels of satisfaction.

Conclusions: Home-based IO administration for patients with solid organ cancers appears to be a feasible and convenient option, with high patient satisfaction and a low incidence of IRR. Further research with a larger sample size may be required to confirm these findings.

2169P Immunotherapy-based treatment in elderly cancer patients: A real-world multicenter study

M. He[1], P. Shen[1], G. Xu[2], L. Xu[3], J. Chen[2], J. Ding[4], K. Chai[2]

[1]Medical Oncology, The First Affiliated Hospital of Medical School of Zhejiang University, Hangzhou, China; [2]Medical Oncology, Tongde Hospital of Zhejiang, Hangzhou, China; [3]Medical Oncology, Hangzhou Red Cross Hospital, Hangzhou, China; [4]Medical Oncology, Hangzhou Cancer Hospital, Hangzhou, Zhejiang, China

Background: The incidence of cancer increases with age, advanced age remains the most important risk factor for most cancers. According to epidemiological statistics, the probability of developing invasive cancer in each age group is highest in the 70 years and older group, reaching 1/4 to 1/3. Immunotherapy is increasingly indicated for solid tumors, but toxicity and efficacy in older adults [age ≥70 years(y)] are unknown. The purpose of this study was to determine age-based differences in OS and treatment-related side effects.

Methods: This is a multicenter retrospective cohort study of patients with advanced cancer. Patients who received ≥1 dose of IO from January 1, 2019 to October 1, 2021 at three centers in China were collected to extract important information from the medical records. The primary outcome was PFS and OS since the start of the first IO treatment, compared between patients of different ages.

Results: We included 302 patients aged 60 to 99 years, of whom 157 were 60-69 years (younger group,YG) and 145 were 70 years and older (older group,OG), including 31 patients aged 80 years and older (senior group,SG). In all age groups, the proportion of patients in the OG group treated with immune combination therapy was relatively less than in the two younger age groups. Adverse event (AE) associated with immunotherapy was not higher in the older group than in the relatively younger cohort. there were no statistical differences in PFS and OS between the YG and OG groups, with median PFS of 12 months vs. 10 months, P=0.5465; median OS NA vs. 32 months, P=0.1429. Further subgroup analysis showed that the SG group had a median PFS of 10 months and median OS of 23 months, which was also not statistically different compared with other groups.

Table: 2169P Immunotherapy-related adverse events

	N (%) of 60-69 N=157	N (%) of 70 and older cohort N=145	P
Any grade toxicity	31.8%	37.9%	0.2788
>=Grade 3 toxicity	10.8%	9.0%	0.7010
>=Grade 3 toxicity types			
Dermatitis	1.9%	4.1%	0.2555
Colitis	2.5%	2.1%	0.7823
Abnormal thyroid function	1.9%	2.8%	0.7140
Hepatitis	3.8%	1.4%	0.2856
Pneumonitis	4.5%	2.8%	0.5449
Other	1.3%	0.7%	0.6049

Conclusions: IO-based therapy is relatively safe in elderly patients and provides a survival benefit in this group, allowing for prospective clinical studies in older patients to further determine the value of immunotherapy.

Background: Chemotherapy combined with immune checkpoint blockers (ICB) is now the standard of care for treatment in multiple advanced tumor types with two spectrums of adverse events related to cytotoxic agents and immune related (irAEs). Clinical manifestations of irAEs can mimic chemotherapy toxicity in several aspects while the management remains completely different.

Methods: We conducted a retrospective review of the medical records for patients with metastatic cancers treated with chemo-immunotherapy combinations at Gustave Roussy Cancer Center from Sep 1st 2020 to Dec 31st 2022, included in the REISAMIC database (Registry of Severe Adverse Reactions to Immunomodulatory Monoclonal Antibodies in Cancer). Adverse events are reported according to the Common Terminology Criteria for Adverse Events v5.0.

Results: Our cohort includes 261 patients with a median age of 64 years [30-93], 79% of patients with lung cancer, 9% triple- negative breast cancer; 8.5% head and neck carcinoma, and 2.5% upper digestive tract tumors. Treatment discontinuation rate for toxicity was 11% in our cohort; we also reported five toxic deaths. A total of 83% of the patients presented all grade adverse events, with 38% grade ≥3 toxicities most commonly hematological. Out of all the adverse events (AEs), 53.4% were attributed to chemotherapy while 15.4% were considered irAEs. Median days until chemotherapy induced AEs was 40 days and the majority resolved in ≤2 weeks, while median days until irAEs was 105 days and the majority required 2-12 weeks until resolution. AEs of special interest included one case of myocarditis, 2 cases of hypophysitis, thyroid disorder in 25 patients, 2 cases of immune mediated diabetes revealed by diabetic ketoacidosis, and 9 cases of autoimmune hepatitis.The relapse rate after immunotherapy rechallenge was 13%.

Conclusions: In this real-life cohort of patients treated with chemo-immunotherapy we observe a reassuring safety profile concordant with data reported in clinical trials. Expert opinion, radiological exams, histological evidence and biological data were employed to distinguish the implication of either drugs in toxic mechanisms in order to tailor the management, and minimize treatment interruptions.

2172P Development and evaluation of the usefulness of an immune-related adverse events interview application

A. Yano[1], S. Ido[2], Y. Hashida[3], S. Sumikawa[1], S. Hasebe[4], T. Fujii[5], N. Hidaka[1], M. Tanaka[1], Y. Yakushijin[4]

[1]Division of Pharmacy, Ehime University Hospital, Toon, Japan; [2]Division of Nursing, Ehime University Hospital, Toon, Japan; [3]Department of Clinical Oncology, Ehime University Graduate School of Medicine, Toon, Japan; [4]Cancer Center, Ehime University Hospital, Toon, Japan; [5]Palliative Care Center, Ehime University Hospital, Toon, Japan

Background: The use of immune checkpoint inhibitors (ICIs) needs monitoring for the development of serious immune-related adverse events (irAEs). Here, we developed a smartphone application (an irAEs self-reported interview system: ISRIS) to enable early detection of irAEs while outpatients are at home and evaluated its usefulness.

Methods: This investigation included outpatients who received ICIs between September 2020 and February 2023 and had the application installed on their smartphones. The investigation items included treatment regimen and its dosage, type of irAE and the grade, frequency of ISRIS usage, and sensitivity and specificity for detecting irAEs to evaluate the efficacy of our ISRIS system.

Results: In total, sixty-one patients (female/male: 13/39, mean age: 65 y.o., range: 26-87 y.o.) installed the application on their smartphones. irAEs occurred in twenty-four patients; the irAEs detectable by the app included interstitial pneumonia (n=7), thyroid dysfunction (n=4), skin disorders (n=4), adrenocortical dysfunction (n=3), colitis (n=2), myocarditis (n=1), uveitis (n=1), liver disorders (n=1), and Guillain-Barré syndrome (n=1). Among patients with irAEs, thirteen patients had installed the application at least one week before the irAE onset; of these, irAEs were detected by ISRIS in eight patients, indicating 62% sensitivity and 57% specificity, respectively.

Conclusions: Our ISRIS application for smartphones allows healthcare professionals to monitor the physical condition of patients with cancer in real time via self-reported interview data for early intervention, even when the patient is at home, facilitating the early detection and response to irAEs. In addition, having healthcare professionals review the results of the interview can reduce patient anxiety about adverse reactions, thereby contributing to treatment continuation.

2173P Exploring the complex needs of older patients receiving targeted therapies and immune checkpoint inhibitors for renal and skin cancers at the Royal Marsden Hospital

N. Cunningham[1], M.M. Fouda[1], V. Vengadasalam[1], R. Macwana[1], K. Day[1], J. Nobbs[1], A.J.S. Furness[2], L.M. Pickering[1], S. Turajlic[1], J. Larkin[1], N.M.L. Battisti[3], K. Young[1]

[1]Medical Oncology Department, The Royal Marsden Hospital - Chelsea, London, UK; [2]Renal and Melanoma Unit, Solid Tumour Cellular Therapy Lead, The Royal Marsden Hospital - Chelsea, London, UK; [3]Department of Medicine - Breast Unit, The Royal Marsden Hospital (Sutton), Sutton, UK

Background: Fifty-four percent of new cancer cases in the UK occur in patients ≥65 years. Prior evidence supports the need for a comprehensive geriatric assessment (CGA) to inform treatment decision making in this heterogenous population. This study aimed to assess the needs of older patients with renal and skin cancers in a tertiary referral centre.

Methods: The Senior Adult Oncology Programme Questionnaire (SAOP3) has been validated as a geriatric screening tool covering functional status and physical performance, nutrition, speech and language, cognition and psychosocial issues. SAOP3 was used to assess out-patients ≥70 years receiving or referred for consideration of systemic anti-cancer therapy (SACT) for renal or skin cancers. Comorbidities, admissions and emergency contacts frequency were obtained from electronic patient records. The primary endpoint was the number of patients identified as potentially requiring geriatric assessment-driven interventions.

Results: Between 29/7/2022 − 18/11/2022, 36 patients were assessed using SAOP3 with a mean age of 74 years (range 70-94). Despite 83% (30/36) of patients being identified as potentially requiring CGA-driven interventions, 28% (10/36) of patients were deemed fit enough for combination therapy including dual immunotherapy (IO) or tyrosine kinase inhibitors (TKI) plus IO. Mobility problems were the most common driver of a recommendation for CGA-led intervention (78%; 28/36) with 31% (11/36)

of patients reporting loss of balance or a fall in the past year. At ≥6 months from screening, 36% (13/36) of patients had ≥1 admission (range per patient 0-5; total 25) and 36% (13/36) patients called the telephone support line (range per patient 0-5; total 27).

Table: 2173P Table of characteristics

Diagnosis	n	%
Renal cell	22	61
Squamous cell carcinoma (skin)	2	6
Melanoma	11	30
Other	1	3
Reason for questionnaire	n	%
New patient	10	28
Change of treatment	6	17
Mid treatment	20	55
ECOG performance status	n	%
0	4	11
1	20	56
2	11	30
3	1	3
Treatment intent	n	%
Palliative	35	97
Adjuvant	1	3
Line of treatment (metastatic)	n	%
1	23	68
2	9	26
3	2	6
Treatment	n	%
Tyrosine kinase inhibitors (TKI)	7	19
Single agent check point inhibitor (CPI)	13	36
TKI + IO	5	14
Dual CPI	5	14
Other	5	14
No SACT after assessment	1	3

Conclusions: Our study highlighted that this patient population has complex needs and supports the establishment of the Senior Adult Oncology Programme in our centre and geriatric oncology services more widely.

2174P The impact of exposure to antibiotic (ATB) and proton pump inhibitor (PPI) therapy on immune checkpoint inhibitor (ICI) treatment on overall survival (OS): A population-based study

L. Eng[1], P.L. Bedard[2], R. Sutradhar[3], V. Aghanya[3], Y. Kaliwal[3], Y. Niu[3], N. Liu[3], Y. Liu[3], M. Powis[1], G. Liu[4], J. Peppercorn[5], S. Saibil[1], M.K. Krzyzanowska[1]

[1]Medical Oncology and Hematology Department, UHN - University Health Network - Princess Margaret Cancer Center, Toronto, ON, Canada; [2]Division of Medical Oncology & Hematology, UHN - University Health Network - Princess Margaret Cancer Center, Toronto, ON, Canada; [3]Cancer Research Program, ICES - Institute for Clinical Evaluative Sciences, Toronto, ON, Canada; [4]Medical Oncology Department, UHN - University Health Network - Princess Margaret Cancer Center, Toronto, ON, Canada; [5]Cancer Care Delivery Research, Massachusetts General Hospital, Boston, MA, USA

Background: PPIs and ATBs have been individually demonstrated to negatively impact ICIs outcomes due to their effects on the gut microbiome. However, many were smaller studies with heterogeneity in study design, ATB classes and exposure windows and few studies have studied both together. Here, we performed a population-level retrospective cohort study evaluating the impact of both PPI and ATB exposure prior to ICI on OS.

Methods: We used population-level administrative data to identify a cohort of cancer patients ≥ 65 years of age receiving ICIs from 06/2012 to 10/2018 in Ontario, Canada and deterministically linked with databases to obtain demographics, co-variates and PPI and ATB prescription claims. Patients were grouped as having PPI only (PPI+/ATB-), ATB only (PPI-/ATB+), both exposures (PPI+/ATB+), or neither (PPI-/ATB-) at 1 year and 60 days prior to ICI. Multivariable cox-proportional hazard models evaluated exposure both within 1 year and 60 days prior to starting ICI on OS, adjusted for age, gender, body mass index, comorbidities, autoimmune history, hospitalization in the past year and treatment facility level at start of ICI therapy.

Results: Among 2737 patients, median age 73; 43% received Nivolumab, 41% Pembrolizumab and 13% Ipilimumab; 53% had lung cancer, 34% melanoma. 59% and 19% of patients received any ATBs 1 year and 60 days before ICI therapy, respectively and PPIs 45% and 26% respectively. Median OS estimate was 306 days. Results at 1 year and 60 days are listed below. In ATB subclass analysis, exposure to both cephalosporins and PPIs within 60 days had the greatest impact on OS compared to PPI-/ATB- (aHR=1.76, 95% CI (1.23-2.48), p=0.002).

Table: 2174P Summary of association of ATB and PPI exposure on ICI outcomes in overall cohort

	1 year before ICI			60 days before ICI		
	N	aHR (95% CI)	P Value	N	aHR (95% CI)	P Value
PPI+/ATB+	799	1.33 (1.16-1.52)	<0.0001	174	1.34 (1.10-1.62)	0.003
PPI+/ATB-	431	1.21 (1.03-1.42)	0.02	550	1.24 (1.10-1.41)	0.0005
PPI-/ATB+	828	1.11 (0.97-1.28)	0.12	358	1.04 (0.89-1.21)	0.66
PPI-/ATB-	679	Reference	-	1655	Reference	-

Conclusions: Exposure to PPIs and ATBs together prior to ICI therapy may be associated with worse OS than exposure to either alone. Interventions aimed at altering the gut microbiome may be required to help improve outcomes for patients on ICIs with prior PPI or ATB exposure.

2175P Sex and age-related differences in immunotherapy-induced toxicities

M.T. da Costa[1], C. Lopes Fernandes[1], D. Silva[1], M.S. Pinho[1], A.A. Mesquita[1], F. Estevinho[1], M.L. Salgado[2], C. Sottomayor[1], H.I. Menezes Magalhaes[3]

[1]Medical Oncology Department, ULS Matosinhos - Hospital Pedro Hispano EPE - SNS, Senhora da Hora, Portugal; [2]Oncology Dept., ULS Matosinhos - Hospital Pedro Hispano EPE - SNS, Senhora da Hora, Portugal; [3]Medical Oncology, Hospital Pedro Hispano, Porto, Portugal

Background: Immune checkpoint inhibitors (ICI) are widely used across various cancers and are associated with immune-related adverse events (irAE) potentially lethal. Therefore, it is important to identify risk factors for developing irAE. Women have a higher risk of AE from cytotoxic therapy, however few studies investigated sex differences with ICI. Elderly remain under-represented in clinical trials, including those with ICI. In this study we aim to detect sex and age differences for toxicities in patients treated with ICI.

Methods: This retrospective study included all cancer patients treated with ICI in a single Portuguese institution between January 2017 to December 2022. Data regarding patient, treatment and toxicity was collected from clinical records. Toxicities were recorded using CTCAE, version 5. A descriptive analysis was performed using SPSS®. The Chi-square test was used for 2 categorical variables: sex (male and female) and age (≥65 and <65).

Results: We included 141 patients with a median age of 66 and the majority (87%) were men. Most patients had lung cancer (76%) and were treated with pembrolizumab (53%). The most reported AE were gastrointestinal (GI) (n=115; 23,8%), cutaneous (n=96; 19,8%) and flu-like symptoms (n=56; 11,6%). Only 14,3% of AE were grade ≥3 and lead to treatment suspension in 11,3% of patients. Women reported a higher mean of AE (4,53 vs 3,19; p=0,03). For grade ≥ 3 toxicities, no differences between sexes were found (5,3% vs 15,6%, p=0,231). Among all AE, no differences were found, except for endocrine AE more likely experienced by women (OR=3,02, p=0,024). There were no differences in all grade and ≥G3 toxicities between age groups with a higher trend in the group ≥ 65 years (18,2% vs 9,3%). In parallel, the elderly discontinued treatment more often (14,3% vs 7,8%) due to toxicity. Patients ≥ 65 years had more all grade GI (OR=2,15; p=0,026) and flu-like AE (OR =2,24; p=0,023). Still, there were more respiratory AE in younger patients (OR=0,21; p=0,006).

Conclusions: Despite study limitations, results showed no sex and age differences in irAE, although women and elderly had a higher number of AE, which translated in higher treatment suspension. This data reinforces the need for further studies to promote age and sex-related interventions in management of irAE.

2176P Rechallenge of immune checkpoint inhibitors after immune-related adverse events: A systematic review

J.Y. Kim[1], C. Shin[2], S. Lee[2], S. Shin[2]

[1]Hemato-Oncology Department, Keimyung University, Daegu, Republic of Korea; [2]Obstetrics and Gynecology, Keimyung University Dongsan Hospital, Daegu, Republic of Korea

Background: Immune check point inhibitors (ICI)-based therapies have been remarkably advancing and dramatically changing the treatment modalities of cancer. This review aimed to comprehensively examine and rechallenge immune-related adverse events (irAE) across the literature.

Methods: We searched for clinical studies regarding the use of ICI published in English up to December 2021 in PubMed, Embase, Cochrane and journal of clinical oncology (JCO). The search strategy was composed of the following terms: [(rechallenge) AND (immune OR immunotherapy OR "immune checkpoint inhibitor")] AND ("side effect" OR "adverse event" OR irAE). Data were extracted by three independent investigators and the disagreements amongst investigators were resolved by consensus.

Results: The average duration of administration of ICI before the occurrence of irAE was 5.8 months (range 0.5 − 9). Discontinuation rate of ICI was 4-36.4% after the occurrence of irAE. IrAE leading to discontinuation varied depending on the type of ICI. However, the most common side effect was colitis with diarrhea regardless of the type of ICI. After ICI rechallenge, second irAE was administered to 40.3-78% of patient, and 48% of patients presented the same type of irAE as the first irAE.

Conclusions: ICI rechallenge appears to be safe given the balance between the advantages of rechallenge and the risk of irAE recurrence maintained by close monitoring.

2177P Immunotherapy adverse events association with inflammation scores: A real-world data analysis from a Portuguese hospital

C.L. Fernandes[1], M. Teixeira da Costa[1], D.J. Silva[1], A.A. Mesquita[1], F. Estevinho[1], H.I. Menezes Magalhaes[2], M. Salgado[1], M.S. Pinho[1], C. Sottomayor[1]

[1]Medical Oncology, ULS Matosinhos - Hospital Pedro Hispano EPE - SNS, Senhora da Hora, Portugal; [2]Medical Oncology, Hospital Pedro Hispano, Porto, Portugal

Background: Immune checkpoint inhibitors (ICI) have revolutionized cancer treatment but they often carry a wide spectrum of immune-related adverse events (irAE), which might preclude treatment continuation. Biomarkers predictive of irAE would be useful to better select and manage patients for ICI therapy.

Methods: This retrospective analysis included patients treated with ≥3 cycles of ICI, regardless of the primary tumour, in a single hospital in Portugal, from January 2017 to December 2022. Data regarding irAE was collected, as well as baseline neutrophil-lymphocyte (NLR), platelet-lymphocyte (PLR) ratios and systemic imune-inflammation index (SII, given by platelets*neutrophils/lymphocytes). Scores were categorized using cutoff values described in literature, as NLR≥3, PLR≥180 and SII≥750. Descriptive analysis was performed using SPSS®. Association between the scores and irAE was analyzed using logistic regression.

Results: 141 patients were included. 87% were males and the median age was 66. Most common diagnoses were non-small cell lung cancer (75%) and head and neck cancer (7%) and main ICI were pembrolizumab (53%), durvalumab (18%) and nivolumab (16%), with a 10 cycles median. 137 (97%) patients developed irAE: digestive (24%), cutaneous (20%), flu-like symptoms (12%) and others. 15% had grade ≥3 irAE, leading to ICI suspension in 11%. 55% died during follow-up, most due to disease progression, 1 due to irAE. Median inflammation scores were 3,5 (NLR), 175 (PLR) and 818 (SII). A statistically significant correlation was found between NLR≥3 and gastrointestinal (p 0,007, OR 0,375) and respiratory AE (p 0,023, OR 3,608); SII≥750 and gastrointestinal (p=0,015, OR=0,413), respiratory (p 0,020, OR 0,255) and musculoskeletal AE (p 0,015, OR 0,342); PLR≥180 and hepatic (p 0,045, OR 2,934) and musculoskeletal AE (p 0,045, OR 0,446). There was no correlation with the presence of grade ≥3 AEs nor with survival.

Conclusions: In this study baseline inflammation scores were associated with some irAEs but not with survival as described in literature. These findings support a correlation between systemic inflammation status and tolerability to immunotherapy and show the value of inflammatory scores as potential biomarkers of irAE.

Background: In cancer immunotherapy, the epidemiology of irAE in real-life is poorly understood due to limited reporting and compartmentalization of the healthcare system. This study aims to determine the incidence, severity, and consequences of irAE of all grades in patients initiating cancer immunotherapy using a prospective and multicenter cohort.

Methods: The study will include 900 patients treated with ipilimumab and/or nivolumab in a French real-life, longitudinal, observational, and e-cohort study. Data collection is conducted through digital questionnaires, with physician validation and soon-to-be-matched analysis with the National Health System.

Results: 658 patients (70.7% men, 29.3% women, mean age 66) were followed up for a median of 198 days. Of those, 75.8% were treated with Nivolumab alone, 1.2% with Ipilimumab alone, and 22.9% with a combination. Lung cancer, clear cell renal carcinoma, and melanoma were the most common histological types treated. At analysis, 115 immune related adverse events (irAE) were observed in 11.7% of patients (30.5 irAE/100 patient/years) at a median time of 155 (+/- 128) days after initiating immunotherapy. Approximately 30% of reported irAE were rheumatological, and the remaining cases included: colitis (15), hepatitis (8), pancreatitis (2), ileitis (1), myocarditis (2), nephritis (2), immuno-induced pneumopathy (3), macrophage activation syndrome (1), type 1 diabetes (2), hypophysitis (3), adrenal insufficiency (9), thyroid disorder (15), bullous pemphigoid (1), uveitis (1), and other autoimmune manifestations (23). 40 patients discontinued immunotherapy due to irAE, and treatment with corticosteroids was administered in 44 patients (57.1%). Methotrexate (n=1), infliximab (n=3), and abatacept (n=1) were also used to treat specific irAE. One patient died as a result of irAE (colitis).

Conclusions: The preliminary results of this prospective study, using an original patient-centered methodology, confirm the expected incidence of secondary autoimmune events related to immunotherapy. Further inclusions and matching with the SNDS database will allow for the completion of these initial analyses if necessary.

2180P Detrimental effect of an early exposure to antibiotics on the outcomes of immunotherapy in a multi-tumor cohort of patients

V. Albarrán, J.J. Serrano, P. Sotoca-Rubio, A.M. Barrill Corpa, V. Alia Navarro, J. Moreno, J.C. Calvo, P. Pérez de Aguado, C. García de Quevedo, C. Gonzalez Merino, P. Guerrero, J. Pozas Perez, M.V. San Roman Gil, D.I. Rosero Rodriguez, J. Chamorro-Perez, P. Alvarez Ballesteros, F. Longo Muñoz, M.E. Olmedo Garcia, P. Garrido Lopez, P. Gajate Borau

Medical Oncology Department, Ramón y Cajal University Hospital, Madrid, Spain

Background: The modulation of microbiome by antibiotics (Abs) seems to interfere with the efficacy of immune checkpoint inhibitors (ICI). Previous data suggest that this

effect is stronger when the exposure to Abs occurs around the beginning of ICI, although this has not been evaluated in large multi-tumor cohorts.

Methods: Retrospective study of patients (pts) with advanced solid tumors who were treated with ICI alone (2016-2022) at a tertiary university hospital. For each pt, the exposure to Abs was registered during several periods of time: from 60 days before to 42 days after 1st cycle (C1) (-60D-D42), from D42 to 6 months (D42-6m) and after 6 months from C1 (>6m). We evaluated its association with the objective response rate (ORR), the disease control rate (DCR), progression-free survival (PFS) and overall survival (OS).

Results: 475 pts were evaluated. The most frequent histologic subtypes were NSCLC (33.9%), urothelial (17.3%), renal (13.7%), melanoma (11.2%) and head and neck (11.0%). 84.8% of pts received anti-PD1/PDL1, 13.3% a combination of anti-PD1 plus anti-CTLA4, and 1.9% anti-CTLA4 monotherapy (42.1% in 1st line, 43.1% in 2nd line, 14.8% in further lines). Performance status (PS) prior to C1 was 0-1 in 84.6%. Median age was 67.5 years. 66.5% of pts received Abs during treatment with ICI (25.7%: 1 cycle; 16.0%: 2 cycles; 11.0%: 3 cycles; 13.8% ≥4 cycles). The most frequently used Abs were beta-lactams (53.8%), quinolones (35.9%), carbapenems (10.9%) and macrolides (10.9%). The early exposure to Abs (-60D-D42) was associated with a lower ORR (27.4% vs 39.4%; $p<0.01$), a lower DCR (37.3% vs 57.4%; $p<0.001$), lower PFS (16.8 m vs 27.8 m; HR 0.66 [95% CI 0.53-0.82; $p<0.001$]) and lower OS (2.5 m vs 6.6 m; HR 0.68 [95% CI 0.55-0.85; $p=0.001$]). The negative impact of Abs was confirmed by a multivariate analysis including PS, type of tumor, disease burden, type of ICI and line of treatment ($p=0.01$). This effect was not significant for pts receiving Abs in D42-6m and >6m.

Conclusions: Our results confirm the detrimental impact of the exposure to Abs on the outcomes of immunotherapy. This effect seems time-dependent, prevailing in pts who receive Abs around the initiation of ICI.

2181P Effect of different corticosteroid treatment strategies on checkpoint inhibitors pneumonitis outcomes

H. Guo, X. Jia, Y. Li, Y. Zhang, X. Fu, X. Yu

Department of Medical Oncology, The First Affiliated Hospital of Xi'an Jiaotong University, Xi'an, China

Background: Immune checkpoint inhibitor (ICIs) has opened a new era in the treatment of malignant tumors, but its clinical application has been severely hindered by various immune-related adverse events. Checkpoint inhibitors pneumonitis (CIP) is one of the most common fatal adverse events.The current guideline-recommended treatment strategies are difficult to achieve precise treatment and efficient coverage of CIP. The optimal timing of ICIs suspension and the initiation and dose of corticosteroids still need to be optimized.

Methods: A total of 121 CIP patients of 672 cancer patients were retrospectively analyzed. The detailed treatment process of CIP patients was recorded. Radiographic changes combined with clinical symptoms classified the outcome of CIP into worsening, stable, and improved.

Results: No association were found between continued ICIs after the diagnosis of CIP and worsened outcome in G1 CIP ($p=0.296$), but continued ICIs treatment was associated with worse outcomes in G2-4 CIP ($p=0.009$, adjusted $p=0.012$). For G2 CIP, prompt corticosteroid treatment is closely related with an improved outcome ($p=0.015$). Initiating corticosteroid in the acute phase is strongly associated with an improved outcome in G2-4 CIP ($p=0.021$, adjusted $p=0.013$). Furthermore, patients in the low-dose corticosteroid group were not only conducive to an improved outcome ($p=0.024$, adjusted $p=0.016$), but also reduced the risk of residual irreversible fibrotic lesions in G2-4 CIP ($p=0.016$, adjusted $p=0.018$).

Conclusions: For G1 CIP, ICIs may be continued conservatively and its safety is manageable. For G2-4 CIP, ICIs should be terminated and corticosteroid therapy initiated as soon as possible after diagnosis to avoid irreversible damage to lung function. Furthermore, initial low doses of corticosteroids(<1mg/kg/d) appear to be more conducive to favorable outcomes than high doses of corticosteroids.

Background: The PRAISE cohort evaluates the incidence, severity and consequences of secondary autoimmune events, OASI (Opportunistic Autoimmunity Secondary to cancer Immunotherapy) or IRAE (Immune-Related Adverse Events). This analysis presents the methodology to involve patients in improving follow-up and tolerability as well as initial Quality of Life (QoL) data.

Methods: PRAISE is a French, longitudinal, observational, prospective, multicentre (59 sites) e-cohort of patients initiating ipilimumab and/or nivolumab cancer immunotherapy using patient-reported outcomes. QoL assessment was designed collaboratively with volunteers from the e-cohort. A literature review and two video conferences with 27 patients guided the choice of QoL questionnaires based on completion time, dimensions, items, and wording.

Results: As of 22/01/2022, monthly patient follow-up forms included a mandatory general QoL questionnaire (EQ-5D-5L) and an optional specific questionnaire (EORTC QLQ-C30). Between 09/12/2019 and 21/04/2023, 861 patients (268 women [31.1%]) were included (age = 66.1 ± 10.9 yrs). Most had lung (SCLC, n=256), kidney (ccRCC, n=204) or melanoma (n=202) cancers and 674 (78.3%) were treated at a metastatic stage. QoL data was available for 409 patients, with 1-month data available for 218 (83.5%) of the 261 patients included after 22/01/22. Of these, 188 (72.0%) completed the EORTC QLQ-C30. The EQ-5D-5L VAS score (67.7 ± 19.9), EQ-5D index (0.66 ± 0.31), and EORTC QLQ-C30 global health score (64.5 ± 21.6) and function scores were significantly worse than in the general population except for emotional functioning (p<0.01).

Table: 2182P 1-month QoL sub-scores

EQ-5D-5L (N=218)	Mobility	Self-care	Usual activities	Pain / discomfort	Anxiety / depression
Problems, N (%)	105 (48.2)*	38 (17.5)*	113 (51.8)*	146 (67,0)*	116 (53,2)*
No problem, N (%)	113 (51.8)	180 (82.5)	105 (48.2)	72 (33,0)	102 (46,8)
EORTC QLQ-C30 (N=188)	**Physical functioning**	**Role functioning**	**Emotional functioning**	**Cognitive functioning**	**Social functioning**
Score, mean (SD)	72.9 (25.5)*	67.5 (32.4)*	77.6 (22.2)	82.1 (24.5)*	74.4 (21.6)*

* Significant difference with general population: EQ-5D-5L: Chi-Squared, p<0.01, comparison values from Gautier et al. 2023. EORTC-QLQ-C30: Double-sided t-test, p<0.01, comparison values from Scott et al. 2008

Conclusions: Patient implication contributed to high response rates to selected QoL questionnaires which show that patients' QoL and functioning are significantly impaired. Integrating these data in the prospective follow-up of this study will provide a more detailed analysis of cancer immunotherapy and potential OASI on patients.

2183P The relevance of HFpEF in immunotherapy-induced myocarditis: An analysis of 65 patients

A. Chapman, A. Johnson, F. Hegazy, N. Garbutt, R. Dobson, A.C. Olsson-Brown

Medical Oncology, The Clatterbridge Cancer Centre - Liverpool, Liverpool, UK

Background: High quality evidence on the incidence of Immune checkpoint inhibitor (ICI) induced-myocarditis and its relationship with LV systolic function is lacking. Anecdotally, a relationship between ICI myocarditis with clinical heart failure in the context of a preserved ejection fraction (HFpEF) was noted and has been investigated here.

Methods: A retrospective analysis of 65 patients with ICI myocarditis was conducted over a 55 month period at the Clatterbridge Cancer Centre, Liverpool UK. A diagnosis of myocarditis was confirmed by cMRI or the cardio-oncology team. Diuresis at any point following myocarditis diagnosis, cMRI findings and peak pro-BNP (BNP) was recorded. Statistical analysis was undertaken with an unpaired t test.

Results: The incidence of ICI myocarditis across all ICI treated patients was 1.74% (n=65/3728); cMRI confirmed (n=53), clinical diagnosis in the absence of cMRI confirmation (n=5) or cMRI clinically unfeasible (n=7).The mean and median EF for all imaged patients (n=58) was 63.07% vs 64%. 82.76% (n=48/58) had a normal / above normal EF. LV impairment was found in 17.24% of patients (n=10/58); 8 mild LVSD, 1 moderate LVSD and 1 severe LVSD. Of all imaged patients 50% (n=29/58) required diuresis. The difference between the mean EF for patients requiring diuresis (EF 61.07%) vs non-diuresed patients (65.14%) was insignificant (p=0.21). 36.21% (n=21/58) of the imaged cohort had HFpEF. The mean peak BNP of diuresed patients was significantly higher ($p<0.01$) than the non-diuresed cohort (11287 vs 6083). The median peak BNP was also higher in the diuresed cohort (7552 vs 2577).

Conclusions: In this cohort ICI myocarditis was characterised generally by a preserved ejection fraction, however 50% of patients illustrated fluid overload and a third displayed HFpEF therefore the absence of LVSD does not exclude ICI myocarditis. Patients presenting with fluid overload and/or elevated pro-BNPs is a common clinical presentation of ICI myocarditis even in the presence of a maintained EF. Patients should be optimised with diuretics alongside immunosuppression in this setting and cMRI should be performed to confirm the diagnosis as ECHO alone is insufficient to do so.

2184TiP Extensive cardiovascular characterization and follow-up of patients receiving immune checkpoint inhibitors: A prospective multicenter study

D.L. Delombaerde[1], J. De Sutter[2], L. Croes[1], D. Vervloet[2], V. Moerman[2], N. Van de Veire[2], A-M. Willems[2], K. Wouters[3], M. Peeters[4], H. Prenen[4], C. Vulsteke[1]

[1]Integrated Cancer Center Ghent, AZ Maria Middelares AZMMSJ, Ghent, Belgium; [2]Cardiology, AZ Maria Middelares AZMMSJ, Ghent, Belgium; [3]Clinical Trial Center (CTC), Antwerp University Hospital, Edegem, Belgium; [4]Multidisciplinary Oncologic Center Antwerp, Antwerp University Hospital, Edegem, Belgium

Background: The increasing use of immune checkpoint inhibitors (ICIs) in the treatment of both advanced and early stages of various malignancies has resulted in a substantial increase in the incidence of cardiovascular (CV) immune-related adverse events (irAEs). The current follow-up guidelines are based on anecdotal evidence and expert opinions, due to a lack of solid data and prospective studies. As many questions remain unanswered, cardiac monitoring, in patients receiving ICIs, is not always implemented by oncologists. Hence, an urgent need to investigate the possible short- and long-term CV effects of ICIs, as ICI approval is continuing to expand to the (neo) adjuvant setting.

Trial design: We have initiated a prospective, multicenter study, i.e., the CAVACI trial, in which a minimum of 276 patients with a solid tumor, eligible for ICI treatment, will be enrolled. The study consists of routine investigations of blood parameters (troponin and N-terminal pro-B-type natriuretic peptide (NT-proBNP) levels, in particular) and a thorough CV follow-up (electrocardiograms, transthoracic echocardiograms, and coronary calcium scoring) at fixed time points for a total period of two years. The primary endpoint is the cumulative incidence of troponin elevation in the first three months of ICI treatment, compared to baseline levels. Furthermore, secondary endpoints include incidence above the upper limit of normal of both troponin and NT-proBNP levels, evolution in troponin and NT-proBNP levels, the incidence of CV abnormalities/major adverse cardiac events, evaluation of associations between patient characteristics/biochemical parameters and CV events, transthoracic echocardiography parameters, electrocardiography parameters, and progression of coronary atherosclerosis. Recruitment of patients started in January 2022. Enrolment is ongoing in AZ Maria Middelares, Antwerp University Hospital, AZ Sint-Vincentius Deinze, and AZ Sint-Elisabeth Zottegem.

2185TiP Belgian FORX trial: FOod interventions to Reduce immunotherapy toXicity

M. Verhaert[1], T. Demuyser[2], N. Adriaenssens[3], N. Vanlaer[4], A. Rogiers[5], B. Neyns[6], S. Aspeslagh[7]

[1]Department of Medical Oncology, Universitair Ziekenhuis Brussel, Jette, Belgium; [2]Department of Microbiology, UZ Brussel - Universitair Ziekenhuis Brussel, Jette, Belgium; [3]Department of Physiotherapy and Rehabilitation, UZ Brussel - Universitair Ziekenhuis Brussel, Jette, Belgium; [4]Department of Medical Oncology, Vrije Universiteit Brussel - Faculty of Medicine & Pharmacy, Brussels, Belgium; [5]Department of Psychiatry and Oncological Rehabilitation, UZ Brussel - Universitair Ziekenhuis Brussel, Jette, Belgium; [6]Medical Oncology Department, Vrije Universiteit Brussel - Faculty of Medicine & Pharmacy, Brussels, Belgium; [7]Oncology Department, UZ Brussel - Universitair Ziekenhuis Brussel, Jette, Belgium

Background: Immune checkpoint inhibitor (ICI) therapy has revolutionized cancer treatment but can cause immune related adverse events (irAEs) which we currently do not know how to prevent. These irAEs influence patients' quality of life and oncological treatment course. The gut plays an essential role in immune homeostasis and gut dysbiosis is implicated in (auto)inflammatory conditions. The American Gut project, an international microbiome study, showed that healthy volunteers who ingested at least 30 different plants (vegetables, fruits, nuts) weekly had a more diverse microbiome than those who consumed 10 or less. A fibre-rich diet has been associated with improved outcome of ICI treatment and with reductions of perceived stress.

Trial design: The FORX trial investigates whether altering the composition of the gut microbiome can improve ICI tolerance. In our tertiary reference centre, we are supplementing the diets of solid tumour patients starting ICI with weekly boxes containing 30 different plants during the first 12 weeks of their treatment. The increased fibre intake is expected to strengthen the gut microbiome and reduce the incidence of irAEs. Stool and blood samples will clarify the microbial and cytokine signatures associated with irAEs. Baseline physical activity and body composition will be assessed given recent retrospective data showing synergistic effects of exercise, body composition and ICI therapy. Quality of life questionnaires will be completed at baseline, week 6 and week 12 throughout the intervention. The FORX trial is the first prospective trial to translate the cited retrospective findings into a concrete dietary advice. Our trial will provide valuable insights in the interaction between the gut microbiome, physical fitness and autoimmunity and serve as a basis for nutritional and probiotic advice. It will empower cancer patients and improve their quality of life.

Clinical trial identification: NCT05832606.

Background: Thymic carcinoma (TC) is a rare but highly aggressive cancer, with no standard treatment for patients who progress after platinum-containing chemotherapy.KN046 is a novel bispecific antibody that inhibits both PD-L1/PD1 and CTLA-4/CD80/CD86 pathways. We conducted this phase 2 study aiming to evaluate the efficacy and safety of KN046 in the TC patients who progressed after front-line chemotherapy.

Methods: Patients documented with histologically TC who progressed after platinum-containing chemotherapy were eligible. KN046 was injected intravenously at 5mg/kg Q2W until tumor progression or unacceptable toxicity. The primary endpoint was ORR by IRC, and secondary endpoints were DoR, PFS, OS, and safety. Response was assessed every 8 weeks. PD-L1 expression was measured using 22C3 PharmDx assay.

Results: From Dec 2020 to Dec 2022, 46 patients were enrolled into the study with a median age of 58 (range:38-69) years. There was no difference in gender distribution (male: female=25:21). 22 patients received more than one line of systemic chemotherapy. Most patients (91.3%) had stage IVB disease, ECOG PS was 0 in 10 (21.7%) and 1 in 36 (78.3%) patients, respectively. 17 patients had positve PD-L1, 25 patients had negative PD-L1 and 4 patients were unknown. The median follow-up time was 16.1 months (ranges:11.1-18.6 months). Of 38 evaluable patients, 7 achieved partial response and 17 remained stable disease, while the other 14 experienced progressive disease. The ORR was 16.3% (95%CI: 6.8%, 30.7%), the mDoR was 10.1 months (95% CI: 7.7, NE). The mPFS was 5.6 months (95%CI: 1.9, 12.8). The mOS was immature, the 18-months OS rate was 74.1% (95%CI: 54.29, 86.32). Among the PD-L1-positive patients, the ORR and PFS were numerically higher than that in PD-L1 negative or status unknown, which was 18.8% vs. 14.8% in ORR and 7.6 months vs 5.6 months in PFS. The most common TRAE of any grade include rash (39.1%), ALT increased (32.6%), AST increased (28.3%). 8 patients experienced $\geq$ grade 3 irAE, 7 (15.2%) patients discontinued study treatment due to TRAE, but there was no death event related with KN046.

Conclusions: KN046 demonstrated promising antitumor activity and acceptable toxicity in thymic carcinoma patients who have received at least one line of chemotherapy.

Clinical trial identification: NCT04469725.

2187P Efficacy and safety of gemcitabine as maintenance treatment in unresectable malignant pleural mesothelioma: A phase II randomized study

M.S. Emam Sobeih, R.M. Gaafar, M.Y. Ismail, O.M.R. Khorshid

Medical Oncology Department, National Cancer Institute - Cairo University, Cairo, Egypt

Background: Unresectable malignant pleural mesothelioma has limited therapeutic options, with controversial data being present on the role of gemcitabine maintenance. the only previuos trial that assessed the gemcitabine as a maintainance is NVALT19 Trial Our randomized, phase 2, open-label study aimed to evaluate the activity of gemcitabine versus best supportive care as maintenance after first-line chemotherapy in this setting.

Methods: Patients with a histologically confirmed disease, having a complete or partial response or disease stabilization after 4-6 cycles of first-line platinum-based chemotherapy were randomized into 2 groups: (1) gemcitabine 1000 mg/m2 IV in Days 1, 8 of a 21-day-long cycle or (2) best supportive care. The treatment was continued until disease progression or unacceptable toxicity. Objective response rate (ORR) was assessed using the mRECIST criteria, and the adverse events were registered according to the CTC-AE v. 4.0.

Results: A total of 64 patients were included (32 in each group), with no differences between group 1 and 2 in the baseline characteristics except body weight (69.3$\pm$15.3 vs 77.4$\pm$15.8, $p = 0.040$) and ECOG PS at randomization (PS I in 25 (78.1%) vs 17 (53.1%), $p = 0.035$, respectively). Most cases in the two groups were of the epithelioid type (87.5% and 84.4%, $p = 1.000$). Platinum-pemetrexed doublet was administered in 46.9% and 53.2%, and platinum-gemcitabine doublet in 50% and 43.8% in groups 1 and 2, respectively, with no significant differences in proportions and in the response (p=0.209) between the groups. Maintenance therapy was associated with better ORR (regression+stabilization in 84.4% vs 25.8% of cases, $p < 0.001$). Dyspnea, fatigue, and chest pain were more common in group 2, while anemia, leucopenia, and nausea were more common in group 1 (all $p < 0.001$). No grade 3-4 toxicity was observed.

Conclusions: Gemcitabine maintenance has therapeutic efficacy and manageable toxicity in patients with malignant pleural mesothelioma who have responded to first-line chemotherapy.

2188P First-line combination of toripalimab and chemotherapy in advanced thymic carcinoma: A prospective, single-arm, phase II trial

H. Shi, H. Zhu, Y. Feng, Y. Liu, P. Xing, X. Hu

Medical Oncology, Chinese Academy of Medical Sciences and Peking Union Medical College - National Cancer Center, Cancer Hospital, Beijing, China

Background: Thymic carcinomas (TCs) are the most aggressive subtype of thymic epithelial tumors. Chemotherapy is the standard treatment for advanced TCs, although achieved a response less than 50%. Immunotherapy has been crucial in the treatment of several malignancies. Here we conducted a phase II, prospective trial to explore the safety and feasibility of toripalimab (a PD-1 inhibitor) plus chemotherapy as first-line treatment in advanced TCs.

Methods: We enrolled patients with ECOG 0 or 1, histologically diagnosis of Masaoka stage III or IV TCs. Patients received toripalimab (240mg, d1, q3w) plus paclitaxel (175mg/m^2, d1, q3w) and carboplatin (AUC=5, d1, q3w) for 4-6 cycles and continued to receive toripalimab (240mg, d1, q4w) maintenance therapy until disease progression, intolerable toxicity, or withdrawal of consent. The primary endpoint was progression-free survival (PFS). Secondary endpoints were objective response rate (ORR), Disease control rate (DCR), duration of response (DoR), overall survival (OS), time to response (TTR) and safety. This study is registered on chinadrugtrials.org.cn, ChiCTR2000039155.

Results: From December 2020 to April 2023, a total of 14 patients (median age: 49, range: 37-68; male: 57.1%) were enrolled. 57.1% of patients were still on treatment (toripalimab maintenance) at the time of analysis. For 12 patients received radiological assessment, 5 partial responses, 7 stable diseases were observed. The ORR was 41.7% and DCR was 100.0%. The median follow-up duration was 7.0 months (range: 0.1-30). Treatment-related adverse events (TRAEs) of any-grade occurred in 13 patients. Grade 3-4 TRAEs occurred in 5 patients (35.7%). The most common grade 3-4 TRAE was myelosuppression (28.6%). Besides, we analyzed the PD-L1 expression, immune microenvironments and genetic mutations in 8 patients' tissues and serum samples using NGS and mIHC. We found that patients with lower TMB had more CD8+T cells and CD56dim NK subtype. Patients with PD-L1 TPS$\geq$1% had a higher proportion of M1 type macrophages, suggesting a greater potential for activating antitumor immunity.

Conclusions: Toripalimab combined with chemotherapy is effective and well tolerated as first-line treatment for patients with advanced TCs.

2189P Combining SBRT with GM-CSF and Peg-IFNα to induce abscopal effects in previously treated patients with stage IV thymic tumors

B. Wang, J. Wen, H. Li, J. Chen, M. Fan

Department of Radiation Oncology, Fudan University Shanghai Cancer Center, Shanghai, China

Background: After the failure of multi-line treatment, patients with stage IV thymic tumors have a poor prognosis and few therapeutic options. Combining stereotactic body radiotherapy (SBRT) with granulocyte-macrophage colony-stimulating factor (GM-CSF) and Pegylated interferon-α (Peg-IFNα) may induce abscopal effects and improve prognosis.

Methods: We conducted this open-label, single-arm, phase II trial to evaluate SBRT plus GM-CSF and Peg-IFNα in previously treated patients with stage IV thymic tumors. A 21-day treatment cycle consisted of SBRT delivered to one metastatic lesion with 30 Gy in 5 fractions from day 1, synchronous subcutaneous injection of GM-CSF 125 μg/m^2 once daily for 14 days, and subcutaneous injection of Peg-IFNα 90 μg on day 8. If the patient has more than two metastatic lesions, another treatment cycle was repeated. After the completion of 1 or 2 treatment cycles, Peg-IFNα therapy was maintained for at least half a year with a subcutaneous injection of 90 μg once a month. The two primary endpoints were the proportion of patients with abscopal effects and the objective response rate (ORR). The secondary endpoints included overall survival (OS), progression-free survival (PFS), and therapeutic safety.

Results: A total of 20 patients from March 2021 to September 2022, were enrolled in this trial, with 1 (5.0%) type A thymoma, 2 (10.0%) type B1 thymoma, 2 (10.0%) type B2 thymoma, 1 (5.0%) type B3 thymoma, 12 (60.0%) thymic squamous cell carcinoma and 2 (10.0%) thymic neuroendocrine tumor. At a median follow-up of 18.6 months, 8 (40.0%) out of 20 patients had abscopal effects, and the ORR was 45.0%.The median OS had not been attained yet. The median PFS was 9.0 months. We observed that patients with abscopal effects tended to have longer OS and PFS than those without abscopal effects. 3 patients (15.0%) experienced Grade 3 treatment-related adverse events (CTCAE version 5.0), among which cardiac insufficiency compelled 1 patient to drop out of treatment.

Conclusions: Combining SBRT with GM-CSF and Peg-IFNα was well tolerated with acceptable toxicity and may represent a promising salvage therapy for previously treated patients with stage IV thymic tumors. The occurrence of abscopal effects is likely to improve patient outcomes.

Clinical trial identification: NCT04517539.

2190P First-line atezolizumab in combination with platinum etoposide in patients with metastatic lung large cell neuroendocrine carcinoma (LCNEC)

G.E. Evangelou[1], I. Vamvakaris[2], V. Kolintzikis[1], V. Nikolaidou[1], O. Fiste[1], V. Koliaraki[3], E.A. Kotteas[1], K. Syrigos[1]

[1]3rd University Deptm of Medicine, National & Kapodistrian University of Athens, Athens, Greece; [2]Department of Pathology, Sotiria Thoracic Diseases Hospital of Athens, Athens, Greece; [3]Division of Immunology, BSRC Alexander Fleming, Vari-Voula-Vouliagmeni, Greece

Background: Large cell neuroendocrine carcinoma (LCNEC) is a rare and aggressive cancer that has a poor prognosis. Most patients are diagnosed in the advanced or metastatic stage and there are no standard therapies for this disease. Although immunotherapy has become an increasingly important component of treatment for many types of cancer, there is limited evidence that immunotherapy is effective in treating LCNEC as well.

Methods: This is a prospective non-randomised study evaluating the effectiveness of first-line atezolizumab in combination with platinum etoposide (APE) versus platinum etoposide alone (PE) in patients with metastatic LCNEC. 22 patients were enrolled between September 2018 and May 2022 and were treated at the 3rd Department of Medicine, Sotiria Chest Disease Hospital in Athens Greece. All patients had histological confirmation of lung LCNEC. 5/22 patients were excluded due to previous systemic treatment (limited stage at initial diagnosis). Because of the small sample size and the lack of randomization, cox regression analysis was used to compare clinical outcomes.

Results: 10/17 (58.8%) patients received a combination of APE and 7/17 (41.2%) patients received PE alone. Multivariate Cox regression analysis for PFS and OS showed that the median PFS in the combination arm was 6.6 versus 6.3 months in the PE arm (p=0.83, 95% CI 0.97 - 1.15) and the median OS was 11.8 in the APE arm versus 7.9 months in the PE arm (p = 0.20, 95% CI 0.06 - 0.79). At the time of the follow-up cut-off point, five patients in the APE arm had an ongoing response to Atezolizumab treatment with a median duration of response of 15.8 months (defined as the time from response to progression/death or follow up cut-off). There was no correlation between TP53, RB1 IHC expression and OS or PFS in either group.

Conclusions: A combination of atezolizumab and platinum etoposide (APE) showed improved OS and a non-significantly better PFS compared to PE alone in patients with metastatic lung LCNEC.

Background: Based on the positive results of the CheckMate-743 trial, first-line (1L) treatment of MPM with ipilimumab in combination with nivolumab (ipi/nivo) has become a standard 1L treatment in patients (pts) with non-epithelioid MPM and epithelioid MPM. Pts who received 1L platinum-pemetrexed are often considered for further-line treatment with ipi/nivo based on the MAPS2 trial results. Here we report on real-world survival outcomes and toxicity with ipi/nivo for treatment of MPM in Switzerland.

Methods: This was a retrospective multicenter analysis in 12 Swiss centers including all pts treated with ipi/nivo for MPM; data cut-off was on May 1, 2023. Pts' characteristics including age, sex, histology, PD-L1, ECOG and previous/subsequent treatments were collected. Efficacy and safety outcomes were assessed by local investigators.

Results: Of 109 patients with MPM (75% epithelioid, 9% biphasic, 16% sarcomatoid) treated with ipi/nivo (start of treatment November 2017-March 2023) median age was 72 years, 91% were males, and 83% had ECOG 0-1 at start of ipi/nivo. Ipi/nivo was given as 1L treatment in 43%, as 2L or further line in 57% of pts. 2 year-completion rate of ipi/nivo was 0%; treatment is ongoing in 16 pts (15%). Median follow-up from start of ipi/nivo was 16.6 months (mo). Efficacy outcomes for ipi/nivo are shown in the table. Highest-grade adverse events (AE) were as follows: 14% G1, 22% G2, 21% G3, 2% G4 and 3% G5 (1 colitis, 2 pneumonitis). Treatment discontinuation rate due to toxicity was 19%.

Table: 2191P Outcomes

	total (n=109)	1L (n=47)	Further line (n=62)
ORR (95% CI)	17 % (11-26%)	21% (11-36%)	15% (7-26%)
DCR (95% CI)	46% (36-56%)	62% (46-76%)	34% (22-47%)
mPFS (95% CI), mo	3.4 (2.9-5.0)	6.5 (3.5-10.6)	2.8 (2.3-3.4)
mOS (95% CI), mo	10.6 (6.1-12.2)	12.6 (6.5-16.5)	6.9 (4.5-11.6)
OS at 6 mo (95% CI)	62% (52-71%)	70% (53-81%)	57% (44-68%)
OS at 12 mo (95% CI)	42% (32-52%)	55% (38-69%)	34% (22-46%)

Conclusions: In this real-world cohort of MPM pts treated with ipi/nivo efficacy outcomes were inferior to those reported in the CM743 and MAPS2 trials, while safety outcomes were similar. Subgroup analyses by histology, PD-L1 expression, age and ECOG will be presented at the meeting.

2192P Quality of life (QoL) of patients (pts) with advanced malignant pleural mesothelioma (aMPM) treated in a real-world setting

A. Mittal[1], L. Everest[1], D. Patel[1], L.J. Zhan[1], C. Brown[1], F. Zaeimi[1], S. Schmid[2], K. Khan[1], K. Dietrich[1], K. Balaratnam[1], M. García Pardo de Santayana[3], L. Eng[1], A. Sacher[1], F.A. Shepherd[1], N. Leighl[1], J. Cho[4], M. de Perrot[5], G. Liu[1], P. Bradbury[1]

[1]Division of Medical Oncology and Hematology, Princess Margaret Cancer Centre, Toronto, ON, Canada; [2]Oncology and Haematology Department, Inselspital - Universitatsklinik fur Medizinische Onkologie, Bern, Switzerland; [3]Medical Oncology Department, Hospital Universitario Ramon y Cajal, Madrid, Spain; [4]Radiation Oncology, UHN - University Health Network - Princess Margaret Cancer Center, Toronto, ON, Canada; [5]Division of Thoracic Surgery, Department of Surgery, University Health Network, Toronto, ON, Canada

Background: Real world QoL data and association with overall survival (OS) for pts with advanced mesothelioma is scarce. Moreover, the associations between health utility scores (HUS) generated from EQ-5D and symptoms as measured by ESAS and pro-CTCAE remain unknown in aMPM pts.

Methods: Through retrospective chart review, clinico-demographic variables and treatment information were captured in pts diagnosed with aMPM between Jan 1, 2004, to Feb 1, 2021 at Princess Margaret Cancer Centre. QoL outcomes were measured using HUS by EQ-5D, ESAS, and pro-CTCAE scales. Changes in QoL were examined by disease state. Survival was examined by baseline QoL using the KM method. Correlation between QoL scales was examined using Spearman's r.

Results: Of 172 pts with baseline QoL data, median age was 69.6 yrs; 73% were males; 52% were ever smokers; 57% had epithelioid aMPM; 82% received systemic therapy for advanced disease. Based on a mixed effects regression model, ESAS pooled physical and pooled psychological were worst at baseline, improved at stable /responding disease (physical, p=0.001; psychological, p=0.001) and worsened at progressive disease (physical, p=0.003; psychological, p=0.02). Similar trends were seen in HUS (stable to progressive disease p=0.03), and pro-CTCAE symptom severity (baseline to stable disease p=0.03) and frequency (baseline to stable disease p=0.008). Pts with high baseline ESAS physical burden had inferior OS: median 12.1 (high) vs 8.2 months (low) p=0.023, with no impact of psychological burden on OS. Weak to moderate correlations were observed between ESAS domains and HU as well as pro-CTCAE domains and HU. Strongest domain correlations were well-being (ESAS r=-0.39), tiredness/ fatigue (ESAS r=-0.39, severity r=-0.38, interference r=-0.44), and shortness of breath (severity r=-0.35, interference r=-0.44), each p<0.05.

Conclusions: Both HUS and ESAS captured disease state well. Individual ESAS and pro-CTCAE domains showed moderate correlations with HUS, thus validating such scores for future integration into routine clinical care. Physical symptom burden as captured by ESAS impacted OS and could be used as a prognostic tool, if validated in prospective studies.

2193P Real-world evidence of the impact of immunotherapy (IT) on overall survival (OS) of patients (p) with malignant pleural mesothelioma (MPM) adjusted for tumor histology

S.M. Cedres Perez[1], A.A. Valdivia[1], J.D. Assaf Pastrana[1], P. Iranzo Gomez[1], A. Callejo Perez[1], N. Pardo Aranda[1], A.F. Navarro Mendivil[1], A. Martinez-Marti[1], I. Priano[1], J.M. Ucha Hermida[1], E. Garcia-Galea[2], J. Gonzalo[2], R. Caro[2], C. Carbonell[2], R. Amat[2], R. Dienstmann[3], E. Felip[1]

[1]Medical Oncology Dept., Vall d'Hebron Hospital Universitari and Vall d'Hebron Institute of Oncology (VHIO), Barcelona, Spain; [2]Medical Oncology Dept., Vall d'Hebron Institute of Oncology (VHIO), Barcelona, Spain; [3]Oncology Data Science (ODysSey) Group, Vall d'Hebron Institue of Oncology, Barcelona, Spain

Background: In 1st-line setting in MPM CheckMate-743 trial demonstrated better outcomes for IT over chemotherapy in p with no-epithelioid histology. However, another trials (MAPS2, DREAM) demonstrated efficacy of IT in all tumors. The objective of this study is to characterize the impact of IT according to histology in p with MPM.

Methods: Clinical records of MPM p treated with IT (anti-PD1/L1) at Vall dHebron University Hospital were reviewed. Associations between clinical variables and outcome were assessed with multivariate time-dependent Cox regression models to adjust for inmortal-time bias and histology. Survival data were calculated by the Kaplan-Meier method.

Results: 228 p were reviewed: median age 68 years (29-88), males: 70%, performance status (PS)1: 69%, epithelioid: 82%. Median overall survival (OS) of the entire cohort was 21.4 months (m) (CI95% 18-23.8). Epithelioid histology, PS 0, stage 1-2 and treatment with cisplatin were associated with significant improvements in OS (p<0.001). Thirty-six p (16%) were treated with antiPD1/L1 (13 p in 1st line, 23 p in 2nd or further lines). In the multivariable time-dependent model, both histology (HR=0.51) and exposure to IT (HR=0.66) had significant impact on OS (P-values <0.1). Patients with epithelioid tumors treated with anti-PD1/L1 at any line had a median OS of 33.1 m (vs 23.8 m for p without IT), while p with non-epithelioid tumors exposed to anti-PD1/L1 had median OS of 19.5 m (vs 14.1 m without IT). In p exposed to IT in 2nd or further lines, median OS for p with epithelioid tumors treated with IT was 24.2 m (vs 13.7 m in p without IT), and for non-epithelioid cases median OS was 6.6 m and 10.0 m for p treated with or without IT respectively.

Conclusions: In our series of real-word MPM treated with IT we did demonstrate a benefit of IT for MPM p. Considering the prognostic effect of histology and the potential immortal time bias for IT exposure, we demonstrated improved OS for p receiving IT with a trend of higher benefit in epithelioid tumors. Ongoing studies combining checkpoint inhibitors plus chemotherapy are evaluating the impact of histology in the outcomes.

2194P Prospective observational study of physical activity measurement using wearable device as an alternative to ECOG PS in patients with advanced lung cancer

K. Ito[1], Y. Suzuki[2], T. Sakaguchi[2], K. Fujiwara[2], Y. Nishii[2], H. Yasui[2], O. Taguchi[2], O. Hataji[2]

[1]Respiratory Center Dept., Matsusaka City Hospital, Matsusaka, Japan; [2]Respiratory Center Dept., Matsusaka Municipal Hospital, Matsusaka, Japan

Background: General health status is commonly evaluated using the ECOG PS scale in patients with solid tumors, including lung cancer patients, which often influences treatment decisions in practice. ECOG PS is classified into categories based on the reference associated with activities, estimation by questionnaire, or the subjective opinion of physicians. The aim of this study is to investigate the feasibility of measuring physical activities, and the association of ECOG PS or prognosis with the measurements of physical activities.

Methods: Patients treated with systemic therapy for lung cancer as outpatients in a single institution were enrolled in this study, Physical activities were estimated using

amue link (SONY, Tokyo) as the werable device for up to 14 days. The measurements for analysis were the sum and mean of three estimated values from wearable device, (1)METS, (2)walking distance, and (3)walking steps. A comparative analysis of measured physical activities over the value of ECOG PS was primary endpoint, with the AUC for the classification of ECOG PS estimated by ROC analysis. An exploratory analysis of the predictive value for survival was performed, and survival curves were compared using the log-rank test (UMIN000047834).

Results: A total of 119 patients out of 121 enrolled patients were analyzed. Among the measurements, mean distance walked (MDW) was identified as candidate for predicting ECOG PS or prognosis with reference to the results by ANOVA and Kruskal-Wallis test. The AUC for classification into ECOG PS < 2 or ≥ 2 based on MDW was 0.818 [95%CI, 0.703 to 0.934] in the ROC analysis, and there was a significant difference in MDW between patients with PS 0 and PS 1 ($p<0.001$). Exploratory analysis showed that the AUC for classification into survival status at 6 months based on MDW was 0.830 [95%CI, 0.711 to 0.949] in the ROC analysis, and survival curves based on the threshold of MDW according to the ROC analysis were significantly different. ($p<0.001$).

Conclusions: Among the measurements, MDW was more correlated with ECOG PS, and the value of MDW has the potential to be a better predictor of general health status compared with ECOG PS categories.

Clinical trial identification: UMIN000047834.

2195P Targeted gene editing with CRISPR for the treatment of pleural mesothelioma

R.D.A. Cerqueda

Facultad de Medicina, UNAM - Universidad Nacional Autonoma de Mexico, Mexico City, Mexico

Background: Pleural mesothelioma is a rare and aggressive cancer that is difficult to treat using traditional methods. Recent advances in gene editing technology, specifically the CRISPR-Cas9 system, have provided new opportunities to target and disrupt cancer-driving genes. In this clinical trial, we aimed to investigate the safety and efficacy of targeted gene editing using CRISPR in patients with pleural mesothelioma.

Methods: We recruited 20 patients with pleural mesothelioma who had not responded to standard therapies. We used the CRISPR-Cas9 system to target four genes commonly associated with mesothelioma: BAP1, NF2, CDKN2A, and TP53. The editing was performed ex vivo on the patients' tumor cells and then reinfused into the patient's body. We monitored the patients for adverse events and evaluated the efficacy of the treatment using radiographic imaging and survival rates.

Results: Of the 20 patients, 18 received the full course of the treatment. We observed no major adverse events related to the gene editing. Radiographic imaging revealed a reduction in tumor size in 14 patients, with three patients showing complete response. Median progression-free survival was 10 months, and median overall survival was 18 months.

Conclusions: Our study provides evidence that targeted gene editing using CRISPR is a safe and potentially effective treatment option for patients with pleural mesothelioma. Further studies with larger patient cohorts are warranted to confirm these findings and assess long-term outcomes. The CRISPR-Cas9 system may represent a promising therapeutic strategy for other types of cancer as well.

2196P PET-CT detects response to treatment with ipilimumab and nivolumab in malignant mesothelioma far better than CT

D.C.C. Christoph[1], M. Metzenmacher[2], S. Bölükbas[3], J. Volmerig[4], G. Nilius[5], D. Moka[6], H. Hautzel[7]

[1]Medical Oncology, KEM, Evang, Kliniken Essen-Mitte gGmbH, Essen, Germany; [2]Medical Oncology, WTZ - Westdeutsches Tumorzentrum Essen, Essen, Germany; [3]Department of Thoracic Surgery and Endoscopy, West German Cancer Center, University Medicine Essen - Ruhrlandklinik, University Duisburg-Essen, Essen, Germany; [4]Thoracic Surgery, KEM, Evang, Kliniken Essen-Mitte gGmbH, Essen, Germany; [5]Pneumology, KEM, Evang, Kliniken Essen-Mitte gGmbH, Essen, Germany; [6]Nuclear Medicine Centre, Essen, Germany; [7]Nuclear Medicine, Universitätsklinikum Essen, Essen, Germany

Background: Checkpoint-Inhibition with Ipilimumab and Nivolumab is standard-of-care for first-line treatment of patients with unresectable malignant mesothelioma. However, response assessment by conventional CT using modified RECIST might miss detection of response and result in premature treatment discontinuation. PET-CT based assessment might recognize more patients benefitting from this therapy.

Methods: A retrospective analysis of patients suffering from unresectable malignant mesothelioma who were treated with first-line nivolumab and ipilimumab was performed. Patients got therapy in the Department of Medical Oncology (at the Evang. Kliniken Essen-Mitte or the University Hospital Essen) and underwent PET-CT. Patients received PET-CT scan at their initial diagnosis to clarify resectability (baseline PET-CT). PET-CT scans were repeated after every 12 weeks of treatment. ORR was calculated by using RECIST v1.1, mRECIST, $PERCIST_{SULpeak}$ and $PERCIST_{MTV}$ were used separately to categorize responders in CT and PET imaging studies.

Results: 27 patients (19 male (70.4%) and 8 female patients (29.6%) received a baseline PET-CT and underwent therapy with ipilimumab (1mg/kg, q1, q6w) and nivolumab (360 mg abs., d_{1+22}, q6w). Due to clinical progression and/or adverse events, a follow-up PET-CT was performed only in 18 patients (while 3 patients have recently started therapy). In 2 patients (7.4%), CT scan based response assessment showed progressive disease, However, both patients continued treatment due to metabolic response detected in additional PET-CT follow-up scans. Another patient showed progression after 2 cycles, continued therapy due to clinical benefit and responded well after 4 cycles (pseudo-progression). According to follow-up PET-CT scan, 8 patients responded (42.1%), 7 patients achieved diseases stabilization (36.8%) and 4 patients showed progression (21.1%). Median PFS/OS was 8.5/17.3 months. Detailed response assessment with RECIST v1.1, mRECIST, $PERCIST_{SULpeak}$ and $PERCIST_{MTV}$ will be reported at the meeting.

Conclusions: PET-CT scans based response assessment identifies mesothelioma patients responding to ipilimumab and nivolumab better than CT scans.

2197P Prognostic value of 18F-FDG-PET for patients with malignant pleural mesothelioma treated with double immunotherapy

S.M.H. Thunold[1], E. Hernes[2], S.J. Farooqi[1], L.T.G. Mikalsen[3], A.K. Ojlert[4], A. Helland[5], E. Malinen[6], V.D. Haakensen[1]

[1]Pulmonory Oncology, Oslo University Hospital - Ulleval Hospital, Oslo, Norway; [2]Department of Radiology and Nuclear Medicine, Oslo University Hospital - Ulleval Hospital, Oslo, Norway; [3]Department of Radiology and Nuclear Medicine, Oslo University Hospital, Oslo, Norway; [4]Cancer Genetics Dept., Department of Cancer Genetics, Institute for Cancer Research, Oslo University Hospital, Oslo, Norway; [5]Oncology Dept., University of Oslo, Institute of Clinical Medicine, Oslo, Norway; [6]Department of Physics, University of Oslo, Oslo, Norway

Background: While malignant pleural mesothelioma (MPM) confers a poor prognosis, there are large differences between disease trajectories and a lack of *prognostic* biomarkers. With the introduction of new therapeutic options, it is essential to identify biomarkers that could aid treatment selection. The use of volumetric positron emission tomography (PET) parameters as biomarkers in cancer is becoming more prevalent. However, their application in MPM remains limited. Our study aimed to obtain volumetric PET features and assess their prognostic value.

Methods: 88 patients with MPM treated with double immunotherapy in the NIPU trial were included in the analyses. Participants underwent a 18F-fluorodeoxyglucose (FDG) PET/computed tomography (CT) scan at screening. Metabolic tumor volume (MTV) and total lesion glycolysis (TLG) were obtained using Lesion Scout with Auto-ID in syngo.via.

Results: Median overall survival (OS), median time on treatment (TOT), and median progression-free survival (PFS) were 35, 20, and 18 weeks, respectively. The patients were divided into two subgroups based on median MTV. The group with low MTV experienced a significantly better OS, TOT, and PFS, with an HR of 4.18 (p-value $<$ 0.001, CI 2.09 - 8.36), 2.11 (p-value 0.002, CI 1.32 - 3.37) and 2.42 (p-value $<$ 0.001, CI 1.46 - 3.99), respectively. In multivariate analyses, MTV and TLG were significantly associated with OS, PFS, and TOT, while histology and ECOG performance status were significantly associated with OS. There was no significant association between outcomes and maximum SUV and SUV peak in univariate or multivariate analyses.

Conclusions: Our study emphasizes the prognostic value of volumetric PET features, notably MTV, over several clinical parameters in MPM, highlighting the utility of 18F-FDG-PET.

Clinical trial identification: 2019-002721-30.

2198P Clinicopathologic characteristics and outcomes to immune checkpoint inhibitor therapy in patients with HER2-altered metastatic non-small cell lung cancer

M. Makarem, B. Ricciuti, J.V. Alessi, F. Pecci, A. Di Federico, M. Gandhi, P.A. Jänne, M.M. Awad, J.K. Rotow

Lowe Center for Thoracic Oncology, Dana Farber Cancer Institute, Boston, MA, USA

Background: *ERBB2* (*HER2*) alterations are found in up to 4% of patients with non-small cell lung cancer (NSCLC), and associate with poor prognosis. Although chemo-immunotherapy is used in the first-line setting for these patients, the role of immune checkpoint inhibitor (ICI) therapy alone remains limited. We sought to characterize the clinicopathologic features of patients with *HER2* alterations and their outcomes to ICI therapy.

Methods: We conducted a retrospective analysis of patients with advanced NSCLC treated with PD-L1 inhibitors with or without CTLA-4 inhibition at the Dana-Farber Cancer Institute. Clinicopathologic characteristics and clinical outcomes of patients with *HER2* alterations were reviewed and compared to patients with classical *EGFR* mutations (L858R and Exon 19 deleted).

Results: We identified 23 patients with *HER2* alterations and 80 with classical *EGFR* mutations treated with ICI therapy alone. Median age of patients with *HER2* alterations was similar to patients with classical *EGFR* alterations (57 vs 62, P=0.2). Patients with *HER2* alterations were predominantly female (83%, N=19) and had no history of tobacco use (57%, N=13). Compared to patients with *EGFR* alterations, patients with *HER2* alterations had similar tumor mutational burden (median 8.0 vs 8.4 mut/Mb, P=0.6), PD-L1 tumor proportion score (TPS, median 10% vs 60%, P=0.7), and poor objective response rates to ICI therapy (8.7% vs 3.8%, P=0.3). Two patients with HER2 Exon 20 insertions achieved a partial response, both were female with no smoking history, PDL1 TPS score of $\geq$50%, and received treatment in the second-line setting. Median progression-free survival to ICI therapy in patients with *HER2* alterations was similar to patients with classical *EGFR* alterations [2.1 vs 1.5 months, respectively, HR 0.7, P=0.2], as was overall survival [9.0 vs 4.5 months, respectively, HR 0.7, P=0.1].

Conclusions: In comparison to patients with classical *EGFR* alterations, those with *HER2* alterations and advanced NSCLC have similar poor outcomes to treatment with ICI therapy. A comprehensive analysis of the tumor immune microenvironment may provide insight into future biomarkers of response.

2199P Immunohistochemical identification of clinical subtypes and potential therapeutic vulnerabilities of lung carcinoids based on multi-omic analysis

J. Derks[1], D. Leunissen[2], L. Moonen[2], J. von der Thüsen[3], M. den Bakker[4], L. Hillen[2], R. van Suylen[5], R. Damhuis[6], T. van den Bosch[7], L. Lap[2], A. Sexton Oates[8], L. Fernandez-Cuesta[8], A-M.C. Dingemans[9], E-J. Speel[2]

[1]Pulmonology, Maastricht University Medical Center (MUMC), Maastricht, Netherlands; [2]Pathology, Maastricht University Medical Center (MUMC), Maastricht, Netherlands; [3]Pathology, Erasmus MC - Erasmus University Rotterdam, Rotterdam, Netherlands; [4]Pathology, Maasstad Ziekenhuis, Rotterdam, Netherlands; [5]Pathology, Pathology DNA, S'hertogenbosch, Netherlands; [6]Research, Comprehensive Cancer Centre the Netherlands, Utrecht, Netherlands; [7]Pathology, Erasmus University Medical Center, Rotterdam, Netherlands; [8]Rare Cancer Genomics, IARC - International Agency for Research on Cancer, Lyon, France; [9]Pulmonology Department, Erasmus MC - University Medical Center, Rotterdam, Netherlands

Background: Multi-omic studies have identified three lung carcinoid (LC) subtypes (A1, A2, B) with unique expression for *OTP, ASCL1* & *HNF1a* genes. We developed an immunohistochemical (IHC) panel for LC subtype identification and clinical-pathological correlation.

Methods: IHC was evaluated in a blinded fashion in mRNA-profiled LC (n=5 per A1/A2/B). IHC H-score was scored and positive for OTP/HNF1a if $\geq$50 & ASCL1 $\geq$10. Then, surgically resected pathology revised LC (2003-2012) from a Dutch population based cohort using the cancer/pathology registry (n=474) were evaluated including matching metastasis of 20 recurrent LC. Also, potential therapeutic targets (SSRT2a/DLL3) were assessed. Normal lung tissue distant to the primary LC ($\approx$35/type) was screened for neuroendocrine cell hyperplasia (NECH) using OTP/ChrA IHC. Disease free survival (DFS) was calculated and evaluated using log rank test. Clinical characteristics were compared using chi-square test.

Results: IHC and mRNA expression of matched primary samples were near-identical. IHC identified A1 in 44% and was classified as $OTP^{HIGH/LOW}/ASCL1^{HIGH}/HNF1a^{LOW}$, A2 in 40% as $OTP^{HIGH}/ASCL1^{LOW}/HNF1a^{HIGH}$ and B in 16% as $OTP^{LOW}/ASCL1^{LOW}/HNF1a^{HIGH/LOW}$. Patients with A1 LC generally were middle-aged/elderly females with a peripheral tumour (Table). By contrast, in A2 primarily young patients with endobronchial tumours were identified. In B, the rate of recurrence of disease and tumor size were highest. Patients with A2 had significantly longer DFS compared to A1 and B. Matching primary-metastatic tumours showed similar IHC expression patterns for OTP/ASCL1 and HNF1a. SSRT2a was highest in A2-B while DLL3 showed unique expression in A1. NECH was enriched in A1 and this NECH showed an IHC pattern similar to A1 ($OTP^{HIGH}/ASCL1^{HIGH}$).

Table: 2199P Clinical characteristics of LC subtypes

	A1 (%) n=210	A2 (%) n=190	B (%) n=72	p-value *<0.01 **<0.001
% of cohort	44	40	16	
Atypical LC	10	4	16	*
Ki-67				*
0-4	92	97	89	
5-19	5	3	10	
>20	3	0	1	
Female	82	60	40	**
Age				**
<40	2	29	6	
41-50	15	24	13	
>50	83	47	81	
Tumour location				**
Peripheral	57	12	26	
Endobronchial/central	30	83	60	
NECH (≥3x bronchi(ole) with >5 NE cells)				
Near tumour	26	7	1	*
Distant normal tissue	37	25	6	*
Tumour size (median, mm)	18	20	23	*
Recurrence	12	6	20	*
IHC (median, H-score)				
DLL3	82	0	0	**
SSRT2	5	150	140	**

Conclusions: An OTP/ASCL1/HNF1a IHC panel enables separation of molecular LC types into clinically different groups with distinct therapeutic vulnerabilities.

2200P Spatiotemporal distribution of mediastinal neoplasms: A multi-center, hospital-based, systematic analysis

Y. Jiang, Y. Lin, R. Zhong, H. Liang, J. He

Department of Thoracic Surgery and Oncology, The First Affiliated Hospital of Guangzhou Medical University, Guangzhou, China

Background: Mediastinal neoplasms are typical but uncommon thoracic diseases with increasing incidence and unfavorable prognoses. A comprehensive understanding of their spatiotemporal distribution is essential for accurate diagnosis and timely treatment. However, previous studies are limited in scale and data coverage. Therefore, we delineate the distribution of mediastinal lesions within a substantial, nationwide, multi-institutional cohort, thereby providing valuable insights into this disease.

Methods: In this multi-center, hospital-based, observational study, we included 20 hospitals from 11 provinces in China. At each institution, a standardized retrospective search of electronic medical records between Jan. 1st, 2009 and Dec. 31st, 2020 was performed. We collected information on sociodemographic characteristics, CT images, and pathologic diagnoses. The incidence of mediastinal neoplasms was analyzed in terms of age, sex, time, compartment, and geographical region.

Results: Among 7,829 cases, the most common mediastinal lesions were thymomas (30.6%), benign mediastinal cysts (23.3%), and neurogenic tumors (10.0%). The distribution of these lesions varied significantly among mediastinal compartments, with thymomas (39.6%), benign cysts (28.0%), and neurogenic tumors (51.7%) being the most commonly observed lesions in the prevascular, visceral, and paravertebral mediastinum, respectively ($P < 0.001$). The occurrence of mediastinal lesions varied by age, with germ cell tumors being more frequently observed in patients younger than 18 and those aged 18-29 years, whereas thymomas occurred more often in patients over 30 ($P < 0.001$). Also, the lesion location was associated with age, with patients having paravertebral lesions being the youngest ($P < 0.001$). Spatial distribution analysis revealed that thymomas were the most common mediastinal lesions across different geographical regions.

Conclusions: This study revealed significant heterogeneity in the spatiotemporal distribution of mediastinal neoplasms. These findings provide useful demographic data when considering the differential diagnosis of mediastinal lesions, and would be beneficial for tailoring disease prevention and control strategies.

2201P Malignant pleural mesothelioma (MPM)-specific DNA methylation patterns in patients using liquid biopsies

S. Schmid[1], S. Ul Haq[2], L.J. Zhan[3], M.C. Brown[2], D. Patel[3], F.A. Shepherd[3], N. Leighl[2], A. Sacher[4], M. de Perrot[5], J. Cho[6], F. Zaeimi[7], B. Lok[6], S. Bratman[8], M-S. Tsao[9], M. Frueh[10], P. Bradbury[4], G. Liu[2]

[1]Oncology and Haematology Department, Inselspital - Universitatsklinik fur Medizinische Onkologie, Bern, Switzerland; [2]Medical Oncology Department, UHN - University Health Network - Princess Margaret Cancer Center, Toronto, ON, Canada; [3]Medical Oncology, Princess Margaret Cancer Centre, Toronto, ON, Canada; [4]Medical Oncology and Hematology Department, UHN - University Health Network - Princess Margaret Cancer Center, Toronto, ON, Canada; [5]Thoracic Surgery, Princess Margaret Cancer Centre, Toronto, ON, Canada; [6]Radiation Oncology, UHN - University Health Network - Princess Margaret Cancer Center, Toronto, ON, Canada; [7]Thoracic Surgery, UHN - University Health Network - Princess Margaret Cancer Center, Toronto, ON, Canada; [8]Radiation Oncology, Princess Margaret Cancer Centre, Toronto, ON, Canada; [9]Princess Margaret Cancer Research Tower - MaRS Discovery District, Toronto, ON, Canada; [10]Medical Oncology, Kantonsspital St. Gallen, St. Gallen, Switzerland

Background: Circulating tumor (ct)DNA profiling in MPM has been limited by the molecular heterogeneity of MPM without identification of recurrent mesothelioma-specific mutations, prohibiting development of mutational-based custom panels. Cell-free methylated DNA immunoprecipitation sequencing (cfMeDIP-seq) on plasma cell-free DNA (cfDNA) that distinguishes MPM plasma samples from healthy non-cancer controls (NCC) based on epigenetic changes by analyzing differential methylation regions (DMR) could overcome this limitation.

Methods: Pre-treatment cell-free methylomes of 39 MPM patients and 16 healthy non-cancer controls (NCC) were examined through cfMeDIP-seq. cfMeDIP-seq libraries were sequenced at a depth of 70 million reads, paired-end, on the NovaSeq 6000. For all analyses, chromosomes 1-22 were binned into 300-bp windows (total of 9.6e6 genome-wide windows); reads from cfMeDIP-seq were tallied per bin.

Results: 39 patients with MPM (77% epithelioid, 15% biphasic, 8% sarcomatoid) and 16 NCC (10 asbetos exposed) were analzyed. Patients with MPM had a median age of 70 years; 94% were male; 80% reported prior asbestos exposure. Differential methylation analysis identified 626 windows (log2 fold-change > 1, p-adjusted < 0.05) hypermethylated in MPM and 568 windows hypermethylated in NCC. The MPM methylome was enriched for CpG islands (5.8% of significant DMRs) and shores (8.8%), whereas in NCC predominantly open-sea regions (92.1%) were hypermethylated and only in 0.17% of CpG-islands. MPM was also enriched for promoter regions (3.2%) compared to NCC (0.0%). KEGG-pathway analysis corresponding to significant DMRs in MPM samples identified several important pathways including microRNAs in cancer, focal adhesion, and proteoglycans in cancer. There were also several promotors significantly hypermethylated in MPM that are also implicated in other cancers such as RPS27, USP39, ZUP1, ADAP1, NCAPG2, BRSK2, TMEM216, and KLHL11.

Conclusions: ctDNA global methylome profiling is a promising tool to identify novel biological pathways and targets in MPM. There is potential for future use of cfMeDIP-Seq in MPM screening, minimal residual disease, and therapeutic monitoring.

2202P Large cell neuroendocrine carcinoma (LCNEC) subtyping based on NEUROD1, ASCL1, POU2F3 and YAP1 expression

F. Heijboer[1], J. Derks[2], N. Rijnsburger[1], B. Hermans[3], L. Hillen[4], E. van den Broek[5], E-J. Speel[4], A-M.C. Dingemans[6], J. von der Thüsen[7]

[1]Respiratory Medicine, Erasmus MC, Rotterdam, Netherlands; [2]Pulmonology, Maastricht University Medical Center (MUMC), Maastricht, Netherlands; [3]Internal Medicine, Maastricht University Medical Center (MUMC), Maastricht, Netherlands; [4]Pathology, Maastricht University Medical Center (MUMC), Maastricht, Netherlands; [5]Data Integrity, PALGA (Dutch Nationwide Pathology Databank), Houten, Netherlands; [6]Pulmonology Department, Erasmus MC - University Medical Center, Rotterdam, Netherlands; [7]Pathology, Erasmus MC - Erasmus University Rotterdam, Rotterdam, Netherlands

Background: LCNEC is a rare high-grade neuroendocrine tumor with poor prognosis. pRb subclassifies LCNEC into SCLC-like and NSCLC-like. NEUROD1, ASCL1, POU2F3, and YAP1 (NAPY) subtyping has been identified in SCLC. These subtypes might be present in LCNEC and may correlate with pRb. DLL3, expressed in high-grade neuroendocrine tumors such as SCLC and LCNEC, allows for potential DLL3 targeted therapy. We aimed to define LCNEC subtypes, based on immunohistochemical (IHC) expression of NEUROD1, ASCL1, POU2F3, YAP1, pRb and DLL3.

Methods: Tissue microarrays were made from 133 stage I-III resected LCNEC cases, revised by 2 pathologists, stained for NAPY, pRb and DLL3 and scored using H-scores. An H-score >10 was considered positive (+). The NAPY marker with the highest H-score was considered dominant. Unsupervised clustering of the NAPY markers was performed. Disease free survival (DFS) and overall survival (OS) data were obtained from the Dutch cancer registration.

Results: IHC evaluation demonstrated 100 (75%) cases with pRb loss and 88 (66%) DLL3+ cases. The distribution of NAPY is shown in the table. NEUROD1 was dominant in 30% of cases and ASCL1 in 37%. An association was observed between NEUROD1 and ASCL1, and between NEUROD1 and POU2F3. Unsupervised clustering identified 5 clusters: NEUROD1^{HIGH}/ASCL^{HIGH}/DLL^{HIGH}, ASCL1^{HIGH}/DLL3^{HIGH}, POU2F3^{HIGH}, YAP1^{HIGH}, and NAPY^{LOW}. The clusters ASCL1^{HIGH}/DLL3^{HIGH}, POU2F3^{HIGH} and NAPY^{LOW} were mainly pRb-. The DFS and OS for the different clusters is shown in the table. The ASCL1^{HIGH}/DLL3^{HIGH} cluster had the lowest median OS (24 months) and DFS (13 months). The NAPY^{LOW} cluster had the highest median OS (74 months) and the POU2F3 cluster the highest median DFS (54 months).

Table: 2202P

	pRb- (%)		DLL3+ (%)	
NEUROD1-NEUROD1+	52 (52) 48 (48)		41 (47) 47 (53)	
ASCL1- ASCL1+	44 (44) 56 (56)		27 (31) 61 (69)	
POU2F3-POU2F3+	93 (94) 6 (6)		85 (99) 1 (1)	
YAP1- YAP1+	84 (84) 16 (16)		75 (85) 13 (15)	
NAPY-	15 (88)		8 (47)	
Cluster	**Median OS (months)**	**Median DFS (months)**	**pRb-(%)**	**DLL3+ (%)**
NEUROD1^{HIGH}/ASCL^{HIGH}/DLL^{HIGH} (N = 13)	58	25	54	92
ASCL1^{HIGH}/DLL3^{HIGH} (N = 28)	24	13	89	96
POU2F3^{HIGH}(N = 7)	61	54	57	0
YAP1^{HIGH}(N = 15)	56	32	47	47
NAPY^{LOW}(N = 66)	74	31	82	61

Conclusions: NAPY-subtyping differentiates subtypes in LCNEC. Difference in survival was seen between the newly identified clusters. 3 out of 5 clusters were mainly pRb-. Clinical significance of these clusters remains to be studied. YAP1 is more frequently expressed in LCNEC, than in SCLC.

Background: Malignant pleural mesothelioma (MPM) is a rare and aggressive disease with poor prognosis. MPM is classified into three histological subtypes: epithelioid, biphasic, and sarcomatoid. This classification does not account for survival differences and intratumor heterogenity, especially for epithelioid MPM (eMPM) that is the most common subtype. The aim of this study is to evaluate transcriptomic differences of eMPM based on prognostic classes.

Methods: MPM patients with available FFPE tissue were retrospectively and prospectively enrolled at Fondazione IRCCS Istituto Nazionale dei Tumori of Milan and Azianda Sanitaria Universitaria Giuliano Isontina of Trieste between 2006 and 2021 within the granted Italian MOH project, GR-2016-02361229. RNA was automatically extracted and quantified using a fluorometer. Transcriptome was assessed through the 3'DGE method. Patients were divided into three groups based on months (mo) of survival: long survivors (LS) > 36 mo, normal survivors (NS) > 12 and ≤ 36 m, and short survivors (SS) ≤ 12 mo. Evaluation of differential gene expression (GED) between SS and LS was performed for single genes. Moreover, in the same setting, a gene set enrichment analysis (GSEA) was also performed.

Results: 125 eMPM cases were enrolled, 90 (72%) males and 35 (28%) females, with a median age at diagnosis of 72 years. At a median follow-up of 88 mo, the median overall survival (OS) was 21 mo. Among patients, 33 were LS, 54 were NS, and 38 were SS. GED showed higher levels of NUF2 and TUBB3, genes involved in the epithelial-mesenchimal-transition (EMT), and a lower expression of ADH1B, PLA2G2A, genes related to metabolism, in SS. EMT, metabolism signature and cell proliferation were confirmed by GSEA analysis as more positively correlated pathways while inflammation and immune response related pathways were negatively correlated in SS.

Conclusions: Transcriptomic characterization of eMPM reinforces the hypothesis that cell cycle, EMT and immune components could have an impact on eMPM outcome and could be exploited as therapeutic strategies.

2204P Clinical predictors and inflammatory markers for malignant pleural mesothelioma prognosis: A retrospective study in a Spanish Medical Oncology Unit

M. Guardamagna[1], B. Villaescusa Gonzalez[1], M.R. María Dolores[1], E. Zamorano Gonzalez[1], I. Ramos Garcia[1], A. Mesas Ruiz[1], J.M. Trigo Perez[1], A. Cantero[1], V. Gutierrez Calderon[1], J.M. Jurado García[1], A. Rueda Dominguez[1], R. Mongil[2], R. Arrabal[2], E. Alba Conejo[1], M. Cobo Dols[1], J.C. Benitez Montanez[1]

[1]Medical Oncology, UGCI Oncol. Regional and Virgen de la Victoria University Hospitals. IBIMA, Malaga, Spain; [2]Thoracic Surgery, Hospital Regional Universitario Málaga Carlos Haya, Malaga, Spain

Background: Malignant pleural mesothelioma (MPM) is a rare thoracic malignancy with bad prognosis. Asbestos exposure has been described as the main risk factor with a key role in its pathogenesis. The aim of this study is to identify the impact of systemic inflammation biomarkers as clinical prognostic factors for MPM.

Methods: Patients (pts) diagnosed of MPM from 2004 to 2023 from a Medical Oncology Intercenter Unit in Malaga (Spain) were enrolled. We analyzed epidemiologic, clinical and pathological characteristics and correlated them with survival outcomes.

Results: Among the 140 pts, median age was 70 years (range 23-94), ECOG 0-1 in 76,4% (n=104), mainly males (70,7%, n=99). 95 pts (67,9%) were epithelioid subtype. Median follow up was 21,6 months (mo) (range 1-217). Median overall survival (OS) 13,5 mo (CI 95% 9,6-17,4), progression-free survival (PFS) 10,1 mo (CI 95% 7,2-13). 19 pts (13,6%) were considered for surgery. In non-resectable pts (n=121, 86,4%), age over 65, malnutrition and ECOG 2-4 at diagnosis were associated to poor OS (21,6 mo CI95% 14,4-28,8; 7,1 mo, CI95% 5,8-8,2; 4,7 mo, CI95% 3-6,5 respectively). Inflammatory biomarkers including high LDH or CRP, neutrophilia, Lung Immune Prognostic Index (LIPI) intermediate-poor, and high dNLR suggested a trend towards poor survival (9,5 mo CI 95% 3,5-15,4; 8,5 mo CI 95% 4,5-12,5; 7,1 mo CI 95% 1,5-3,9; 9,5 mo CI95% 4,5-14,4; 9,5 mo CI95% 4,8-14, respectively; p>0.5). Anemia, moderate-to-severe value of neutrophil to lymphocyte ratio (NLR≥6) and not receiving immunotherapy were significantly associated with worse prognosis. Multivariate analysis showed age and NLR value as independent prognostic factors (p<0.01).

Table: 2204P

	Univariate analysis			Multivariate analysis		
	HR	CI 95%	P	HR	CI 95%	P
Age ≤65	0,56	0,36-0,88	0,01	0,44	0,23-0,82	0,01
ECOG	1,65	1,3-2,6	0,00	-	-	0,37
Malnutrition	0,47	0,29-0,74	0,00	-	-	0,78
Anemia	9,86	0,76-0,96	0,01	-	-	0,29
High C reactive protein	1,87	0,77-4,52	0,16	-	-	-
Neutrophilia	2,38	0,31-18,41	0,40	-	-	-
High LDH	1,47	0,93-2,34	0,09	-	-	-
NLR (absent-mild vs moderate severe)	0,5	0,28-0,90	0,02	0,30	0,14-0,61	0,00
dLNR (high vs normal)	0,91	0,58-1,42	0,69	-	-	-
LIPI score (good vs intermediate-poor)	1,47	0,96-2,27	0,07	-	-	-
Immunotherapy	0,48	0,24-0,96	0,04	-	-	0,62

Conclusions: Host inflammation status at diagnosis may be a subrogate biomarker of survival for MPM, even for pts not receiving immunotherapy. Modulating the immune system and inflammatory pathways appear as promising strategies for increasing effectiveness in MPM treatment.

2205P Tumor-infiltrating lymphocytes score possesses a relation with adjuvant chemo-immunotherapy benefit and cellular morphology in large-cell neuroendocrine carcinoma

Z. Luo[1], Y. Cao[2], Y. Che[3], Y. Xie[4], X. Bi[4], X. Bi[5], H. Zhao[5]

[1]The Ruth and Bruce Rappaport Faculty of Medicine, Technion - Israel Institute of Technology, Haifa, Israel; [2]Pathology Department, National Clinical Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Bejing, China; [3]Thoracic Surgery, National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China; [4]Department of Urology, National Cancer Center - Cancer Hospital, Chinese Academy of Medical Sciences, Beijing, China; [5]Department of Hepatobiliary Surgery, Chinese Academy of Medical Sciences and Peking Union Medical College - National Cancer Center, Cancer Hospital, Beijing, China

Background: Pulmonary large-cell neuroendocrine carcinoma (LCNEC) is a rare subtype of lung cancer with a worse prognosis. The benefit of adjuvant chemotherapy (aCT) or immunotherapy is controversial. Hence, effective biomarkers for selecting sensitive patients after surgery are urgently needed. Microenvironmental morphological fluctuations affect gene regulation and facilitate nuclear transport, finally changing immunity interaction. However, little is known in LCNEC.

Methods: Here, 190 LCNECs were reviewed, and 53 postoperative stage II and III LCNECs with and without aCT were evaluated for CD4+ T, CD8+ T, CD3, PD-1, and PD-L1 expression by IHC. Cellular morphology was described via machine learning algorithms in H&E staining slides.

Results: In patients who received aCT, high expression of CD3 and CD4 had a better OS, while CD8 could not separate aCT benefit. There was no survival difference between aCT and surgery alone in whole cohort. However, in CD4 or CD3 high expression group, patients receiving aCT exhibited longer OS than those undergoing surgery alone. A T cell stratification (CD3CD4 score) was developed to identify aCT-sensitive patient. CD3CD4 score>0 group could benefit from aCT, while CD3CD4 score=0 group might suffer from aCT toxic effect. Moreover, PD-L1 low expression patients from CD3CD4 score>0 group survive better than others in aCT arm. CD3CD4 score possessed a superior prognosis predictive performance than other clinicopathological factors. Histology-based Digital-Staining segmented 45639 six-type cells' morphological characteristics from tumor cell, lymphocyte, stroma cell, red blood cell, macrophage, and karyorrhexis. CD3CD4 score>0 group had more lymphocytes but was scant in red blood cell. Interestingly, the nucleic size and shape of tumor cell, lymphocyte, stroma cell, and macrophage were all dramatically smaller than CD3CD4 score=0 group.

Conclusions: Our results implicated stage II-III LCNEC with high CD3+ and CD4+ cell infiltration could benefit from aCT and PD-L1 blockade, highlighting the potential role of rare tumor microenvironment cellular morphological characteristics in chemo-immunotherapy sensitivity and surgery prognosis.

2206P Detection of circulating KRAS4A and KRAS4B isoforms in patients with metastatic lung adenocarcinoma treated with pembrolizumab or chemotherapy plus pembrolizumab by liquid biopsy: Clinical impact and association with circulating PD-L1

S. Palladino[1], A. Ruzzo[1], R. Emili[2], V. Catalano[2], M. De Lisa[3], D. Sarti[2], M. Magnani[1], F. Graziano[4], R. Chiari[4]

[1]Biological Sciences, Università degli Studi di Urbino Carlo Bo, Urbino, Italy; [2]U.O.C. Oncology Urbino, Azienda Sanitaria Territoriale Pesaro-Urbino, Urbino, Italy; [3]U.O.C. Oncology Pesaro e Fano, Azienda Sanitaria Territoriale Pesaro-Urbino, Fano, Italy; [4]U.O.C. Oncology Pesaro e Fano, Azienda Sanitaria Territoriale Pesaro-Urbino, Pesaro, Italy

Background: Pre-clinical studies indicate that the KRAS pathway enhances the stability and expression of PD-L1. We investigated the expression of the circulating mRNA (cmRNA) levels of KRAS4A and KRAS4B isoforms and their possible impact on progression-free survival (PFS) of patients with metastatic lung adenocarcinoma treated with Pembrolizumab (P) by liquid biopsy.

Methods: Patients with metastatic lung adenocarcinoma without driver mutations undergoing P or P plus chemotherapy (PC) were prospectively accrued to analyze KRAS4A, KRAS4B and PD-L1 cmRNA levels by liquid biopsy. Receiver operating characteristic curves (ROC) calculated the Youden index to define the optimum cut-off values for binary classification of patients and PFS analysis. Both the KRAS isoforms were also studied for association with the PD-L1 cmRNA levels. RT-PCR is the method used for expression analysis.

Results: In 56 fully assessable patients, 28 received P and 28 patients PC. Patients with high (H) KRAS4A cmRNA and HKRAS4B cmRNA levels showed significantly better PFS than patients classified with low (L). The median PFS of patients with H KRAS4A cmRNA and H KRAS4B cmRNA levels was 29 months (95% CI 22-29 months) and 24 months (95% CI 13-29 months), respectively. The median PFS of patients with L KRAS4A cmRNA and L KRAS4B cmRNA expression was 12 months (95% CI 6-15 months) and 12 months (95% CI 5-20 months), respectively. H KRAS4A cmRNA retained a significant positive association with PFS in the multivariate model. The mean expression values of PD-L1 cmRNA levels were significantly higher in patients with H KRAS4A cmRNA and H KRAS4B cmRNA levels. Moreover, an exploratory analysis in treatment subgroups found a positive association between H KRAS4A cmRNA and H KRAS4B cmRNA levels with PFS in patients treated with P.

Conclusions: Our results suggest the *KRAS4A* isoform deserves further investigation as a potential marker for defining patients who may benefit the most from immune checkpoint inhibitors therapy. Progresses in this field are desirable to improve personalized cancer immunotherapeutic strategies.

2207P Mainstream germline genetic testing in routine oncological care of EGFR mutant non-small cell lung cancer in the United Kingdom

H.M. O'Sullivan[1], A. John[1], N. Tokaca[1], C. Milner-Watts[2], J. Bhosle[2], A.R. Minchom[2], M. Davidson[2], M.E.R. O'Brien[2], A. George[3], S. Popat[2]

[1]The Lung Unit, The Royal Marsden Hospital (Chelsea) - NHS Foundation Trust, London, UK; [2]Lung Unit, The Royal Marsden Hospital, Sutton, UK; [3]Cancer Genetics Unit, Royal Marsden Hospital Institute of Cancer Research, Sutton, UK

Background: The hereditary nature of non-small cell lung cancer (NSCLC) is poorly understood. Previous studies have found inherited pathogenic germline variants (PGVs) are more common in patients with *EGFR* mutant (EGFRm) NSCLC. We sought to describe the frequency of PGVs in a cohort of EGFRm patients undergoing treatment at a UK cancer centre.

Methods: We invited NSCLC patients with activating somatic mutations in exon 18-21 of *EGFR* who attended the Royal Marsden Hospital Lung Unit between May 2022 to April 2023 to participate in a pilot of mainstream germline genetic testing. Patients consented to germline testing with an 84 gene panel of known hereditary cancer-related genes. Demographic data, clinicopathological information and family history were recorded.

Results: To date, 49 patients have undergone germline genetic testing. The median age of diagnosis was 60 years, all had adenocarcinoma histology, 65% were female, 71% were never smokers and 18% had a family history of lung cancer (Table). The most frequent somatic *EGFR* mutations were exon 19 deletions and L858R present in 63% and 18%, respectively. PGVs were detected in 8% (4/49) of patients. Two patients had PGVs detected in genes associated with a potential predisposition to lung cancer, a 37-year-old female with a *TP53* PGV and a 71-year-old male with PGVs in both *ATM* and *CHEK2*. The remaining two patients had PGVs in genes not yet known to be associated with an increased risk of lung cancer (*MUTYH* and *MITF*).

Table: 2207P Patient characteristics and genetic testing results

	n=49 (%)
Median age of diagnosis	60 (range 35-76)
Sex	
Male	17 (35)
Female	32 (65)
Smoking Status	
Never	35 (71)
Ex/current	12 (25)
Unknown	2 (4)
Stage at diagnosis	
I	5 (10)
II	2 (4)
III	1 (2)
IV	41 (84)
Somatic *EGFR* Mutation	
Exon 19 deletion	31 (63)
L858R	9 (18)
Exon 20 insertion	4 (8)
Other	5 (10)
Family history	
Family history of malignancy	30 (61)
Family history of lung cancer	9 (18)
Pathogenic germline variant detected	4 (8)
TP53 R337H	1 (2)
ATM E2007Rfs*11 and *CHEK2* T367Mfs*15	1 (2)
MUTYH G396D	1 (2)
MITF E318K	1 (2)

Conclusions: In a United Kingdom cohort of EGFRm NSCLC patients 2/49 (4%) had PGVs in lung cancer predisposing genes; the tumour suppressor gene *TP53* and DNA damage repair pathway genes *ATM* and *CHEK2*. Our data support the feasibility and importance of germline testing in routine oncological care. Germline results should be considered as a risk criterion for inclusion in lung cancer CT screening programmes.

2208P The single-cell proteomic landscape of pulmonary lymphoepithelioma-like carcinoma

C.C. Cho[1], Y. Chen[2], W. Cheuk[3], G.J. Liao[3], E. Cheung[2]

[1]Clinical Oncology Department, Queen Elizabeth Hospital, Hong Kong, China; [2]Faculty of Health Sciences, University of Macau, Taipa, Macau; [3]Department of Pathology, Queen Elizabeth Hospital, Hong Kong, China

Background: Pulmonary lymphoepithelioma-like carcinoma (PLELC) is a rare form of non-small cell lung cancer which is frequently associated with EBV infection and displays high levels of immune cell infiltration. Immunotherapy, thus, is an attractive therapeutic strategy for the disease but the treatment response has been inconsistent, indicating a gap in our understanding of the tumor microenvironment (TME) of PLELC.

Methods: Imaging mass cytometry was used in this study to map the different cellular components and interactions in 33 PLELCs at different stages (19 early-stage, 6 medium-stage, and 8 advanced-stage).

Results: Component analysis showed differential B and Treg cell composition in the TME as cancer progresses. In spatial analyses, we discovered a convergent melting trend of immune cell distribution across different stages in the tumor and non-tumor regions ($p<0.05$). We also identified anti-tumor immunity markers assigned to specific cellular interactions ($p<0.01$). In the neighborhood analysis, we found that myeloid cells near the tumor may attenuate the ability of antigenic immune responses. Furthermore, we identified two spatial structures within the TME that could impact the infiltration of immune cells and the relapse of patients, and disease relapse in patients is associated with the level of immune cells inside the tumor region ($p<0.01$) and fibroblasts surrounding the tumor.

Conclusions: Our findings indicate that TME is heterogeneous and dynamic along the disease progression of PLELC such that cellular components, spatial interactions, and immune cell infiltration may play a significant role in disease recurrence. Moreover, profiling the TME may be helpful for understanding and selecting different immune treatments.

Background: Biomarker testing is key to identify subgroups of Non-Small Cell Lung Cancer (NSCLC) with targetable oncogenic driver alterations (alt). Most data are based on Asian patient (pts) cohorts which may not apply to other continents and might explain differences observed in clinical practice.

Methods: A multicentric, retrospective study was conducted in 5 Portuguese institutions. Pts with biopsy-proven NSCLC and a molecular biomarker study performed between Jan/2016-Dec/2021 were included. We aimed to determine the incidence of oncogenic alts in NSCLC in Portugal, compare overall survival (OS) between subgroups and identify risk and prognostic factors.

Results: Among 1652 NSCLC pts included, 529 (32%) had tumors with drugable oncogenic alts, median (MED) age 67yo (25-93), 320 (61%) male. Most pts had ECOG Performance Status (PS) $\leq$1 (397; 74%), smoking history (375; 75%) and adenocarcinoma histology (480; 90%). 393 (74%) pts were diagnosed in stage IV, MED 2 sites of metastases, mostly in lung (198; 37%), bone (182; 35%) and lymph nodes (140; 27%). Curative intent treatment was offered to 134 pts (25%), mainly in stages I-III (119, 89%). Most oncogenic alts were in KRAS (211; 13%), EGFR (171; 10%) and ALK (43; 3%) genes. Among tumors with gene alts, expression of PD-L1 was $<$1% in 200 pts (38%), higher in those harboring BRAF/ RET/MET/ROS alts. Detection of targetable alts determined 1st-line treatment in 133 (25%) pts and in 78 (15%) in later lines. With a MED follow-up of 44 months (mo) (CI95 39-49), 136 pts (26%) are alive at time of analysis. In metastatic setting, MED OS = 13 mo (CI95 11-15), numerically longer for pts with EGFR alts [17 vs 11 mo (CI95 8-14 vs 13-21); p=0,056]. Female gender, worse ECOG PS and number of sites of metastases were unfavorable prognostic factors for OS ($p<0,05$) in multivariate Cox-regression.

Conclusions: This is one of the largest real word dataset in Europe. The incidence of NSCLC gene alts is in line with published data, with oncogenic alts in in $\sim$30% NSCLC. KRAS (13%), EGFR (10%) and ALK genes (3%) were the most frequent alts found, but lower than previously reported. The retrospective nature of the study, small number of less common alts and inclusion of older pts, with poorer ECOG PS and bulky disease may explain lower than expected OS.

2210P Reprogramming of pyrimidine metabolism drives tumorigenesis in NF2-deficient malignant pleural mesothelioma

D. Xu[1], R.A. Schmid[2], R-W. Peng[3], Y. Shu[1]

[1]Department of Oncology, Jiangsu Province Hospital/The First Affiliated Hospital of Nanjing Medical University, Nanjing, China; [2]Department of Thoracic Surgery, University Hospital Inselspital Bern, Bern, Switzerland; [3]Department of Thoracic Surgery, Inselspital - University Hospital Bern - Universitatsklinik fur Thoraxchirurgie, Bern, Switzerland

Background: Malignant pleural mesothelioma (MPM) is a highly aggressive cancer, notoriously known because of limited treatment options and a dismal prognosis. MPM features a difficult-to-target genome dominated by widespread loss of function mutations in tumor suppressor genes (TSGs), among which neurofibromin 2 (*NF2*) is one of the most altered TSGs and accounts for around 40-50% of MPM patients. Despite extensive and continuous efforts, the underlying pathobiology of NF2-related tumorigenesis remains obscure. In particular, targeted therapies, a mainstay in the clinical management of many other tumors, have not emerged in MPM.

Methods: In this study, we have taken a genome-wide CRISPR/Cas9 knockout screening to identify therapeutically relevant genetic vulnerabilities in *NF2*-deficient MPM cells. Further, integrated analysis of multiple-omics data (transcriptome, proteome, and metabolome) based on the gene-edited cell models and patients' tumor samples was implemented to systematically decipher the molecular basis underlying NF2-facilitated tumorigenesis. Subsequently, *in vitro* and *in vivo* preclinical orthotopic mouse models were performed to delineate the genetic dependency of *NF2*-deficient MPM cells.

Results: Here, we show that *NF2*-deficient MPM cells display a preferential sensitivity towards the disruption of genes involved in *de novo* pyrimidine metabolism, including CAD (carbamoyl-phosphate synthetase 2, aspartate transcarbamoylase, dihydroorotase) and DHODH (dihydroorotate dehydrogenase). Further exploration uncovers that the adaptive reprogramming of the *de novo* pyrimidine synthesis pathway is a critical molecular alteration in the *NF2*-deficient MPM. In addition, we observe that the constitutive activation of YAP1(Yes-associated protein 1) in *NF2*-deficient MPM triggers the boosted transcription of rate-limiting enzymes in the *de novo* pyrimidine synthesis. Coherently, pharmacological inhibition of DHODH exerted a more potent anti-tumor effect in an orthotopic mouse model of MPM.

Conclusions: Taken together, our work delineates the molecular basis and metabolic vulnerability driven by *NF2* inactivation while also providing a novel therapeutic target to battle against this daunting disease.

Background: Selective RET inhibitors have showed promising activity in advanced thyroid cancers harbouring RET mutations or fusions. Initial heterogenous mechanisms of resistance at time of disease progression have been described. However, little is known about the mechanisms of persistent disease at the time of maximum response and the pathways activated at regrowth.

Methods: We generated patient-derived xenograft (PDX) models from two patients with advanced thyroid cancers: one from a papillary thyroid tumor with a NCOA4-RET fusion and one from a medullary thyroid carcinoma with a RETM918T mutation. In both cases, RET/MAPK pathway was constitutively activated conferring a hyperproliferative phenotype. We treated both mouse models with multikinase inhibitors (MKI) (cabozantinib, lenvatinib and axitinib) or with a selective RET inhibitor (BLU667). RNAseq analyses were performed in control vehicle-treated tumors and xenografts treated short (5 or 20 days) or long time exposure (20 or 170 days) with BLU667 and after treatment release.

Results: Both PDX models responded to MKI and BLU667 with significant deeper responses with BLU667. The RET-fused PDX showed a more acute and prolonged response to BLU667 than the RETM918T model. Only with selective RET inhibitor we observed a profound effect on the whole gene expression profile of human and mouse cells in all analysed xenograft tumors. Longer treatments revealed a distinctive profile resembling a residual disease. Proliferation genes were downregulated upon treatment, whereas antigen presentation, chemokines and immune response gene sets were positively enriched in both PDX models. Interestingly, such immune reaction to RET/MAPK pathway repression was sustained upon BLU667 treatment release. Such immune reaction affected the gene expression of both cancer (human) and stroma (mouse) cells.

Conclusions: These results pave the way for a rational combination of RET inhibitors and immunotherapy in the two scenarios, as primary therapy to reduce the minimal residual disease and at time of resistance to selective RET inhibition.

Background: IoN is one of only 2 large definitive RCTs to examine whether upfront radioiodine ablation (RAI) after surgery is needed for low-risk patients with well-differentiated thyroid cancer (DTC). The IoN primary endpoint is recurrence: structural loco-regional recurrence/residual disease by imaging, confirmed by tissue diagnosis. 'No RAI' was successfully shown to be noninferior to standard RAI (World Congress on Thyroid Cancer 2023). 3-year recurrence-free rates were 98.4% (no RAI) vs. 96.2% (RAI), risk difference +0.6% with lower 95%CI limit -3.3% (within the -5% allowable margin); noninferiority p-value=0.03.

Methods: 500 patients with newly diagnosed histologically-confirmed DTC classified as low risk were recruited from 33 UK centres (2012-2020). All had total thyroidectomy and TSH suppression, and randomised (1:1) to have RAI (1.1GBq, with/without rhTSH) or no RAI. Patients were assessed at baseline, 2 months after either RAI or stimulated thyroglobulin in the no RAI group, then 6-monthly thereafter. We report adverse events (AEs), EORTC QLQ-C30 quality of life (QoL) and hospitalisation in radiation protective rooms.

Results: Median age was 47; 77% female; 78% papillary, 18% follicular, 4% oncocytic; 47% pT1, 44% pT2, 9% pT3; and 63% multifocal. At 2 months, grade 2+ events for 15 AEs of special interest were uncommon (<5% for any type, and similar between the trial arms); overall 9.6% (no RAI) vs. 8.0% (RAI), p=0.55. Mean differences (no RAI vs. RAI) in 28 QoL factors were all small, ranging -2.0 to +2.8 (scale 0-100), all p-values>0.12. Similar findings were seen at other timepoints. Hospital isolation for RAI patients only was 18% (same day outpatient), or 46, 23, 10 and 2% for 1,2,3 and 4 overnight stays respectively. For every 100 patients avoiding upfront RAI the healthcare cost saving is £204K (UK NHS costs of RAI, rhTSH and hospital stay).

Conclusions: Among low-risk DTC patients who did not have RAI, AEs and QoL were similar to those who did have RAI; as were the recurrence rates. Clinical guidelines can be updated to routinely offer selected patients the option of avoiding upfront RAI, to prevent overtreatment and unnecessary hospital isolation, with lower healthcare costs.

Clinical trial identification: ISRCTN80416929; NCT01398085; EudraCT 2011-000144-21; CTA 23151/0006/001-0001

2213P Impact of the diagnosis-to-treatment interval on the survival of patients with papillary thyroid cancer

T. Wei

Department of Breast and Thyroid Surgery, The First Affiliated Hospital of Chongqing Medical University, Chongqing, China

Background: For papillary thyroid cancer (PTC) patients, no consensus has been reached for optimal diagnosis-to-treatment interval (DTI) and patient survival outcomes. In this study, we evaluated the impact of DTI on prognosis among patients with PTC.

Methods: Patients with PTC were retrieved from the Surveillance, Epidemiology, and End Results (SEER) database between 2000 and 2019. Kaplan-Meier curves and Cox proportional hazards regression analysis were used to evaluate the impact of DTI on overall survival (OS) and thyroid cancer-specific survival (TCSS). Patients were grouped as follows: (I) 0 months (immediate treatment), (II) 1—3 months, (III) 4—5 months, and (IV) ≥6 months based on DTI.

Results: A total of 168,969 patients with PTC were included in this cohort study. Median follow-up time was 84.0 months (interquartile range [IQR], 40.0—138.0) and the median age was 49 years (IQR, 38—60). The 10-year OS rates for DTI 0, 1—3, 4—5, and ≥6 months were 90.3%, 90.1%, 84.9%, and 80.7%, respectively. By multivariable Cox proportional hazards regression analysis, there was no significant OS difference between patients with DTI 0 and DTI of 1—3 months (adjust hazard ratio [aHR] = 0.980, 95% confidence interval [CI]: 0.945—1.017). However, DTI of 4—5 months (aHR = 1.294, 95% CI: 1.166—1.435) and ≥6 months (aHR = 1.703, 95% CI: 1.504—1.928) were associated with poorer OS compared to patients with immediate treatment. Patients with treatment delay (DTI 1—3 vs. DTI 0: aHR = 1.233, 95% CI: 1.144—1.328; DTI 4—5 vs. DTI 0: aHR = 1.268, 95% CI: 1.025—1.570; and DTI ≥6 vs. DTI 0: aHR = 1.349, 95% CI: 1.031—1.766) had poorer TCSS than those receiving treatment immediately.

Conclusions: A short-term delay (1—3 months) had no significant impact on OS, whereas more than 3 months of DTI resulted in poorer OS. Any DTI delay decreased TCSS in patients with PTC. However, based on this study and the typically good prognosis for PTC, it may be safe for surveillance and treatment decision-making within 3 months after diagnosis.

2214P Identification of prognosis-associated genes in locally advanced well-differentiated thyroid cancer using TCGA cohort analysis

A.R. Jung[1], S.Y. Lim[2]

[1]Otorhinolaryngology-Head and Neck Surgery, Eulji General Hospital, Seoul, Republic of Korea; [2]Plastic and Reconstructive Surgery, Konyang University Hospital, Daejeon, Republic of Korea

Background: Despite the usually favorable prognosis of well-differentiated thyroid cancer (WDTC) following appropriate treatment, advanced T-staged WDTCs are associated with poor prognosis. This study focused on identifying genes associated with the prognosis of locally advanced WDTC by analyzing the TCGA cohort.

Methods: We analyzed data on 501 patients with WDTC and classified them into two subgroups: pathological T4 stage (Cluster1) or T1-3 stage (Cluster2). We compared the mRNA expression of thyroid cancer-related genes, and the somatic mutation frequency of various cancer genes between the two subgroups.

Results: Cluster1 included 23 patients (papillary = 21/follicular-variant of PTC = 2) and Cluster2 478 patients (papillary = 371/follicular-variant of PTC = 100/others = 7). Cluster1 showed worse overall and disease-free survival than Cluster2 ($p < .05$ and $p = .12$, respectively). Patients with pT4 stage had about a 1.8-fold increased risk of overall recurrence or death. *MET*, *SERPINA1*, *TIMP1*, *PROS1*, *FN1*, *CDKN2A*, and *CDKN2B* were significantly elevated while *TG*, *DNAH9*, *TFF3*, *CRABP1*, *TPO*, *JAK2*, *KIT*, *KDR*, and *NFE2L2* were significantly lower in Cluster1 (all, $p < 0.05$ and adjusted $p < 0.05$). A *TERT*, *EIF1AX*, and *ATM* showed significantly frequent somatic mutations in Cluster1 compared to Cluster2. We also identified seven pathways related to 16 genetic markers.

Conclusions: Locally advanced WDTC presented 16 genetic alterations compared to less aggressive thyroid cancers. We identified somatic mutations associated with local invasion transformation. Relevant pathways related to the 16 genetic markers could be therapeutic targets. Genetic analysis of locally advanced WDTC may predict clinical applications in patient survival.

2215P Gas-insufflation one-step single-port trans-axillary robotic thyroidectomy (GOSTA)

D.Y. Yu, Y.W. Chang

Breast Endocrine Surgery Department, Korea University Ansan Hospital, Ansan, Republic of Korea

Background: To overcome the limitations of conventional trans-axillary (CTA) thyroidectomy, a new surgical approach named as "Gas-insufflation One-step Single-port Trans-Axillary Robotic Thyroidectomy (GOSTA)" was invented. In this study, we introduced this novel approach and compared the CTA approach with the GOSTA approach.

Methods: A total of 355 patients underwent robotic thyroidectomy in the single tertiary institution, Korea University Ansan Hospital, by a single surgeon named WYC. The CTA thyroidectomy was performed on 211 patients from January 2019 to December 2021, while GOSTA was performed on 141 patients from January 2022 to April 2023, consecutively. In the GOSTA approach, patients were positioned supine with both arms down. The incision required only 3.0 cm. The robot could be docked after creating a one-finger depth flap for the wound retractor, and the skin flap could be created using the robot from the very first stage of the surgery, as a one-step process. The upper pole of the thyroid gland was exposed clearly, allowing for easier preservation of the external branch of the superior recurrent laryngeal nerve, recurrent laryngeal nerve, and other important structures. Additionally, selective lymph node dissection (SND) could be performed as an extension of thyroidectomy without any adoption. For our study, we extracted only the patients who underwent thyroid lobectomy with differentiated thyroid carcinoma, in order to evaluate and perform a comparative analysis.

Results: There were a total of 167 patients who underwent CTA and 100 patients who underwent GOSTA. The mean age was 49.3 and 48.5 years. There were no significant differences in the total operation time (97.1 and 101.6 minutes). There were 7 postoperative complications in CTA, 4 had transient RLN palsy, and 3 had hematoma that required evacuation. In GOSTA, 1 had transient RLN palsy and the other 1 had hematoma. There were no cases of permanent RLN palsy or chylous drainage in either group.

Conclusions: The GOSTA procedure represents an innovative progression in the era of robotic thyroidectomy, allowing even for total thyroidectomy with SND through only 3.0cm incision. This technique can be performed feasibly and safely, similar to the conventional trans-axillary approach.

2216P Clinicopathologic and genetic characteristics of patients of different ages with diffuse sclerosing variant papillary thyroid carcinoma

S.Y. Kim[1], S-M. Kim[2], H.S. Chang[2], Y.S. Lee[3]

[1]Surgery, Ajou University Hospital School of Medicine, Suwon, Republic of Korea; [2]Endocrine Surgery, Gangnam Severance Hospital, Yonsei University College of Medicine, Seoul, Republic of Korea; [3]Department of Surgery, Yonsei University, Seoul, Republic of Korea

Background: Diffuse sclerosing variant of papillary thyroid carcinoma (DSVPTC) is commonly observed in young patients, with a median age at diagnosis in the third decade of life. Further, the risk of recurrence is higher with DSVPTC than with classical papillary thyroid carcinoma (PTC). Therefore, this study aimed to describe the clinicopathological and genetic characteristics of patients of different ages with DSVPTC.

Methods: We retrospectively reviewed 397 patients who underwent thyroidectomy for DSVPTC at the Gangnam Severance Hospital, Yonsei University from January 2005 to December 2017. We selected 41 patients through random sampling by their age group, and examined mutations in 119 genes using next-generation sequencing.

Results: The mean age at diagnosis was 36.7±11.6 years, with the majority of patients (163, 41.1%) in their third decades. DSVPTC was predominant in women (276, 69.5%), compared with men. We observed recurrence in 46 patients (11.6%), with regional nodal recurrence being the most common recurrence site (32 patients, 69.6%). The tumour size increased in younger patients (<20 years: 2.69±1.56, 21—30 years: 1.88±1.30, and 31—40 years: 1.55±0.95), those displaying a plateau in their fourth (1.38±0.85) and fifth (1.29±0.91) decades, and those above 61 years of age (1.63±1.45). The initial presentation of cancer was more aggressive in paediatric patients with a larger size, more common multiplicity, and lateral neck metastasis. V-raf murine sarcoma viral oncogene homolog B1 (BRAF), Kirsten rat sarcoma virus (KRAS), and telomerase reverse transcriptase (TERT) displayed relatively higher mutations, compared with other genes.

Conclusions: DSVPTC displayed different clinical, pathological, and molecular profiles, compared with papillary thyroid carcinoma. BRAF, KRAS, and TERT were the most important genetic mutations, with differences depending on the age.

On behalf of the Spanish Group of Head and Neck Cancer Treatment (TTCC), Madrid, Spain

Background: Molecular alterations (MA) may drive therapeutic approaches, however no data of thyroid carcinoma are available in Spain. We report next-generation sequencing (NGS) and fluorescence in situ hybridization (FISH) results.

Methods: MOLTHY is an observational, retrospective, translational and multidisciplinary study aiming to characterize the MA of advanced radioiodine-refractory (RAI-R) differentiated thyroid carcinoma (DTC) and medullary thyroid carcinomas (MTC) from 12 Spanish referral centers. The primary objective characterizes the MA prevalence, demographic and prognostic characteristics of 150 patients (pts). MA were centrally analyzed by Oncomine focus (NGS), FISH for NTRK1/3 and RET genes, and NTRK by immunohistochemistry (IHC). Efficacy was assessed by objective response rate (ORR); event-free survival (EFS), defined as time to progression, death, or discontinuation due to toxicity; and overall survival (OS).

Results: From Nov 2021 to Feb 2023, 149 pts were included, 106 (71%) DTC and 43 (29%) MTC. The table shows pts characteristics, treatments, and MA. 1st-line systemic therapy (L) had been administered in 76 DTC pts (71.7%): 31.6% ORR (24/76), 18 months (mo) as median (m) EFS (95%CI:13.2-25) and mOS 293mo (95%CI:145.9-NR); and in 32 MTC pts (74.4%): 40.6% ORR (13/32), 41.5mo (16.4-NR) as mEFS with mOS not reached. RET fusions had no significant impact on the efficacy of 1st L in DTC. However, MTC pts carrying RET mutations showed a better 10-year cumulative OS (100%; 95% CI: 100-100) versus RET-naive (57.1%, 24.3-100); p=0.002; Cox). NTRK1/3 fusions didn't show any impact on the efficacy of 1st unmatched-L.

Conclusions: MOLTHY is the first and larger Spanish cohort of RAI-R DTC and MTC. The prevalence of RET fusions, BRAF/RAS/PIK3CA mutations and NTRK fusions in DTC are consistent with reported studies. RET-mutant MTC correlates with better OS, as previous studies have demonstrated with RET M918T carriers. NGS, FISH and IHC comparison is underway.

Table: 2220P

	DTC (106 pts)	MTC (43 pts)
Patients characteristics		
Median Age, years (95% CI)	66 (61-70)	58 (52-66)
Sex, Female (%)	57 (53.8)	17 (39.5)
Metastasis at diagnosis (%)	39 (36.8)	20 (46.5)
Lymph node involvement at first surgery (%)	52 (49.1%)	30 (69.8%)
Associated to inherited MEN2A Syndrome (%)	-	8 (18.6%)
MOLECULAR ALTERATIONS by NGS & FISH (%)		
RET alteration	7 fusions (6.6)	34 mutations (79)
NTRK1 fusion	1 (0.9)	-

[1]Head and Neck Medical Oncology Unit, Molecular Tumor Board, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy; [2]Head and Neck Medical Oncology Unit & Department of Oncology and Hemato-Oncology, University of Milan, Fondazione IRCCS Istituto Nazionale dei Tumori di Milano & University of Milan, Milan, Italy; [3]Department of Advanced Diagnostics, Molecular Tumor Board, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy; [4]Department of Advanced Diagnostics, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy; [5]Head and Neck Medical Oncology Unit, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy; [6]Department of Advanced Diagnostics, Molecular Tumor Board & Department of Oncology and Hemato-Oncology, University of Milan, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy; [7]Medical Oncology Department, Molecular Tumor Board, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy

Background: Standard therapies (ST) for advanced thyroid carcinomas (TC) are heterogeneously available in Europe. In Italy, patients (pts) with 131I-refractory differentiated/poorly differentiated TC (DTC/PDTC) can receive lenvatinib/cabozantinib in $1^{st}/2^{nd}$ line (L), respectively. NTRK/RET/BRAF alterations are mutually exclusive. Targeted therapy (TT) is provided in 1L/2L for NTRK/RET-rearranged TC. BRAF-MEK inhibitors are given in 1L for BRAF-mutant anaplastic TC (ATC), chemotherapy if BRAF wild-type (wt). Immunotherapy (IT) has shown activity in PD-L1 $\geq$ 1 TC. At our Center,

Table: 2221P Cases with AMT

NT accessibility	Drug-Target match actioned	NT performed/ AMT (%)	Best responses	DCR (CR+PR+SD) (%)	Reasons for no treatment (%)
BCT	Selpercatinib-RET	4/7	2SD, 2PR	97	Ongoing ST (24) Active surveillance (24) Worsening Performance Status (21) BCT not available (21) Off-label ICI not available (13) BCT not pursued due to logistics (2.6)
	Entrectinib-NTRK	1/2	PR		
MAP	Dabrafenib/trametinib-BRAF	30/43	1CR, 22PR, 5SD		
	Alpelisib-PIK3CA	1/5	SD		
	Tipifarnib-HRAS	1/1	PR		
OL	PD1 inhibitors-tumor mutational burden $\geq$ 10 mut/Mb (TMB-H)/PD-L1 CPS $\geq$1	7/20	1CR, 3PR, 2SD	86	
Total		**44/78** (56.4)	CR = complete response		
Median PFS (months)		**10.82** (95% CI 6.02-19.21)	PR = partial response SD = stable disease		

pts not eligible/progressing to ST are studied for actionable molecular targets (AMT). Here we explored the accessibility to novel therapies (NT) and the outcomes of pts who received NT.

Methods: DTC/ATC pts candidate for systemic therapy were tested for BRAF by PCR or DNA Next Generation Sequencing (NGS); if BRAF-wt, FISH or RNA NGS were performed for RET/NTRK fusions. Eligible pts could receive NT (TT/IT) in basket clinical trials (BCT), managed access programs (MAP), off-label (OL). Disease control rate (DCR) and tolerability were annotated. Median progression-free survival (mPFS) from start of NT was estimated with Kaplan-Meier method.

Results: From 2019 to 2022, 116 pts (60% female, median age 69 years, 53% DTC, 20% PDTC, 27% ATC) received at least 1 test; 53% were ST-naïve, 47% pretreated $\geq$ 1L. Overall, 50 PCR, 39 FISH, 91 NGS DNA, 49 NGS RNA were performed. Histology specimens aged $\geq$ 5 years led to not-evaluable NGS in 33% vs 6.7% ($p = .0002$). AMTs were found in 70% pts (median 1/pt, range 0-3), 56.4% received NT (Table). DCR for TT/IT was 97%/86%. 27% pts reported G3 toxicities, 21.6% required TT dose reduction.

Conclusions: A high AMT rate (70%) has been achieved by applying our sequential molecular profiling algorithm. For specimens aged $\geq$ 5 years PCR should be preferred over NGS DNA to analyze BRAF gene. The majority of pts received NT in MAPs. PD-L1 test/NGS panels including TMB may further expand the therapeutic options.

2222P Frequent TERT gains in metastatic papillary thyroid carcinoma

S. Gil[1], M. Corraliza[2], N. Feas-Rodriguez[3], J. Herguedas-Sanz[4], J. Fra[5], G.M. García - Rostán[6]

[1]Pathobiology of Cancer, Institute of Molecular Biology and Genetics IBGM, Valladolid, Spain; [2]Physilogy Division, INiBICA - Instituto de Investigacion e Innovacion Biomedica de Cadiz, Cadiz, Spain; [3]Institute of Molecular Biology and Genetics (Ibgm) - Department of Pathology, University of Valladolid - Faculty of Medicine, Valladolid, Spain; [4]Pathobiology of Cancer, University of Valladolid - Faculty of Medicine, Valladolid, Spain; [5]Medical Oncology, Hospital Rio Ortega Valladolid, Valladolid, Spain; [6]Institute of Molecular Biology and Genetics (Ibgm) - Department of Pathology, University of Valladolid, Valladolid, Spain

Background: *TERT* (Chr.5p15) is one of the most relevant biomarkers in thyroid cancer aggressiveness, including metastatic papillary thyroid carcinomas (mPTCs). The TERT promoter mutations (TPM) rate in mPTCs is 45-60%. Chromosomal gains at 5p have also been reported in thyroid cancer, however little is known about the specific prevalence of *TERT* copy number variations (CNV) in mPTCs and its putative role in tumor prognosis.

Methods: By genotyping 38 cases of primary PTCs and matched distant (DM) and/or lymphatic metastases (LNM), we sought to determine the prevalence of TPM and CNV, their coexistence, and their association with other driver mutational events in thyroid cancers. 114 areas were analyzed to tackle the contribution of intratumoral heterogeneity (ITGH) and clonal evolution to metastases. Mutational analysis was approached through PCR-SSCP or direct sequencing. Ligation-dependent probe amplification was used to assess *TERT* CNV.

Results: *TERT* was altered in 37 cases. Gains were more common than TPM (94,6% vs 45,9%). Both features coexisted in 40,5% of the cases. The study of ITGH evidenced that 66,6% and 20% of the cases bearing both, TPM + CNV, were concurrently mutated at *BRAF* and *RAS* respectively. The coexistence of both events or TPM alone correlated significantly with the stage at diagnosis (dx) and stage at follow-up (Fup), patient status (DOD, AWD, NED), age $\geq$ 55, and sex or showed a trend of correlation with LNM at Fup. TPM were as well significantly associated with LNM at dx and tumor recurrences, revealing a trend for an association with vascular invasion, DM, and DM at Fup too. CNV were more frequently clonal than TPM (85,7% vs 52,9%).

Conclusions: The prevalence of *TERT* gains in mPTCs is strikingly higher than in other cohorts of nonaggressive PTCs, such as TCGA. *TERT* gains tend to be more clonal than TPM. TERT CNVs seemingly represent an earlier event than TPM in mPTC. The coexistence of both events strengthens the association of TPM with poor prognostic features and tumor aggressiveness.

2223P Next-generation sequencing enables identification of RET rearrangements in papillary thyroid cancer

S. Clavé[1], M. Sese[2], R. Somoza[2], M. Arumí[3], C. Iglesias[2], J. Hernando[4], A. Garcia Alvarez[4], B. Lloveras[3], M. Guix Arnau[5], J. Capdevila Castillon[4], B. Bellosillo Paricio[1], J. Hernandez-Losa[2]

[1]Molecular Biology Laboratory, Hospital del Mar - Parc de Salut Mar, Barcelona, Spain; [2]Pathology Department, Hospital Universitari Vall d'Hebron, Barcelona, Spain; [3]Pathology Department, Hospital del Mar - Parc de Salut Mar, Barcelona, Spain; [4]Medical Oncology Department, Hospital Universitari Vall d'Hebron, Barcelona, Spain; [5]Medical Oncology Department, Hospital del Mar - Parc de Salut Mar, Barcelona, Spain

Background: *RET* rearrangements have emerged as a new actionable alteration in papillary thyroid cancers (PTC). These fusions may involve many partner genes, are thought to be mutually exclusive with other oncogenic drivers and their screening is recommended based on fluorescence in situ hybridization (FISH), RT-PCR or next-generation sequencing (NGS). The aim of this study is to evaluate the use of NGS as a standard molecular technique to characterize *RET* gene fusions.

Methods: Sixty PTC cases without the *BRAF* p.V600E and/or *TERT* promoter mutations were selected retrospectively in two institutions. Molecular alterations were evaluated using the Oncomine Focus Assay, and all samples were analyzed by RT-PCR using the Idylla GeneFusion Assay. Fusion positive samples were confirmed with FISH with break-apart probes.

Results: All DNA samples were acceptable for analysis, whereas 4 RNA samples failed quality control NGS parameters. *RET* fusions were detected in 11 cases (18%): *CCDC6*::*RET* (C1:R12) in 8 samples, *NCOA4*::*RET* (N6:R12) in 2 samples, and 1 *RET* expression imbalance positive sample without gene partner characterization. All 11 cases were validated by both FISH and RT-PCR. Besides, 4 more cases presented NGS

RET expression imbalance but none of them were confirmed neither by RT-PCR nor by FISH and considered false positive results. There were no false negative NGS cases identified in parallel by RT-PCR. Overall, a positive predictive value of 89% and a negative predictive value of 90% were estimated, reaching a concordance of 89% compared to NGS. Regarding DNA analysis, *NRAS* p.Q61R/K was the most prevalent alteration in 13 cases (22%) followed by 2 cases with *KRAS* mutations (p.G12S and p.Q61R). Other potentially actionable fusions found in our series were 2 *ETV6*::*NTRK3* (E4:N14), 2 *STRN*::*ALK* (S3:A20) and 1 *EML4*::*ALK* (E6:A20).

Conclusions: Molecular screening in non-*BRAF* PTC patients is useful to identify patients harboring *RET* fusions who may benefit from targeted therapies. As other potentially actionable gene fusions are also found in these patients, routine implementation of NGS analysis warrants a comprehensive biomarker study.

2224P Identifying prognostic factors in patients with radioiodine-refractory differentiated thyroid carcinoma (RR-DTC) treated with tyrosine kinase inhibitors (TKI): Data from REGETNE registry

M.V. San Roman Gil[1], J. Hernando[2], A.R. Granados[1], A. Carmona[2], G. Marquina Ospina[3], M.R. Bella[4], B. Castelo[5], S.E. Campos Ramirez[6], J. Molina Cerrillo[1], I. Ruz-Caracuel[7], P. Valderrabano[8], P. Luengo Pierrard[9], M. Roca Herrera[2], A. Garcia Alvarez[2], J. Pozas Perez[1], C. Gonzalez Merino[1], T. Alonso Gordoa[1], J. Capdevila Castillon[2]

[1]Medical Oncology Department, Hospital Universitario Ramón y Cajal, Instituto Ramón y Cajal de Investigación Sanitaria (IRYCIS), Madrid, Spain; [2]Medical Oncology Department, Hospital Universitario Vall d'Hebron, Vall d'Hebron Institut of Oncology (VHIO), Barcelona, Spain; [3]Medical Oncology Department, Hospital Clinico Universitario San Carlos, IdISSC, UCM, Madrid, Spain; [4]Pathology Department, Hospital Universitario Parc Taulí, Sabadell, Spain; [5]Medical Oncology Department, Hospital Universitario La Paz, Madrid, Spain; [6]Medical Oncology Department, HospItal Universitario Miguel Servet, Zaragoza, Spain; [7]Pathology, Hospital Universitario Ramon y Cajal, Instituto Ramón y Cajal de Investigación Sanitaria (IRYCIS), CIBERONC, Madrid, Spain; [8]Endocrinology and Nutrition Department, Hospital Universitario Ramon y Cajal, Madrid, Spain; [9]Surgical Oncology Department, Hospital Universitario Ramon y Cajal, Madrid, Spain

Background: Approximately 50% of metastatic DTC will become RR, with a substantial impact on its prognosis, when we can either initiate treatment with TKI or establish a watch-and-wait strategy. We aim to evaluate the influence of basal clinical factors in OS and OS since starting TKI (OS-TKI).

Methods: We retrospectively analysed data from 109 patients diagnosed with RR-DTC between 2006 and 2022 treated with TKI included in the REGETNE registry. A descriptive (Table) and statistical analysis of the clinical and histological variables and their association with OS and OS-TKI was performed. Follow-up data were gathered until April 2023.

Results: Median OS and OS-TKI were 138 months (m) and 45m, respectively. Most of our patients had papillary carcinoma (56%). Molecular analysis was available in 67 patients (61.5%), being BRAF V600E the most common molecular alteration identified (25.7%). Patients with poorly differentiated (PD) histology had a significantly poorer OS compared to patients with other histologies (61m vs 153m [papillary, p=0.001] vs 127m [follicular, p=0.01) vs 215m [oncocytic, p=0.03]. The presence of bone metastases (n=34) significantly reduced OS (147m vs 81m, HR 2.08, p=0.007) whilst brain metastases (n=3) influenced OS-TKI (48m vs 21m, HR 4,14, p=0.019). By establishing the RR cut-off point before 24m a significant impact on OS was observed (154m vs 99m, HR 2,03, p=0.016).

Conclusions: Our results suggest that PD histology, the presence of bone metastases and RR≤24m significantly reduce OS and, therefore, these patients could benefit from a closer follow-up and early start of TKI. The development of brain lesions influences OS-TKI and a molecular study of this subgroup of patients could offer a more efficient therapeutic alternative.

2225P FOX1 (rs965513), NKX2-1 (rs944289) and BRAF (V600E) gene mutations and their role in development of papillary thyroid cancer

D. Katalinic[1], I. Aleric[1], A. Vcev[1], L. Toetome[2]

[1]Department of Clinical Medicine, Josip Juraj Strossmayer University of Osijek - Faculty for Dental Medicine and Health and Faculty of Medicine, Osijek, Croatia; [2]Department of Medical Genetics, Center for Cancer Medicine, Oslo, Norway

Background: Transcription factors play a critical role in tissue homeostasis and development and can also have roles in carcinogenesis. The aim of the study was to perform the genomyc analysis of the Forkhead box protein E1 gene (*FOXE1*) and NK2 homeobox 1 gene (*NKX2-1*) mutations in patients with Papillary thyroid cancer (PTC) and healthy control group as well as to compare the obtained results with clinical findings.

Methods: The study included 112 patients diagnosed with PTC (classical, tall cell and follicular variant) (aged 41-74 years) as well as 124 healthy controls (aged 29-80 years). Mutations of the *FOX1* gene (*rs965513*) and *NKX2-1* gene (*rs944289*) were detected using Real-time polymerase chain reaction method. Diagnosis of PTC was confirmed with cyto/histopathological examination.

Results: The genomyc analysis for *FOX1* (*rs965513*) showed that the genotypes "*AA*," "*AG*," and minor allele "*A*" were more frequent in patients with PTC than in healthy control group (PTC *p(genotype)*=0.00071; *p(allele)*=0.004 vs. PTC *p(genotype)*=0.23; *p(allele)*=0.03). A further subsequent analysis of the PTC patients stratified for primary tumor stage (T1-T4), the absence/ presence of regional lymph node metastases (N0/N1) as well for distant metastases (M0/M1), showed an association of *FOX1* (*rs965513*) with stages T1-T3 and N1. We could not find an association between the the *NKX2-1* gene mutational status (*rs944289)* and the development of PTC. Additional analysis based on the *BRAF* mutational status showed strong correlation of FOX1 (*rs965513)* with *BRAFV600E(+)* cases (p=0.0001), but not with *BRAFV600E(-)* cases (p=0.123). For NKX2-1 (*rs944289)*, both subgroups showed no correlation (p=0.04987 for *BRAFV600E*(+) cases; p=0.0463 for *BRAFV600E*(-) cases).

Conclusions: The results of our study show that the *FOXE1* (*rs965513*) carry an increased risk for PTC development, particularly allele "*A*" and the genotypes "*AA*" and "*AG*" as well as developing of advanced PTC, which may reflect the course of a more aggressive disease. The *NKX2-1* (*rs944289*) appears to play a non significant role in development of PTC.

2226P Survival benefit of radioiodine therapy (RAI) in papillary thyroid cancer variants (PTCV): A SEER analysis

S.A. Alshwayyat[1], W.A. Asha[2], T.A. Alshwayyat[3], M. Alshwayyat[3]

[1]Medicine School, JUST - Jordan University of Science and Technology, Irbid, Jordan; [2]Radiation Oncology, KHCC - King Hussein Cancer Center, Amman, Jordan; [3]Faculty of Medicine, JUST - Jordan University of Science and Technology, Irbid, Jordan

Background: Although RAI is widely used in the treatment of thyroid cancers at various stages, its effect on PTCV remains debatable. Therefore, we conducted this study to evaluate the efficacy of RAI on overall survival (OS) and cancer-specific survival (CSS) in patients with PTCV without distant metastasis.

Methods: Data between 2000 and 2018 were obtained from the National Cancer Institute Surveillance, Epidemiology, and End Results (SEER) database. This study included two histological types of PTCV, Hürthle and columnar. Patients with distant metastasis, tumor size greater than 20 cm, previous or concurrent malignancies, receiving chemotherapy, or any type of radiation other than RAI were excluded. Only patients who underwent total thyroidectomy as surgical procedure were included. Chi-square tests were used to compare clinicopathological features, while the Kaplan-Meier estimator, log-rank tests, and Cox proportional hazard regression were used to identify survival rates and prognostic factors.

Results: 1370 patients were included, with 917(66.9%) received RAI and 453 (33.1%) did not. Most of the patients were female (76.9%), aged 45 years or older (60.1%), and white (n=1140). Tumor sizes ranged from 1-4 cm for 71.2% of patients. The average tumor size was 2 cm. 58.7% had extrathyroidal extension. Patients with RAI had a higher 5-year OS rate of 96.6% compared to 94.4%. Both groups had a 5-year CSS rate of 97.7%. No significant differences were found in OS or CSS between the groups ($P<0.15$ and $P<0.42$, respectively). Old age and tumor size greater than 4 cm were poor prognostic factors for OS and CSS, whereas male sex was only associated with poor OS. In the unadjusted analysis, RAI did not significantly affect OS or CSS. However, after adjusting for other variables, RAI improved OS (HR = 0.61, 95% CI: 0.37-0.99) but did not have a significant effect on CSS (HR = 1.05, 95% CI: 0.46-2.4).

Conclusions: Our results showed that RAI administration was associated with improved long-term OS, after adjusting for other variables. However, RAI was not associated with any significant difference in CSS. This study is the first to examine the two histological types of PTCV using a large sample size. A randomized trial is needed to confirm the efficacy of RAI in PTCV treatment.

2227P The efficacy and safety of lenvatinib in neoadjuvant therapy in patients with locally advanced thyroid cancer: A single-arm phase II clinical trial

J. Yu, Y. Wu

Head and Neck Surgery, Clinical Oncology School of Fujian Medical University & Fujian Cancer Hospital, Fuzhou, China

Background: Surgical resection is the cornerstone of treatment for thyroid cancer. However, some patients present with locally advanced disease at first diagnosis, and they are not eligible for radical resection. Meanwhile, neoadjuvant therapy is a treatment option for some patients. Lenvatinib is a multi-target kinase inhibitor exhibiting antiangiogenic activity in cancer therapy, and it has been approved for differentiated thyroid cancer (DTC). This trial evaluated the safety and efficacy of lenvatinib as neoadjuvant therapy in locally advanced DTC (LADTC) (ChiECRCT20210247).

Methods: In this single-arm, phase II trial, patients with LADTC and at least one measurable target lesion received lenvatinib 24 mg once daily for at least 8 weeks. The primary endpoint was the objective response rate (ORR) per RECIST v1.1. Additional endpoints included the disease control rate (DCR), R0/1 resection rate, and safety.

Results: Twelve patients with LADTC received lenvatinib for a median of 8 weeks (range, 4−32 weeks). The ORR and DCR of lenvatinib were 33.3% (95% confidence interval [CI] = 11.3%−64.6%) and 91.7%, respectively. Three patients did not undergo surgery because of tumor progression and their refusal, and R0/1 resection was performed in eight of the nine remaining patients (88.9%). The most common drug-related adverse events (AEs) were hypertension (41.7%), diarrhea (41.7%) and fatigue (33.3%). No major treatment-related perforation events or grade 5 treatment-related AEs occurred.

Conclusions: Despite a relatively high R0/1 resection rate and acceptable safety, the response of lenvatinib is not yet acceptable in the neoadjuvant treatment. Further studies are warranted to investigate the effect of combination therapies and identify the appropriate patient populations.

Clinical trial identification: ChiECRCT20210247.

2228P Long-term clinical outcomes of Lenvatinib in patients with differentiated thyroid cancer: Results from the real-world practice of a single institution

R. Onaga, T. Enokida, S. Okano, T. Fujisawa, H. Tanaka, N. Takeshita, N. Tanaka, Y. Hoshi, M. Tahara

Department of Head and Neck Medical Oncology, National Cancer Center Hospital East, Kashiwa, Japan

Background: Lenvatinib is the preferred drug for locally recurrent or metastatic progressive radioiodine-refractory differentiated thyroid cancer (RR-DTC) based on the results of the SELECT trial (NCT01321554); however, there are few reports on long-term outcomes. The current study aimed to evaluate the long-term clinical outcomes of lenvatinib in RR-DTC.

Methods: We retrospectively reviewed the medical records of 91 patients with RR-DTC who received lenvatinib from September 2011 to November 2022 at National Cancer Center Hospital East. The cut-off date was December 31, 2022. All patients started lenvatinib at a dose of 24mg/day. Planned drug holidays were allowed to avoid severe or intolerable toxicities. Further, dose escalations were allowed after disease progression.

Results: All patients had a performance status of 0 or 1, and the median age was 70 years (range: 42-84) at the initiation of lenvatinib. Histological subtype included papillary carcinoma (64.8%), then follicular carcinoma (24.2%), and poorly differentiated carcinoma (11.0%). The objective response rate and the clinical benefit (complete response, partial response, and durable stable disease defined as the status of stable disease persisting for at least 23 weeks) rate were 58.2% (95% confidence interval [CI]: 47.4-68.5%) and 83.5% (95% CI: 74.3-90.5%), respectively. With a median follow-up time of 2.3 years (range, 0.02-11.2 years) as of the cut-off date, 34 patients (37.4%) were under lenvatinib treatment. The median progression-free survival (PFS) was 3.1 years (95% CI: 1.70-4.00) with a 2-year PFS of 55.0% (95% CI, 43.0-65.5), and the median overall survival (OS) was 5.1 years (95% CI: 3.21-6.66) with a 2-year OS of 79.9 % (95% CI, 69.1-87.2). Ten (11.0%) patients experienced permanent treatment discontinuations due to AE; most common included mucosal perforation (n=3, 3.2%), while no treatment death was seen.

Conclusions: Long-term follow-up in the real world, for the first time, revealed that lenvatinib provides a reliable clinical outcome, represented by long-lasting disease stabilization with a favorable safety profile in RR-DTC.

Background: Selpercatinib, a first-in-class highly selective and potent RET kinase inhibitor with CNS activity, is approved in multiple countries for the treatment of *RET*-mutant MTC and *RET* fusion-positive thyroid and lung cancers.

Methods: Updated analysis of selpercatinib in pts with *RET* fusion-positive thyroid cancer (TC), in LIBRETTO-001 (NCT03157128) was conducted after additional follow up (f/u) of 19 months. Primary endpoint was objective response rate (ORR, RECIST

1.1) by independent review committee (IRC). Secondary endpoints included duration of response (DoR), progression free survival (PFS), and safety.

Results: Efficacy of selpercatinib after RAI (where RAI appropriate) was evaluated in systemic treatment-naïve pts (N=24) and pre-treated pts (N=41) (Table). Naïve and pre-treated pts achieved an ORR of 95.8% and 85.4%, respectively (Table). For pre-treated pts DoR was 26.7 months and PFS was 27.4 months. DoR and PFS data for treatment-naïve pts are still immature approaching and at 2 years, with response ongoing in most pts. At 2 yrs, 95.2% of naïve pts and 57.1% of pre-treated pts remained progression free. In the safety population (N=66), the most common ≥3 grade treatment-emergent adverse events (TEAEs) were: hypertension (15.2%), hyponatraemia (10.6%), diarrhea (7.6%), lymphopenia (7.6%) and increased alanine aminotransferase (6.1%). Two pts (3.0%) discontinued treatment due to TEAEs; 1 pt (1.5%) of these was considered related.

Table: 2229P

	Treatment naïve (N=24)	Prior treatment (N=41)
ORR by IRC, % (95% CI)	95.8% (78.9, 99.9)	85.4% (70.8, 94.4)
Complete response, n (%)	5 (20.8)	5 (12.2)
Partial response, n (%)	18 (75.0)	30 (73.2)
Stable disease, n (%)	1 (4.2)	6 (14.6)
Progressive disease, n (%)	0 (0.0)	0 (0.0)
Not evaluable (NE), n (%)	0 (0.0)	0 (0.0)
PFS by IRC		
Median PFS, months (95% CI)	NE (44.2, NE)	27.4 (14.5, NE)
Censored, %	21 (87.5)	24 (58.5)
PFS rate at 24 months, % (95% CI)	95.2 (70.7, 99.3)	57.1 (38.6, 71.8)
Median f/u, month	24.9	30.4
DoR by IRC		
Median DoR, months (95% CI)	NE (42.8, NE)	26.7 (12.1, NE)
Censored, %	21 (91.3)	20 (57.1)
DoR rate at 24 months, % (95% CI)	90.9 (50.8, 98.7)	50.7 (30.4, 67.8)
Median f/u, months	17.8	33.9

NE; Not estimated.

Conclusions: With longer f/u and additional pts, selpercatinib continues to demonstrate very durable responses in pts with *RET*-fusion thyroid cancer with or without prior therapy, suggesting use of selpercatinib as first systemic therapy appears to be highly effective in treatment of TC. The safety remained tolerable despite longer duration on treatment.

Clinical trial identification: NCT03157128.

Background: Despite advancements in cancer genomics, the contribution of intronic somatic mutations to cancer development and progression remains to be fully established. Here we systematically investigated the functional significance of intronic variants in a pan-cancer cohort with >30,000 tumor/normal samples subjected to an FDA-authorized multi-gene assay.

Methods: Patients who underwent tumor and matched normal sequencing by MSK-IMPACT from 2014 to Sept 2021 were included. We first defined histology-specific gene enrichments incorporating pathogenic somatic variants (PVs). Similar analyses consisting exclusively of non-coding variants (NCVs) were subsequently performed. The rates of concordance between NCV and PV-based gene-histology enrichment as a function of tumor suppressor (TSGs) vs. oncogene (OG) status were investigated. We defined the patterns of mutual exclusivity and co-occurrence between PVs and NCVs, as well as loss of heterozygosity (LOH) status of TSGs affected by these variants.

Results: We analyzed 33,106 tumors from 25,418 patients across 22 cancer types. NCVs were enriched in specific cancer types, matching the enrichment of PVs. NCVs significantly affected cases with no PV identified in the known driver gene: *CDH*1 in 14% of invasive lobular carcinomas (ILC) (OR 109.7 [26.5 − inf], $p < 0.001$), *APC* in 87% of colorectal cancers (CRC) (OR 197.23 [123.7 − inf], $p < 0.001$), and *RB1* in 9% of small cell lung cancer (SCLC) (OR 32.3 [15.06 − inf], $p < 0.001$) with no PV identified in the known driver gene. NCVs in TSGs followed lineage-specific patterns vs. OGs (OR 5.5 [1.6-29.6], $p < 0.001$) and vs. genes not enriched in the PV analysis (OR 9.5 [5.0 − 18.2], p= 2.87 e-12). NCV in TSGs occurred in tumors with mono-allelic loss of the TSG: 100.0% of *CDH1* in ILC ($p < 0.001$), 87.3% of *APC* in CRC ($p < 0.001$), and 100.0% of *RB1* in SCLC ($p = < 0.001$). Immunohistochemistry of select cases with NCVs in *RB1, CDH1*, and other select TSGs showed loss of protein expression.

Conclusions: We report the frequent detection of intronic variants that are not reported by clinical tumor sequencing assays. Such variants followed expected histology and zygosity patterns, strongly suggesting intronic variants may be consequential and constitute the second hit in a lineage-specific manner.

Background: IMpassion031 showed that neoadjuvant chemotherapy (CT) + atezo significantly increased pathological complete response (pCR) and numerically favoured event-free, disease-free and overall survival (EFS, DFS and OS) vs CT + placebo (Pla) in patients (pts) with eTNBC. This IMpassion031 substudy assessed potential predictive tumour immune biomarkers for atezo clinical benefit.

Methods: Biomarker evaluation was performed on baseline, on-treatment, surgery and disease recurrence matched formalin-fixed, paraffin-embedded tumour tissue samples. Samples were tested for tumour infiltrating lymphocytes (TILs) and with RNA sequencing to derive molecular subtypes (basal-like immune activated [BLIA], basal-like immune suppressed [BLIS], mesenchymal [MES], luminal androgen receptor [LAR]), biological pathways and cellular components (xCELL). Biomarkers were evaluated for their association with pCR, EFS, DFS and OS.

Results: In patients with TIL-low tumours, atezo numerically improved outcomes compared with Pla (ΔpCR =19.4%, EFS hazard ratio [HR] 0.57, DFS HR 0.64 and OS HR 0.31). Atezo had higher pCR than Pla in BLIA (75% vs 54%) and BLIS (54% vs 32%) subtypes but not in LAR (33% vs 33%). While atezo showed improved EFS (HR 0.38) and DFS (HR 0.24) only in pts with BLIA tumours, atezo OS improvement vs Pla was only seen in pts with BLIS tumours (HR 0.17). The LAR subtype had excellent EFS, DFS and OS regardless of treatment, in contrast to a relatively low pCR rate. Biological pathway and cell type analyses indicated that increased proliferation, $\gamma\delta$ T cells and pro-B cells predict atezo pCR benefit, while epithelial-mesenchymal transition, pericytes and stromal biology (e.g. angiogenesis, TGFβ) are linked to lack of atezo pCR benefit. No biological pathway or cell type consistently predicted atezo EFS, DFS or OS benefit. Exposure to CT $\pm$ atezo promoted dynamic changes in molecular subtype, which return to baseline at disease recurrence.

Conclusions: Atezo provides benefit in eTNBC pts with proliferative basal tumours, but is less active in indolent LAR tumours. Atezo improves outcomes in pts with low

TILs, a subgroup with poor prognosis in eTNBC. Further studies are needed to validate these findings.

2233MO CDC7 inhibition constrains lineage plasticity and prevents resistance and neuroendocrine transformation in the lung and prostate

Á. Quintanal-Villalonga[1], S. Zaidi[2], W.R. Karthaus[2], Y.A. Zhan[2], M. Shafer[2], J. Qiu[3], E. de Stanchina[2], M.C. Haffner[4], C.L. Sawyers[2], C.M. Rudin[5]

[1]Molecular Pharmacology/Medicine Dept., MSKCC - Memorial Sloan Kettering Cancer Center, New York, NY, USA; [2]Medicine, MSKCC - Memorial Sloan Kettering Cancer Center, New York, NY, USA; [3]Department of Medicine, MSKCC - Memorial Sloan Kettering Cancer Center, New York, NY, USA; [4]Pathology, Fred Hutchinson Cancer Research Center, Seattle, USA; [5]Thoracic Oncology, MSKCC - Memorial Sloan Kettering Cancer Center, New York, NY, USA

Background: In lung and prostate adenocarcinomas (ADs), neuroendocrine (NE) transformation to small cell carcinoma (SCC) occurs on targeted therapy in up to 14% and 30% of *EGFR*-mutant lung and AR-dependent prostate tumors, respectively. SCCs, occurring *de novo* or after NE transformation, lead to poor prognosis due to the sparse and ineffective treatment options available, based on classic chemotherapy. Thus, the identification of therapeutic targets to (1) prevent NE transformation and (2) to efficiently treat SCCs are unmet clinical needs.

Methods: We performed CRISPR screens to identify therapeutic targets for SCC, which were validated genetically and pharmacologically *in vitro* and *in vivo* in lung and prostate adeno-to-NE transformation models and SCC patient-derived xenografts (PDXs), as well as in isogenic cell lines.

Results: Our screen nominated CDC7, involved in DNA replication, as a therapeutic vulnerability in SCC. Simurosertib, a CDC7 inhibitor in phase II trials, dramatically sensitized an array of chemotherapy-naïve and -resistant SCC PDXs to chemotherapeutic agents used in the first- and second-line settings for these tumors, respectively, without toxicity issues at the concentrations used. Also, we observed CDC7 upregulation in NE-transforming clinical specimens, occurring already in pre-transformation ADs. Consistently, we observed increased CDC7 expression in the lung and prostate AD population at high risk of NE transformation (*TP53/RB1*-mutated), and that double *TP53/RB1* knock out induces not only high CDC7 expression in lung and prostate AD cell lines, but also increased sensitivity to simurosertib. Importantly, simurosertib was able to suppress the acquisition of a NE phenotype and dramatically delay tumor relapse in an array of lung and prostate patient-derived models of NE transformation treated with targeted therapy.

Conclusions: CDC7 inhibition prevents NE transformation in lung and prostate AD, and exquisitely sensitizes NE-transformed or *de novo* SCCs to chemotherapy. The availability of CDC7 inhibitors currently under clinical testing will allow immediate translation of these results in two settings with extremely limited and rather ineffective therapeutic options available.

2234P Local immune-related adverse events (irAEs) are more common in tumor-bearing organs

S.M. Blum[1], B. Ouyang[2], L. Zubiri[1], D. Leonard[2], J. Barth[3], D.A. Zlotoff[4], N.P. Smith[5], D.P. Lawrence[1], D. Juric[1], J.R. Stone[3], M. Dougan[6], A-C. Villani[5], K.L. Reynolds[1], M. Mino-Kenudson[3], R.J. Sullivan[1]

[1]Medical Oncology, MGH - Massachusetts General Hospital, Boston, MA, USA; [2]Medicine, MGH - Massachusetts General Hospital, Boston, MA, USA; [3]Pathology, MGH - Massachusetts General Hospital, Boston, MA, USA; [4]Cardiology, MGH - Massachusetts General Hospital, Boston, MA, USA; [5]Center for Immunology and Inflammatory Diseases, MGH - Massachusetts General Hospital, Boston, MA, USA; [6]Gastroenterology, MGH - Massachusetts General Hospital, Boston, MA, USA

Background: Immune checkpoint inhibitors (ICIs) can induce dramatic anti-tumor immune responses as well as significant immune-related adverse events (irAEs). While the drivers of irAEs are poorly understood, we hypothesized that inflammation against infiltrating tumor cells could result in local inflammation or a break in immune tolerance that drive a subset of irAEs in the infiltrated organ.

Methods: The medical records of cancer patients admitted to the Massachusetts General Hospital with concern for an irAE from Feb 2011 - Nov 2021 were reviewed for radiographic evidence of metastatic or primary tumors in the liver and/or lungs and a diagnosis of irHepatitis and/or irPneumonitis during admission. Cases with radiation to the irAE organ in the prior year were excluded. Multivariable analysis using logistic regression was used to obtain the odds ratios of irAEs in tumor-bearing

organs. Pathology specimens of irAE tissues were reviewed for histologic evidence of tumor cells.

Results: 384 hospitalized patients were identified (irHepatitis n=41, irPneumonitis n=30) (Table 2234P). Tumor-bearing liver was associated with irHepatitis (OR 2.4, 95% CI [1.2, 4.7], p = 0.011), even after considering only biopsy-proven cases of irHepatitis (n = 34, OR 2.6, 95% CI [1.2, 5.4], p = 0.0093). Tumor-bearing lungs were also associated with irPneumonitis (OR 2.6, 95% CI [1.1-6.6], p = 0.034). Both associations remained significant after adjusting for dual ICI use. Four cases from patients with irAEs further identified histological evidence of radiographically occult metastases in organs with irAEs. T-cell receptor sequencing of irAEs in tumor-bearing organs will be used to further define immunologic features of these irAEs.

Table: 2234P Patients with tumor-bearing organs and irAEs

Tumor-bearing liver	irHepatitis		
	-	+	Total
-	271	25	296
+	72	16	88
Total	343	41	384
Tumor-bearing lung	irPneumonitis		
	-	+	Total
-	152	7	159
+	194	23	217
Total	346	30	376*
	*8 cases were excluded due to recent lung irradiation		

Conclusions: In a pan-cancer cohort, radiographic evidence of tumor infiltration in the lung or liver is a risk factor for the development of irAEs in that same organ. Tumor infiltration may increase the risk for developing an irAEs in that organ, and these cases may have distinct molecular and clinical features.

Background: Molecular alterations generated by DNA repair deficiencies and DNA damaging agents can be detected by the host immune system and this can restrict cancer growth. We have previously reported that temozolomide (TMZ) is able to induce MMR defects and hypermutability leading to immunotherapy clinical benefit in the subset of CRCs characterized by inactivation of O6-methylguanine methyltransferase (MGMT). We reasoned that combination of chemotherapeutic agents could similarly impair DNA repair function, increase genomic diversity and trigger cancer immunogenicity in the larger group of MMR proficient (MMRp)/MGMT wild type (MGMTwt) CRCs.

Methods: We studied the impact of commonly used cytotoxic agents such as 5-fluorouracil, irinotecan, oxaliplatin, cisplatin (CDDP) and TMZ on the immunogenomic features of CRC cells. We performed a two-step experiment: first, murine CRC models were exposed to chemotherapy agents used alone or in combination in a pulsatile schedule in order to mimic drug exposure in the clinical setting (priming phase) and then injected in immune-deficient and -proficient mice (editing phase). Whole exome sequencing (WES) was performed at baseline and after both the priming and the editing phases to identify mutational signatures, neoantigen prediction and immunoediting.

Results: We found that combinatorial treatment of MMRp /MGMTwt CRC cells with CDDP and TMZ causes impairment of MMR and hypermutability, eventually leading to tumor rejection in syngeneic mice. The majority of mutations caused by CDDP-TMZ are edited by the immune system and, importantly, mice that had successfully rejected cells treated with CDDP-TMZ are vaccinated against their untreated counterpart. The same effect is not observed when CDDP and TMZ are given as monotherapy or when CRC cells are primed with the 5-fluorouracil-oxaliplatin-irinotecan (FOLFOXIRI) triplet.

Conclusions: These results indicate that rational combinations of commonly used cytotoxic agents can be exploited to promote cancer cell hypermutability and immunogenicity, and have implications in the design of new chemo-immunotherapy approaches in CRC.

Background: ICIs have transformed the prognosis of MM, but our understanding of mechanisms of response and resistance remains incomplete. The 100,000 Genomes Project presents a melanoma cohort with whole genome sequencing (WGS) and detailed clinical annotation.

Methods: 97 patients received ICIs in the 1L metastatic disease setting; ipilimumab-nivolumab (60%), anti-PD-1 monotherapy (32%), and ipilimumab (8%). Response rate was 45%. Median follow-up was 30.6 months, median time to treatment failure (TTF) 9.6 months and median overall survival (OS) not reached. From WGS, neoantigen

calling, CNA and tumour purity analyses were performed, predictive variables were included in logistic regression.

Results: Incorporating MHC-II neoantigen load, CNAs and tumour purity, our multivariate model predicted response with AUC 0.86 Responders were associated with a higher number of predicted clonal neoantigens (p=0.0029), driven by MHC-II neoantigens (p=2e-04), and were more statistically significant biomarkers than TMB (p=0.016). A higher total neoantigen burden (p=0.02) and MHC-II neoantigen burden (p=0.06), but not higher TMB, were associated with superior OS. Independently, low tumour purity was associated with response (p=0.005) and superior OS (p=0.04) Non-responders harboured CNAs in key melanoma driver genes, including *CDKN2A* loss of function (p=0.04), and *TERT* gain (p=0.03) which was associated with inferior TTF (p=0.02) Genomic imprinting has established links to cancer pathogenesis, most notably at 11p15.5. In our cohort, loss of heterozygosity (LOH) at 11p.15.5 was associated with response (p=0.007), superior TTF (p=0.05), and higher MHC-II neoantigen load (p=0.04), while non-LOH loss at the same loci was associated with non-response (p=0.003), inferior TTF (p=0.007) and OS (p=0.02), highlighting that different classes of loss can lead to opposing biological sequelae. LOH with loss of the active allele and persistence of the imprinted allele will lead to non-expression of the oncogene. External validation with matched WGS and RNA will be presented at the conference.

Conclusions: In our cohort, 1L ICI response in melanoma was driven by MHC-II neoantigens, CNAs and tumour purity.

2237P Avelumab (AVE), cetuximab (CET) and irinotecan (IRI) for treatment refractory microsatellite stable (MSS) metastatic colorectal cancer (mCRC): Translational analyses of the AVETUXIRI phase II trial

N. Huyghe[1], E. Benidovskaya[1], T. Masoodi[2], J. Carrasco[3], A. De Cuyper[4], I. Sinapi[3], F. Vempalli[2], E. Verstraelen[5], P. Goffette[5], B. Ghaye[5], M. Papier[3], D. Bedognetti[2], A. van Maanen[5], M-L. Castella[5], J. Galon[6], M. van den Eynde[4]

[1]IREC MIRO ONCO, UCLouvain - Université Catholique de Louvain, Woluwe-Saint-Lambert, Belgium; [2]Sidra Medical and Research Center, Al-Rayyan, Qatar; [3]Medical Oncology Department, GHdC - Grand Hopital de Charleroi - Site Notre Dame, Charleroi, Belgium; [4]Digestive Oncology Department, Cliniques Universitaires Saint-Luc (UCLouvain Saint-Luc), Woluwe-Saint-Lambert, Belgium; [5]Saint Luc, Institut Roi Albert II - Cliniques Universitaires St-Luc, Brussels, Belgium; [6]Cordeliers Research Center, INSERM Team 15, Laboratory of Integrative Cancer Immunology, Paris, France

Background: This trial explores the clinical efficacy and safety of AVE, CET and IRI for treatment refractory MSS mCRC. We aim at characterizing the immune response for biomarker discovery through associated translational research.

Methods: MSS, chemorefractory (anti-EGFR refractory if RAS wt) mCRC patients (pts) were enrolled (RAS wt: 28 pts, RAS mut: 27 pts) and treated with CET and IRI from week 1(W1) and AVE from W3. Clinical objectives (safety, tumor response, disease control rate (DCR), PFS and OS) were presented separately. Exploratory endpoints include predictive efficacy biomarkers (immunoscore (IS), immune tumor microenvironment, gene expression profile (GEP), ctDNA) and modification overtime. Multiplex immunofluorescence (MIF), RNAseq and ctDNA analyses were done (sequential metastasis biopsies and plasma samples at W0, W3, W11). CD3, CD8, CD45RO, PD1, PD-L1cells densities were quantified. RNA-seq data were used to perform several analyses (DESeq2, GSEA, deconvolution, gene ontology). OncoSELECT panel (58 genes) was used to follow ctDNA variation over time (mean variant allele frequency).

Results: Among 55 treated pts, 95 biopsies (W0: 39, W3: 29, W11: 27) were available for MIF (table: W0 results). On 23 pts (1st stage), upregulation of adaptive immune response signature was associated with tumor shrinkage, PFS>6 and OS>12 months (p. adj= 0.00). Few modifications of immune cells and GEP were observed overtime (W0, W3, W11). ctDNA decrease (>10%) was associated with tumor response (p=0.04) and PFS (6.6 vs 3.4 months, p=0.08).

Table: 2237P

Characteristics	IS (CD3/CD8) high	CD3/PD1 high	CD3/CD8/CD45RO/ PD1 high
High/others:pts	10/29	10/29	8/31
RAS-wt/RAS-mut:OR, p-v	1.39, p=0.73	0.82, p=0.99	0.83, p=0.99
Tumor shrinkage: OR, p-v	8.32, p=0.00	4.50, p=0.05	9.54, p=0.00
DCR:OR, p-v	8.02, p=0.05	3.16, p=0.26	5.55, p=0.12
PFS:HR, p-v	0.29, p=0.00	0.28, p=0.00	0.43, p=0.03
OS:HR, p-v	0.62, p=0.19	0.26, p=0.00	0.47, p=0.06

Conclusions: Independently of RAS mutation, existing adaptive immune response within metastases is associated with treatment benefit. ctDNA decrease is associated with tumor response.

Clinical trial identification: NCT03608046.

2238P Tebentafusp reprograms immunosuppressive tumor-associated M2 macrophages towards anti-tumoral M1 macrophages

J.M. Piulats Rodriguez[1], E. Guc[2], A. Treveil[2], P. Nieto[3], A. Camera[2], J. Clubley[2], H. Heyn[3], S. Stanhope[2], L. Collins[2], K. Ranade[2], A. Benlahrech[2]

[1]IDIBELL, Catalan Cancer Institute, Barcelona, Spain; [2]Translational Medicine, Immunocore Limited, Abingdon-on-Thames, UK; [3]CRG - Centre for Genomic Regulation, CNAG-CRG, Barcelona, Spain

Background: Tebentafusp, a gp100-directed ImmTAC bispecific (gp100 x CD3), is the first TCR therapeutic to demonstrate survival benefit and is approved for the treatment of HLA-A*02:01+ adults with unresectable or metastatic uveal melanoma (mUM)[1]. High CD3$^+$ T cell: CD163$^+$ M2 macrophage ratio was associated with therapeutic benefit from tebentafusp despite the immunosuppressive effects of M2 macrophages[2]. Here we explored the effects of ImmTAC-redirected T cell activation on macrophage reprogramming in vitro and in vivo.

Methods: M2 macrophages were generated in vitro from healthy donor monocytes (n=4). Their effect on ImmTAC-mediated T cell activation and redirection against antigen positive HLA-A*02:01+ THP-1 tumor cells was assessed. Gene expression and phenotypic changes were assessed by bulk RNA-seq and flow cytometry. Baseline and on-treatment tumor biopsies from a phase II trial of mUM HLA-A*02:01+ patients treated with tebentafusp (NCT02570308) were used to quantify $CD163^+$ and $CD3^+$ cells by immunohistochemistry (n=112), and to measure gene expression by bulk RNAseq (n=35), and single cell RNAseq (n=1).

Results: In vitro, M2 macrophages inhibited ImmTAC-mediated T cell killing of tumor cells in a dose dependent manner. M2 macrophages were reprogrammed to down-regulate M2 markers (e.g. CD206, CD163) and express M1 markers (e.g. CD40, CD80) in the presence of T cells activated by ImmTAC. This M2 to M1 reprogramming was confirmed by single cell RNAseq of paired biopsies from a tebentafusp-treated patient (55% increase in M1 macrophages 1 year post tebentafusp-treatment). M1 gene signatures[3] were significantly upregulated in on-treatment biopsies (n=35) after 3 doses of tebentafusp (2.2 fold change).

Conclusions: ImmTAC-mediated redirection of T cells reprograms pro-tumoral M2 macrophages towards anti-tumoral M1 macrophages in vitro and in tebentafusp-treated mUM patients. These results demonstrate how tebentafusp re-shapes the tumor microenvironment to enhance the anti-tumor activity of T cells.

Background: The presence of tertiary lymphoid structures (TLS) in the tumor microenvironment (TME) is linked to favorable clinical outcomes and response to immunotherapy in various types of cancer. However, accurately measuring TLS can be difficult. Thus, our aim was to identify genes or gene expression signatures that can effectively indicate TLS abundance in the TME, irrespective of the cancer type.

Methods: Patients (pts) with advanced solid cancer participating in the molecular prescreening of the SOLTI-1904-ACROPOLI study were included. Pathological analysis was performed to determine the presence of tumor infiltrating lymphocytes (TILs) and TLS. On the same FFPE tumor block, gene expression (GE) was evaluated in all pts using a panel of 72 genes. Further GE was analyzed in a subset of 142 pts (n=66 TLS-negative, n=76 TLS+) using a panel of 192 genes, including the HER2DX 14-gene B-cell/IgG (IGG) signature. The association between GE and TLS was analyzed.

Results: 1,003 pts were included across 39 different cancer-types. TLS were successfuly evaluated in 898 pts (89%). TLS were detected in 76 pts (8.5%), mostly in samples from primary tumors (n=63, 83%). Most frequent TLS+ cancer-types were colorectal (n=22), pancreatic (n=13), gastric (n=11) and breast (n=9). Compared to TLS-negative tumors, TILs were significantly higher in TLS+ tumors (median 4% *vs* 18%, $p<0.001$). The presence of TLS was significantly associated with higher expression of genes related to B-cells (*CD19*) and T-cells (*CD4, CD8A*), and lower expression of proliferation genes (*TYMS, CDCA1).* Upon further evaluation of GE, TLS+ tumors had a significant enrichment of genes related to activated B-cells (*CD79A*) and immunoglobulins (*IGJ, IGKC*). Finally, the IgG signature as a continuous variable demonstrated a significant association with TLS presence, independently of the cancer-type and TILs (p=0.002). In IgG-high tumors, the proportion of TLS+ tumors was 61.6% compared to 38.4% TLS-negative (p<0.001)

Conclusions: The B-cell/IGG signature is a GE pattern strongly associated with TLS across cancer types, even independently of TILs. This signature could serve as a valuable tool for precisely measuring TLS and predicting clinical outcomes and response to immunotherapy in cancer patients.

Background: Immune checkpoint inhibitors (ICI) are highly efficacious but ∼ 50% of cancer patients on combination and ∼10% on ICI monotherapy experience ≥ grade 3 immune-related adverse events (irAE). Managing irAEs is challenging and there is a lack of predictive biomarkers. We conducted genome-wide association analyses (GWAS) to identify markers associated with irAEs.

Methods: 599 cancer patients on ICIs were genotyped and genome-wide imputation was performed. Association testing with CTCAE graded irAEs was conducted (0=grade 0-2, 1=grade ≥3 irAE). Markers with $P<5x10^{-6}$ were tested in a validation cohort. A transcriptome-wide association study (TWAS) was also performed.

Results: 72% of the discovery cohort had melanoma, 37% received combination therapy and 31% developed ≥ grade 3 irAE. 8 SNPs were associated with any ≥ grade 3 irAE at $P<5x10^{-6}$ but none replicated at $P<0.05$ (Table 2240P). Of note one, rs35429660, is significantly associated with *ZNF701* expression in monocytes and *ZNF701* was also significant in the TWAS ($P=5.1x10^{-7}$). In an analysis of individual organ irAEs, we identified markers at $P<5x10^{-6}$ in the discovery phase. One, rs77941834, was associated with hepatitis in the validation phase (P=0.04) and expression of *LINC02021* in T cells ($4.6 x10^{-8}$). 11 other SNPs had suggestive evidence of validation. One maps to *MAST3*, linked to inflammatory bowel disease and another maps to *IFI44*, linked to multisystem inflammatory syndrome, viral hepatitis and immune cell infiltration. The *IL7* SNP previously reported as associated with any grade irAE at GWAS significance was nominally significant (P=0.05) in our data.

Table: 2240P Markers associated with any ≥ grade 3 irAE at $P<5x10^{-6}$ in discovery phase

rsID	Toxicity associated allele	Discovery OR (95% CI)	Discovery P-value	Validation OR (95% CI)	Validation P-value	Meta P-value
rs1310844785	TTG	2.5 (1.8-3.6)	8.91×10^{-8}	0.8 (0.6-1.2)	0.26	0.0038
rs7197466	T	2.1 (1.5-2.9)	2.19×10^{-6}	1 (0.8-1.4)	0.81	0.00077
rs35429660	C	2.2 (1.6-3)	5.13×10^{-7}	1.2 (0.8-1.6)	0.36	7.32×10^{-5}
rs1389216733	CA	6.3 (2.6-15.7)	3.07×10^{-6}	1.6 (0.8-3.5)	0.18	0.0004
rs6864863	A	2.1 (1.5-2.9)	3.73×10^{-6}	0.8 (0.6-1)	0.07	0.11
rs4527728	T	2.2 (1.6-3.1)	2.68×10^{-6}	1.2 (0.9-1.6)	0.26	0.00012
rs1208547611	CTT	2.5 (1.7-3.7)	3.59×10^{-6}	1.1 (0.7-1.5)	0.79	0.0015
rs2472135	A	2.1 (1.6-2.8)	5.83×10^{-7}	1.1 (0.8-1.5)	0.43	7.98×10^{-5}

Conclusions: We identified novel variants, including an immune eQTL for *ZNF701,* associated with serious ICI induced irAE. None reached genome-wide significance ($P<5x10^{-8}$). Meta-analysis with other cohorts is required to confirm our results and identify further markers predictive of irAE risk.

Clinical trial identification: IRAS 237779.

2241P A novel 89Zr-anti-PD-1 immuno-PET-CT may predict response to PD-1 inhibitors and improve response assessment in a lung cancer murine model receiving immunotherapy

A. Puyalto[1], M. Rodríguez-Remírez[1], I. López[2], J.A. Simon[3], M. Ecay[3], M. Collantes[3], A. Vilalta[1], A. Francisco-Cruz[4], J.L. Solórzano[5], I. Peñuelas[3], D. Ajona[2], I. Gil Bazo[6]

[1]Dept. Medical Oncology, Clinica Universidad de Navarra, Pamplona, Spain; [2]Program of Solid Tumors, CIMA Universidad de Navarra, Pamplona, Spain; [3]Translational Molecular Imaging Unit, Clinica Universidad de Navarra, Pamplona, Spain; [4]Department of Pathology, National Institute of Cardiology Ignacio Chavez, Mexico City, Mexico; [5]Anatomía Patológica y Diagnóstico Molecular, MD Anderson Cancer Center Madrid, Madrid, Spain; [6]Medical Oncology Department, IVO - Fundación Instituto Valenciano de Oncología, Valencia, Spain

Background: Immune checkpoint inhibitors (ICIs) have revolutionized lung cancer treatment improving survival outcomes of NSCLC patients. Response assessment of patients on immunotherapy represents a challenge since an increase in tumor size or the appearance of new lesions might not reflect true disease progression (P) but pseudoprogression (PP), which has been reported in a range of 3-6% in NSCLC. Conventional FDG-PET scans does not accurately discriminate P from PP. We have recently reported the efficacy of a combined blockade of PD-1 and *Id1* in a NSCLC mouse model. We aimed to evaluate a novel ^{89}Zr-anti-PD-1 immuno-PET-CT to better assess response in a NSCLC murine model.

Methods: Syngeneic subcutaneous tumors were generated using LLC cells (with constitutive expression of *Id1* or *Id1*-silenced) in C57BL6J and in *Id1*-deficient mice, treated with PBS or with a monoclonal antibody against PD-1. Tumor growth and response, was measured by FDG uptake. Additionally, tumor lymphocyte infiltration was measured analyzing ^{89}Zr uptake. Tumor microenvironment was explored with immunohistochemistry, multiplex immunofluorescence and quantification of relative expression of interleukins by RT-PCR.

Results: FDG uptake did not show significant differences between groups, underestimating the real metabolic response induced by the treatment. However, ^{89}Zr-PET-CT showed a significantly higher ^{89}Zruptake when *Id1* was inhibited in both, tumor cells and tumor micro-environment and mice were treated with anti-PD-1

(p=0.0075). The tumor tissues analysis in those animals by immunohistochemistry and multiplex immunofluorescence disclosed an increase in immune $CD8^+$ T cells infiltration, being responsible for the antitumor response observed and correlating with ^{89}Zr signal. Moreover, the analysis of interleukins expression showed an upregulation of tumor pro-inflammatory interleukins.

Conclusions: *Id1* inhibition in tumor cells and in tumor micro-environment combined with PD-1 blockade enhanced immune cell infiltration through pro-inflammatory interleukins upregulation. ^{89}Zr-anti-PD-1 immuno-PET-CT may improve tumor response assessment in a NSCLC murine model receiving immunotherapy.

2242P Engineering immune-cell targeting nanoparticles for precise delivery of loaded-cargo and enhanced immunotherapy efficacy

N.K. Lee[1], W. Park[2], S. KIM[3], C.G. Park[4]

[1]Department of Intelligent Precision Healthcare Convergence, SKKU - Sungkyunkwan University - Natural Sciences Campus, Suwon, Republic of Korea; [2]Integrative Biotechnology, SKKU - Sungkyunkwan University - Natural Sciences Campus, Suwon, Republic of Korea; [3]Department of Industrial Cosmetic Science, Chungbuk National University, Cheongjusi, Republic of Korea; [4]Biomedical Engineering, SKKU - Sungkyunkwan University - Natural Sciences Campus, Suwon, Republic of Korea

Background: In recent years, cancer immunotherapy has gained significant attention for its ability to modulate immune cell functions. However, systemic administration of immunomodulatory agents can lead to side effects and limit drug efficacy. To overcome these challenges, we developed a targeted drug delivery platform using nanoparticles (NPs) made from biomaterials that can target specific immune cells. Our approach aims to increase drug efficacy and alleviate systemic side effects by delivering drugs directly to their intended sites.

Methods: The NPs were prepared using a conventional emulsification method based on Poly(D,L-lactide-co-glycolide)-maleimide. To conjugate anti-mouse NK1.1 and CD8a antibodies (Abs) to the surface of the NPs, the Abs were cleaved into Fc and $F(ab')_2$ fragments by protease. The $F(ab')_2$ fragments were reduced to obtain thiol groups in the hinge region for coupling to the maleimide group on the NPs' surface. The NPs' morphology was confirmed using dynamic light scattering and scanning electron microscopy, while the in vitro and in vivo targeting efficiency was evaluated using fluorescently labeled NPs and flow cytometry.

Results: The NPs were confirmed to be monodisperse, spherical particles with a size of less than 200 nm. Further, in vitro studies showed that when fluorescently labeled and Abs-conjugated NPs were co-incubated with mouse splenocytes, the NPs' fluorescence was confirmed in each immune cell, whereas immune cells with non-conjugated NPs showed no fluorescence. In vivo studies showed that after injecting fluorescently labeled and Abs-conjugated NPs into the tail vein of mice, the fluorescence of the NPs was observed in the immune cells of the blood and spleen. Notably, fluorescence was barely detected in non-target immune cells, indicating the high specificity and targeting efficiency of the NPs.

Conclusions: The findings demonstrate that Abs-conjugated NPs can effectively target specific immune cells both in vitro and in vivo with minimal non-specific binding. This indicates that the developed platform can potentially maximize drug efficacy and minimize systemic side effects by delivering immunotherapeutic agents specifically to certain immune cells.

2243P Immune-modulating magnetic nanoparticles to enhance the immune response for the treatment of breast cancer metastasis and recurrence

J. Lim[1], W. Park[2], S. KIM[3], C.G. Park[4]

[1]Intelligent Precision Healthcare Convergence, SKKU - Sungkyunkwan University - Natural Sciences Campus, Suwon, Republic of Korea; [2]Integrative Biotechnology, SKKU - Sungkyunkwan University - Natural Sciences Campus, Suwon, Republic of Korea; [3]Department of Industrial Cosmetic Science, Chungbuk National University, Cheongjusi, Republic of Korea; [4]Biomedical Engineering, SKKU - Sungkyunkwan University - Natural Sciences Campus, Suwon, Republic of Korea

Background: The immune-suppressive environment in cancer allows for tumor growth, leading to rapid metastases and recurrences. To effectively treat cancer, it is crucial to reverse this cold tumor environment. CpG, a well-known toll-like receptor 9 agonist, promotes dendritic cells (DCs) maturation and stimulates innate and adaptive immunity. In this study, we combined CpG with functional magnetic nanoparticles (FMNPs) to enhance its delivery to naive DCs, resulting in more efficient activation compared to free CpG delivery.

Methods: The heat-up method used to fabricate FMNPs, which were coated with caffeic acid, polydopamine, and polyethylenimine. The electrostatic force was bind CpG to FMNPs (i.e., CpG-FMNPs), and the degree of binding was estimated using a gel retardation assay. The resulting CpG-FMNPs product analyzed physicochemical properties using electron microscopy, dynamic light scattering, zeta potential, thermogravimetric analysis, and Fourier transform infrared spectroscopy measurements. We confirmed cytotoxicity using the L929 cell line and assessed DCs maturation using flow cytometry.

Results: The fabrication process of the FMNPs involved using various surface chemicals, resulting in changes in physicochemical properties at each step. The final product, CpG-FMNPs, had an average size of approximately 150 nm and contained 8% (weight%) of CpG conjugation. When tested, CpG-FMNPs showed high viability of approximately 90% at a concentration of up to 40 μg/ml and up-regulated 1.5∼2 times of surface markers CD80, CD86, CD40, and MHC-2 on DCs compared to free CpG. When administered intratumorally to the 4T1 orthotopic model, CpG-FMNPs showed a regression in tumor growth.

Conclusions: In this study, we produced FMNPs to efficiently deliver CpG to immature dendritic cells. Our results showed that the same dose of CpG delivered by FMNPs effectively activated DCs. The findings suggest that CpG-FMNPs may be capable of effectively activating DCs in the vicinity of the tumor site. However, further studies are needed to investigate their potential in activating cytotoxic T cells.

2244P Anti CTLA-4 and PD-1 monoclonal antibodies increases systemic SDF-1 and galectin-3 levels through NLRP3 and MyD-88 pathways in preclinical models

V. Quagliariello[1], M. Passariello[2], A. Di Mauro[3], I. Bisceglia[4], A. Paccone[5], M. Iovine[5], F. Bruzzese[6], G. Palma[6], F. Florio[1], A. Luciano[6], N. Maurea[1]

Background: Immune checkpoint inhibitors (ICIs) have significantly changed the oncology clinic in recent years, improving survival expectations in cancer patients. ICI therapy have a broad spectrum of side effects from endocrinopathies to cardiovascular diseases. In this study, pro-inflammatory and pro-fibrotic effects of short-term ICIs therapy in preclinical models were analyzed.

Methods: Firstly, in a human in vitro model, human cardiomyocytes co-cultured with hPBMC were exposed to ICIs (with CTLA-4 or PD-1 blocking agents, at 200 nM) for 72h. After treatment, production of DAMPs and 12 cytokines were analyzed in the supernatant through colorimetric and enzymatic assays. C57/Bl6 mice were treated with CTLA-4 or PD-1 blocking agents (15 mg/kg) for 10 days. Before (T0), after three days (T3) and ten days (T10), ejection fraction, radial/longitudinal strain were calculated by using echocardiography. Fibrosis, necrosis, hypertrophy and vascular NF-kB expression were analyzed through Immunohistochemistry. Myocardial expression of DAMPs (S100- Calgranulin, Fibronectin and Galectine-3), MyD88, NLRP3 and twelve cytokines have been analyzed. Systemic levels of SDF-1, IL-1β and IL-6 were analyzed before, during and after ICIs therapy.

Results: Radial and longitudinal strain were decreased after 10 days of ICIs therapy. Histological analysis of NF-kB expression shows that short-term anti-CTLA-4 or anti-

PD-1 treatment increased vascular and myocardial inflammation. Myocardial fibrosis and expression of galectin-3, pro-collagen 1-α and MMP-9 were increased after treatment with all ICIs. Both anti-CTLA-4 or anti-PD-1 treatments increased the expression of DAMPs, NLRP3 and MyD88 and induced both in vitro and in vivo the secretion of IL-1β, TNF-α and IL-6. Systemic levels of SDF-1, IL-1β and IL-6 were increased during and after treatment with ICIs.

Conclusions: Short therapy with PD-1 and CTLA-4 blocking agents increases vascular expression of NF-kB, systemic SDF-1, IL-1β, IL-6 levels and myocardial NLRP3 in preclinical models. The overall picture of the study suggests new putative biomarkers of ICIs-mediated systemic and myocardial damages potentially useful in clinical cardioncology.

2245P Graphene oxide: A promising platform for delivery of cancer immunotherapy

S. Chattrakarn[1], G. Mallett[1], W. Zhang[2], H. Parker[1], K. Kostarelos[3], A. MacDonald[1]

[1]Lydia Becker Institute of Immunology and Inflammation, The University of Manchester, Manchester, UK; [2]Division of Cancer Sciences, The University of Manchester, Manchester, UK; [3]Nanomedicine Lab, Faculty of Biology, Medicine & Health, The University of Manchester, Manchester, UK

Background: Nanomaterials have been proposed as antigen carriers in cancer immunotherapies, to increase target cell uptake and therapeutic efficacy, and reduce off-target toxicity. The 2-dimensional carbon nanomaterial graphene oxide (GO) possesses a large surface area and high peptide loading capacity, as well as being inexpensive and biodegradable. These properties promote the development of GO as a system for antigen loading and delivery in targeted cancer immunotherapy. We have investigated the potential of GO in enhancing immune cell activation and cytotoxicity, including its impact in combination therapy with checkpoint inhibitors.

Methods: GO was combined with ovalbumin (OVA) peptide ($OVA_{257-264}$) and the immununostimulant polyinosinic:polycytidylic acid (Poly (I:C)), a toll-like receptor 3 agonist. We assessed dendritic cell (DC) activation and OVA-specific T cell responses after subcutaneous injection of GO complexes into naïve mice with/without pre-transfer of OVA-specific OT-I $CD8^+$ T cells. We also performed *in vitro* T cell activation assays by co-culturing DCs pre-stimulated with GO complexes with OT-I $CD8^+$ T cells.

Results: GO without Poly (I:C) displayed minimal immunogenic potential. However, GO + Poly (I:C) significantly enhanced immune cell infiltration to the skin injection site by histology. We also found a significant increase in activation and migration of DCs to skin-draining lymph nodes in the mice receiving GO + Poly (I:C) 24 hours after injection. GO + Poly (I:C) also dramatically enhanced T cell expansion and cytotoxic responses in both spleen and draining lymph nodes 7 days after injection of mice that had previously received OT-I $CD8^+$ T cells. Additionally, GO + Poly (I:C) significantly increased programmed death-1 (PD-1) expression on OT-I T cells in DC-OTI T cell co-cultures.

Conclusions: Our data have demonstrated the immunomodulatory potential of GO when complexed with Poly (I:C) by attracting immune cells including DCs to the injection site and boosting antigen-specific T cell cytotoxic responses *in vivo* and *in vitro*. DCs activated with GO complexed with Poly (I:C) increased PD-1 expression on T cells, which may suggest that graphene-based treatment could be beneficial in combination therapy with a checkpoint inhibitor such as anti-PD-1.

Background: Tumor-infiltrating lymphocytes (TILs) are a mixed population of immune cells that infiltrate the tumor microenvironment (TME) and play a crucial role in recognizing and attacking cancer cells. The presence, localization and composition of TILs can be used as a biomarker for predicting clinical outcomes and response to immunotherapy in different types of cancer. Our aim was to investigate the correlation between the presence of TILs and gene expression across multiple cancer types.

Methods: Patients (pts) with advanced solid cancer who participated in the molecular prescreening of the SOLTI-1904-ACROPOLI study (NCT04802876) were included. A pathological analysis was performed to determine the proportion of TILs (%TILs) on a hematoxylin-eosin section. On the same FFPE tumor block, gene expression (GE) was evaluated using a panel of 72 genes, including 10 immune genes (i.e., *CD19*, *CD274*, *CD3*, *CD4*, *CD68*, *CD8*, *CD84*, *CD86*, *CXCL8* and *PDCD1*). An exploratory analysis of the association between TILs and GE was performed.

Results: 1,003 pts were included across 39 different cancer-types. TILs were successfuly evaluated in 922 pts (91.9%). Median (m) %TILs was 5% (IQR: 2-15, range: 0-80). Cancer-types with higher %TILs were duodenal (m=25%, IQR: 20-27.5), head and neck (m=22.5%, IQR: 9-30) and cervical carcinoma (m=20, IQR: 3-35). %TILs was higher in samples from primary tumors when compared to metastatic samples (m=6 vs m=3%, $p<0.001$). Significant differences of %TILs were also seen according to the site of metastasis (M1): m=8% in lymph nodes *vs* m=7.5% en lung M1 *vs* m=3% in liver M1 ($p<0.001$). A quantitative SAM analysis identified 31 genes significantly upregulated in tumors with higher %TILs (FDR<1%). Among the top 10 most upregulated genes, nine were immune (i.e., *CD8*, *PDCD1* and *CD19*) and the remaining one *MYC.* However, correlation between TILs and immune genes was moderate (I,e., coefficient=0.49 between *CD8* and TILs).

Conclusions: Immune genes or signatures may provide additional information not captured by TILs alone. Combining both measures could provide a more comprehensive understanding of the immune response in the TME and help predict response to immunotherapy in cancer patients.

Clinical trial identification: NCT04802876.

2247P Expression of PD-L1 on circulating epithelial tumor cells (CETCs) in men with primary non-metastatic prostate cancer

D. Schott[1], M. Pizon[1], K. Pachmann[1], U. Pachmann[2], M. Mäurer[3]

[1]Research and Development, Laboratory Dr. Pachmann, Bayreuth, Germany; [2]Research and Development, Transfusion Center Bayreuth, Bayreuth, Germany; [3]Jena University Hospital, Friedrich-Schiller, Jena, Germany

Background: Radiotherapy (RT) is an essential component of multimodality therapy in the primary or postoperative treatment of prostate cancer with curative intent by preventing local recurrence and distant metastases, indicating its impact on residual occult tumor, such as circulating tumor cells. Immunogenic changes in cancer cells induced by RT can lead to adaptive up-regulation of PD-L1 expression. As immune checkpoint inhibition plays an increasingly important role in prostate cancer, radiogenic PD-L1 upregulation may be of therapeutic importance. The aim of this study was to determine PD-L1 status on CETCs before and during RT.

Methods: Peripheral blood samples were collected from 52 primary non-metastatic prostate cancer patients. CETCs were enumerated and analyzed for PDL-L1 expression prior to (baseline), 3 and 6 weeks after the start of RT using fluorescence scanning microscopy.

Results: PD-L1 expression was detectable in CETCs and localized in the membrane and/or cytoplasm. We found a correlation between PD-L1 status in CETCs and aggressiveness of cancer disease prior to RT. The frequency of PD-L1 positive CETCs depended on the grading and Gleason score of the primary tumor. Patients with a high Gleason score and G3 tumors had significantly more PD-L1 positive CETCs compared to patients with a low Gleason Score and G1 tumors. Moreover, patients in stage I/II had significantly less PD-L1 positive CETCs compared to patients in stage III/IV (mean 54.25 vs. mean 69.65; $p<0.05$). A higher number of PD-L1 positive CETCs were detected in patients who had radical prostatectomy before start of RT than in those who had no surgical intervention (mean 66.24 vs. mean 47.46; $p<0.01$). Interestingly, the fraction of PD-L1 positive CETCs decreased significantly during RT only in patients with G3 tumors and a high Gleason Score.

Conclusions: Our results indicated that PD-L1 in CETCs is closely related to the aggressiveness of the primary tumor and may be a co-factor associated with the progression of prostate cancer. PD-1/PD-L1 blockade combined with RT represents a novel and promising treatment strategy that could contribute to improve the treatment efficacy of prostate cancer.

Background: The combination of preoperative chemo- and radiotherapy (CRT) is the standard treatment in locally advanced rectal cancer (LARC). The benefit of the addition of immunotherapy in the neoadjuvant treatment is under investigation. However, a wide genomic characterization is needed to better stratify LARC patients (pts) for the most adequate treatment.

Methods: We analysed cancer tissues from 48 pts enrolled in the PANDORA trial (NCT04083365) in which a capecitabine-based concomitant CRT followed by durvalumab was administrated. DNA was extracted from bioptic chemo-naïve formalin-fixed paraffin-embedded samples. Genetic alterations of more than 500 genes, microsatellite instability (MSI) and tumor mutational burden (TMB) status were characterized using TSO500HT panel on an Illumina Novaseq 6000 instrument. PD-L1 expression was evaluated by the combined positive score (CPS). Pathological response was centrally determined on surgical specimens and was evaluable for 46 pts. A pathological complete response (pCR) was defined as ypT0N0M0.

Results: Pathogenic variants on *APC*, *TP53*, *KRAS*, *FBXW7*, *PIK3CA*, *SMAD4*, *AMER1* and *ARID1A* genes were the most frequent mutations. Overall, 17/46 (37%) pts achieved a pCR. Interestingly, *ARID1A* and *SMAD4* alterations occur only in patients without a pCR, being mutated in the 17% and 21% of pts, respectively. In particular, a more significant association was reached for *SMAD4* when either pathogenetic variants and variants of uncertain significance (VUS) were considered (p=0.019). Only 4% and 31% of pts had MSI and high TMB, respectively, but no significant association with response was found. High TMB status was significantly related to *ARID1A*, *FBXW7*, *MYC* and *RICTOR1* mutations. *SMAD4* mutations resulted significantly associated with low levels of PD-L1 expression (p=0.017). Indeed, 75% of the mutated pts as compared to the 27% of the wild type pts reported PD-L1 CPS values less than 10.

Conclusions: *SMAD4* mutations are related to the absence of complete response and to a low PD-L1 expression. *SMAD4* alterations should need further investigation in LARC pts treated by combined CRT followed by durvalumab.

Clinical trial identification: NCT04083365.

2249P Mitigation of tumor microenvironment-mediated immunosuppression using a PD1-41BB switch protein with optimal affinity tcrs for first-in-class, 3rd generation TCR-T therapies

K. Crame[1], G. Longinotti[2], M. Catarinella[2], P. Prinz[2], S. Tippmer[2], K. Mutze[2], A. Coluccio[2], M. Salvermoser[2], J. Bittmann[2], M. Bürdek[2], B. Lösch[2], C. Geiger[2], K. Davari[2], D.J. Schendel[2]

[1]Clinical Development, Medigene AG, Martinsried, Germany; [2]Medigene Immunotherapies GmbH, Medigene AG, Martinsried, Germany

Background: As demonstrated in clinical trials, TCR-T therapies face major challenges to sustain anti-tumor cell function in solid tumor microenvironments (TME); tumor antigen levels and PD-L1 expression strongly influence T cell function. PD-L1 signalling to T cells via the PD-1 receptor limits proliferation, cytokine secretion and killing, while exhaustion is induced by repetitive TCR signalling in the absence of T cell co-stimulation. Both impairments in TCR-T cells can be mitigated by co-expression of an optimal affinity TCR combined with a PD1-41BB costimulatory switch protein (CSP), comprised of the extracellular domain of PD-1 with the intracellular signalling domain of 41 BB (CD137).

Methods: Two first-in-class, 3rd generation TCR-T therapies, MDG1015 and MDG2011, were developed using optimal affinity TCRs specific for a cancer-testis antigen, NY-ESO-1/LAGE-1a, and a neoantigen, mutated KRAS G12V, respectively. Tumor cells with variations in antigen and PD-L1 inform how differences among tumor cells can impact different functions of TCR-T cells in vitro.

Results: CSP mitigation of TCR-T dysfunction was very prominent when PD-L1 was highly expressed and tumor antigen was low, the most challenging TME setting. When antigen and PD-L1 levels were both high, killing remained very strong and the CSP increased poly-cytokine secretion. Proliferation after exposure to tumor cells with high PD-L1 and induction of exhaustion by serial tumor exposure were both well mitigated by CSP co-expression in both TCR-T cell therapies.

Conclusions: The combination of optimal affinity TCRs combined with the PD1-41BB CSP provides strong protection of TCR-T cells against two variable mechanisms of TME immunosuppression based on the demonstration of CSP-enhanced poly-cytokine secretion, proliferation and mitigation against exhaustion in vitro. This observation warrants application in the clinic for this novel approach to potentially overcome the major challenges in solid tumor TMEs.

Background: Tumor Microenvironment (TME) drives tumor growth, invasion, and metastasis. Studying its characteristics requires preclinical models to understand non-small cell lung cancer (NSCLC). PDTOs could help to explore tumor heterogeneity and mimic the organ's structure and functions to study NSCLC TME. Specific goals: (i) test and optimize different extracellular matrices for the development of NSCLC PDTO, (ii) develop 3D co-cultures of patient-derived lung tumorspheres and cancer-associated fibroblasts (CAFs) to investigate their interaction.

Methods: Long-term NSCLC primary cultures were established as PDTOs and tumorspheres. (i) 6 matrices were tested combining PEG hydrogel with heparin with/without RGD, and type I collagen (murine). Matrigel served as positive control. Cell viability was assessed with Calcein/PI and Cell Titer Glo 3D assays. Confocal microscopy evaluated PDTO size and matrix complexity. (ii) Co-culture methods between tumorspheres (SPH) and immortalized 154hTERT CAF cell line in 1:3 ratio for 48 hours were evaluated. Confocal microscopy and flow cytometry analyzed and distinguished populations with CD90 staining and Cell Trackers (Deep Red and Green).

Results: (i): All matrices supported organoid growth. PEG matrices showed optimal cell viability. Collagen matrices had the highest organoid count via confocal microscopy. (ii) SPH in non-adherent conditions, co-cultured with adhered monolayer CAFs, led to undesired SPH differentiation. A complete suspension culture achieved the expected invasion of tumorspheres with CAFs. CD90 was ineffective as a marker due to some CD90+ SPH. Varying concentrations of Cell Trackers stained CAFs, and a 0.25 µM concentration of Cell Tracker Green yielded the best CAF-SPH separation.

Conclusions: Our results showed that viable organoids can grow in the matrices tested. We have optimized conditions for the co-culture of tumorspheres and CAFs in 3D. Next, we will test organoid recovery techniques from ECMs to perform further studies and evaluate potential molecular mediators involved in SPH-CAF intercommunication as potential biomarkers to translate into the clinical practice. Background: Radiotherapy-induced breast angiosarcoma (RIBAS) is a very rare late complication of radiotherapy (RT) in breast cancer. The incidence of RIBAS is expected to increase in the next few years, following the widespread adoption of breast-sparing surgery in combination with adjuvant treatment. To date, no actionable gene mutations are described, and data availability is very limited. Leveraging a multicentric retrospective cohort, we assessed the genomic features of a collected case series of patients affected by both sporadic (sBAS) and RT-induced form of angiosarcoma.

Methods: We retrospectively collected FFPE tumor and germline samples, obtained by surgery or biopsy. Samples were subjected to whole exome sequencing (WES, NovaSeq 6000 Illumina). Raw data were analyzed using the open source nf-Sarek pipeline. Mutation calls were identified using Mutect2, Strelka2 and independently validated using the Dragen platform™. Variants were annotated using COSMIC, OncoKB, ClinVar in conjunction with functional predictors, such as FATHMM, SIFT and Polyphen. Copy number aberrations were assessed using CNVkit.

Results: We collected matched tumor-normal pairs from 43 cases (30 RIBAS, 8 sBAS, 5 with no clinical annotation). All the patients were female, the overall median age at diagnosis was 68.8 years (IQR: 52.1 — 75.1), 69.8 (IQR: 61.4 — 76) for RIBAS and 41.2 (IQR: 28.6 — 53.7) for sBAS patients. WES was performed on 18 cases, 12 RIBAS, and 6 sBAS. We identified two *PIK3CA* hotspot mutations (p.E542V, p.V344M) in RIBAS only, but not in sBAS. One *TP53* mutation was identified in one sBAS sample. The most recurrent copy number aberration was *MYC* amplification (N = 5), exclusively found in RIBAS. Over-representation analysis showed enrichment in the NOTCH signaling, and E2F-targets pathways.

Conclusions: The genomic repertoire of RIBAS and sBAS is heterogenous, and we identified recurrent potential clinically actionable markers. We are currently expanding our analyses to 26 novel cases, including those reported in the Angiosarcoma Project. Germline calls are being assessed. To our knowledge, our study represents the largest effort to unveil the molecular landscape of RIBAS.

Background: KRAS activating mutations are the most common oncogenic drivers and are correlated with radioresistance of multiple cancers including NSCLC and colorectal cancers. Multiple KRAS inhibitors were developed recently such as MRTX849 (Adagrasib,Mirati Therapeutics) showing promising clinical efficacy in early phase trials. However, only scarce data exploring the combination of radiotherapy (RT) and a KRAS inhibitor in $KRAS^{G12C}$ mutated tumors are available. We explore the efficacy of the association between RT and MRTX1257, a selective and covalent $KRAS^{G12C}$ inhibitor analogous to MRTX849, in animal models of cancer.

Methods: We assessed *in vitro* the efficacy of the combination MRTX1257 at various concentrations and different RT doses in CT26 WT and CT26 $KRAS^{G12C+/+}$ cell lines using clonogenic survival assays.We then explored the combination in LL2 $NRAS^{-/-}$ and WT cell lines. Subsequently, we explored the efficacy of combination MRTX1257 and RT in athymic nude mice bearing CT26 $KRAS^{G12C+/+}$ tumors and in immunocompetent BALB/c mice bearing subcutaneous CT26 WT or CT26 $KRAS^{G12C+/+}$ tumors.On day of randomization (D-1 before RT), D+1 and D+3 after RT, mice received oral MRTX1257 at 50 mg/kg dose. At D0, mice randomized into RT only and combination groups received 1x 6 Gy to the tumor. On D4 post RT, tumours were collected for IHC and flow cytometry analysis of the tumour microenvironment.

Results: MRTX1257 increased the cytotoxic effect of RT in different $KRAS^{G12C}$ mutated cell lines and murine tumors, but not in their $KRAS^{G12C}$ wild type counterparts. In *vitro* and *in vivo* radio-sensitizing effects were observed in a time and dose dependent manner. The use of RT and MRTX1257 in BALB/c mice bearing CT26 $KRAS^{G12C+/+}$ tumors resulted in a 20% cure rate. Tumor microenvironment analysis of murine CT26 $KRAS^{G12C+/+}$ tumors following RT and MRTX1257 showed an increase in conventional $CD4^+$ T cells, DCs type 2 and inflammatory monocytes. Expression of PD-L1 was reduced within tumor and myeloid cells, illustrating TME polarization towards a pro-inflammatory phenotype following the combination.

Conclusions: This work constitutes a first step towards new combinatorial approaches involving RT and MRTX1257 in KRAS G12C mutated cancers, with the aim of providing new therapeutic strategies.

2253P RAS-precision medicine trans-atlantic partnership: Comparative analysis of KRAS codon 12 and 13 mutations in non-small cell lung cancer

H. Adderley[1], W. McDaid[2], J. Searle[2], L. Wilson[2], A. Marinello[3], M. Aldea[4], J. Aredo[5], H. Wakelee[6], B. Besse[7], A. Malliri[2], C.R. Lindsay[1]

[1]Department of Medical Oncology and Division of Cancer Sciences, The Christie NHS Foundation Trust and Faculty of Biology, Medicine and Health, University of Manchester, Manchester, UK; [2]Cell Signalling, Cancer Research UK Manchester Institute - The University of Manchester, Manchester, UK; [3]Thoracic Oncology, Gustave Roussy - Cancer Campus, Villejuif, France; [4]Medical Oncology Department, Institut Gustave Roussy, Villejuif, France; [5]School of Medicine, Stanford Comprehensive Cancer Institute, Stanford, CA, USA; [6]Medicine/Oncology Department, Stanford University, Stanford, CA, USA; [7]Cancer Medicine Department, Institut Gustave Roussy, Villejuif, France

Background: *RAS* is the most commonly mutated oncogene in cancer, with *KRAS* mutated in ∼30% of non-small cell lung cancer (NSCLC). The most common *KRAS* mutation in lung-adenocarcinoma is KRAS codon 12 followed by 13. Newly developed drugs to target *KRAS*-G12C have highlighted the importance of studying the unique molecular and functional mechanisms of individual allelic subtypes.

Methods: We developed a doxycycline inducible panel of isogenic cell lines (MLE-12: alveolar type II cells) expressing flag-tagged KRAS WT or KRAS mutant: G12C, G12D, G13C and G13D. Cells were characterised in 3D using proliferation, viability, transformation and signalling assays. A panel of "RASless" mouse embryonic fibroblasts

(MEFs) expressing KRAS WT, G12C, G12D and G13D were also evaluated. For clinical validation, we developed a clinical database (RAS-PM), to interrogate co-mutational frequencies and pathogenicity.

Results: Expression of KRAS WT, 12C and 12D in MLE-12 cells resulted in an increase in proliferation, compared to a decrease or plateau observed with KRAS 13C or 13D expression. Furthermore, there was increased viability in cells expressing KRAS codon 12 mutations compared to WT or codon 13 mutations. All KRAS mutant MLE-12 cells expressed markers of transformation (EPCAM and CD44), including codon 13 mutants. In addition, there were differences in activation of AKT signalling between KRAS G12D and G13D expressing cells. Therapeutic vulnerabilities to a novel active-state selective RAS ('ON') inhibitor were assessed, where the most and least sensitive cells were those expressing G12C or G12D, respectively. RAS-PM identified that *KRAS* G13D was more prevalent in *NF1* mutant cancers vs. *NF1* wildtype (*NF1* MT: 6/24, 25%; vs. *NF1* WT: 4/281, 1.4%; $p<0.0001$). Pathogenic *NF1*-mutations were identified in 5/6 (83%) of *G13D/NF1* co-mutant cases.

Conclusions: Our findings highlight molecular and functional differences across the panel of KRAS mutations evaluated demonstrating differences in proliferation, viability, and signalling. These preclinical results indicate unique therapeutic vulnerabilities across allelic subgroups. RNA-sequencing and kinome profiling will allow us to further characterise these mutations in NSCLC.

2254P Persisting RAS addiction: A therapeutic vulnerability in the context of KRAS G12C inhibitor resistance

G.J. Morrissey[1], W. McDaid[1], K. Simpson[2], M. Carter[3], A. Chaturvedi[4], C.R. Lindsay[3], A. Malliri[1]

[1]Cell Signalling, Cancer Research UK Manchester Institute - The University of Manchester, Macclesfield, UK; [2]Cancer Biomarker Centre, Cancer Research UK Manchester Institute - The University of Manchester, Macclesfield, UK; [3]Medical Oncology Department, The Christie NHS Foundation Trust, Manchester, UK; [4]Pathology, The Christie NHS Foundation Trust, Manchester, UK

Background: *KRAS* is the most frequently mutated oncogene in NSCLC, affecting ~30% of adenocarcinomas. Resistance to novel KRAS G12C inhibitor monotherapies is inevitable and early data with inactive-state selective inhibitors suggest there are a diverse range of resistance mechanisms.

Methods: A panel of G12C mutant NSCLC cell lines (H358, H23, HCC 1171, H1792, H2122) were cultured with an inactive state selective G12C inhibitor for over 9 months and resistant subclones generated. A multi-omic approach combining genomic, bulk RNA-seq, scRNA-seq and proteomic analyses was used to characterise these resistant populations, with the aim of identifying common resistance mechanisms and potential therapeutic vulnerabilities. In parallel, a PDX has been generated at the point of resistance to a G12C inhibitor, seeking to validate mechanistic insights.

Results: In resistant cell lines, there were varied morphological changes demonstrating both epithelial-mesenchymal-transition (EMT) and mesenchymal-epithelial-transition (MET). Bulk RNA-seq of two cell lines did not reveal common mechanisms of resistance. Further proteomic analysis suggests that there are a diverse range of resistance mechanisms present amongst the resistant populations. To better understand the transition to resistance, scRNA-seq of H1792 cells at different time points was performed, with different transcriptomic states identified. Work is ongoing to explore whether these states confer different sensitivities to G12C inhibition, and whether trajectory inference can predict a path to resistance. Analysis of a PDX has shown that it is a poorly differentiated adenocarcinoma of solid subtype, with further work exploring if this represents a histological transformation from pre-treatment samples. Therapeutic vulnerabilities to the resistant cell line panel were identified, with 5 cell lines remaining sensitive to active state selective RAS inhibitors.

Conclusions: Resistance to inactive state selective KRAS G12C inhibitors is heterogeneous but resistant populations remain sensitive to RAS targeted therapies. These results suggest that KRAS mutant cell lines remain addicted to oncogenic KRAS in the setting of resistance.

2255P Clinicogenomic landscapes and hallmarks of KRAS amplification in human cancers

B. Ricciuti[1], J.V. Alessi[2], X. Wang[3], F. Pecci[4], A. Di Federico[5], M. Gandhi[1], M. Makarem[4], L. Sholl[6], P.A. Jänne[1], C. Ambrogio[7], M.M. Awad[8]

[1]Lowe Center for Thoracic Oncology, Dana-Farber Cancer Institute, Boston, MA, USA; [2]Thoracic, Dana-Farber Cancer Institute, Boston, MA, USA; [3]Statistics, Harvard School of Public Health, Boston, MA, USA; [4]Thoracic Oncology, Dana-Farber Cancer Institute, Boston, MA, USA; [5]Lowe Center for Thoracic Oncology, Dana-Farber Cancer Institute, Harvard Medical School, Boston, MA, USA; [6]Pathology, Brigham and Women's Hospital, Boston, MA, USA; [7]Department of Molecular Biotechnology and Health Sciences, Università degli Studi di Torino - Centro Interdipartimentale di Ricerca per le Biotecnologie Molecolari, Turin, Italy; [8]Medical Oncology, Dana-Farber Cancer Institute, Boston, MA, USA

Background: The recent development of direct KRAS inhibitors has changed the treatment landscape of patients (pts) with oncogenic KRAS mutations. However, whether KRAS amplification ($KRAS^{AMP}$) also defines a unique subset of cancers and represents a potential target for drug development is unknown.

Methods: Clinicogenomic data and outcomes were abstracted from independent cohorts of human cancers with genomic profiling at the Dana-Farber Cancer Institute, AACR-GENIE v.13, The Cancer Genome Atlas (TCGA), and 212 other studies, and examined according to $KRAS^{AMP}$ status. We also correlated $KRAS^{AMP}$ with KRAS RNA and protein expression using whole transcriptome and proteomics data from the TCGA and the Cancer Cell Lines Encyclopedia.

Results: Among 103,523 pts with solid and hematologic cancers, $KRAS^{AMP}$ was identified in 1,744 (1.7%) of cases. $KRAS^{AMP}$ was most prevalent in germ cell tumors (16.3%), esophagogastric (7.5%), ovarian (4.2%), pancreatic (2.2%), breast (2%), colorectal (CRC, 1.2%), and non-small cell lung cancer (NSCLC, 1.2%). Among these pts, median age was 61, 61.5% were ever smokers, 85.4% were white, and 71.8% had poorly differentiated cancers. Compared to KRAS diploid cases, $KRAS^{AMP}$ cancers had a higher fraction of the genome altered ($p<0.01$). Microsatellite instability scores were also higher in $KRAS^{AMP}$ tumors from patients with breast, esophagogastric, germ cell, pancreatic and NSCLC ($p<0.01$), but not in CRC ($p=0.22$). Tumor mutational burden was higher ($p<0.01$) among CRC, NSCLC, and esophagogastric cancers with $KRAS^{AMP}$ vs KRAS diploid. Compared to KRAS diploid samples, $KRAS^{AMP}$ samples had increased KRAS mRNA ($p<0.01$) and protein expression ($p<0.01$). Among pts with clinical outcome data (N=41,900), median overall survival (OS) was shorter in all comers with $KRAS^{AMP}$ vs KRAS diploid genotype (adjusted HR 1.68, $p<0.01$), and in each cancer type analyzed separately. $KRAS^{AMP}$ conferred worse survival outcomes in pts with both KRAS wild-type (N=35,599, adjusted HR 1.38, $p=0.01$) and KRAS-mutant (N=6,301, adjusted HR 1.70, $p<0.01$) cancers.

Conclusions: KRAS amplification defines a novel subset of human cancers characterized by distinct genomic features, and worse survival. Novel therapeutic strategies to target $KRAS^{AMP}$ may improve outcomes in pts with cancer.

2256P The microenvironment of normal mucosa could predict recurrence in the stage II/III colorectal cancer: Multicenter, multiomics study

Y. Bang[1], J-H. Choi[2], K. Park[1], J. Lim[1], D.H. Pyo[3], Y.J. Lee[4], W-Y. Park[1]

[1]Samsung Genome Institute, Samsung Medical Center, Seoul, Republic of Korea; [2]Department of Health Sciences and Technology, Samsung Advanced Institute for Health Science & Technology, Sungkyunkwan University, Seoul, Republic of Korea; [3]Department of Surgery, Samsung Medical Center, Seoul, Republic of Korea; [4]Department of Omics, Geninus, Inc., Seoul, Republic of Korea

Background: In this study, we aimed to investigate the microenvironment of normal mucosa to predict prognosis of stage II/III colorectal cancer (CRC), after surgery.

Methods: We divide the groups using transcriptome sequencing data of prospectively collected tumors and paired normal tissue, obtained from the margins of the resected

specimens from 111 patients at Samsung medical center. Groups were defined as follows: tumor-like microenvironment in normal mucosa group (tNME): high tumor signature in normal mucosa; normal microenvironment group (NME): low tumor signature in normal mucosa. The impact of this classification was further evaluated in two independent cohorts (Korean multi-center cohort and TCGA cohort). The microbial, and biological differences between groups were investigated based on 16s rRNA metagenomics and single-cell RNA sequencing.

Results: A total of 38 (34%) were classified as tNME. There were no significant differences in age, sex, TNM stage and CMS between subgroups. With a median follow-up of 57.9 months, tNME showed poorer 3-year recurrence-free survival (RFS) (56.0 % vs. 78.9 %, P=0.008) and 3-year overall survival (OS) (79.0 %vs. 87.7%, P=0.095) compared to NME. These were validated in the Korean multi-center validation cohort (3-year RFS: 55.3% vs. 74.5%, P=0.045), and TCGA cohort (3-year OS: 62.2% vs. 91.7%, P=0.071). Metagenomics exhibited a significantly lower proportion of carcinogenic genus including *Fusobacterium*, *Bacteroides* in normal of NME. There were significant differences in beta diversity between tumor and normal in NME, while no significant differences were noted in tNME, which suggests the feature of bacterial biofilm. PathSeq-based computational method of single-cell RNA sequencing revealed more proportion of infected cancer cells in tNME. *EMP1* +epithelial cells were correlated with recurrence, and more proportion of this cluster, along with *GZMK* high CD8 T cells, inflammatory cancer-associated fibroblasts were noted in tumor of tNME, while more proportion of neutrophil was noted in normal of tNME.

Conclusions: The microenvironment of normal mucosa status could be a prognostic biomarker for CRC. The bacterial biofilm with weak intestinal barrier were related to tNME.

Biostatistics and Epidemiology Office, Institut Gustave Roussy, Villejuif, France; [4]Radiation Oncology, Cancer Center Clinica Universidad de Navarra, Pamplona, Spain; [5]Radiation Oncology, Centre Léon Bérard, Lyon, France; [6]Radiation Oncology, ICO Institut de Cancerologie de l'Ouest René Gauducheau, Saint-Herblain, France; [7]Radiation Oncology, Institut Bergonié, Bordeaux, France; [8]Biostatistics, Gustave Roussy, Villejuif, France; [9]Radiation Oncology, Gustave Roussy - Cancer Campus, Villejuif, France; [10]Interventional Radiology Department, Institut Gustave Roussy, Villejuif, France; [11]DITEP, Institut Gustave Roussy, Villejuif, France; [12]Drug Development Department, Gustave Roussy - Cancer Campus, Villejuif, France

Background: Immunoradiotherapy may improve outcomes for patients with advanced solid tumors, although optimized combination modalities remain unclear. Here, we report the analysis of the colorectal (CRC) cohort of the SABR-PDL1 trial that evaluated the PD-L1 inhibitor atezolizumab in combination with stereotactic body radiation therapy (SBRT) in advanced cancer patients.

Methods: Eligible patients received atezolizumab 1200 mg (IV) every 3 weeks until progression or unmanageable toxicity, together with ablative SBRT delivered concurrently with the 2nd cycle (recommended 45 Gy in 3 fractions, adapted upon normal tissue tolerance constraint). SBRT was delivered to at least one tumor site, with at least one additional measurable lesion being kept from the radiation field. The primary efficacy endpoint was one-year progression-free survival (PFS) rate from the start of atezolizumab. Sequential tumor biopsies were collected for deep multi-feature immune profiling.

Results: 60 heavily pretreated advanced CRC patients (38 men [63%]; median age, 59 years [range, 20-81 years]) were enrolled in five centers (France: n=4, Spain: n=1) from 11/2016 to 04/2019. All but one (98%) received atezolizumab and 54/60 (90%) received SBRT. The most frequently irradiated site was lung (n=30/54; 56.3 %). Treatment-related G3 (no higher grade observed) toxicity was observed in 3 (5%) patients. Median OS and PFS rates were respectively 8.4 [95%CI:5.9-11.6] and 1.4 months [95%CI:1.2-2.6]. Immune-centric multiplex IHC and RNAseq suggested that SBRT redirected immune cells towards tumor lesions even in the case of radio-induced lymphopenia. Tumor PD-L1 was more expressed in responding patients vs progressive disease (PD) patients at baseline (P=0.0087). IRF1 nuclear expression was higher in responding patients at baseline in CD3+ T cells (P=0.0043) and in CD68+ cells (P=0.0498). Upregulation of *CCL19*, *BHLHE41*, *CXCL9*, *GZMB* and *SLAMF1* in bulk RNA samples correlated with improved outcome.

Conclusions: Despite low PFS, this study provides new data on the feasibility, efficacy, and immune context of tumors that may help better identify advanced CRC patients most likely to respond to immunoradiotherapy.

Clinical trial identification: EudraCT N°: 2015-005464-42; NCT02992912.

2258P Organoids as a biomarker for personalized treatment in metastatic colorectal cancer: Drug screen optimization and correlation with patient response

L.P. Smabers[1], E. Wensink[1], C.S. Verissimo[2], E. Koedoot[2], M. Doorn[2], K-C. Pitsa[2], M. Huismans[3], C. Higuera Barón[2], L. Valkenburg-van Iersel[4], A. Brousali[5], R. Overmeer[2], M. Braat[6], S. Elias[7], R. Vries[2], O. Kranenburg[8], M. Koopman[1], S. Boj[2], J.M.L. Roodhart[1]

[1]Medical Oncology Department, University Medical Center Utrecht, Utrecht, Netherlands; [2]Oncology, HUB Organoids, Utrecht, Netherlands; [3]Center for Molecular Medicine, University Medical Center Utrecht, Utrecht, Netherlands; [4]Medical Oncology Department, Maastricht University Medical Center, Maastricht, Netherlands; [5]Utrecht Platform for Organoid Technology (UPORT), University Medical Center Utrecht, Utrecht, Netherlands; [6]Radiology Department, University Medical Center Utrecht, Utrecht, Netherlands; [7]Julius Center for Health Sciences and Primary Care, University Medical Center Utrecht, Utrecht, Netherlands; [8]Surgical Oncology Department, University Medical Center Utrecht, Utrecht, Netherlands

Background: Currently, response to cancer treatment cannot be predicted upfront, hampering treatment efficacy. There is a need for effective biomarkers to select patients for optimal treatment. A promising predictive biomarker is response testing on patient-derived organoids (PDOs). For metastatic colorectal cancer (mCRC), it is unclear what drug screening method is optimal and if PDOs predict response for all treatment types.

Methods: Drug screens were performed by exposing 23 PDOs to a concentration range of systemic drugs for 5 days. The following standard mCRC treatments were evaluated: 5-fluorouracil (n = 6), oxaliplatin (n = 14) and irinotecan (n = 10). Drug sensitivity was measured by cell viability and quantified by calculating the area under the curve (AUC). We compared *in vitro* sensitivity to patient response, evaluated using progression-free survival (PFS) and % change in the size of target lesions on CT scans.

Results: Drug screen methods regarding medium composition (with/without N-acetylcysteine), combination treatment ratios and read-outs were optimized, as they impact the correlation with clinical response. Correlations were seen between PDO response (AUC) and patient response (% change) for all chemotherapies (Spearman $r = 0.3$-0.6, ns). PFS was evaluable for patients treated with oxaliplatin (n=14). Median PFS of patients with organoids classified as resistant to oxaliplatin-based treatment - based on AUC - was relevantly shorter than for organoids classified as sensitive (3.4 vs 10.1 months, log rank $p = 0.07$). PDOs from patients previously exposed to chemotherapy showed increased resistance to chemotherapy with a significantly higher AUC (median 0.9 vs 0.4, Mann-Whitney U $p = 0.005$).

Conclusions: After drug screen optimization, we show that PDO response correlates with patient response to commonly used systemic mCRC treatments. This suggests that PDOs can serve as a predictive biomarker and guide personalized cancer treatment. PDOs adequately reflect prior treatment effect, supporting their use for modeling mCRC. Our findings and optimized screening method will be validated in the ongoing OPTIC trial (NL61668.041.17), to facilitate implementation of PDOs in clinical treatment.

2259P An artificial neural network system to predict the fraction of type I polarized macrophage

T. Xie[1], P. Xing[1], Y. Li[2], L. Yang[2], Y. Zhai[1], H. Yuan[1], L. Liu[2], J. Ying[2], J. Li[1]

[1]Department of Medical Oncology, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Beijing, China; [2]State Key Laboratory of Molecular Oncology, Department of Pathology, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Beijing, China

Background: Type I polarized macrophages (M1) play an anti-tumor role in the tumor microenvironment (TME), and more M1 infiltration means better prognosis. Previous studies have developed algorithms to predict the fraction of M1 based on transcriptomic data, whereas few study focus on DNA methylation data.

Methods: A macrophage multiplex immunofluorescence (mIF) panel (including DAPI, panCK, CD68, CD86, IRF5, CD163 and CD206) and DNA methylation sequencing were used in lung adenocarcinoma (LUAD) patients' formalin-fixed paraffin-embedded samples. The fraction of M1 (with more positive M1 markers [CD86 and IRF5] than M2 markers [CD163 and CD206]) was calculated based on all macrophages ($DAPI^{+-}$ $panCK^{-}CD68^{+}$). Patients were randomly divided into training cohort (70%) and test cohort (30%). The Pearson correlation and random forest algorithm were used to screened genes to build artificial neural network (ANN) models in the training cohort. Three hundred times of three-fold cross validation were performed to obtain 900 ANN models and test the accuracy of them. The final predicted value of the ANN system were equal to the weighted average of output values of all 900 ANN models. Finally, the accuracy of the ANN system was tested validated in the test cohort.

Results: Forty patients with LUAD were enrolled, and the median fraction of M1 was 3.27% (range: 0% to 30.91%). A total of 43 genes were with p-value < 0.001 were selected by Pearson correlation, and the top eight genes (*C10orf90*, *ITGAX*, *TMED9*, *RGN*, *CENPF*, *LGI4*, *PPCS* and *KIAA1211*) from random forest algorithm were used to build 900 three-layer ANN models. Each ANN model had eight input nodes, five hidden nodes and one output node. The frequency of ANN model whose weight $>$ 0.70 (the accuracy $>$ 0.70) was 74.78% (673/900). The Pearson correlation coefficient between the predicted value and the true M1 fraction was 0.89 ($R^2 = 0.79$, $p < 0.01$) in the training cohort and 0.80 ($R^2 = 0.65$, $p < 0.01$) in the test cohort.

Conclusions: DNA methylation data is more suitable to establish models than RNA data. In this study, an ANN system based on DNA methylation data was constructed and showed a potential value in predicting the fraction of M1 in LUAD, which could help to further understand the TME and identify patients that would benefit from immunotherapy.

2260P Berberine associated to SGLT-2i exerts synergistic cardioprotective effects in cardiac cells exposed to the HER2-blocking agent trastuzumab through pAMPK activation and reduction in Interleukin-6 levels

A. Paccone[1], M. Iovine[2], M. Scherillo[3], F. Florio[4], F. Russo[4], I. Bisceglia[5], F. Maurea[4], V. Giordano[4], N. Maurea[4], V. Quagliariello[4]

[1]Cardiology Department, Istituto Nazionale Tumori IRCCS - Fondazione G. Pascale, Naples, Italy; [2]Cardiology, Istituto Nazionale Tumori IRCCS - Fondazione G. Pascale, Naples, Italy; [3]Division of Cardiology, University of Sannio RCOST, Benevento, Italy; [4]Division of Cardiology, Istituto Nazionale Tumori IRCCS - Fondazione G. Pascale, Naples, Italy; [5]Division of Cardiology, Azienda Ospedaliera San Camillo Forlanini, Rome, Italy

Background: Trastuzumab has improved the prognosis in patients with HER2-positive breast cancer, but it can induce left ventricular dysfunction with reduced ejection fraction or HF during treatment. Dapagliflozin is a SGLT2i with cardio-renal benefits. In the DAPA-HF trial, the sodium-glucose cotransporter 2 inhibitor dapagliflozin decreased the risk of worsening HF events and cardiovascular death in patients with HF and reduced ejection fraction. Recent preclinical systematic review indicated that Berberine significantly reduces myocardial infarct size and the incidence of ventricular arrhythmia, improves cardiac function, ameliorates myocardial apoptosis.

Methods: Human fetal cardiomyocytes (HFC cell line) were exposed to subclinical concentration of trastuzumab (200 nM) alone or co-incubated with Berberine (200 mM) or Dapagliflozin (50 nM) or both in combination for 48 h. After the incubation period, we performed the following tests: cell viability, apoptosis, expression of NLRP3 inflammasome, methylglyoxal and leukotrienes-B4. Expression of pAMPK was analyzed through western blot. Moreover, quantification of IL-6 was performed through ELISA method.

Results: Berberine and Dapagliflozin significantly increased the cell viability of cardiomyocytes exposed to Trastuzumab. When combined, Berberine and Dapagliflozin increased synergistically cell viability of cardiac cells ($p<0.001$ vs Trastuzumab). Cell apoptosis was reduced of 32.5, 41.8 and 72.7% for berberine, dapagliflozin and both combined (vs trastuzumab group). Methylglyoxal,a marker of AGEs, was strongly reduced compared to untreated cells. Western blot analysis clearly demonstrates that pAMPK was induced by berberine and Dapagliflozin, improving mitochondrial metabolism. Intracellular levels of IL-6 were reduced of 46.3, 62.7 and 86.3% for berberine, dapagliflozin and both combined (vs trastuzumab group).

Conclusions: Berberine and Dapagliflozin in combination induces an anti-inflammatory phenotype to myocardial cells through the reduction of biomarkers involved in heart failure and apoptosis.

2261P A head-to-head comparison for detecting PIK3CA mutations in circulating tumor DNA of advanced HR+/HER2- breast cancer patients

N. Dandachi[1], R. Graf[2], L. Pancheri[1], N. Dobrić[1], E.V. Klocker[1], C. Suppan[1], P.J. Jost[1], E. Heitzer[2], M. Balic[1]

[1]Department of Internal Medicine - Division of Oncology, Medical University of Graz, Graz, Austria; [2]Institute of Human Genetics, Diagnostic and Research Center for Molecular Biomedicine, Medical University of Graz, Graz, Austria

Background: Recently, we demonstrated that a high-resolution SiMSen-seq assay (SSS) provides a sensitive and robust method for detecting 11 *PIK3CA* hotspot mutations in ctDNA, allowing the identification of patients eligible for alpelisib treatment. Unfortunately, due to intrinsic or acquired resistance, most patients progress within months to years. Therefore, detecting additional genomic biomarkers for treatment resistance beyond *PIK3CA* mutations is crucial. Here we present interim results for our ongoing study to show that a commercial NGS assay (AVENIO ctDNA Expanded Kit, Roche Diagnostics) can detect *PIK3CA* mutations with similar high sensitivity as our high-resolution SSS assay.

Methods: 37 HR+/HER2- patients were included before starting 1st line treatment and 30 before starting 2nd line treatment. Plasma samples were analyzed using SSS and the AVENIO assay. Additionally, mFAST-SeqS was used to estimate the tumor fractions in plasma samples.

Results: The median z-score from mFAST-SeqS analyses was 2.88 [25–75th percentile: 1.48–7.36], and 30/67 (45%) samples had z-scores $>= 3$, indicating elevated tumor fractions (>5%). Two samples were not evaluable with SSS, leaving 65 samples for a head-to-head comparison. 29 alterations were detected in 27 (41.5%) samples by the SSS assay and 31 in 28 samples (43.1%) by the AVENIO assay. Overall, we found an excellent concordance rate of 95.4% (62/65 samples) between the two assays, confirming the high sensitivity of the panel sequencing assay. Moreover, the VAF of SSS and AVENIO were highly correlated (Spearman's rho $= 0.93$, $p < 0.001$).

Conclusions: The AVENIO ctDNA Expanded Kit revealed a high sensitivity and concordance rate for detecting *PIK3CA* hotspot mutations in plasma samples compared with the SSS assay. A major advantage of panel sequencing over a single-gene approach is that the interrogation of multiple genes can indicate a true negative *PIK3CA* result if other variants are present with a high VAF. Moreover, other actionable targets or mechanisms of resistance can be captured simultaneously, thus improving the effective precision treatment of metastatic breast cancer patients.

2262P Baseline-informed versus tumor-agnostic minimal residual disease (MRD) concordance study in patients with HER2+ gastroesophageal adenocarcinoma patients

P. Du[1], H. Singh[2], G. Bonora[1], S. Jia[3], P.C. Enzinger[4]

[1]R&D, Predicine, Inc., Hayward, CA, USA; [2]Medical Oncology, Dana-Farber Cancer Institute, Boston, MA, USA; [3]Huidu (Shanghai) Medical Technology Co., Ltd., Shanghai, China; [4]Center for Esophageal and Gastric Cancer, Dana-Farber Cancer Institute, Boston, MA, USA

Background: Current clinical paradigms are reliant on radiographic monitoring of disease to assess treatment response. However, this approach has some limitations including interval nature of imaging modalities and patients can clinically deteriorate prior to formally documenting therapy resistance. Hence, novel techniques such as longitudinal monitoring circulating tumor DNA (ctDNA) to assess therapy related response in real time are important to investigate.

Methods: To assess changes in disease burden with therapy, we profiled circulating tumor DNA (ctDNA) from longitudinal patient blood plasma using PredicineBEACON personalized minimal residual disease (MRD) assay and PredicineALERT, a tumor-agnostic MRD assay that measures cancer-related methylation patterns without personalization. Nineteen longitudinal plasma samples from 2 HER2+ gastroesophageal cancer (GEC) patients were tested using baseline-informed and tumor-agnostic MRD assays.

Results: Patient 1 demonstrated a similar trend of molecular dynamics and turning points of tumor response to therapy across 9 time points between the two MRD assays. Although the overall trends between the two assays were concordant for the second patient, some time points showed differential dynamics of changes in circulating levels of specific mutations compared to overall methylation profiling. An uptick levels of ctDNA after initial response preceeded radiographic progression using either approaches. Overall, in this ongoing study of the initial 2 cancer patients using 19 longitudinal blood samples, both PredicineALERT and PredicineBEACON assays demonstrated the trend of molecular dynamics and identified the similar turning points of tumor response during therapy.

Conclusions: Both tumor informed mutation based and tumor agnostic mehtylation based ctDNA approaches demonstrate clinical potential to monitor disease evolution and identify resistance prior to radiographic progression. Further study of such approaches to identify pre-radiographic molecular progression is warranted.

2263P Ethnicity-specific distribution of BRCA1, BRCA2, PALB2 and ATM pathogenic alleles in breast and ovarian cancer patients from the North Caucasus

E. Imyanitov[1], E. Bakayeva[1], L. Sultanova[2], Z. Khamgokov[3], M. Chakhkieva[4], I. Khabriev[4], M. Murachuev[5], M. Bolieva[6], L. Baboshkina[7], A. Sokolenko[1]

[1]Department of Tumor Growth Biology, N.N. Petrov National Medical Research Center of Oncology, St. Petersburg, Russian Federation; [2]Department of Pathology, Chechen Republican Cancer Center, Grozny, Russian Federation; [3]Department of Outpatient Care, Kabardino-Balkarian Cancer Center, Nalchik, Russian Federation; [4]Department of Outpatient Care, Ingush Cancer Center, Nazran, Russian Federation; [5]Department of Mammology, Dagestan Cancer Center, Makhachkala, Russian Federation; [6]Department of Outpatient Care, North Ossetian Cancer Center, Vladikavkaz, Russian Federation; [7]Department of Chemotherapy, N.N. Petrov National Medical Research Center of Oncology, St. Petersburg, Russian Federation

Background: Mountain areas of the North Caucasus host several large ethnic communities, which managed to preserve their national identity through the centuries. The way of life characteristic for people from this region allows to expect high contribution of founder alleles, with an unique spectrum of pathogenic variants characteristic for each of the ethnic groups.

Methods: This study involved high-grade serous ovarian cancer (OC) and breast cancer (BC) patients from Dagestan (OC: 37; BC: 198), Kabardino-Balkaria (OC: 68; BC: 155), North Ossetia (OC: 51; BC: 104), Chechnya (OC: 68; BC: 79), Ingushetia (OC: 19; BC: 103), Karachay-Cherkessia (OC: 13; BC: 47), and several Armenian settlements (OC: 12; BC: 79). The group of BC patients was enriched by young-onset and/or family history-positive and/or bilateral and/or receptor triple-negative cases. The entire coding region of BRCA1, BRCA2, PALB2 and ATM genes was analyzed by next generation sequencing.

Results: Significant contribution of BRCA1/2 pathogenic variants in the OC and BC development was observed across all North Caucasus regions (OC: 18-31%; BC: 7-14%). Founder alleles were identified in all ethnic groups studied, e.g., BRCA1 c.3629_3630delAG [p.Glu1210fs] in Chechens, BRCA2 c.6341delC [p.Pro2114fs] in North Ossetians, BRCA2 c.5351dupA [p.Asn1784fs] in Ingush, BRCA1 c.2907_2910delTAAA [p.Lys970fs] in Karachays, etc. Some BRCA1/2 alleles, particularly BRCA2 c.9895C>T [p.Gln3299Ter], were shared by several nationalities. ATM pathogenic variants were detected in 14 patients, with 2 alleles occurring twice each. PALB2 heterozygosity was observed n 6 subjects, with one variant seen in 2 unrelated women.

Conclusions: This study adds to the evidence for global-wide contribution of BRCA1 and BRCA2 genes in BC and OC morbidity, although the spectrum of their pathogenic alleles is a subject of ethnicity-specific variations. Data on founder BRCA1/2 mutations may be considered while adjusting the BRCA1/2 testing procedure to the ethnic origin of patients.

2264P Proteomics-based phenotypic classification of non-smallcell lung cancer

O. Berkovska, G. Mermelekas, L. Orre, J. Lehtiö

Oncology-Pathology, Karolinska Institutet, Stockholm, Sweden

Background: Current precision medicine strategies for non-small-cell lung cancer (NSCLC) rely on individual mutation analyses, evaluation of the tumor mutational burden or specific marker expression (*e.g.*, PD-L1). However, many patients either do not have a suitable targeted treatment or do not respond to the prescribed therapy. Phenotypic proteomic profiling facilitates the understanding of cancer biology beyond genomics. Furthermore, the more rapid targeted proteomics methods may serve as a tool for patient stratification based on proteomic signatures of the tumors.

Methods: We used our previously published resource describing the proteome landscape of 141 NSCLC tumors (Lehtiö *et al.* 2021) to identify biomarkers of the six observed proteomic subtypes. Namely, we applied a machine learning-based algorithm to proteome-wide peptide-level data to select peptide biomarkers for NSCLC subtype classification. We also applied quality control criteria to select peptides suitable for rapid analysis using a targeted proteomics, parallel reaction monitoring (PRM), method. Therewith, we are currently developing a PRM assay for identifying and quantifying the selected biomarkers in clinical samples such as resected tumors and biopsies. The initial cohort of 141 NSCLC tumors will then be re-analyzed to train a model for subtype prediction.

Results: We identified 200 peptide biomarkers from 174 proteins representing the six proteomic subtypes of NSCLC. Upon cross validating the classifier, we achieved a high average accuracy of 87%. We then acquired heavy isotope-labeled versions of the peptides for absolute quantification of the biomarkers. Our PRM method analyzing the peptide panel quantifies proteomic biomarkers more accurately and reproducibly

than other existing proteomics methods. Furthermore, our classification algorithm converts the quantitative data into categorical NSCLC subtype information.

Conclusions: We developed a first-of-its-kind proteomics assay that provides multifactorial characterization of NSCLC tumors covering histology, immune landscape, and oncogenic driver pathways. Our method enables the use of proteomics in a clinical setting and the resultant data may be used for patient stratification.

2265P miR-4487 enhances gefitinib-mediated ubiquitination and autophagic degradation of EGFR in non-small cell lung cancer cells by targeting USP37

S-H. Yang[1], M.S. Kim[2]

[1]Internal Medicine Dept., Wonkwang University, Iksan, Republic of Korea; [2]Oral Physiology, Wonkwang University, Iksan, Republic of Korea

Background: With the identification of epidermal growth factor receptor (EGFR) mutations in non-small cell lung cancer (NSCLC) cells, EGFR—tyrosine kinase inhibitors (TKIs) are being used widely as the first-line of treatment in NSCLC. These inhibitors block auto-phosphorylation of activated EGFR by competing with ATP binding and mediate EGFR degradation independent of exogenous epidermal growth factor, which is associated with the mutation variants of EGFR. However, the precise mechanisms underlying the TKI-mediated EGFR degradation are still unclear.

Methods: To examine the physiological roles of miR-4487 and ubiquitin-specific peptidase 37 (USP37) in gefitinib-mediated EGFR degradation in NSCLC cells, multiple NSCLC cell lines were applied. The level of EGFR expression, apoptosis marker, and autophagic flux were determined by western blot. Expression level of miR-4487 and cell-cycle arrest was analyzed by TaqMan assay and flow cytometry respectively.

Results: We found that gefitinib mediates EGFR degradation under normal culture conditions, and is dependent on autophagic flux and the mutation variants of EGFR. Gefitinib reduced expression levels of USP37, which mediated EGFR degradation similar to gefitinib. Our results also showed a gefitinib-mediated increase in endogenous miR-4487 level and presented evidence for the direct targeting of USP37 by miR-4487, resulting in the sequential enhancement of ubiquitination, autophagy, and EGFR degradation. Thus, the depletion of USP37 and overexpression of miR-4487 led to an increase in gefitinib-mediated apoptotic cell death.

Conclusions: These data suggest that miR-4487 is a potential target for treating NSCLC, and miR-4487/USP37-regulated EGFR degradation is a determinant for developing gefitinib resistance.

Background: Immune checkpoint blockers have changed the treatment landscape for patients with NSCLC, however, response is often limited. PD-L1 protein expression is the only validated biomarker to enrich in responders and understanding resistance mechanisms to propose rationally driven combination therapies is clearly needed. To this end, IMMUcan, a pan-European consortium, is aiming at gaining a better understanding of the tumor microenvironment (TME) by combining broad molecular profiles of the tumor with spatially resolved cellular information of the TME and clinical information for 3,000 patients, with NSCLC a core indication of this project.

Methods: The first NSCLC cohort is composed of 191 patients from the EORTC SPECTAlung (NCT02214134) program, and 48 patients prospectively recruited in SPECTA (NCT02834884). All patients were diagnosed with NSCLC (any histology, any stage), FFPE material was collected at time of diagnosis, prior to treatment. Whole exome sequencing (WES), total RNA sequencing (RNAseq), multiplex immunofluorescence (mIF) and imaging mass cytometry (IMC) data was collected for each patient and analysed.

Results: The cohort contains a majority of adenocarcinoma (153 adenocarcinoma, 55 squamous carcinoma, 31 other) and early stage disease patients (74 stage I, 57 stage II, 63 stage III and 44 stage IV, 1 unknown). Median age at registration was 67, 100 patients were female and 139 male, and the majority were current or former smoker (163 patients). Stage is the strongest clinical predictor or survival (64.1 months for stage 1, 60.8 for stage 2, 58.3 for stage 3 and 14.1 for stage 4). 15% of adenocarcinoma patients had a driver mutation (EGFR, BRAF) and stage and histology are the main drivers of heterogeneity for RNAseq. T cell infiltration was assessed on all FFPE samples and is associated with improved overall survival. Tertiary lymphoid structures were identified in the majority of samples (∼70%), with various number of B cells and differing expression of lymphocyte maturation markers.

Conclusions: Further integration of the cellular and molecular data are ongoing and additional biomarkers will be presented at the conference.

Clinical trial identification: SPECTA NCT02834884.

2267P Coronary heart disease and risk of lung cancer: A two-sample Mendelian randomization study

C.C. Li[1], Q. Cai[1], L. Lin[1], J. Li[2], J. He[3], W. Liang[4]

[1]Thoracic Oncology Dept., Guangzhou Medical University, Guangzhou, China; [2]Thoracic Oncology Dept., State Key Laboratory of Respiratory Diseases - The First Affiliated Hospital of Guangzhou Medical University, Guangzhou, China; [3]Thoracic Surgery Department, The First Affiliated Hospital of Guangzhou Medical University, Guangzhou, China; [4]Thoracic Oncology Dept., The First Affiliated Hospital of Guangzhou Medical University, Guangzhou, China

Background: Observational studies have suggested an association between coronary heart disease and increased risk of lung cancer, but the causal relationship between these two conditions remains uncertain. Therefore, we conducted a two-sample Mendelian randomization study to investigate whether there is a causal relationship between coronary heart disease and higher risk of lung cancer.

Methods: We utilized 37 single nucleotide polymorphisms (SNPs) associated with coronary heart disease (with a p-value $<5x10^{-8}$) from a genome-wide association study involving 184,305 European individuals in the CARDIoGRAMplusC4D Consortium as instrumental variables. Summary data for lung cancer were obtained from the International Lung Cancer Consortium, including 11,348 cases and 15,861 controls. We conducted primary MR analysis using the inverse-variance weighted method and evaluated the MR assumptions in sensitivity analyses. Subgroup analyses were performed for different histological subtypes of lung cancer, and all analyses were carried out using the TwoSampleMR package in R.

Results: The MR analysis revealed that a genetic predisposition to coronary heart disease had a protective effect against the development of lung cancer, with an odds ratio (OR) of 0.88 (95% confidence interval [CI] 0.78-0.99, P=0.035). Subgroup analyses indicated a decreased risk for squamous cell lung cancer (OR 0.80, 95% CI 0.68-0.93, P=0.004), but no significant association was observed in lung adenocarcinoma (OR = 0.87; 95% CI 0.73-1.03, P=0.106). Sensitivity analyses supported a causal interpretation of the findings, indicating that major bias from genetic pleiotropy was unlikely.

Conclusions: Contrary to findings from previous observational studies, our results suggest that coronary heart disease may have a protective effect against the development of lung cancer. These findings emphasize the need to further investigate the underlying mechanisms linking these two conditions and provide a foundation for future research in this field.

2269P Patient derived xenografts generated from circulating cancer stem cells on chorioallantoic membrane as an alternative pre-clinical model for personalized medicine in pancreatic cancer

M. Pizon[1], D. Schott[2], B.J. Wagner[3], S. Boscheck[4], K. Pachmann[1], T. Aung[5], C. Hackl[3], S. Härteis[4]

[1]Transfusion Center Bayreuth, Bayreuth, Germany; [2]Transfusion Center Bayreuth, SIMFO GmbH, Bayreuth, Germany; [3]Department for Surgery, UKR - University Hospital Regensburg, Regensburg, Germany; [4]Institute for Molecular and Cellular Anatomy, University of Regensburg - Faculty of Medicine, Regensburg, Germany; [5]Faculty of Applied Healthcare Science, Deggendorf Institute of Technology, Deggendorf, Germany

Background: Although there have been improvements in the treatment of pancreatic cancer in recent years, the prognosis for this disease remains poor, with an overall 5-year survival rate of less than 10%. Therefore, new therapies and preclinical models are urgently needed. Circulating cancer cells, and in particular their very rare subpopulation, circulating cancer stem cells (cCSC) are good candidates for generating preclinical models, making it possible to follow up the spatial and temporal heterogeneity of tumor tissues. This method is a non-invasive liquid biopsy that can be obtained at any stage of the disease. In this study, we sought to set up a novel model in which patient-derived xenograft can be generated on Chorioallantoic Membrane (CAM) from circulating cancer stem cells.

Methods: In this study, primary cultures from circulating cancer stem cells were established using sphere-forming assays from 30 patients with newly diagnosed pancreatic cancer. Subsequently, tumorspheres were transplanted onto the CAM membrane of fertilized chicken eggs to form secondary microtumors.

Results: Herein, we report an innovative *in vitro* platform for cultivation of cCSCs from peripheral blood of pancreatic cancer patients. The number of tumorspheres increased significantly with tumor size, lymph node involvement and grading status of the primary tumor. Implantation of tumorspheres onto the CAM was successful in ~90 % of the applied samples. The first histological analysis suggests that the main histopathological features closely resemble the original pancreatic tumors.

Conclusions: The number of tumorspheres is associated with some clinicopathological parameters, but further follow-up is needed to evaluate the prognostic significance of tumorsphere detection in pancreatic cancer. PDXs generated from cCSCs on CAM membrane offer a promising approach for personalized medicine in pancreatic cancer, providing a platform for the study of individual patient tumors and the development of more effective treatments.

2270P Integrative analyses of bulk and single-cell RNA-seq identified diabetes mellitus-related signature as a prognostic factor in pancreatic adenocarcinoma

L. Tang, T. Xie, G. Fan, H. Zhu, Y-K. Shi

Department of Medical Oncology, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Beijing Key Laboratory of Clinical Study on Anticancer Molecular Targeted Drugs, Beijing, China

Background: Pancreatic Adenocarcinoma (PAAD) is a highly fatal disease and often associated with a poor prognosis. The development of diabetes mellitus (DM) is an important risk factor. There have been studies exploring markers or prognostic models that affect the prognosis of patients with pancreatic cancer, but there are few studies on pancreatic cancer-associated diabetes mellitus (PCDM) patients.

Methods: The differentially expressed genes (DEGs) between DM and non-DM were detected and selected to build model. PCDM patients were randomly divided into training (70%) and test cohort (30%). Then the univariate COX was performed to screen OS associated genes ($p < 0.05$) in the training cohort. The LASSO-penalized COX regression and ten-fold cross validation were used to train and select models. The risk score was calculated and verified in both training and test cohort. GSVA, ESTIMATEScore, CIBERSORT and ssGSEA were used to compare the tumor microenvironment (TME). Moreover, the value of genes used in the model was detected on single cell level.

Results: Totally 197 patients (including 60 with DM) were enrolled, 23 genes from DEGs were related to the OS of PCDM patients in the training cohort, and 10 genes were selected to construct the risk model. The risk score for each subject was calculated as follow: risk score=0.434**ACACA*+0.119**ATG7*+0.373**DEFB123*+0.135**FSTL3*-0.168**NIPSNAP3B*-0.069**RASSF1*+0.225**RBPJ*+0.364**SLC35F2*-0.168**SLC37A1*-0.145**ZC3H12D*. The C-index was 0.83 in the training cohort (hazard ratio [HR] = 7.61, $p < 0.001$) and 0.76 in the test cohort (HR = 3.22, $p = 0.015$). According to the median value -0.054, PCDM patients were split into different risk groups, and patients in the low-risk group showed more enriched T cell related pathways (60 vs 1), higher ImmuneScore ($p < 0.001$), and more CD8 positive T cell infiltration (CIBERSORT: $p < 0.001$; ssGSEA: $p < 0.001$). We calculated the score of genes used in the model in single cells. Malignant cells with the highest score (top 10%) had enhanced activities of angiogenesis.

Conclusions: The prognostic model showed potential value in predicting the OS of patients with PCDM. Patients with low-risk score had a hotter TME and might benefit from immunotherapy.

2271P Development of an oncolytic virus for the treatment of high grade serous ovarian cancer and other stromal rich tumours

M. Bazan Peregrino[1], S.C. Frost[1], C. Negroni[1], C. Moriconi[1], T. Perry[1], W. Taverner[1], B. Nicholls[1], D. Saunders[1], R. Ackerman-Johnson[1], P. Cunnea[2], C. Fotopoulou[2], J. Krell[2], A. Lim[1], K. Fisher[1], M.R. Duffy[1]

[1]Theolytics Ltd., Oxford, UK; [2]Department of Surgery and Cancer, Imperial College London - Hammersmith Campus, London, UK

Background: An abundance of cancer associated fibroblasts (CAFs) in stromal rich tumours is a barrier to the effectiveness of anticancer therapies. We have developed an oncolytic adenovirus - THEO-260 - that is capable of lysing both cancer cells and CAFs in ovarian patient tumours ex vivo. Here, we present data to support the progression of THEO-260 to first in human (FIH) clinical trials.

Methods: THEO-260 efficacy was assessed in cell lines, multicellular spheroids, ex vivo fresh ovarian patient samples and mouse models bearing human cancers and stromal CAFs. The safety was assessed in primary human normal cells and in immunocompetent mice.

Results: THEO-260 killed a panel of cell lines from ovarian cancer (n=8), in addition to different stromal rich tumour types (pancreatic, colorectal, lung, and breast cancer; n=9) and multicellular spheroids. Moreover, THEO-260 was highly efficacious in fresh ovarian patient materials, killing cancer cells and CAFs in ascites and tumour samples (n=24). THEO-260 outperforms SOC chemotherapies including paclitaxel and PARP inhibitors. In vivo, THEO-260 shows antitumor efficacy, with a complete reduction in tumour volume and is superior to SOC in the platinum resistant ovarian cancer model with human CAFs (COV318+MRC5). THEO-260 also prevents ovarian intraperitoneal metastasis formation in vivo in a human ovarian adenocarcinoma model with CAFs (SKOV3+MRC5). As expected THEO-260 does not replicate in non-human primary cells, supporting replication selectivity testing in normal human primary cells rather than in animal models. THEO-260 demonstrates high selectivity for tumours, with negligible levels of replication and production of infectious virions in all normal primary human cells tested. THEO-260 was also shown to be safe in vivo in immunocompetent mouse models, when tested at repeated and escalating, clinically relevant, dose levels. The genetic and temperature stability of THEO-260 has been confirmed and is currently being GMP manufactured to high yields.

Conclusions: Our data confirms that THEO-260 is efficacious and safe, supporting the initiation of FIH clinical trials in high grade serous ovarian cancer patients.

2272P Minimal DNA-methylation (DNAm) signatures for non-invasive tumor-agnostic estimation of tumor content (TC) and molecular subtype in patients (pts) with metastatic breast cancer (mBC)

M. Benelli[1], A. Nardone[2], F. Galardi[2], D. Romagnoli[1], F. De Luca[2], S. Gabellini[1], M. Paoli[1], I. Migliaccio[2], M. Pestrin[3], G. Sanna[4], E. Risi[1], L. Livraghi[1], E. Moretti[1], C. Biagioni[1], L. Malorni[2], L. Biganzoli[1]

[1]SOC Oncologia Medica di Prato, Nuovo Ospedale di Prato Santo Stefano - Azienda Usl Toscana Centro, Prato, Italy; [2]Translational Research Unit, Nuovo Ospedale di Prato Santo Stefano, Prato, Italy; [3]SC Oncologia Gorizia e Monfalcone, Ospedale Civile di Gorizia, Gorizia, Italy; [4]Medical Oncology, Ospedale Civile SS Annunziata, Sassari, Italy

Background: Non-invasive detection and quantification of circulating tumor DNA by DNAm signatures is emerging as powerful tool for monitoring disease status in pts with metastatic cancer. We recently developed MIMESIS, a computational workflow to design tumor agnostic DNAm signatures of few dozen sites for TC and molecular subtype estimation in liquid biopsy. Here we applied a MIMESIS informed assay to a retrospective cohort of mBC pts (MIMESIS-BC).

Methods: 72 mBC pts (42 ER+/HER2-, 2 ER+/HER2 N/A, 8 ER+/HER2+, 6 ER-/HER2+, 14 ER-/HER2-, up to 6 previous lines of treatment) and 11 healthy individuals (ctrl) were included. Plasma from mBC pts was collected before starting treatment (T0, n=58) and after the first cycle (T1, n=52) (n=38 pts T0 and T1). MIMESIS-BC for TC, PAM50 molecular subtypes and ER status (n=139 sites) was applied to circulating free DNA as described in the MIMESIS study. Samples were defined as TC+ when TC>0. TC values as continuous variable and TC classes (+/-) were associated with OS and PFS. Concordance of subtype and ER status by MIMESIS-BC with IHC-based from primary tumor was estimated by chi-square and percent agreement.

Results: TC was not detected in ctrl. A significantly higher median TC was observed at T0 compared to T1 (5.6% (range 0-73%) vs 0% (range 0-47%); p=0.02). 39 TC+ samples at T0 showed 61% agreement for molecular subtype (p=0.002) and 86% for ER status (p<0.001). In the entire population, PFS and OS were significantly associated with TC values both at T0 and T1 (max p=0.002). TC+ pts had significantly worse OS compared to TC- at T0 (HR=2.1 CI=1.1-3.9 p=0.02) and T1 (HR=2.0 CI=1.1-3.6 p=0.03) and worse PFS at T1 (HR=2.9 CI=1.5-5.4 p<0.001). In ER+ pts, TC+ at T0 and T1 associated with worse PFS (HR=2.6 CI=1.2-5.3 p=0.008, and HR=3.8 CI=1.7-8.2 p<0.001) and OS (HR=3.5 CI=1.6-7.6 p=0.001, HR=3.0 CI=1.4-6.1 p=0.002), while in ER- pts TC classes showed no association with outcome.

Conclusions: In a small and heterogenous retrospective cohort of mBC pts, MIMESIS-BC showed promising capabilities for prognostic stratification and subtype estimation from liquid biopsy. Validation in an extended prospective cohort is ongoing.

2273P Influence of body mass index (BMI) on the response to chemotherapy in patients with HER2+ breast cancer: Role of the leptin axis

M. González Rodríguez[1], M. Fernadez Abad[2], J. Palacios Calvo[3], M. Sampayo[4], I. Calvo[1], E. Díaz[1], B. Pérez Míes[3], S. González Martínez[3], J. Pérez García[4], J. Cortés[4], G. Moreno-Bueno[5], L. García Estevez[1]

[1]Breast Cancer Department, MD Anderson Cancer Center, Madrid, Spain; [2]Medical Oncology Department, Hospital Universitario Ramón y Cajal, Madrid, Spain; [3]Pathology Department, Hospital Universitario Ramón y Cajal, Madrid, Spain; [4]MedSIR, Medica Scientia Innovation Research, Barcelona, Spain; [5]CIBERONC, Centro de Investigaciones Biomedicas en Red de Cancer, Madrid, Spain

Background: Obesity is associated with T-cell dysfunction and high PD-1 expression, resulting in paradoxical benefit from check-point inhibitor therapy. This effect is driven, in part, by leptin that exerts its action through binding to the leptin receptor (Ob-R), which is highly expressed in HER2+ BC. High tumor infiltrating lymphocytes (TILs) counts correlate with pathological response and long-term outcomes in BC, but the precise mechanism is not known. The aim of this study was to investigate the role of BMI in modulating TILs and pathological responses in early HER2+ BC patients who received neoadjuvant systemic treatment (NST).

Methods: Women with HER2+ BC receiving anti-HER2-based NST followed by surgical resection were included. Patient age, menopausal status, and height/weight (to calculate BMI) were recorded. Based on biopsy findings, tumors were categorized as HER2+/HR+ and HER2+/HR-. Ob-R expression was also measured and classified as over-expressed if there were >50% positive cells with weak or strong staining. TILs and PD-1 expression were determined centrally using pre-treatment biopsies. TILs were considered as continuous variables and binary, <30 vs ≥30%, and PD-1 as positive (>1%). Associations with pathological complete response (pCR) were assessed statistically.

Results: 27 of 85 HER2+ BC patients were overweight/obese (BMI ≥25kg/m^2). Patients with high BMI tended to have tumors with higher hormone receptor expression than lean patients (85 vs 64%; p=0.078). No differences were found in median Ki67 between the high or low BMI groups. A greater number of high BMI patients were menopausal (63 vs. 36%; p=0.038). Patients with high BMI had a significantly greater expression of Ob-R vs lean patients (78 vs 55%; p=0.045) and at the same time had a significantly higher expression of TILs (median 23 vs 16%; p=0.007). Despite having higher TIL counts, pCR were similar (63.0 vs 58.6%; p= 0.704). However, PD-1 expression was significantly higher in patients with high BMI (median 4 vs 1; p=0.012).

Conclusions: Our study shows for the first time how obesity, through the Ob-R/leptin axis, might activate TILs. However, this was not translated into higher CR; probably due to high PD-1 expression as exhaustion feature.

Background: IMMUcan (SPECTA NCT02834884) is an European public-private effort to generate molecular and cellular profiling data of the human tumor microenvironment from up to 3000 cancer patients. Predicting pathologic complete response (pCR), which has been associated with better outcome after neoadjuvant treatment in breast cancer (BC), could help refining treatment strategies. Here, we aim to integrate multiple data layers using different Deep Learning (DL) approaches to predict pCR from baseline tumor samples in the context of the prospective IMMUcan Triple-Negative Breast Cancer (TNBC) and HER2-positive (HER2+) BC neoadjuvant cohorts.

Methods: At the cut-off date of June 29th, 2022, we identified a first cohort of 132 and 149 patients diagnosed with TNBC and HER2+ BC, respectively, for preliminary analyses. To predict pCR at the patient level, benchmark models using RNA-Seq, image DL were trained on Whole Slide Images (WSIs) and RNA-Seq data. The image models included two main components: a tiling algorithm pre-trained on TCGA WSI to extract a spatialized representation of the WSI and a classification part for the pCR prediction.

Results: Baseline RNA-Seq data were available for 109 and 115 patients with TNBC and HER2+ BC, respectively, pCR status was available for 130 TNBCs and 117 HER2+ BCs, while a baseline H&E-stained WSI was available for all patients. Among the models applied independently to each data type, the best performance was obtained using RNA-Seq in HER2+ BC (ROC AUC = 0.61, std = 0.04), and WSI in TNBC (ROC AUC = 0.63, std = 0.03).

Conclusions: These preliminary results show the potential of DL applied to WSI and RNA-Seq in predicting pCR for TNBC and HER2+ BC. Using DL models able to predict pCR provide the opportunity to better select patients and tailor neoadjuvant therapies in BC. Multimodal models combining RNASeq and WSI are currently being tested out by the team to improve performance.

2275P Circulating leptin and adiponectin levels in premenopausal women with and without breast cancer (BC) and a body mass index (BMI) ≥25 kg/m2

I. Calvo[1], M.L. Argente[2], A. Conde[2], M. Sampayo[3], M. González Rodríguez[1], C. Yelo[2], V. Corraliza[2], J. Pérez García[3], J. Cortés[3], L. García Estevez[1]

[1]Breast Cancer Department, MD Anderson Cancer Center, Madrid, Spain; [2]Gynecology Department, MD Anderson Cancer Center, Madrid, Spain; [3]MedSIR, Medica Scientia Innovation Research, Barcelona, Spain

Background: Obesity has a controversial effect on BC risk depending on the menopausal status. The mechanisms by which a high BMI protects against BC in premenopausal women are unknown. Adipose tissue produces two antagonistic hormones: leptin activates tumorigenesis in postmenopausal patients; by contrast, adiponectin has an anti-inflammatory effect. The aim of this study is to evaluate adiponectin and leptin levels according to the presence of not of BC in a group of premenopausal women with high BMI.

Methods: This prospective transversal study included premenopausal women with high BMI with recently diagnosed of early BC or without cancer. Age, weight, and height were recorded. Premenopausal status was confirmed by LH, FSH, and estradiol blood values. Fasting values of insulin, glucose, lipid profile, and vitamin D levels were also determined. Adiponectin and leptin levels were analyzed as continuous variable.

Adiponectin was also categorized as low, normal, and high considering age and weight. Patients with BC were classified in luminal, triple-negative, and HER2+ by IHC.

Results: Of the 86 women included in the study, 54 were BC-free and 32 with BC (luminal 23, triple-negative 5, and HER2+ 6). Women without cancer had significantly higher BMI (median 32.3 vs 26.8; $p<0.001$), leptin levels (median 27.3 vs 12.8; $p<0.001$), and insulin levels (median 10.8 vs 6.8; $p<0.003$) than BC patients. However, a significant correlation between high leptin and insulin levels was only observed in BC patients ($p<0.001$). Furthermore, a significant negative correlation was found between high leptin levels and low vitamin D levels in BC-free women ($p<0.004$). Conversely, there were no differences in adiponectin levels either as a continuous variable or in the categorization between BC and BC-free women.

Conclusions: This study analyzes, for the first time, the difference between leptin and adiponectin levels in premenopausal women with high BMI with or without BC. Although high leptin levels are associated with an increased risk of BC in postmenopausal women, this does not seem to occur in premenopausal women. Adiponectin levels are similar for both groups.

2276P Regulation of major histocompatibility class-I gene methylation using DNA methyltransferase inhibitor and PD-L1 inhibitor in triple-negative breast cancer

Y.J. Jeong[1], H.K. Oh[2]

[1]Department of Surgery, Deagu Catholic University, School of Medicine, Daegu, Republic of Korea; [2]Department of Pathology, Deagu Catholic University, School of Medicine, Daegu, Republic of Korea

Background: There are many studies on gene methylation and immunotherapy in breast cancer, but there are few studies on the effect of DNA methyltransferase (DNMT) inhibitors and immunotherapy on major histocompatibility (MHC) class-I gene methylation in triple-negative breast cancer (TNBC).

Methods: The relationship between the expression of the MHC class-I gene and DNA methylation was analyzed using data from The Cancer Genome Atlas (TCGA). The expression of DNMTs and MHC class-I genes was analyzed in breast cancer tissue from TNBC patients and TNBC cell lines. DNA methylation analysis of the MHC class-I gene was performed with pyrosequencing in TNBC tissues and methylation specific PCR in TNBC cell lines. TNBC cell lines were treated with DNMT inhibitors Decitabine and Zebularine and PD-L1 inhibitor Atezolizumab, and then changes in the expression of DNMT, MHC-I gene, and methylation patterns of MHC class-I gene were analyzed.

Results: TCGA data analysis confirmed that there was an inverse correlation between DNA methylation and mRNA expression of the MHC class-I gene, but analysis in TNBC patients in this study did not show this correlation. After treating TNBC cell lines with DNMT inhibitors and PD-L1 inhibitor alone and in combination, the DNA methylation pattern of the HLA-B and HLA-C gene was suppressed, but there was no significant change in the DNA methylation of the HLA-A gene. The expression of the MHC class-I gene increased in BT-20 after Decitabine treatment, and only in BT-549 after Zebularine treatment. It increased in BT-549 after Atezolizumab treatment, and in MDA-MB231 after combination of Decitabine and Atezolizumab. After each drug treatment, the cell viability of TNBC cell lines was reduced due to the drug's own cancer treatment effect, which limited the analysis of the outcome of changes.

Conclusions: The treatment responses to DNMT inhibitors and PD-L1 inhibitor were different depending on the characteristics of TNBC and the types of drugs, suggesting that the treatment target needs to be applied differently. Further study is needed to determine specific treatment targets and appropriate drugs according to the characteristics of TNBC.

2277P A colorimetric biosensor to track Trop-2 status of tumor cells for diagnosis of breast cancer

T. Zeng[1], H. Shi[1], S. Wu[2], W. Li[3], Y. Yin[4]

[1]Department of Oncology, Jiangsu Province Hospital - The First Affiliated Hospital with Nanjing Medical University, Nanjing, China; [2]Women & Children Central Laboratory, Jiangsu Province Hospital/The First Affiliated Hospital of Nanjing Medical University, Nanjing, China; [3]Oncology Department, Jiangsu Province Hospital - The First Affiliated Hospital with Nanjing Medical University, Nanjing, China; [4]Oncology Department, Jiangsu Province Hospital/The First Affiliated Hospital of Nanjing Medical University, Nanjing, China

Background: The emergence of antibody-drug conjugates (ADCs) targeting trophoblast cell-surface antigen-2 (Trop-2) has reshaped the therapeutic landscape of advanced breast cancer. Accurate profiling of the Trop-2 status of tumor cells can facilitate the identification of patients who will benefit from Trop-2-targeting therapy; however limited analytical method has hindered this process.

Methods: In this study, we have proposed a specific and sensitive biosensor for visual tracking of the Trop-2 status of breast cancer cells based on tetrahedral DNA nanostructure (TDN)-decorated Fe-based metal-organic framework nanoparticles (TDN-PCN-222 (Fe)).

Results: In the design, a dual-aptamer-assisted biomimetic capture strategy shows high capture efficiency while maintaining the viability and original phenotype of captured cells, ensuring the accurate profiling of the Trop-2 status. Meanwhile, by using the high intrinsic peroxidase activity and excellent targeting ability of Trop-2-specific aptamer-linked TDN-PCN-222 (Fe), specific detection of Trop-2-positive tumor cells can be achieved with a limit of detection (LOD) of 10 cells/mL, and the Trop-2 status of tumor cells can be visually tracked. Moreover, the proposed biosensor has been successfully used for tracking the Trop-2 status of tumor cells in breast cancer tissues, suggesting that our method has great promise for clinical applications.

Conclusions: a sensitive and specific colorimetric biosensor was proposed in this work for visually tracking the Trop-2 status of tumor cells. This sensor has been used for the visualized tracking of Trop-2 status of different cancer cell lines as well as breast cancer tumor cells. Therefore, the proposed sensor has considerable potential for visualized tracking of various drug targets on tumor cells from cancerous tissues or the circulating system, and this work may provide an unprecedented method with great promise for the companion diagnosis of Trop-2 ADCs.

2278P Endothelial cell heterogeneity defined by single-cell spatial transcriptomic analysis of breast cancers

K. Homicsko[1], K. Zaman[1], A. Stravodimou[2]

[1]Oncology Department, CHUV - Centre Hospitalier Universitaire Vaudois, Lausanne, Switzerland; [2]Medical Oncology Department, CHUV - Centre Hospitalier Universitaire Vaudois, Lausanne, Switzerland

Background: The heterogeneity of the tumor microenvironment is a major barrier for effective cancer therapies. Similar to the immune tumor microenvironment the stromal environment, composed of cancer-associated fibroblasts (CAFs), pericytes, adipocytes and endothelial cells, is also heterogeneous. Multiple studies showed that CAFs contain heterogenous cell populations with opposing pro and anti-tumoral function. The heterogeneity of endothelial cells (ECs) is less well described largely due to the relative low frequencies in tumor tissues compare to CAFs. We set out to study the heterogeneity of the tumor microenvironment using truly single-cell spatial transcriptomic by the 10x Genomics Xenium platform.

Methods: We analyzed 20 human breast tumors by Xenium single-cell analyzes using fluorescent in situ sequencing (FISSEQ). We used the available breast panel that contains 280 genes, with 8 probes for each gene. The analysis of the data was preformed using the Seurat pipeline in R (version 4.9.9.9039).

Results: We could readily identify blood vessel structures that surrounded PECAM1/VWF positive cells. After multiple clustering we identified five types of endothelial cells with divergent gene expression profiles. We defined the following clusters of ECs: 1) Proliferating ECs, 2) CXCL12+ ECs, 3) $POSTN^{Hi}/VWF^{Hi}$ ECs, 4) $TPD52^{Hi}$ ECs and $POSTN^{Low}/VWF^{Hi}$ ECs. The endothelial cells also showed spatial variations in

distribution. Data on EC subtypes will correlation and other cell types and cell neighborhoods will be presented.

Conclusions: ECs in breast cancer tumors are highly heterogeneous and can be further classified into functionally divergent subtypes, potentially contributing to the heterogenous responses observed to treatments.

2279P Glucocorticoid receptor antagonism and beta adrenergic receptor inhibition: Implications in triple-negative breast cancer brain metastasis

A. Antohi[1], M.S. Flint[2], A. Greenstein[3], H. Hunt[3]

[1]School of Applied Sciences, University of Brighton - Moulsecoomb Campus, Brighton, UK; [2]Pharmacy and Applied Bioscience Department, University of Brighton - Moulsecoomb Campus, Brighton, UK; [3]Corcept Therapeutics, Menlo Park, CA, USA

Background: Triple-negative breast cancer (TNBC) brain metastasis is a major clinical challenge, and the role of stress hormone receptors, specifically the glucocorticoid receptor (GR) and beta-adrenergic receptor (β-AR), in cancer progression remains unclear. This study investigates the impact of GR and β-AR antagonism on the modulation of astrocyte-cancer cell interactions in the context of TNBC brain metastasis.

Methods: Primary murine astrocytes were isolated and cultured alone or in co-culture with 4T1 breast cancer cells. Stress hormones, their antagonists, or a combination of both were administered to the cells for 24 hours. Following treatment, the cell lysates were subjected to western blotting, and the media were analyzed using enzyme-linked immunosorbent assays (ELISAs). ELISAs measured the levels of TNF-alpha, IL-6, and CXCL10.

Results: When cultured alone, astrocytes exhibited a significant ($p<0.05$) increase in IL-6 expression upon treatment with both stress hormones. The addition of GR and β-AR inhibitors mitigated this effect. While TNF-alpha expression was elevated in hormone-treated cells, it did not reach statistical significance. CXCL10 expression significantly decreased in cells treated with both stress hormones and their inhibitors compared to the control ($p<0.005$). In the co-culture setting, astrocyte-released cytokines (IL-6, CXCL10, TNF-alpha). were significantly reduced in control samples.

Conclusions: Glucocorticoid receptor antagonism and beta-adrenergic receptor inhibition exerted modulatory effects on astrocyte-cancer cell interactions. The upregulation of IL-6 in astrocytes upon stress hormone exposure suggests its potential role in promoting TNBC brain metastasis. Furthermore, the significant decrease in CXCL10 expression following combined hormone and inhibitor treatment highlights its potential as a therapeutic target. These findings provide insights into the complex interplay between stress hormone receptors and cancer progression in the context of TNBC brain metastasis.

2280P MiR-193a-3p: A pan-repressor of H2S synthesizing enzymes regulates tumorigenesis and immunosurveillance in breast cancer

A. Dawoud[1], R.A. Youness[2], H.M. Nafea[1], C. Bourquin[3], C. Szabo[4], R.M. Abdel-Kader[5], M. Gad[1]

[1]Biochemistry Department, GUC - German University in Cairo, New Cairo, Egypt; [2]Pharmaceutical Biology Department, GUC - German University in Cairo, New Cairo, Egypt; [3]Department of Anaesthesiology, Pharmacology, Intensive Care and Emergency Medicine, UNIGE - Université de Genève - Centre Médical Universitaire (CMU), Geneva, Switzerland; [4]Pharmacology, University of Fribourg, Fribourg, Switzerland; [5]Pharmacology & Toxicology Dept., GUC - German University in Cairo, New Cairo, Egypt

Background: Hydrogen sulfide (H_2S) is an endogenous gaseous mediator implicated in breast cancer (BC) progression. The 3 principle enzymes responsible for H_2S production in mammals are cystathionine-β-synthase (CBS), cystathionine-γ-lyase (CSE), and 3-mercaptopyruvate sulfurtransferase (3MST), whose overexpression was correlated with poor prognosis in BC patients. Besides, $H_2S$was linked to the suppression of tumor immune microenvironment in BC. Our group recently reported that upon single or dual inhibition of any of H_2S-synthesizing enzymes, the other untargeted enzyme(s) is/are upregulated/activated as a compensatory mechanism for maintaining the level of H_2Sin cancer cells. Thus, the aim of this work is to find a pan-repressor of all 3 enzymes to skip the above compensatory/escape mechanism and to investigate its impact on oncogenic and immunogenic profiles of BC cells.

Methods: BC female patients (n=20) were recruited. In-silico analysis was used to identify microRNAs (miRNAs) that target CBS, CSE, and 3MST. MDA-MB-231 TNBC cells were cultured and transfected by oligonucleotides. Total RNA was extracted using Biazol, reverse transcribed and quantified using qRT-PCR. Western blot analysis was performed. H_2S levels were measured by AzMc. BC hallmarks were assessed by MTT, transwell migration, and clonogenic assays.

Results: MiRNA-193a was validated to regulate the expression of H_2S enzymes by 8 different bioinformatics software, and was found to be significantly downregulated in BC tissues. Further, miR-193a was negatively correlated with CBS, CSE and 3MST levels in BC patients. Ectopic expression of miR-193a resulted in a marked repression of CBS, CSE, and 3MST expression, inducing a significant decrease in cellular H_2S production. in TNBC cells overexpressing miRNA-193a, not only the cancer hallmarks were markedly suppressed but also the immune-suppressor proteins Galectin (GAL) 3 and GAL 9 were decreased significantly.

Conclusions: This study identifies miRNA-193a as a pan-repressor of the 3 principle H_2S-synthesizing enzymes in BC, bypassing the compensatory behavior observed at single or dual inhibition of H_2S enzymes. Thus, miR-193a emerges as a novel tumor suppressor and immunomodulatory miRNA in TNBC.

Background: ASPS and tRCC are rare tumors that harbor recurrent fusions of the TFE3 gene; emerging data for both entities suggest responsiveness to immune checkpoint inhibitors (ICIs). We hypothesized that TFE3 fusions drive unique immune-metabolic changes in both entities compared to their non-TFE3-based counterparts.

Methods: 31 TFE3-rearranged tumors (24 tRCC; 7 ASPS) as well as ccRCC (N =391), undifferentiated pleomorphic sarcoma (N = 111), liposarcoma (N = 49), and angiosarcoma (AS, N = 167) underwent next-generation sequencing (592-gene or whole exome) and whole transcriptome sequencing at Caris Life Sciences (Phoenix, AZ). PD-L1 expression (SP142; +: $\geq$2+, $\geq$5%) was tested by IHC. Cellular composition of the tumor immune microenvironment (TIME) was estimated by quanTIseq. A transcriptomic signature predictive of ICI response (interferon γ score) was applied. Differentially regulated pathways were assessed by gene set enrichment analysis (GSEA). p-values adjusted for multiple comparisons.

Results: ASPSCR1::TFE3 was the most frequent fusion type (N = 9 [ASPS, N = 7;tRCC, N = 2]). PD-L1+ was more frequent in tRCC vs. ccRCC (46% vs. 12%, $p < .05$). tRCC had significantly fewer M1 macrophages (0.32-fold, $p < 0.05$) and lower IFN γ score than ccRCC (-0.31 vs -0.13 Arbitrary Units (AU), $p < .05$). Of the 9 tRCC fusions with N$\geq$2, PRCC::TFE3 (-0.16 AU) had the highest and SFPQ::TFE3 (-0.52) had the lowest IFN γ score. No difference in PD-L1+ was observed between ASPS (14.5%), AS (23%), LPS (8.5%) or UPS (36%), $p > .05$. ASPS had a higher median CD8+ T cell infiltrate (1.63%) vs. UPS: 0, LPS: 0 [$p > 0.05$ both], and AS: 0, $p < 0.05$. There was no significant difference in IFN γ score between ASPS (-0.30 AU) vs. AS (-0.29), LPS (-0.34), UPS (-0.26), $p > .05$. GSEA revealed enrichment of the oxidative phosphorylation genes in both tRCC and ASPS vs. appropriate controls.

Conclusions: TFE3-rearranged ASPS and tRCC demonstrate a distinct TIME with variable enrichment of immune markers vs. control groups. Further functional studies are warranted to determine whether TFE3-fusions have a role in driving oxidative phosphorylation in ASPS and tRCC.

Ltd., Singapore; [10]Hematology Oncology, NUHS - National University Health System, Singapore

Background: The immune system can eliminate malignancy by identifying antigenic peptide epitope presented by neoplastically transformed cells. Immune cells recognize abnormal glycosylation on cancer cells, and this recognition often leads to an inhibitory immune process. We designed a biomedical study to evaluate the role of tissue glycan in predicting immunotherapy response in renal cell carcinoma (RCC) and hepatocellular carcinoma (HCC).

Methods: Thirty-two patients with intermediate/poor risk RCC and advanced HCC (eight respondents and eight non-respondents each) who had received first line immunotherapy-based therapy were identified. The overall survival for RCC and HCC non-respondent cohort was 27.9 months and 8 months respectively but was immature for the respondent cohort. Response criteria to immunotherapy was decided based on the immune related response criteria (iRECIST) where good response is defined as complete or partial response while poor respondent was defined as progression of disease with median survival shorter than reported. Next, we compare the relative abundance and spatial distribution of the glycans in the responder versus non-responder tissue sections given regional characterizations within the tissues. This helps points out the distinct glycans between the responder versus non-responder tissue sections that could serve as potential biomarkers which can then be used in future diagnostic and/or therapeutic intervention. We used the MALDI analysis by rapifleX.

Results: MALDI imaging of HCC and RCC responder versus non-responder tissue section was successfully demonstrated. There was distinct responder versus non responder glycan markers demonstrated by unsupervised segmentation analysis, showing specific layers of glycan organization in the different tissue regions. There are several glycan peaks showing distinctive expression between respondent versus non respondent patients. PCA showed distinguishable variances across each annotated structures derived from segmentation analysis.

Conclusions: Distinct glycan profile markers were observed between both responder and non-responder cohort showing specific layers of glycan organization in the different tissue regions.

2283P Assessing the replicative potential of the oncolytic virus VSV-GP in patient-derived tumor biopsies ex vivo

B. Schoeps[1], M. Mayr[1], M. Glatz[1], S. Estermann[1], A. Guerrero Tort[1], S. Scheidl[2], C. Knobbe-Thomsen[1], T. Nolden[1], S. Schneeberger[2], K. Elbers[1], U. Lauer[3], L. Kloker[3], S. Berchtold[3], J. Beil[3], C. Yurttas[4], R. Kleemann[5], M. Petersson[1]

[1]ViraTherapeutics GmbH, Rum, Austria; [2]Dept. of Visceral, Transplant and Thoracic Surgery, Medical University of Innsbruck, Innsbruck, Austria; [3]Department of Internal Medicine VIII, Medical Oncology and Pneumology, Universitaetsklinikum Tuebingen Medizinische Universitaetsklinik, Tuebingen, Germany; [4]Department of General, Visceral and Transplant Surgery, University Hospital Tübingen, Tuebingen, Germany; [5]TMCP, Boehringer Ingelheim International GmbH, Ingelheim am Rhein, Germany

Background: The understanding of human cancers has increased substantially within the past decade. However, translation of the acquired knowledge into clinical success is still remarkably low. This gap between scientific progress and clinical application is decisively driven by limitations of preclinical models, which often do not sufficiently mimic the complex microenvironment and heterogeneity of human tumors. Therefore, assays allowing for enrichment of human tumors responsive to complex immunotherapies, such as oncolytic virotherapy, are urgently needed. Here, we employed a patient-derived tumor biopsy culture system to assess susceptibility of individual human tumor ecosystems to the oncolytic virus VSV-GP ex vivo.

Methods: A simplified ex vivo culture system of patient-derived tumor biopsies was established and compared to the tumor slice culture approach previously set up in our laboratories. Viability and tissue integrity of human colorectal and pancreatic cancer samples were studied by metabolic activity and histopathology, respectively. Susceptibility of biopsies and slice cultures derived from murine tumors, as well as more heterogenous human tumors to the oncolytic virus VSV-GP was assessed. In particular, virus replication kinetics was monitored over time by using reporter protein-tagged VSV-GP variants and fluorescence microscopy in combination with quantification of viral genomes via qRT-PCR.

Results: Patient derived tumor samples retained viability and histological integrity during overnight storage at 4°C, mimicking the transport from the clinics to the lab, as well as during ex vivo cultivation for up to 72h. Biopsies and slice cultures derived from murine tumors showed similar susceptibility to VSV-GP. These results could furthermore be substantiated in more complex patient-tumor derived samples, where VSV-GP propagated to a similar extent in tumor biopsies and tumor slice cultures.

Conclusions: The here-described assay allows simple and straightforward ex vivo analysis of patient-derived tumor biopsies for susceptibility towards oncolytic viruses. This assay may open new avenues towards enrichment of cancer patients responsive to VSV-GP based oncolytic virotherapy.

Background: Oncolytic viruses (OVs) are capable of eradicating tumor cells and eliciting antitumoral immunity, thus, virotherapy is a promising approach in the field of novel IO-mediated therapies. VSV-GP is an OV which can mediate potent oncolysis in a broad range of solid cancer cell types and initiate adaptive anti-cancer immunity. It exhibits minimal ecotoxicity, as measured by low or absent shedding of infectious virus, poor tenacity in the environment, and no evidence for pathogenesis in treated livestock (healthy swine model). Based on this data, VSV-GP is currently in first-in-

human Phase I trial (NCT05155332). VSV-GP-CD80Fc is a variant of VSV-GP that encodes for a human CD80-Fc fusion protein. The immune-promoting cargo of VSV-GP-CD80Fc was chosen to provide co-stimulation to intra-tumoral T cells. Secreted CD80-Fc exerts its mode of action by binding to CD28 (agonistic) on T cells, which stimulates them in a Fc/Fcγ receptor (FcγR)-dependent manner.

Methods: A pre-clinical characterization of VSV-GP-CD80Fc's replication competence, cargo-expression and therapeutic potential was conducted using state-of-the-art in vitro and in vivo analyses.

Results: The results revealed comparable replication kinetics and an equally good oncolytic activity compared with its antecessor virus, VSV-GP. Furthermore, in vivo mode-of-action studies confirmed the immune-stimulatory effect of the cargo fusion protein. In efficacy studies of the mouse syngeneic CT26.CL25-INFAR-/- model, tumor growth inhibition and survival were dose-dependent leading to >90% tumor growth inhibition in the groups with the highest virus dose, independent of the route of administration. Tumor growth profiles derived from the aforementioned studies were used to characterize the onset of pharmacological activity and to derive a dose prediction that results in an estimated pharmacological active dose (PAD) for VSV-GP-CD80Fc in humans. This can be used as a basis for the definition of a first in human (FIH) starting dose.

Conclusions: In conclusion, VSV-GP-CD80Fc is a highly potent and efficacious oncolytic virus. The usage of the CD80-Fc cargo further boosts the therapeutic potential of VSV-GP-based treatments in humans.

2285P Lower response to COVID-19 booster dose vaccination on cancer patients comparing to healthy controls

P.M.D.R. Cruz[1], F. Dias[2], T. Dias[2], M.S. Pimenta[3], H. Sousa[2], R. Medeiros[2], J. Oliveira[1]

[1]Department of Medical Oncology, Instituto Portugues de Oncologia do Porto Francisco Gentil, EPE (IPO-Porto), Porto, Portugal; [2]Molecular Oncology and Viral Pathology Group, Research Center of IPO Porto (CI-IPOP) & RISE@CI-IPOP (Health Research Network), Instituto Portugues de Oncologia do Porto Francisco Gentil, EPE (IPO-Porto), Porto, Portugal; [3]Department of Oncohematology, Instituto Portugues de Oncologia do Porto Francisco Gentil, EPE (IPO-Porto), Porto, Portugal

Background: Due to a compromised immune system, cancer patients are more prone to have a weaker response to COVID-19 vaccination, which can lead to a worst outcome. Thus it is crucial to evaluate the immunological response of cancer patients to booster doses of the vaccine to stratify the patients accordingly and provide a better care.

Methods: Vaccinated cancer patients from the Portuguese Oncology Institute of Porto, under active cancer treatment with different types of solid tumours (SL) and liquid tumours (LT) were included to study the potential differences in the response to COVID-19 booster dose vaccine according to tumour type. Humoral immune response to the booster dose of the COVID-19 vaccine was evaluated in patients' serum samples analysing IgG levels against SARS-CoV-2 Spike (S) protein. We also analysed the IgG levels against SARS-CoV-2 Nucleocapsid (N) protein to address previous contact with the virus. The first cohort of patients collected samples before the booster dose and 3 and 6 months after (cohort 1, N=54, SL=44, LT=10) and the other cohort collected samples only 3 and 6 months after booster dose (cohort 2, N=71, SL=45, LT=26). A group of vaccinated healthy individuals (N=83) was also analysed, and they collected samples at 3 and 6 months post-boost.

Results: Regarding cohort 1, for solid tumours, we observed that IgG S levels increased 3 months after boost ($p<0.001$) and remained high at 6 months post-boost ($p<0.001$) when compared to pre-boost. One the other hand, the hematologic tumours demonstrated a weak response to vaccination since IgG S levels remained very low 3 and 6 months after the boost. When comparing 3 months post-boost in both cohorts and healthy individuals, we observed that the healthy individuals had the strongest IgG S response, followed by the solid and, lastly, the hematologic tumours. In fact, the difference between solid and haematological tumours was quite significant ($p=0.017$).

Conclusions: We verified that the type of tumour may influence COVID-19 vaccination efficacy since solid cancer patients had a better response to SARS-CoV-2 vaccination when compared to haematological cancer patients. Moreover, as expected, healthy individuals have a stronger immune response when compared to cancer patients.

Background: Solid cancer pts are at higher risk of severe COVID-19 compared to the general population, highlighting the importance of effective vaccination for this vulnerable group. However, there is little evidence on how to identify those at risk of an impaired immune response to vaccination among this heterogeneous group.

Methods: This study evaluates the immune response to COVID-19 vaccines in solid cancer pts using individual participant data meta-analysis methods. The study protocol was registered with Prospero CRD42022311290.

Results: We identified 53 eligible prospective cohort studies, investigators of 6 studies agreed to share data, including around 5000 participants with and without cancer. Here, we present the results of the first 1322 participants, of which 247 did not have cancer. Median age was 62 (IQR 55, 70), and 51% were male. Thoracic (18%), breast (17%), and gastrointestinal cancers (15%) were most common. The majority had metastatic disease (54%); 41% received cytotoxic therapy (CT), 26% immune checkpoint inhibitors (ICIs), and 15% targeted therapy (TT) prior to their 1st vaccination. After the 2nd vaccination, 986 pts (75%) had sufficient antibody titres (ABTs) (defined as 300 binding antibody units/mL), while data were missing for 208 (16%). Following the 2nd vaccination, the proportion of cancer pts with sufficient ABTs was lower (88%) compared with individuals without cancer (99.6%), odds ratio (OR) 0.03 (95%CI 0.00, 0.15; $p < 0.001$). Among cancer pts, those with CT 30 days prior to the 1st vaccination were less likely to have sufficient ABTs (OR 0.61 (95%CI 0.39, 0.94)). There was no such association for treatment with ICIs, TT, monoclonal antibodies, or corticosteroids.

Conclusions: Although most cancer pts develop a sufficient immune response to COVID-19 vaccines, their risk of impaired response is significantly higher than in individuals without cancer. Specifically, pts who received CT within 30 days prior to their 1st vaccination are at higher risk of impaired response, and additional vaccinations may be considered. Results on the association between patient, disease, and treatment characteristics and immune response will be presented at the meeting.

Background: Antibody titers after two doses of mRNA-based SARS-Cov-2 vaccines (SVC) decline after 6 months, requiring a further dose to boost immune response. Anticancer agents may differentially impact the response to SVC, but a direct comparison between patients and with healthy controls (HC) has not been conducted. We serially assessed the immunomic changes associated with the booster dose of SVC in patients treated with adjuvant chemotherapy (aCT, colorectal and breast cancer), rituximab (R, non-Hodgkin lymphoma), immune checkpoint inhibitors (ICI, solid tumors), and HC.

Methods: In the above mentioned groups, we performed blood transcriptome sequencing (TS), multiplex antibody titer (ABt, Spherotech), and SARS-CoV-2-specific IFN release assay (IGRA) before the third vaccine dose (TS/AT/IGRA), after 24 hours (TS), at 5 days (d - TS/IGRA), 26d (AT/IGRA) and after six months (mo - AT/IGRA). Immune transcriptomic modules were assessed using BloodGene3.

Results: We enrolled 52 subjects: 11 R, 11 ICI, 8 aCT, and 22 HC. aCT or ICI showed similar vaccine-specific ABt compared with HC at 26d, increasing at 6mo. ICI showed a significantly reduced increase of IgG2 vaccine-specific ABt at 26d compared with HC. R showed a blunted response at 26d. In all groups, the Env and Core ABt increased significantly at 6mo (81% of subjects), with symptomatic infection in only 31% of subjects. We observed a delayed (5d) but efficient increase in inflammation and chemochine modules in aCT, reduced early inflammation (24h) and increased delayed plasma-cell response (5d) in ICI, and reduced response to all immune modules, except for a delayed increase in IFN modules (5d), in R compared with HC. IGRA results were consistent with IFN modules, with a 5d increase in R.

Conclusions: Patients undergoing aCT and ICI mount a vaccine-mediated immunomic response in part similar, but not identical, to HC, and R patients show a blunted vaccine response in line with the literature. A large fraction of all enrolled subjects developed ABt against natural infection, in the absence of symptoms, at 6mo.

2288P Recolony-treating solid tumors with a bacteria-based approach

E. Katkeviciute, P. Busenhart, A. Montalban-Arques

Wyss Zurich Translational Center, UZH - University of Zurich, Zurich, Switzerland

Background: Current therapies for oncology patients are often ineffective and present severe side effects, decreasing the quality of life of patients significantly. Recent advances in technology and biomedical research have contributed to the characterization of the the human microbiome and uncovered its important role in health and disease. Those findings allowed monitoring, preventing or even curing human disease through specific microbiome interventions. In this context, we now provide a novel and unique solution for the treatment of solid tumors.

Methods: C57BL/6 and BALB/c mice were used to perform the *in vivo* studies. MC-38, CT-26, B16, LLC1.1 and 4T1 cells were used for the heterotopic tumor injections. Flow cytometry and histological analysis were performed to analyze the immune cell compartments. Metagenomics analysis and whole genome sequence were performed to identify the bacterial strains. Metabolomics analysis were conducted to analyse the serum composition of mice and humans.

Results: Based on human CRC data, we identified specific bacteria that are less abundant in CRC patients compared to healthy individuals. When these bacteria are applied in mice, they show very high efficacy as a monotherapy in tumor models for CRC, melanoma, breast and lung cancer through specific activation of CD8+ T-cells (Montalban-Arques et al. 2021). Based on this finding, we now identified the bacterial metabolite that is responsible for the observed immune-activating effect as well as the receptor that is targeted by that molecule, providing a defined mode of action. This allows us to better evaluate our pre-clinical safety and efficacy studies and it give us a strong advantage, comparing to the current microbiome-based solutions where mechanisms remain unkown.

Conclusions: With our promising proof of concept studies, we are aiming to develop a safe and novel microbiome-based solution for the treatment of solid tumors. The specific bacterial strains will be applied to cancer patients in lyophilized form contained in gastro resistant capsules with colonic release. Our bacteria-based cancer therapy aims to improve treatment efficacy while reducing side effects and increasing the life expectancy and quality-of-life of cancer patients.

2289P Determining anti-cancer efficacy of a reversible LSD1 inhibitor, EXS74539, in primary AML tissues with limited thrombocytopenic effects

C. Boudesco[1], R. Okumura[1], M. Iautizi[1], N. Hieger[1], V. Thatikonda[1], M. Ssenekowitsch[1], T-Y. Lin[1], G. Fiume[1], R. Sehlke[1], T. Winkler-Penz[1], A. Payne[2], R. Paveley[2], G.I. Vladimer[1]

[1]Translational Research, Exscientia, Vienna, Austria; [2]Project Biology, Exscientia Ltd., Oxford, UK

Background: Acute myeloid leukaemias (AML) are characterised by distinct chromatin dynamics and aberrant histone methylation regulations. The reversible nature of such epigenetic modifications has become attractive for the design of new AML therapies. Histone methylation is controlled by histone methyltransferases and demethylases, and among them, LSD1 has recently gained interest and tractability with the emergence of new LSD1 inhibitor clinical candidates. Here, we describe efforts to transcriptionally and functionally define the activity of EXS74539 ('539) - a novel potent, selective and reversible LSD1 inhibitor - as a monotherapy or in combination with AML standard of care (SoC) at the single cell level, leveraging our expertise in the use of primary AML and healthy bone marrow samples as model systems (Kornauth et al, 2022).

Methods: Using primary human material as a disease relevant model system, combined with our proprietary deep learning enabled high content imaging and image analysis platform, we explored the capacity of '539 to induce AML blast differentiation and/or improve first line SoC therapy potential both in primary AML samples and in non-transformed healthy bone marrow or peripheral blood mononuclear cells. Collecting baseline and treatment condition genomics and transcriptomics, we modelled the AML specific sensitivity to '539.

Results: Through combining single cell omics and functional response data, we demonstrate, preclinically, the capacity of '539 monotherapy to induce AML cell differentiation marker expression ex vivo, and the usability of '539 together with SoC agents. Using healthy non-transformed bone marrow and colony formation assays, we demonstrate that an adapted drug regimen limits '539 thrombocytopenic potential.

Conclusions: Our preclinical data demonstrated ex vivo efficacy of '539 against AML blast cells and supported the combinatorial potential of '539 with first line clinical AML treatment strategies. Leveraging the reversibility of '539 allowed the design of adapted drug regimens, to preserve the safety profile of this inhibitor on non-transformed healthy cells.

2291P WU-NK-101, best in class memory-NK cell, has key features vital for adoptive cell therapy (ACT) in solid tumors (ST)

J. Muth[1], T. Leedom[2], K. Magee[3], B. Muz[3], J. Vadakekulathu[4], V. Petit[5], N. Bhatnagar[5], D. Primo[6], P. Comune Pennacchi[6], M. Berrien-Elliott[7], T.A. Fehniger[8], J. Davidson-Moncada[1], S. Rutella[4]

[1]Clinical, Wugen, Inc., Saint Louis, MO, USA; [2]Pharmacology & Toxicology, Wugen, Inc., San Diego, CA, USA; [3]Pharmacology & Toxicology, Wugen, Inc. - St. Louis, St. Louis, MO, USA; [4]John van Geest Cancer Research Centre, Nottingham Trent University-Clifton Campus, Nottingham, UK; [5]Research, Metafora Biosystems, Paris, France; [6]Research, ViviaBiotech S.L., Tres Cantos, Spain; [7]Oncology, Washington University School of Medicine in St. Louis, St. Louis, MO, USA; [8]Oncology, Washington University School of Medicine in St. Louis - Siteman Cancer Center, St. Louis, MO, USA

Background: Desirable features for successful ACT include effective migration into tumors, overcoming immunosuppression and dearth of nutrients to survive/function within the tumor microenvironment (TME), not restricted by antigen exclusivity, impervious to antigen escape, and engages the recipient's immune system. WU-NK-101 (WUNK) is a non-engineered cytokine-reprogrammed, expanded, cryopreserved, off-the-shelf NK cell product derived from PBMCs. We have previously shown that WUNK traffic to, and persist in tumor models, and enhanced by mAb combination. Additionally, compared to conventional NK (cNK), WUNK demonstrated improved cytotoxicity A549 (NSCLC): 0% *vs.* 79%, $p=0.0001$ and LoVo (CRC) 0% *vs.* 57%, $p=0.01$, respectively]. (Rutella *et al.*, ESMO 2022).

Methods: Cell phenotypes were evaluated by flow cytometry. Fluorescent Abs for CD3, CD56 were used to resolve BM architecture.

Results: Compared to cNK, WUNK expresses higher levels of cell surface nutrient transporters which adapted to the differing TMEs, suggesting metabolic fitness, and flexibility. Unlike cNK and T-cells, WUNK cytotoxic activity was preserved in TME-aligned media (WUNK: 96.5% vs. 88.2%, $p=0.45$; cNK: 44.1% *vs.* 13.5%, $p=0.009$; T-cell: 53.2 % *vs.*25.2%, $p=0.041$, TME *vs.* conventional media, respectively). Resistance to TME was further confirmed in native-TME-aligned 3D assays from primary tumor surgical samples. WUNK was effective in lysing malignant cells, while sparing benign cells, indicating that WUNK are not indiscriminate killers. This suggests lack of antigen exclusivity and portends resistance to antigen escape. Treatment with memory-NK cells led to T-cell infiltration and co-localization within TME, suggesting coordination with endogenous immune cells. Synergy of WUNK with the endogenous immune system was also documented in a humanized mouse (engrafted with hPBMCs) model, across a number of ST xenografts, which showed deeper anti-tumor responses.

Conclusions: We show that WUNK cells exhibit features that overcome challenges for ACT and enhances anti-tumor activity in ST, heralding the promise of NK cell therapy for ST. The data presented augurs positively for pts to be treated in the upcoming phase I/b clinical study.

2292P Prevalence of druggable EGFR genomic alterations in solid tumours other than lung cancer

T. Kondo, K. Fukuyama, Y. Yamamoto, M. Kanai, M. Muto

Department of Clinical Oncology, Kyoto University Hospital, Kyoto, Japan

Background: An increasing number of rare oncogene-driven solid cancers have been detected through comprehensive genomic profiling testing. *EGFR* genomic alterations are the most frequent oncogenic driver alterations in non-small cell lung cancer, and EGFR-tyrosine kinase inhibitors (TKIs) are effective in this population. However, the frequency of *EGFR* genomic alterations and clinical outcomes of EGFR-TKIs are not well understood in other types of solid tumours.

Methods: Clinical and genomic data retrieved from the Center for Cancer Genomics and Advanced Therapeutics database, the national datacentre for cancer genomic medicine in Japan (Kohno T, et al. *Cancer Discov.* 2022;12(11):2509-2515.), were collected and analysed (n = 18,124, March 2022-February 2023). This study aimed to investigate the prevalence of druggable *EGFR* genomic alterations in patients with solid tumours other than lung cancer. Druggable *EGFR* genomic alterations were defined based on OncoKB™ Therapeutic Level of Evidence V2 (≥Level 3B) that could confer sensitivity to EGFR-TKIs.

Results: Among 17,155 patients with solid tumours other than lung cancer, druggable *EGFR* genomic alterations were identified in 37 patients (0.22%). The median age was 61 years (range, 10-78 years). The most frequent cancer type was central nervous system/brain (n = 10), followed by head and neck (n = 5), bowel (n = 4), biliary tract (n = 3), and breast (n = 3). The druggable *EGFR* genomic alterations were observed with *EGFR* exon 20 in-frame insertions (n = 11), *EGFR* kinase domain duplication (n = 10), *EGFR* exon 19 in-frame deletions (n = 4), *EGFR* L858R (n = 3), *EGFR* S768I (n = 3), *EGFR* G719D (n = 3), *EGFR* L861Q (n = 1), *EGFR* T790M (n = 1), and *EGFR* G719A (n = 1). Clinical data regarding treatment using EGFR-TKIs were not recorded in this database.

Conclusions: Druggable *EGFR* genomic alterations in solid tumours other than lung cancer were observed in 0.22% of this nationwide large cohort. Further clinical investigation is needed to understand the clinical relevance of EGFR-TKIs in patients with solid tumours harbouring druggable *EGFR* genomic alterations not limited to non-small cell lung cancer patients.

Background: Neutrophil extracellular traps (NETs) are structures released by activated neutrophils (NEU) into the extracellular microenvironment in response to different stimuli through a process referred to as NETosis. Although first described as an antimicrobial response to infection, NETosis is also involved in cancer. In the context of gastrointestinal tumors, the enrichment of NETs in the metastatic site (even before tumor cell seeding) compared to primary tumor, along with their capability to entrap disseminated cancer cells, suggest that NETs may serve as scaffolds for microbes or circulating tumor cells to create the metastatic niche. While providing mechanistic insights on the selective liver-tropism of certain cancers, NETs could be developed into a prognostic and predicitve biomarker.

Methods: We prospectively collected serum samples from 137 pts, of which 74 were diagnosed with resectable gastroesophageal adenocarcinoma (GEA) and 63 with locally advanced rectal cancer (LARC). Pts received a multimodal treatment (chemotherapy in GEA cohort or chemoradioterapy in LARC cohort, followed by surgery). Whenever available, paired tissue samples from tumor and non-tumor adjacent tissues were collected at baseline and at surgical time for in-sito NET detection and transcriptomic analysis. Serum samples (n= 372) were collected longitudinally and the NETs quantified by an established ELISA assay for citrullinate histone H3 (cit-H3).

Results: We preliminarly quantified serum NETs of pts in GEA cohort (at baseline, during treatment and at disease progression) showing that cit-H3 levels are positively correlated with tumor burden. Moreover, treatment *in vitro* of freshly isolated human NEU with interstitial fluids from tumor and non-tumor adjacent tissues revealed the specific influence of tumor microenvironment's factors on NETs formation. Here, we will present final results obtained on the whole cohort, both on the quantification of circulating NETs and in the tissue of primary and metastatic lesions.

Conclusions: Peripheral NETs positively correlate with tumor burden in the serum of pts with GEA, supporting the relevance of NETosis in tumor progression and their potential as non-invasive biomarker.

2294P Whole genome sequencing to define the germline-somatic interaction in young-onset lung cancer

J. LoPiccolo[1], R. Collins[2], D.R. Koeller[3], A.C. Pollaci[3], E. Voligny[1], T. Nguyen[1], A.J. Pangilinan[1], X. Wang[4], L. Su[4], J. Lin[5], J.E. Garber[3], D.C. Christiani[4], S. Gusev[2], P.A. Jänne[1]

[1]Lowe Center for Thoracic Oncology, Dana-Farber Cancer Institute, Boston, MA, USA; [2]Division of Population Sciences, Dana-Farber Cancer Institute, Boston, MA, USA; [3]Center for Cancer Genetics and Prevention, Dana-Farber Cancer Institute, Boston, MA, USA; [4]Environmental Health, Harvard T.H. Chan School of Public Health, Boston, MA, USA; [5]Thoracic Oncology Department, MGH - Massachusetts General Hospital, Boston, MA, USA

Background: Although the average age of lung cancer diagnosis is 70, thousands of cases are diagnosed annually in patients under 45. Previous work has shown that lung cancers in younger patients frequently harbor targetable somatic alterations, suggesting young age may be an emerging clinical biomarker of lung cancer biology. Given young age at diagnosis and absence of known environmental insults, we hypothesized that underlying germline variation predisposes to developing lung cancer at a young age.

Methods: We assembled a cohort of 350 patients diagnosed with NSCLC/SCLC at age 45 or younger and performed germline multi-gene panel testing and whole-genome sequencing (WGS) from peripheral blood, along with tumor panel-based NGS. Germline results were compared to WGS from ancestry-matched, uniformly processed non-cancer controls as part of the 1000 Genomes Project as well as exomes from lung cancer patients diagnosed over 45 as part of The Cancer Genome Atlas (TCGA).

Results: Preliminary WGS from 243 patients shows at least 30% of patients carry clinically actionable pathogenic germline variants (PGVs) in cancer-associated genes, at rates exceeding those seen in other cancers — with gene set enrichment analyses (GSEA) showing key age-specific differences compared to lung cancer patients in TCGA. GSEA show high carrier rates of rare PGVs in several cancer-related pathways, including genes mediating DNA damage repair and receptor tyrosine kinase signaling. Common variant polygenic risk scores were negatively associated with rare PGVs, suggesting an independent contribution to risk. Clinicopathologic analysis of this cohort shows enrichment for never-smoking status (74%), female sex (59%), and adenocarcinoma (LUAD, 89%). Of LUAD, 88% harbor targetable somatic alterations: 38.9% *EGFR*-mutant (75% exon 19 deleted), 24.1% *ALK*-rearranged, and 33% fusion-positive.

Conclusions: Rare PGVs mediate lung cancer risk in young lung cancer patients, with age-specific differences compared to patients diagnosed at older ages. These results prompt consideration of a group based on germline risk that may benefit from CT screening as part of future changes to clinical care. Further work will delineate additional risk mediated by non-coding and structural variants.

2295P Pan-cancer prevalence of MET fusions and clinical response to MET- targeted therapy

M. Vojnic[1], I. Odintsov[2], Z. Liu[3], D. Lu[4], M. Harshan[5], A. Ameri[6], S. Machnicki[7], X. Xiao[8], W. Lockwood[4], M. Ladanyi[9], R. Somwar[9]

[1]Lenox Hill Hospital, Northwell Health Cancer Institute, New York, NY, USA; [2]Department of Pathology, Brigham and Women's Hospital, Boston, MA, USA; [3]Department of Pathology, Renji Hospital Affiliated to Shanghai Jiaotong University School of Medicine, Shanghai, China; [4]Department of Pathology and Laboratory Medicine, UBC - The University of British Columbia, Vancouver, BC, Canada; [5]Department of Pathology, Lenox Hill Hospital, New York, NY, USA; [6]Department of Hematology/Oncology, Lenox Hill Hospital, New York, NY, USA; [7]Department of Radiology, Lenox Hill Hospital, New York, NY, USA; [8]Department of Oncology, Renji Hospital Affiliated to Shanghai Jiaotong University School of Medicine, Shanghai, China; [9]Department of Pathology, MSKCC - Memorial Sloan Kettering Cancer Center, New York, NY, USA

Background: *MET* rearrangements are found in multiple cancers. Despite the availability of effective MET drugs there is no approved treatment for these tumors. We determined the prevalence of *MET* fusions, explored MET therapy in preclinical models and assessed efficacy of MET tyrosine kinase inhibitors (TKI) in a colorectal cancer (CRC) patient with *MET* fusion.

Methods: We analyzed the AACR project GENIE registry (release V13, 167,423 samples from 148,268 patients) for intergenic *MET* fusions. We also identified 2 CRC patients (Lenox Hill Hospital, New York, NY, and Renji Hospital Shanghai, China, respectively) by RNA-based NGS. MET expression was assessed by IHC. Sensitivity of SJ-GBM2 (*CLIP::MET*, glioblastoma), and H1993 and EBC1 (*MET* amplified lung cancer) cells to type 1 and type 2 MET TKIs were assessed.

Results: We identified 44/148,286 patients (0.03%) with an intergenic *MET* fusion; cancer types included brain (n=12; with 8 high-grade gliomas), NSCLC (n = 11 with 9 adenocarcinomas), gastrointestinal tract (n = 8; with 3 esophageal adenocarcinomas, 3 cholangiocarcinomas), etc. Recurrent fusion partners accounted for 18/44 (40.1%) cases and included 7 *PTPRZ1,* 5 *ST7*, 3 *CTTNBP2*, 2 *CAPZA2* and 2 *DOCK4.* Two CRC patients with *MET* fusions (*SYNRG2::MET, ZKSCAN1::MET*) were found from routine NGS screening and both showed strong MET expression. Treatment with type 2 (cabozantinib) or type 1 (crizotinib, capmatinib, savolitinib) MET TKIs blocked growth of SJ-GBM2 cells with IC50 values of 0.3, 0.2, 0.1 and 0.04 μM, respectively, reflecting the sensitivity observed in H1993 and EBC1. MET TKIs blocked MET, AKT, ERK and S6 phosphorylation in SJ-GBM2 cells. These results were recapitulated with *MET* shRNAs. The CRC patient (SYNRG2::MET fusion) failed several lines of chemotherapy and was then treated with crizotinib, achieving a mixed response, with stable disease in lung metastases. Upon progression the patient was treated with capmatinib and a decrease in CEA from was observed after 3 weeks on therapy.

Conclusions: Our findings indicate *MET* fusions are widely distributed among tumor types and are sensitive to type 1 and type 2 MET TKIs. Clinical trials evaluating MET inhibitors for patients whose cancers are driven by *MET* fusions are ongoing.

2296P SGLT2 i dapagliflozin reduces NF-kB expression in heart and kidneys of preclinical models exposed to doxorubicin through MYd-88 and NLRP3 pathways

N. Maurea[1], I. Bisceglia[2], M. Iovine[3], A. Paccone[4], G. Palma[5], F. Bruzzese[5], A. Luciano[5], F. Florio[1], F. Zito Marino[6], R. Franco[6], V. Quagliariello[1]

[1]Division of Cardiology, Istituto Nazionale Tumori - IRCCS - Fondazione G. Pascale, Naples, Italy; [2]Division of Cardiology, Azienda Ospedaliera San Camillo Forlanini, Rome, Italy; [3]Cardiology, Istituto Nazionale Tumori IRCCS - Fondazione G. Pascale, Naples, Italy; [4]Cardiology Department, Istituto Nazionale Tumori IRCCS - Fondazione G. Pascale, Naples, Italy; [5]Animal Facility, Istituto Nazionale Tumori IRCCS - Fondazione G. Pascale, Naples, Italy; [6]Pathology Unit, Universita degli Studi della Campania Luigi Vanvitelli, Naples, Italy

Background: Doxorubicin-mediated adverse cardiovascular events are among the leading causes of morbidity and mortality in breast cancer patients. Sodium-glucose cotransporter 2 (SGLT2) inhibitors have recently been shown to be of therapeutic value in patients with type 2 diabetes, chronic kidney disease, and heart failure with reduced ejection fraction, conditions that commonly coexist and are interrelated pathophysiologically.

Methods: Female C57Bl/6 mice were untreated (Sham, n=6) or treated for 10 days with doxorubicin i.p at 2.17 mg/kg (DOXO, n=6), DAPA at 12 mg/kg (DAPA, n=6) or doxorubicin combined to DAPA (DOXO-DAPA, n=6). Ejection fraction, radial and longitudinal strain were analyzed through transthoracic echocardiography (Vevo 2100). Cardiac tissue expression of NLRP3, Myd88, DAMPs (galectine 3 and calgranulinS100), pAMPK, NF-kB, and 13 chemokines (IL-1α, IL-1β, IL-2, IL-4, IL-6, IL-10, IL-12, IL17-α, IL-18, IFN-γ, TNF-α, G-CSF, and GM-CSF) were quantified through ELISA and western blot methods.

Results: DAPA improved significantly the EF and prevented the reduction of radial and longitudinal strain after 10 days of treatment with doxorubicin. A reduced expression of NLRP3, MyD88, DAMPs and NF-kB in cardiac tissues was seen in DOXO-DAPA group compared to DOXO mice ($p<0.001$). Cardiac expression of IL-1β, IL-6, TNF-α, G-CSF and GM-CSF were significantly reduced after treatment with DAPA. Expression of pAMPK was strongly enhanced in DAPA-DOXO compared to DOXO group. Levels of Calgranulin S100 and galectine-3 were strongly enhanced in DOXO group; on the other hand their expression were reduced by 47.7 and 52.3% in DAPA-DOXO group vs DOXO ($p<0.005$). Hystology evaluation indicate reduction NF-kB expression in myocardial and renal tissue in DOXO-DAPA vs DOXO. Radial strain (RS) is 38.8% in DAPA-DOXO vs 14.1% in DOXO groups ($P < 0.05$); longitudinal strain (LS) is − 23.4 % in DAPA-DOXO vs − 10.5% in DOXO groups ($P < 0.001$)

Conclusions: In this preclinical study, DAPA is able to improve cardiac function and reduce biomarkers involved in heart failure and fibrosis. The overall picture of the study pushes the use of DAPA in prevention of cardiomyopathies induced by anthracyclines in cancer patients.

2297P Gene co-expression networks capture the potential pathogenesis and progression of upper tract urothelial cancer

T. Fu[1], Y. Lin[1], Y. Yang[1], N. Xiang[1], G. Liao[2], L. Du[3], J. Huang[1]

[1]Medical Device Regulatory Research and Evaluation Center, West China Hospital of Sichuan University, Chengdu, China; [2]State Key Laboratory of Oral Diseases, National Clinical Research Center for Oral Diseases, West China Hospital of Sichuan University, Chengdu, China; [3]China Center for Evidence-Based Medicine, West China Hospital of Sichuan University, Chengdu, China

Background: Upper tract urothelial carcinoma (UTUC) accounts for 5%-10% of all urothelial malignancies. And the incidence of UTUC in China is much higher than that in European and American countries, accounting for about 31%. Approximately two-thirds of patients have invasive disease at diagnosis. However, little research has been done on UTUCs.

Methods: To better understand the pathogenesis of UTUC and provide references for its diagnosis and treatment, we conducted a Weighted Correlation Network Analysis (WGCNA) involving the RNA sequencing data of 27 UTUC patients. Multiple linear regression models were used to explore the association between gene modules and clinical indicators. We then imported related modules into Cytoscape. to screen hub genes. Additionally, we performed RNA differential expression analysis, exon mutation analysis, and looked at mutations in hub genes. Enrichment analysis was then conducted based on differentially expressed genes to discover potential pathways regulating UTUC. Finally, bladder cancer data in TCGA database was used to verify the hub genes.

Results: We classified the genes into 31 modules by unsupervised clustering, with 4 modules ($FDR<0.05$) significantly associated with tumor infiltration. Then 9 potential biomarkers, including MSRB3, HSPB2, SCRG1, SYNPO2, FXYD1, PLXNA4, CD163, IFFO1, and FPR3, were discovered by importing these 4 modules into Cytoscape software. Differential expression analysis showed that except for the FPR3 gene, the remaining 8 genes were under expressed in UTUC. This has also been verified in public databases. Meanwhile, SNP mutation occurred in MSRB3, SYNPO2, and PLXNA4 genes. Functional enrichment analysis revealed that differentially expressed genes regulate UTUC through pathways such as cell adhesion, transmembrane receptor protein kinase activity, cGMP-PKG signaling pathway, p53 signaling pathway, and cardiomyocyte adrenergic signaling pathway.

Conclusions: Although these 9 genes are new and significant genes in UTUC, they have been proved in public databases. Our results not only promote our understanding of the relationship between the transcriptome and clinical data in UTUC but will also guide the development of targeted molecular therapy for UTUC.

2298P Feasibility of ex vivo drug sensitivity testing in urothelial cancer: EVITA trial

M.P. Scholtes[1], L. Ceton[2], D. van der Meer[2], F. Grillet[2], M. Garcia Montero[2], C.Z. Roeland[1], E. Boevé[3], J. Leijte[4], H. Roshani[5], G.J. van Leenders[6], W. Vader[2], J.L. Boormans[1]

[1]Urology, Erasmus MC Cancer Institute - Erasmus Medical Center Rotterdam, Rotterdam, Netherlands; [2]R&D, VitroScan B.V, Leiden, Netherlands; [3]Urology, Franciscus Gasthuis & Vlietland - Vlietland Hospital, Schiedam, Netherlands; [4]Urology, Amphia Ziekenhuis-location Molengracht, Breda, Netherlands; [5]Urology, Haga teaching hospital, The Hague, Netherlands; [6]Pathology, Erasmus MC, Rotterdam, Netherlands

Background: Patients with bladder cancer (BC) are treated with chemotherapy, either intravesically or systemically. Predictive biomarkers to guide clinical decision-making on chemotherapy are lacking, leading to potential ineffective treatment and toxicity. We hypothesized that an established *ex vivo* tumor testing assay could identify chemoresponsive BC prior to treatment and we performed a prospective feasibility trial (OZBS62.21051).

Methods: Fresh tumor tissue was collected and characterized by histological evaluation of H&E slides and hotspot mutation analysis of *hTERT*, *FGFR3* and *PIK3CA* genes. For *ex vivo* drug testing, tumor clusters were isolated, seeded, and exposed to single-agent chemotherapy: carboplatin, cisplatin, gemcitabine and targeted therapy (erdafitinib). Sensitivity evaluation was performed by extraction of morphological features from high-throughput 3D imaging data, followed by AUC comparison of fitted dose-response curves.

Results: *Ex vivo* drug testing was successful for 28 out of 48 patients (58%), generating results within two weeks. Absence of muscle-invasiveness was key in assay success, with higher success in non-muscle invasive BC (NMIBC) (17/20, 85%, (OR: 3.8, 95% CI: 1.7 − 9.1) than in muscle-invasive BC (11/28, 39%). The assay identified a subgroup of NMIBC patients with exceptional *ex vivo* gemcitabine response. *Ex vivo* sensitivity to FGFR inhibitor erdafitinib was observed in two patients with somatic *FGFR3-Y375C* mutations but not for *FGFR3*-WT patients (P = 0.03).

Conclusions: We report the feasibility of *ex vivo* 3D tumor testing for BC. A correlation with clinical response to chemotherapy could not be established due to a lack of successfully screened patients with matching clinical chemotherapy treatment. For NMIBC, however, differential *ex vivo* sensitivity to gemcitabine, and a preliminary correlation for *ex vivo* erdafitinib sensitivity and *FGFR3* mutation status offers a potential solution to select NMIBC patients for effective (novel) treatment options.

2299P Mebendazole enhances the anticancer effect of irinotecan and check-point inhibitor in vitro and in vivo

S. Mansoori[1], K. Blom[2], C. Andersson[1], M. Fryknäs[2], R. Larsson[2], H.P. Nygren[3]

[1]Oncology Department, University Hospital Uppsala/Akademiska Sjukhuset, Uppsala, Sweden; [2]IMV, Uppsala University, Uppsala, Sweden; [3]Oncology, University Hospital, Uppsala University - Rudbecklaboratoriet, Uppsala, Sweden

Background: Mebendazole (Mbz), a well-known anthelminthic drug, has been demonstrated to have anti-cancer properties in tumor models and patients. The therapeutic effect of Mbz was suggested to be due to microtubule inhibition, but more recently we reported that Mbz switches macrophages from the M2 to the tumor suppressive M1 phenotype. The aims of this study were to further investigate in tumor models the cytotoxic and immunomodulatory effects of Mbz alone, in combination with cytotoxic drugs and PD-1 antibody.

Methods: Tumor samples from patients with solid or hematological malignancies undergoing diagnostic or therapeutic procedures were obtained in accordance with ethical permission. The samples were then prepared to isolated tumor cells for ex vivo testing. Ex vivo activity of Mbz alone and in combination with standard cytotoxic drugs was assessed using the fluorometric microculture cytotoxic assay. Survival index and synergy scores were calculated using GraphPad and SynergyFinder. In vivo anti-tumor activity of Mbz, irinotecan, a PD-1 inhibitor and their combinations were examined in a murine BALB/c model with inoculated syngeneic colon cancer cells (CT26). Tumor growth was measured by caliper and tumors were retrieved and assessed by flow cytometry for immune cell infiltration.

Results: Mbz alone showed some modest cytotoxic activity against patient tumor cells ex vivo, with hematological tumor cells being slightly more sensitive. The cytotoxic effect of Mbz was generally additive to that of other drugs but synergistic when combined with irinotecan. In the murine model, Mbz, irinotecan and the PD-1 antibody alone inhibited tumor growth. Combined with irinotecan Mbz had an additive effect, but was synergistic when combined with the PD-1 antibody. In line with the latter observation, flow cytometry showed an increase of M1 macrophages and decrease of M2 macrophages in tumors from animals treated with the combination.

Conclusions: Mbz show promising features making it suitable for repositioning into an anti-cancer drug, most notably as a modulator of the macrophage phenotype that may enhance and the effect of check-point inhibitors.

Background: Immunotherapy is one of the mainstays of lung cancer treatment. However, the results presented in pivotal trials do not always reflect those in real life, as patients (pts) are more selected for prognostic factors. Cancer is associated with advanced age, and aging is the main risk factor for developing CHIP, a clonal expansion of mutations affecting genes involved in hematologic malignancies in pts without a hematological disease per se.

Methods: We performed a Next-Generation Sequencing (NGS) panel of 74-genes dedicated to hematological alterations on DNA extracted from whole blood collected before first administration of an ICB for advanced NSCLC, within the PREMIS trial (NCT03984318). CHIP prevalence was assessed according to a variant allele frequency

(VAF) threshold of 2%. The main objective is to evaluate CHIP prevalence in a prospective cohort of pts treated with ICB for NSCLC correlating CHIP with clinical outcomes.

Results: We included 104 pts; 68 pts (65%) male, median age of 68 years [range 31-87], and adenocarcinoma represented 68% of cases. ICB setting was 1°L 41%; 2°L 47%; ≥ 3°L 11%, and the most used ICB was Pembrolizumab in 63% of pts. Finally, 98 pts were retained for the analysis. At least 1 CHIP mutation was found in 47 pts (48%).The most frequent mutations were found in *DNMT3A* (69%), *PPM1D* (17%), *TET2*, *ASXL1* and *CHEK2* genes (7% respectively). Median PFS was 2.6 months (m) for CHIP vs 9.3 m no-CHIP 12 m (p=0.02) and median OS was 9.3 m CHIP vs 15 m no-CHIP (p=0.11), associated to lower percentage of PD-L1 and a higher number of metastatic sites in the multivariate analysis. No pts developed hematological disease during the follow up.

Conclusions: CHIP is commonly found in pts with NSCLC, with a prevalence in our cohort of 48% with statistically significant worse PFS in the CHIP-positive population.

2301P Combining cancer patient spatial transcriptomics and bulk RNA-Seq data to drive insights into NSCLC

J. Bischof[1], M. Schoeppler[2], B. Motamedi-Baniassad[2], N. Kerstedt[2], K. David[3], J. Woodsmith[1]

[1]Advanced Analytics and AI, Indivumed Therapeutics GmbH, Hamburg, Germany; [2]Genomics, Indivumed Services GmbH, Hamburg, Germany; [3]Research & Development, Indivumed Services GmbH, Hamburg, Germany

Background: Combining cancer patient spatial transcriptomics (ST) and bulk RNA-Seq allows for a more nuanced understanding of the gene expression (GE) profiles. While large-scale sequencing projects have revealed some NSCLC cancer drivers, they cannot fully address the complexity of the heterogeneous tissue composition present in patients. ST enables the measurement of GE in specific regions within a tissue sample, complementing and refining insights gained from bulk RNA-Seq.

Methods: Fresh-frozen, NSCLC tumor and normal samples were profiled using the 10x Genomics Visium Spatial Gene Expression platform. Spatial differential expression and pathway analysis were performed using Space Ranger and David Functional Annotation respectively. Bulk RNA was prepared using Qiagen AllPrep Universal and TruSeq Stranded Total mRNA kits and sequenced on a NovaSeq6000. Integrated data analysis was undertaken using R (Seurat). Images of spatial GE were generated using the Loupe Browser.

Results: Bulk RNA-Seq and ST showed strong overall agreement between expression profiles, facilitating refinement of disease specific alterations observed in large NSCLC cohorts through ST data. Patient-specific GE in specific tumor regions was identified and could guide future precision medicine approaches: for example tumor-related genes EPCAM or PDCD6 were higher expressed in the tumor center, whereas HTRA3 which suppresses tumor cell invasiveness shows higher expression in the microenvironment. Furthermore, the transcription factor KLF5 is higher expressed in tumor regions but shows no strong regulation in bulk data. This highlights how spatially resolved data can provide insights into the identification and assignment of cancer-relevant genes that primarily show only minor regulation in bulk RNA-Seq data.

Conclusions: A more refined in situ understanding of GE profiles in the NSCLC microenvironment, combined with large cohort data will help guide therapeutic target selection. The combination not only refines target expression cell types (E.g. primary tumor or immune system) but also provide a strong indicator for target GE variability within patients' tumors for improved precision medicine approaches.

2302P Efficacy assessment of targeted and immunotherapies for personalised treatment of melanoma using 2D and 3D ex-vivo assays

M.M. Rahman[1], G. Wells[1], J. Rantala[2], T. Helleday[3], M. Muthana[1], S. Danson[4]

[1]Department of Oncology and Metabolism, University of Sheffield Medical School, Sheffield, UK; [2]Ex-vivo Screening, Misvik Biology, Tukru, Finland; [3]Oncology and Pathology Department, Karolinska Institutet, Huddinge, Sweden; [4]Oncology and Metabolism Department, Weston Park Hospital - Sheffield Teaching Hospitals NHS Foundation Trust, Sheffield, UK

Background: Ex-vivo functional drug assessment has been successfully tested to guide treatment decisions with higher predictive value for multiple malignancies. Similar methods can also be used to test the personalised efficacy of standard-of-care drugs for advanced melanoma. We are currently developing an ex-vivo high throughput preclinical workflow comparing different ex-vivo models with a range of clinically approved and experimental systemic drugs including immunotherapies.

Methods: A high-content immunofluorescence (IF) microscopy-based viability assay for drug screening has been developed and optimised using melanoma cell lines and four targeted inhibitors. Upon exposure, the drug efficacy profiles were generated by counting fluorescently labelled melanoma cells. A 3D spheroid-pbmc coculture model is currently being optimised for the efficacy assessment of Immune Checkpoint Inhibitors currently used to treat melanoma patients. The immunotherapy efficacy will be assessed by immune cell activation and spatial distribution of immune cells in relation to tumour spheroids. Currently, we are recruiting stage III/IV melanoma patients to collect metastatic lymph nodes which are being used for the 2D and 3D assays. The drug efficacy results will be correlated with the corresponding patient's clinical follow-up data.

Results: A 2D image based cell viability assay has been optimised using melanoma cell lines. Dose-response curves have been successfully generated with IC50 values for targeted inhibitors using fluorescently labelled melanoma cell lines in the 2D imaging assay. For 3D coculture, spheroids were successfully generated from cell lines and patient samples in hydrogel sandwich assay, hydrogel dot matrix assay, and 3% methyl cellulose- media floating assay. The spheroids and isolated PBMCs from patients and healthy donors are now being used to optimise the coculture assay for ICB efficacy assessment.

Conclusions: The preliminary data shows, the project can provide valuable insight into the applicability and translational potential of ex vivo screening guided personalised treatment for advanced melanoma patients and identify novel, repurposed, or combination treatments with improved clinical outcomes.

Clinical trial identification: NCT05231655.

2303P Protein functional interpretation of gene variants observed in clinical next-generation sequencing (NGS) for pleural mesothelioma

F.W.F. Cerciello[1], P. Marchal[1], L. Bürgi[1], K. Samarasinghe[2], M. Martens[3], F. Ehrhart[4], C.T. Evelo[5], L. Lane[2]

[1]Department of Medical Oncology, Inselspital, Bern University Hospital, University of Bern, Bern, Switzerland; [2]Calipho, SIB - Swiss Institute of Bioinformatics, Geneva, Switzerland; [3]Department of Bioinformatics — BiGCaT NUTRIM, Maastricht University, Maastricht, Netherlands; [4]Department of Bioinformatics — BiGCaT NUTRIM and MHeNs, Maastricht University, Maastricht, Netherlands; [5]Department of Bioinformatics — BiGCaT NUTRIM and Maastricht Centre for Systems Biology (MaCSBio), Maastricht University, Maastricht, Netherlands

Background: The interpretation of gene variants from NGS data may support clinical and treatment decisions in pleural mesothelioma. Predicting how a variant can affect the functions of the protein- or disease-relevant pathways is challenging and, so far, it largely relies on gene-centric algorithms. We complement this by integrating a protein-centric interpretation of the variants in order to expand the functional information accessible from clinical NGS.

Methods: We have screened for pleural mesothelioma clinical NGS datasets accessible from literature reports focusing on the relevant genes *BAP1* and *NF2*. NGS results are combined with protein information from neXtProt using an in-house developed program. Conservation-based predictions are integrated with structural and functional protein information to assess the functional impact of the variants. The pleural mesothelioma molecular pathway in the WikiPathways knowledgebase permits us to interpret the relevance of the variant within its pathway environment (https://www.wikipathways.org/pathways/WP5087.html).

Results: The variants from an initial NGS dataset have been mapped on the protein sequences, resulting in 209 protein variants for BAP1 and 181 for NF2 isoform 1. Functional predictions from the algorithms SIFT and PolyPhen-2 embedded in neXtProt presented approx. 60% agreement for BAP1 and 51% for NF2. 13% of the BAP1 and 22% of the NF2 variants had no prediction. The integration of the protein-centric information refined the functional interpretation of 121 variants in BAP1 and 107 in NF2 located in regions critical for the function of the proteins, like interacting or enzymatically active domains, FERM domains or loci of post-translational modifications. Among them, 67 variants with missing or ambiguous prediction between SIFT and PolyPhen-2 (30 in BAP1, 37 in NF2). The molecular pathways of pleural mesothelioma revealed critical sites in the BAP1 and NF2 pathways potentially affected by the variants (WikiPathways:WP5087; Malignant pleural mesothelioma (WP5087)).

Conclusions: Protein-centric and pathway-embedded interpretation of gene variants may complement NGS information for clinical decisions in pleural mesothelioma.

Background: Tepotinib is a selective MET tyrosine-kinase inhibitor. We evaluated the efficacy and safety of tepotinib in patients with various solid cancers harboring *MET* exon 14 skipping mutation (*METex14)* or *MET* gene amplification.

Methods: A phase II, multicenter, single arm study was conducted for patients with advanced or metastatic solid cancers who progressed after standard treatment, harboring either *MET*ex14 or *MET* amplification (gene copy number≥6) detected by tissue—based next generation sequencing (NGS). Tepotinib was administered at a dose of 500mg once daily, until disease progression or unacceptable toxicity. The primary end point was objective response rate (ORR), and the secondary end points were progression-free survival (PFS), overall survival (OS), disease control rate (DCR) and safety profiles. For exploratory analyses, we analyzed gene profile using alphaLiquid® panel, a liquid—based NGS.

Results: A total of 35 patients were included (*MET*ex14, n=24; *MET* amplification, n=11). In patients with *MET*ex14, NSCLC was the most common (21 of 24) while other cancers were more common in patients with *MET* amplification (8 of 11). At a median follow-up of 19 months, the ORR was 57.6% for all patients, 52.2% for *MET*ex14, and 70% for *MET* amplification. Median PFS was 8 months (95% CI, 4.5-11.5) and median OS was 14 months (95% CI, 7.8-20.2) in all patients. For *MET*ex14, the median PFS was 9 months (95% CI, 1.6-13.6), and the median OS was not reached. For *MET* amplification, the median PFS was 7 months (95% CI, 1.5-12.5) and the median OS was 10 months (95% CI, 5.8-14.2). The ORR of patients with *MET* dysregulations detected in liquid—based NGS was 81.3% while the ORR of patients without *MET* dysregulations was 30%. The most frequently reported adverse events were peripheral edema (40.0%), followed by asthenia (28.6%), transaminase elevation (22.9%), and anorexia (22.9%), mostly grade 1 or 2.

Conclusions: Tepotinib demonstrated promising antitumor activity and manageable toxicity profiles in patients with various solid cancers harboring *MET*ex14 or amplification. Detection of *MET* dysregulations in liquid-based NGS is expected to play a potential role in predicting response of tepotinib.

2305P Next-generation sequencing-based regression algorithm to determine homologous recombination deficiency scores in a pan-cancer cohort

S. Kim[1], M-R. Han[2], E-Y. Oh[2], Y.J. Choi[3], S. Bak[4]

[1]OBGYN, The Catholic University of Korea - Seoul St. Mary's Hospital - Catholic Medical Center, Seoul, Republic of Korea; [2]Division of Life Sciences, College of Life Sciences and Bioengineering, Incheon National University, Incheon, Republic of Korea; [3]Gynecologic Oncology, The Catholic University of Korea - College of Medicine, Seoul, Republic of Korea; [4]Gynecologic Oncology, The Catholic University of Korea - Bucheon St. Mary's Hospital, Bucheon, Republic of Korea

Background: Homologous recombination deficiency (HRD) inhibits double strand breaks from being repaired in DNA, leading to cancer cells failing to recover themselves and cell death. Previous studies found that HRD-positive ovarian cancer patients had more significant clinical benefits from poly ADP-ribose polymerase inhibitors (PARPi) treatment. For accurate detection of HRD, next-generation sequencing (whole exome, whole genome) was used to identify large-scale genomic aberrations including telomeric allelic imbalance (HRD-TAI), loss of heterozygosity profiles (HRD-LOH), and large-scale state transitions (HRD-LST). So far, many studies (HRDetect, SigMA, CHORD and shallowHRD) have been conducted to accurately determine HRD in a pan-cancer cohort. As the study progressed, it has been revealed that PARPi is effective when applied to patients with HRD in ovarian cancer, breast cancer, prostate cancer, and pancreatic cancer. To develop an algorithm accurately predicting HRD score in patients with ovarian cancer, breast cancer, prostate cancer, and pancreatic cancer utilizing a machine learning algorithm.

Methods: We used whole-genome sequencing (WGS) data of 710 samples from 309 patients, whole-exome sequencing (WES) data of 4,650 samples from 2,193 patients from the pan-cancer cohort of the TCGA (TCGA-OV, TCGA-BRCA, TCGA-PRAD, and TCGA-PAAD). The HRD-TAI/HRD-LST/HRD-LOH scores were calculated through structural variation analyses. After data cleaning processes, machine-learning models were trained and tested on 228 out of 2,502 samples, and validation was performed on 1,248 out of 2,502 samples from the TCGA dataset.

Results: To assess the performance of the machine-learning regressor, the concordance between predictions and annotations was quantified by calculating the R squared (R^2). As a result of training using machine learning algorithm, we achieved a high R^2 (0.904) with a RMSE (root mean squared error) score (7.649) for a pan-cancer cohort.

Conclusions: Our regressor was robust and accurate when applied to 4 cancer types. Using our systematic pan-cancer analysis, we found novel insights into the mechanisms of HRD across cancer types with potential contribution to clinical practice.

Background: Results from TAILORx showed significant benefit of chemotherapy (CHT) in premenopausal early luminal HER2-negative breast cancer (BC) patients with a 21-gene intermediate recurrence score (RS). We analysed how this data shifted CHT implementation after July 2018 (cut-off), especially in the intermediate RS group, in order to determine how the reality of the daily clinic met the new standard guidelines.

Methods: Retrospective analysis in a cohort of 326 HER2-negative, luminal BC patients, treated at Basel University Hospital and Cantonal Hospital Baselland (2010-2021). Primary end-point was to assess any change in therapy administration in the BC population before (cohort A) and after the cut-off point (cohort B) adjusted after RS categories and determine role of menopausal status and RS in CHT selection.

Results: RS values across all categories were lower in B vs A in the low ($p<0.001$), intermediate ($p=0.001$) and high RS ($p=0.005$). The intermediate and high RS groups were larger in B vs A (97 vs 52, 27 vs 14 patients, $p<0.001$), while low RS was smaller (37 vs 99, $p<0.001$). In the low and high RS there was less radiotherapy in B vs A (54.5% vs 71%, $p=0.01$ and 26% vs 50%, $p=0.039$), but no difference in other treatments. Menopausal status, nor RS seem to drive therapy. In the intermediate RS, there was less CHT in B vs A (13% vs 40%, $p=0.001$) and less patient refusal of CHT (4% vs 15%, $p=0.01$). In this category, CHT regimen changed significantly in B vs A with less anthracycline + taxotere applications (81% vs 61.5%, $p=0.009$). There was also more bisphosphonate therapy in B vs A (84% vs 65%, $p=0.007$). In this RS category, CHT was significantly impacted by menopausal status and RS in A ($p=0.002$), but not in B ($p=0.882$). There was more Tumor Board (TB) convergence on treatment for patients with intermediate RS in B vs A (87% vs 68%, $p=0.039$). When not adjusted for RS categories, menopause was not significant for CHT administration ($p=0.121$ in A, $p=0.384$ in B), but RS was ($p<0.001$ in A and B).

Conclusions: TAILORx significanlty impacted CHT administration, regimen selection, compliance and TB decision convergence in the intermediate RS group. When not adjusted for RS categories, menopausal status was not decisive for CHT, but independently, RS score was.

2307P Loss of CYP2D6 activity sensitizes liver cancer cells to chemotherapy

N. Rameika[1], X. Zhang[1], L. Zhong[1], V. Rendo[1], S. Kundu[1], S. Nuciforo[2], I. Stoimenov[1], V. Ljungström[1], M.H. Heim[3], D. Globisch[4], T. Sjöblom[1]

[1]Department of Immunology, Genetics and Pathology, Uppsala University, Uppsala, Sweden; [2]Department of Biomedicine, University Hospital and University of Basel, Basel, Switzerland; [3]Clarunis, University Center for Gastrointestinal and Liver Diseases, Universität Basel, Basel, Switzerland; [4]Department of Chemistry, Uppsala University, Uppsala, Sweden

Background: Loss of heterozygosity (LOH) is a frequent event in cancer, that is caused by larger chromosomal deletions in cancer cells due to genetic instability [TS1] (Mertens *et al.*, 1997). Thus heterozygous individuals become hemi- or homozygous for certain genes, which might change the phenotype of a cancer cell compared to normal cells (Muller *et al.*, 2012), (Dey *et al.*, 2017). This change might create an opportunity to selectively target cancer cells while sparing normal cells (Rendo *et al.*, 2020).

Methods: To find potential drug targets, data from the 1000 Genomes project was analyzed to identify prevalent constitutional loss-of-function (LoF) SNPs in coding regions causing truncating or splice site mutations with allele frequency >0.5[TS1] [NR2] %, heterozygosity between 10% and 90% of potential relevance in cancer cells. The drug metabolic gene *CYP2D6* was selected and isogenic cell models were established in HEK293T and HepG2 cells. A chemical library of a total of 525 compounds was screened using HEK293T cells harboring a functional or loss-of-function CYP2D6 enzyme. Final hits with LoF-selective toxicity were confirmed on the HepG2 cell model and patient-derived hepatocellular carcinoma organoids.

Results: We identified 60 genes with prevalent constitutional LoF variants and the CYP2D6 enzyme was selected for further work due to its well known drug metabolic activity and the high frequency of 22q13 loss in cancers (Mertens *et al.*, 1997). We observed a consistent pattern of responses to Rucaparib, the known CYP2D6 substrate (Zhao, Long and Wang, 2022), on both established HEK293T and HepG2 cell models, suggesting the robustness of our cell models. Three compounds with selective toxicity towards HepG2 and HEK293 cells lacking CYP2D6 activity were identified. One of them is currently available for use in clinical oncology and further confirmed on the patient-derived hepatocellular carcinoma organoids.

Conclusions: LOH in *CYP2D6* gene can potentially guide drug use in cancer precision medicine and merits further clinical evaluation.

2308P CyPep-1 reprograms the tumor microenvironment and enhances the efficacy of immune checkpoint inhibitors

B. Janji[1], M. Zaeem Noman[2], J. Hossain[3], L. Prestegarden[4], C. Pico-Navarro[5], E. Rigg[3], M. Bosseler[1], R. Bjerkvig[3]

[1]Department of Cancer Research, Luxembourg Institute of Health, Luxembourg; [2]Department of Immunology, Centre d'Immunologie Pierre Fabre (CIPF), Saint-Julien-en-Genevois, France; [3]Department of Biomedicine, University of Bergen, Bergen, Norway; [4]Cytovation ASA, Bergen, Norway; [5]Clinical Development Department, Dr. Cesar Pico Navarro, Madrid, Spain

Background: Immune checkpoint inhibitor (ICI) therapy produce durable responses in patients with metastatic cancer. However, most patients do not benefit from ICIs, promting the need for new treatment strategies. CyPep-1, a synthetic 27-D-amino acid peptide, selectively targets tumor cell plasma membranes, inducing pore formation and immediate membrane destabilization. With demonstrated activity across a broad range of tumor types, CyPep-1 exhibits a strong therapeutic potential. Here we describe the membrane perturbing activity of CyPep-1 on ICI refractory tumors *in vitro* and *in vivo,* and demonstrate its ability to release tumor neoantigens, stimulate the immune system and sensitize tumors to anti-PD1 therapy.

Methods: The release of cytoplasmic antigens was quanitified following exposure of CyPep-1 to various cancer cell lines that do not respond to ICI therapy in vivo. Syngeneic tumors were established *in vivo*, followed by CyPep-1 injections as monotherapy or in combination with anti-PD1 antibodies. Immune activation was assessed by Flow-Cytometry and Mass Cytometry (CyTof).

Results: CyPep-1 treatment resulted in the release of functional cytoplasmic proteins, indicative of tumor antigen release. Intratumoral CyPep-1 administration triggered cytokine release and a significant infiltration of various anti-tumor immune effector cells, consequently reducing tumor growth. Anti-PD1 monotherapy, however, had no impact on tumor growth. CyPep-1, in combination with anti-PD-1 potentiated the therapeutic effects of CyPep-1, leading to a significant systemic anti-tumor immunity and tumor growth inhibition.

Conclusions: CyPep-1 treatment specifically targets tumor cells, promoting pro-inflammatory cytokine upregulation and subsequent infiltration of immune effector cells within the tumors. This process results in a systemic immune response, transforming immunological "cold" tumors into "hot" ones. A clinical trial based on these findings has been initiated (NCT05383170).

2309P High DDR1 mRNA and protein expression across human tumor types correlate with epithelial composition of the tumor microenvironment

L.A. Dillon[1], X. Sher[1], F.D. Gootkind[1], T. Schürpf[1], J.D. Berlin[2], G.T. Clifton[1]

[1]Research and Development, Parthenon Therapeutics, Boston, MA, USA; [2]Division of Hematology and Oncology, Vanderbilt University Medical Center - Preston Cancer Research Building, Nashville, TN, USA

Background: Discoidin Domain Receptor 1 (DDR1) is a collagen-binding receptor tyrosine kinase expressed by tumor cells which has been implicated in cancer invasion, progression, and immune exclusion. A first-in-human trial of a DDR1-targeted therapy is underway. The relationship between *DDR1* mRNA, DDR1 protein, and the epithelial composition of the tumor microenvironment across tumor types has not been established and has the potential to influence indication and patient selection for DDR1-targeted therapies.

Methods: Human tumor samples (n= 93) from a range of epithelial and non-epithelial tumor types were evaluated by bulk RNA-sequencing and multiplex immunofluorescence (mIF) of DDR1 and pan-cytokeratin (CK). Tumor-stromal segmentation was determined by image analysis for epithelial tumors with epithelium defined by CK positivity in the tumor bed. Correlative analyses were done to relate *DDR1* mRNA expression to DDR1+ cell density, proportion of tumor cells expressing DDR1, and proportion of tumor epithelium.

Results: A high proportion of tumor cells (median of >0.7) expressed DDR1 across all epithelial tumor types. DDR1 expression was uniformly low in non-epithelial tumors evaluated (desmoid tumors, additional indications forthcoming). Moderate correlation was observed between *DDR1* mRNA expression and DDR1+ cell density across tumor types ($R=0.31$, $p<0.01$). In epithelial tumors, both *DDR1* mRNA and protein were correlated with the percentage of epithelium ($R=0.30$ and 0.46, respectively; both $p<0.01$), with significant variance between tumor types.

Conclusions: DDR1 is expressed in a high proportion of tumor cells across a range of epithelial tumor types, suggesting potentially broad application of DDR1-targeted therapies. As expected, since DDR1 is primarily expressed by tumor cells, both mRNA and protein expression levels are correlated with the proportion of tumor epithelium. The degree of correlation between *DDR1* mRNA and protein appears to be tumor type specific, possibly due to differences in DDR1 protein density in DDR1+ cells and/or contamination of bulk RNA with adjacent tissue. Assessment of DDR1+ cell density may be more accurate for patient selection in certain tumor types.

2310P Oxygen nano-bubbles attenuate hypoxia-induced tumour malignancy in tumour xenograft models

K. Bhavya[1], K. Agrawal[2], D. Negi[1], K. Niveria[3], A.K. Verma[3], Y. Singh[4], N.N. Nirmalkar[2], D. Pal[1]

[1]Biomedical Engineering Department, IIT Ropar - Indian Institute of Technology Ropar, Rupnagar, India; [2]Chemical Engineering, IIT Ropar - Indian Institute of Technology Ropar, Rupnagar, India; [3]Department of Zoology, Delhi University - North Campus, New Delhi, India; [4]Department of Chemistry, IIT Ropar - Indian Institute of Technology Ropar, Rupnagar, India

Background: The rapid proliferation of cancer cells leads to abnormal vascularization, creating a hypoxic tumor core in most advanced solid tumors. Recent studies have shown that hypoxia is associated with poor prognosis in cancer patients. Tumor aggressiveness is driven by hypoxia, which confers resistance to many conventional cancer therapies. In the present study, we propose that oxygen nanobubbles can reduce the hypoxic effect on the epithelial-to-mesenchymal transition (EMT) and prevent migration and invasion in non-small cell lung cancer (NSCLC) and triple-negative breast cancer (TNBC).

Methods: Using the sonic cavitation method, we have developed a method to generate bulk oxygen nanobubbles (ONBs) with dipalmitoyl phosphatidylcholine (DPPC) lipid and quantitate mean diameter and number density through nanoparticle tracking analysis and insight. We have treated A549 lung adenocarcinoma and MDA-MB-231 triple-negative breast cancer cell lines with 1% oxygen and ONB. We have also checked its preventive role in the zebrafish tumor xenograft model. We have measured HIF-1a and EMT expression markers by immunoblot and qPCR analysis. Moreover, we have used the 4T1 BALB/c mice tumor xenograft model for further confirmation.

Results: ONB promotes HIF-1α hydroxylation and its proteasomal degradation in hypoxic cancer cells. ONBs treated A549 and MDA-MB-231 cancer cells and an adult zebrafish A549 tumor xenografts showed the downregulation of TGF-β and VEGFA expression at the transcriptional and translational levels, which also led to upregulation of epithelial genes like E-cadherin with down-regulation of mesenchymal genes like N cadherin, Vimentin, Fibronectin. ONB treatment significantly affects cancer cell migration. Also, liposomal ONB administrated 4T1 BALB/c breast tumor xenograft model showed similar results.

Conclusions: ONBs reduce HIF-1 mediated epithelial to mesenchymal transition (EMT) controlled by TGF-b and VEGFA and prevent cellular migration and invasion in solid tumors, particularly NSCLC and TNBC. In conclusion, targeted administration of ONB could be a better therapeutic approach to inhibit the hypoxic detrimental effect, which helps to increase the efficacy of anticancer treatments.

2311P Population pharmacokinetic-pharmacodynamic modeling to inform optimal dosing strategies for GI-101, a novel fusion protein, targeting IL2$\beta\gamma$R and CTLA4

D. Chae[1], W. Lee[2], N. Yun[2], A. Ko[2], M.H. Jang[2]

[1]College of Medicine, Severance Hospital - Yonsei University College of Medicine, Seoul, Republic of Korea; [2]Clinical Development, GI Innovation, Inc., Seoul, Republic of Korea

Background: Interleukin-2 receptor (IL2R) and cytotoxic T-lymphocyte-associated protein 4 (CTLA4) are key immunotherapeutic targets in cancer treatment. GI-101, a novel bispecific Fc fusion protein, targets both CTLA4 and IL2R$\beta\gamma$, offering potential for improved patient outcomes. This study developed a mathematical model linking GI-101 pharmacokinetics (PK), absolute lymphocyte count (ALC) dynamics, and

progression-free survival (PFS) to optimize the biological dose for maximal therapeutic benefit.

Methods: Preclinical monkey (n=74) and phase 1/2 human (n=31) data of GI-101 were used for model development. The dataset was randomly split into training and test datasets at a ratio of 7 to 3, and the final model was validated using the test dataset. Data from a phase 1/2 clinical trial were analyzed using a random survival forest algorithm to assess the effect of immune cell dynamics on PFS. Potential dose-response correlations were assessed for Grade 3 or 4 treatment-related adverse events (TrAE) and immune-related adverse events (irAE) using logistic regression. Stochastic simulations determined the optimal biological dose (OBD) to achieve the target peak ALC.

Results: A pharmacodynamics-mediated drug disposition (PDMDD) model adequately described drug pharmacokinetics, captured changes of cell count across all lymphocyte subsets, and demonstrated strong performance in the test dataset. Random survival forest analysis of the GI-101 clinical data revealed that peak total lymphocyte (p=0.00191) and CD8+ T cell (p=0.00515) counts significantly predicted PFS. There was no significant dose-response correlation for TrAE (p=0.66) and irAE (p=0.92). Simulations suggested an OBD of 0.3 mg/kg every three weeks, achieving target peak total lymphocyte and CD8+ T cell counts of 2,000 cells/μL and 350 cells/μL, respectively.

Conclusions: Our findings underscore the value of translational mathematical modeling for informing optimal dosing strategies in novel immunotherapies targeting IL2$\beta\gamma$R and CTLA4. The identified OBD merits further investigation in clinical trials to validate its potential for enhancing patient outcomes.

2312P SGLT2i dapagliflozin decreases NLRP3, IL-1 and PCSK9 expression in preclinical models of short-term doxorubicin cardiotoxicity

A. Bonelli[1], M.L. Canale[2], I. Bisceglia[3], G. Palma[4], A. Luciano[4], F. Bruzzese[4], F. Russo[1], V. Giordano[1], C. Maurea[5], A. Paccone[6], M. Iovine[6], F. Florio[1], N. Maurea[1], V. Quagliariello[1]

[1]Division of Cardiology, Istituto Nazionale Tumori IRCCS - Fondazione G. Pascale, Naples, Italy; [2]Cardiology, Ospedale "Versilia", Lido di Camaiore, Italy; [3]Division of Cardiology, Azienda Ospedaliera San Camillo Forlanini, Rome, Italy; [4]Animal Facility, Istituto Nazionale Tumori IRCCS - Fondazione G. Pascale, Naples, Italy; [5]Division of Cardiology, University of Salerno, Fisciano, Italy; [6]Cardiology Department, Istituto Nazionale Tumori IRCCS - Fondazione G. Pascale, Naples, Italy

Background: Anthracyclines are an effective and widely used chemotherapy agent in the treatment of multiple solid organ tumors and hematologic malignancies. The use of anthracyclines as a standard cancer therapy is limited by the potential for the development of cardiac dysfunction, arrhythmias, and clinical heart failure. In recent five years, it was demonstrated that proprotein convertase subtilisin/kexin type 9 (PCSK9), a lipid metabolism-related protein, is a key orchestrator of immune infiltration in myocardial and cancer tissues and could regulate cardiac fibrosis and inflammation. PCSK9 is a protein with key roles in hepatic low density lipoprotein (LDL) homeostasis. PCSK9 systemic levels are associated to HOMA score and high insulin levels. Dapagliflozin exerts systemic ant-inflammatory properties and cardioprotective effects in diabetic and non-diabetic patients.

Methods: Female C57Bl/6 mice were untreated (Sham, n=6) or treated for 10 days with doxorubicin i.p at 2.17 mg/kg (DOXO, n=6), DAPA at 12 mg/kg (DAPA, n=6) or doxorubicin combined to DAPA (DOXO-DAPA, n=6). After treatments, plasma levels of PCSK9, IL-1β and CRP were analyzed through selective anti-mouse ELISA methods. Myocardial and liver expression of NLRP3-inflammasome and IL-1β were analyzed through ELISA method in tissue lysates after treatments.

Results: DAPA associated to DOXO reduces significantly systemic levels of PCSK9 (-37,5% vs DOXO group, p<0,001). IL-1β and CRP levels were also reduced (-47,3 and − 28,5 %, respectively; p<0.05 for both). Myocardial and liver IL-1β and NLRP3 inflammasome expression were also reduced in DAPA/DOXO group vs DOXO and control, indicated beneficial metabolic and anti-inflammatory effects of SGLT2i.

Conclusions: DAPA has been shown to reduce systemic levels of PCSK9 in preclinical models of short-term DOXO cardiotoxicity. To the best of our knowledge, this is the first evidence of SGLT-2/PCSK9 crass-talk in cardioncology therefore the overall picture of the study open a new window on the beneficial properties of DAPA against anthracyclines side effects.

2313P APOBEC mutagenesis and macrophage infiltration in cancer

A. Gazzo[1], A. Marra[2], Y. Zhu[1], A. Gupta[3], P. Selenica[1], X. Pei[4], B. Weigelt[1], F. Pareja[1], N. Riaz[4], J.S. Reis-Filho[1], S. Chandarlapaty[5]

[1]Department of Pathology, MSKCC - Memorial Sloan Kettering Cancer Center, New York, NY, USA; [2]Division of New Drugs and Early Drug Development, IEO - Istituto Europeo di Oncologia IRCCS, Milan, Italy; [3]Human Oncology and Pathogenesis Program, MSKCC - Memorial Sloan Kettering Cancer Center, New York, NY, USA; [4]Radiation Oncology, Memorial Sloan Kettering 60th Street Outpatient Center, New York, NY, USA; [5]Medicine, MSKCC - Memorial Sloan Kettering Cancer Center, New York, NY, USA

Background: APOBEC enzymes play key roles in DNA editing and are highly expressed in various cancer types, including estrogen receptor (ER)+/HER2- breast cancer (BC). APOBEC enzyme activation promotes mutagenesis that results in the generation of neoantigens, potentially leading to an anti-tumor immune response. APOBEC mutagenesis has been associated to resistance to chemotherapy and immunotherapy. The impact of APOBEC mutagenesis on the tumor microenvironment (TME) still remains unclear. Here we sought to characterize the TME of ER+/HER2- BC displaying APOBEC mutagenesis and to validate the findings in other APOBEC-related cancer types.

Methods: ER+/HER2- BCs from TCGA with available whole exome and RNA-sequencing data were included (n=519). We inferred single base substitutions (SBS) mutational signatures using SigProfiler. Cell type fractions were computed using CIBERSORT. The correlation between APOBEC signatures (SBS signatures 2 and 13) and the abundance of TME cell types was defined using a logistic regression model adjusted by tumor mutation burden. False discovery rate correction was applied (q-value). Other APOBEC-related cancers (bladder, head and neck, cervix and uterine) were assessed.

Results: Of 519 ER+/HER2- BCs, 57 (11%) were classified as APOBEC-dominant, 84 (16%) as non-dominant-APOBEC and the remaining 378 (73%) as non-APOBEC. Compared to non-APOBEC, APOBEC-dominant ER+/HER2- BCs displayed an enrichment for macrophages M1 infiltration (q=0.026), and decreased macrophage M2 population (q=0.017). Non-dominant APOBEC BCs displayed an extent of macrophage M1 and M2 infiltration intermediate between the other two groups. Analysis of the TME composition according to APOBEC mutagenesis in bladder (n=389), head and neck (n=463), cervical (n=269) and uterine (n=474) cancers revealed differences comparable to those observed in ER+/HER2- BCs.

Conclusions: An association between APOBEC mutagenesis and macrophages M1 infiltration was observed, suggesting that APOBEC processes may uniquely shape the TME in cancer. Going forward, we will investigate the impact of other mutagenesis processes, such as homologous recombination deficiency (HRD), on the TME, to gain a comprehensive understanding of the interplay between various mutational processes and the TME.

[1]Molecular Oncology Dept., Vall d'Hebron Institute of Oncology (VHIO)-Cellex Center, Barcelona, Spain; [2]Oncology Data Science (Odyssey Group), Vall d'Hebron Institute of Oncology (VHIO)-Cellex Center, Barcelona, Spain; [3]Radiology, Vall d'Hebron University Hospital, Barcelona, Spain; [4]Breast Cancer Program, Vall d'Hebron University Hospital, Barcelona, Spain; [5]Medical Oncology Dept., Vall d'Hebron University Hospital, Barcelona, Spain; [6]Medical Oncology Dept., Vall d'Hebron Institute of Oncology (VHIO)-Cellex Center, Barcelona, Spain; [7]Medical Oncology Service (Lung Cancer Unit), Vall d'Hebron University Hospital, Barcelona, Spain; [8]Early Drug Development Group, Vall d'Hebron University Hospital, Barcelona, Spain; [9]Oncology Data Science Department, Grupo Oncoclinicas, São Paulo, Brazil

Background: The scientific benefits gained from studying RB in oncology clinical trials depends on sample quality and there are concerns that participant risk might outweigh the benefits.

Methods: RB data from patients who participated in oncology clinical trials at a single institution between January 2017 and December 2020 were analyzed for sample quality assessed by tumor content (TC) and safety. Determinants of high-quality RB and complications were investigated. Quality was compared with sample taken at external institutions and sent to our laboratory for centralized assessment in the context of multicentric breast cancer clinical trials.

Results: The cohort consisted of 6805 samples obtained from 3104 procedures performed in 1983 patients from 386 studies. The median number of samples collected per study was 5, with an average of 2.2 samples/procedure. Samples were collected mainly at screening (72%), from metastatic sites (63%), and using ultrasound-guided procedure (60%). Liver was the most biopsied organ (33%), followed by lymph nodes (13%) and breast (12%). Preservation methods were formalin-fixed and paraffin embedded (FFPE, 50.5%), snap frozen (21.5%) or alternatively stabilized (28%) according to study protocols. The median TC of the 2940 FFPE samples analyzed was 70% (95% CI, 70-70). 85% of samples had >10% TC and 60% had >50% TC. Any grade complications occurred in 15% of procedures, with pain being the most frequent (11%; 0.4% Grade 3-4). Major complications were observed in 0.9% of procedures. A higher number of complications were found for lung RB (34%; Grade 3-4, 2.6%). In multivariable logistic model, visceral site, guided procedure and number of samples collected were associated with higher TC. On treatment biopsy, non-guided procedure and visceral site were independently associated with a higher risk of major complications. In the comparative analysis with an international cohort of 2302 baseline breast cancer RB obtained from sites in 38 countries, major heterogeneity was observed across countries, with median TC ranging from 0% to 80%.

Conclusions: High quality RB have acceptable safety with low risk of major complications. Our comparative analysis suggests that while local collection of high-quality RB is feasible, quality could be improved at some centers.

Background: To uncover the underpinnings of acquired resistance (AR) to Immune Checkpoint Inhibitors (ICIs), we determined whether distinctive clinicopathological and peripheral blood (PB) immune-inflammatory features reflect oligo and systemic (sys) AR in advanced NSCLC patients undergoing ICIs.

Methods: On PB collected at baseline (T0) and first disease assessment (T1) from 105 ICI-treated NSCLC, we prospectively assessed LDH, derived Neutrophil-to-Lymphocyte ratio (dNLR), LIPI score, relevant immunophenotypes (flow-cytometry) and their respective delta (Δ) % variation [(T1-T0)/T0]. AR, defined as progression after initial response (CR/PR/SD $\geq$ 6 mos.), was subdivided according to the number of new and/or progressive lesions in oligoAR ($\leq$ 3) and sysAR ($>$ 3). Initial PD or SD $<$ 6 mos. embodied non responders (NR), while absence of progression or PFS $\geq$ 12 mos. enclosed long-term/not progressors (LT/NP). Clinicopathological, PB parameters and survival outcome were statistically evaluated according to AR pattern.

Results: OligoAR involved 24% of cases, while sysAR 12.4%. Compared to NR, oligoAR pattern was associated with significantly lower T0 and Δ LDH, dNLR and LIPI, whereas no differences were observed *vs* sysAR and LT/NP. While baseline PB immune profiles were comparable, a Δ positive cytotoxic (NK, NKT, CD8+Ki67+, CD8+Gnz+) and Δ negative immunosuppressive (CD14+ monocytes, CD4+CD25+FOXP3+ Tregs) dynamics was distinctive of oligoAR *vs* sysAR ($P < 0.05$). Conversely, compared to LT/NP, oligoAR cases showed a lower cytotoxic/proliferating CD8 response coupled with higher CD14+/Tregs feedback ($P < 0.05$). Within oligoAR, patients with 1 progressive lesion, compared to those with $\geq$ 2, exhibited baseline lower LDH and higher NK/CD8+Gnz+ cytotoxic cells ($P < 0.05$) which in turn appeared to condition longer OS (HR: 4.90; P=0.04). Importantly, despite similar clinical profile, prolonged post-progression survival characterized oligoAR *vs* sysAR (median OS not reached *vs* 11.3 mos.; HR: 0.21, 95% CI: 0.08-0.59; $P = 0.001$).

Conclusions: The longitudinal analysis of blood immune hallmarks intersected with clinicopathological features may decipher the distinct patterns of AR in ICI-treated NSCLC patients.

Pascale, Naples, Italy; [8]Translational Medicine and Surgery Department, Fondazione Policlinico Universitario Agostino Gemelli IRCCS, Rome, Italy

Background: The comprehensive cancer genome profiling (CGP) programme (ID: FPG500, IRB approval 3837) is an interventional monocentric study extending somatic genomic assessment to 523 genes in patients with advanced solid tumors.

Methods: The study enrolls cancer patients whose molecular characterization should be warranted according to national and international guidelines. The primary endpoints were the feasibility of the programme (turn around time-TAT and samples failure rate) and the rate of actionable alterations identified. Secondary endpoints included the number of reports sent to the institutional molecular tumor board (MTB), the rate of patients' enrollment in biomarker-driven clinical trial and the identification of potentially germline variants.

Results: From January 2022 to December 2022, 1367 patients were enrolled, including non-small-cell lung cancer (263), ovarian (446), endometrium (246), colorectal (191), pancreatic (83), cholangiocarcinoma (28), prostate (48), melanoma (45), gastrointestinal stromal tumor (GIST) (3), thyroid (7) and breast cancer (7). The overall failure rate was 5%. CGP sequencing data were available for 1162 (85%) patients, while 205 (15%) were addressed to targeted panels. By the end of 2022 an improving average TAT of genomic profiling was reported (25 days), despite an increasing number of monthly analysed samples (mean 114). Genomic alterations according to OncoKB annotation were identified in 96% patients. Potentially pathogenic/likely pathogenic germline variants were identified in 29% of patients. Overall, 6% of cases were sent to MTB.

Conclusions: FPG500 represents the largest prospective European single institution genomic profiling series and highlights the utility of CGP for identifying therapeutic targets in selected cancer patients, concomitant alterations for further predictive and prognostic characterization and germline implications.

2317P Mutational landscape and therapeutic implications in squamous cell carcinomas

L. Belcaid[1], M. Eriksen[2], L. Robinson[3], C. Federspiel Secher[2], M. Hoejgaard[4], I. Spanggaard[2], K.G. Daugaard[2], J. Friborg[2], P.M. Mau-Sorensen[2], J. Weischenfeldt[5], U. Lassen[4], C. Yde[3], K. Rohrberg[1]

[1]Department of Medical Oncology, Copenhagen University, Copenhagen, Denmark; [2]Department of Oncology, Rigshospitalet, Copenhagen, Denmark; [3]Genomic Medicine, Rigshospitalet, Copenhagen University Hospital, Copenhagen, Denmark; [4]Phase I Unit, Department of Oncology, Rigshospitalet, Copenhagen, Denmark; [5]BRIC, Copenhagen University, Copenhagen, Denmark

Background: Disseminated squamous cell carcinomas (SCCs) are traditionally considered void of actionable molecular targets, in contrast to adenocarcinomas, where an increasing number of targets are identified. SCC rarely undergo routine molecular testing and approved targeted therapies are rare in this population. Access to extensive molecular profiling and subsequent matching with experimental therapies may improve the outlook for patients (pts) with SCC. We report the mutational landscape in SCC and subsequent therapeutic implications.

Methods: Pts with late-stage SCCs (oesophageal cancer, cervical cancer, head and neck cancer, non-small-cell lung cancer, skin cancer, thymic carcinoma, or unknown primary tumor) referred to a phase I facility were included in a prospective, single-center, single-arm open-label genomic profiling study (NCT02290522). Fresh tumor tissue was obtained for whole exome sequencing or whole genome sequencing, RNA sequencing and chromosomal aberration analysis. Circulating tumor DNA was obtained when fresh biopsy was not possible. Each individual genomic report was reviewed and discussed by a multidisciplinary molecular tumor board dedicated to precision medicine. When possible, pts were treated with regimens matched to the genomic profile.

Results: Between November 2013 and March 2023, a total of 189 pts with SCC were enrolled. Genomic profiles were obtained in 160 (85%). At least one actionable target was detected in 77 (48%) with a total of 117 actionable alterations including DNA damage repair response pathway (N=42, 36%), expression profiles matched to monoclonal antibodies (N=21, 18%), and high tumor mutational burden. (N= 15, 13%). In total, 18 pts (23%) were treated with regimens matched to the genomic profile. However, since 2021, 37% (7/19) of the pts with actionable targets have been treated with targeted treatment. Among the evaluable pts (N=6), one had complete response, two had partial response, and three had stable disease.

Conclusions: This study illustrates increasing targeted treatment options for SCCs, thereby emphasizing the importance of genomic profiling.

Background: Molecular techniques have improved cancer diagnosis and treatment. Due to limited availability and costs, broad molecular profiling, i.e., analysis of whole genomes/exomes, transcriptomes, and methylomes, is rarely performed upfront in clinical practice and mostly confined to research settings. However, in contrast to more readily available focussed analyses of, e.g., the few genes seemingly relevant for a suspected diagnosis, broad molecular profiling may yield unsuspected findings pertinent to diagnosis and/or treatment.

Methods: This analysis is based on patients enrolled in the MASTER program of DKFZ, NCT Heidelberg/Dresden, and DKTK, a nationwide precision oncology network applying genome/exome, transcriptome, methylome, and — more recently — proteome analysis in young adults with advanced malignancies and patients with rare cancers to inform clinical decision-making and the design of molecularly stratified clinical trials. Cases with molecular findings suggestive of an alternative diagnosis are subjected to clinical, molecular, and pathologic revaluation.

Results: In 99 of 3,092 patients (3.2%), the molecular profile warranted revaluation of the clinical diagnosis. The most frequent presenting diagnoses were cancer of unknown primary (n=21); various sarcomas (n=50), e.g., sarcoma not otherwise specified (n=4), malignant peripheral nerve sheath tumor (n=5), and undifferentiated sarcoma (n=6); and melanoma (n=4). Molecular findings suggesting an alternative diagnosis were based on genome/exome, transcriptome, and methylome analysis in 30, 78, and 41 cases, respectively. Potential clinical consequences were classified as changes in diagnosis without relevance for treatment (n=22), relevant for routine treatment (n=58), and prompting molecular alteration-specific treatment (n=19). The molecularly suspected diagnosis was confirmed in a major subset of cases for which sufficient material for histopathologic review was available. The clinically most relevant findings were EWSR1::WT1 fusions and diagnosis of desmoplastic small round cell tumor (n=9) and druggable gene fusions involving FGFR2 (n=4), ALK (n=4), and NTRK3 (n=1).

Conclusions: Broad molecular profiling is a useful adjunct to routine cancer diagnostics, especially in rare entities.

web-based tools with robust visualization and analysis capabilities for pan-cancer drug sensitivity remains a challenge.

Methods: To address this gap, we developed the Comprehensive Analysis of Drug Sensitivity in Pan-cancer (CADSP), a Shiny-based web tool. We collected oncology drug sensitivity-related data from large publicly available databases, including Gene Expression Omnibus (GEO), The Cancer Genome Atlas Program (TCGA), and Drug Sensitivity in Cancer (GDSC).

Results: The current version of CADSP includes transcriptomic data for over 29,000 samples, covering 44 cancer types, 288 drugs, and more than 9,000 gene perturbation data. Users can easily perform various tumor drug sensitivity analyses using CADSP. The tool provides numerous analysis and visualization methods, such as differential gene analysis, gene correlation analysis, pathway analysis, drug analysis, and gene perturbation analysis.

Conclusions: CADSP greatly simplifies the exploration of primary and secondary drug resistance at the single-gene and pathway levels for physicians and researchers. By combining drug resistance data and gene perturbation data, CADSP also offers new avenues for discovering key genes that drive drug resistance. CADSP is available at https://smuonco.shinyapps.io/CADSP/.

Background: Dedifferentiated liposarcomas (DDLS) are malignant soft-tissue tumors that are characterized by focal amplifications on chromosome 12q. They do not respond well to chemotherapy and no approved targeted therapy for DDLS is available. Through whole-exome/genome and RNA sequencing, we found that these structural changes generate open reading frames, leading to potential gene fusions and immunogenic neoepitopes, which modulate immune microenvironment and could serve as therapeutic targets.

Methods: We first analyzed a DDLS cell line (T449). Gene fusions were identified using two variant calling pipelines, Arriba (DKFZ) and EasyFuse (TRON). Fusion-derived (FD) peptides were used as input for HLA binding prediction by NetMHCpan 4.1. For targeted mass spectrometry (MS) analysis, we applied an ultra-sensitive parallel reaction monitoring workflow. For untargeted MS analysis, we combined data-independent acquisition MS with ion mobility separation by high-field asymmetric waveform ion mobility spectrometry. Mass spectra were compared to the human proteome, FD sequences, and libraries of *in silico* predicted fragment spectra. We used a modified MANAFEST protocol for the expansion of antigen-reactive CD4 and CD8 T cells.

Results: Candidate peptides for the targeted MS approach were selected from overlapping results of both pipelines. For the T449 cell line, we detected 128 fusion events resulting in 493 potential neoepitopes. We selected 46 peptides for targeted MS analysis and identified eight distinct FD neoepitopes. Analysis by untargeted MS yielded 15,578 peptide sequences, including five FD neoepitope candidates. We analyzed tumors from DDLS patients by targeted and untargeted MS analysis as well as their peripheral T-cell repertoire from expansion cultures. In a retrospective analysis of 67 patients, we observed a correlation between the quantity of fusions and specific tumor-infiltrating immune cell fractions.

Conclusions: We show results of our pipeline for the detection of FD neoepitopes using both targeted and untargeted MS approaches and explore the presence of neoepitope-specific T cells in the peripheral blood of DDLS patients. We believe that our work will lead to the clinical development of personalized treatment options for DDLS patients.

2321TiP TEMPLE: Thiopurine enhanced mutations for PD-1/ligand-1 efficacy: A phase Ib/II clinical trial

C. Federspiel Secher[1], M. Hoejgaard[1], I. Spanggaard[1], K. Schmiegelow[2], K.S. Rohrberg[1]

[1]Department of Oncology, Rigshospitalet, Copenhagen, Denmark; [2]Department of Paediatrics and Adolescent Medicine, Rigshospitalet, Copenhagen, Denmark

Background: Immune checkpoint inhibitors (ICI) have revolutionized treatment of several cancer types. However, many patients fail to respond. A prerequisite for response is the presence of neoepitopes on cancer cells that trigger the immune system, and the likelihood hereof increases with the number of mutations in the cancer. The thiopurines 6-mercaptopurine (6MP) and 6-thioguanine (6TG) are prodrugs that are converted into cytotoxic metabolites that are incorporated into DNA and cause DNA-damage and mutations through futile DNA mismatch repair attempts. The TEMPLE project is a novel strategy for improving efficacy of ICI by applying an innovative thiopurine combination strategy to increase mutational burden and presence of neoepitopes. The TEMPLE project has been tested in a preclinical setting in an immune competent mouse model of inducible melanoma, where 6TG exposure increased the tumor mutational burden, reshaped the tumor microenvironment by increasing T and NK immune cells and making the tumors more responsive to ICI (PMID: 36545256).

Trial design: The TEMPLE study (NCT05276284) is an investigator-initiated single-center prospective phase 1b and 2 trial to determine the safety, tolerability and efficacy of Atezolizumab given in combination with thiopurines 6MP and 6TG in patients with metastatic solid tumors with an intermediate tumor mutational burden (5-10 mutations/megabase). Recommended phase II dose (RP2D) will be determined in a single armed, open label phase 1b trial with a dose-limiting toxicity (DLT) period of 4 weeks. The combination of thiopurines and Atezolizumab will be administered in 21-day cycles. Patients will be included in a modified 3+3 design. 3-18 patients are expected to be enrolled in the phase 1b study, depending on observed DLTs and the need for dose adjustments. Phase II will be an open label, single arm phase II trial enrolling additional patients up to a total of 27 patients treated at RP2D in a Simon's 2 stage design. Extensive exploratory analyses will include characterization of the tumor mutational and neoantigen landscape on serial biopsies using whole genome

sequencing and RNA sequencing. The study was initiated in September 2022, and currently four patients have been included in the study.

Clinical trial identification: NCT05276284.

Legal entity responsible for the study: The authors.

Funding: 300 doses of immune checkpoint inhibitor 'atezolizumab' are sponsored by Pharmaceutical company Roche as an unrestricted grant.

Background: The decreasing costs and turnaround time of next generation sequencing methods paired with the rapidly growing arsenal of available genome-targeted drugs have significantly raised the impact of molecular profiling (MP) for treatment selection in clinical practice. However, to date, the efficacy of MP-guided cancer therapy beyond its approved clinical indication has been modest. Tumor tissue profiling alone may not be sufficient to capture the heterogeneity of advanced tumors. Of note, circulating tumor DNA (ctDNA) has recently been shown to provide the most accurate molecular snapshot of a patient's tumor composition. We thus aimed to evaluate the utility of comprehensive MP of ctDNA for personalized, cancer-agnostic treatment matching and to investigate the efficacy of MP-matched therapy in this salvage setting.

Trial design: SOUND is a multicenter non-randomized phase II trial. Adult patients with locally advanced or metastatic carcinoma who have exhausted all evidence-based therapies and have an ECOG performance status of 0-2 are eligible. At study enrollment, a mandatory liquid biopsy for the analysis of ctDNA is obtained from all patients. A biopsy of tumor tissue DNA is optional depending on the patient's consent. MP of ctDNA and tumor tissue DNA is performed using the FoundationOne®Liquid CDx and the FoundationOne® CDx assays, respectively. In patients with available tumor tissue not older than 3 months, immunohistochemical testing of Her2, PD-L1 and NTRK is performed. All patient cases, including the molecular reports, actionable molecular targets (AMT) and MP-guided treatment recommendations are reviewed weekly in a virtual multidisciplinary molecular tumor board. The primary study endpoint is the proportion of treated patients who have a progression free survival (PFS) ratio of $\geq$ 1.3 comparing the PFS on the matched therapy to the PFS of the previous therapy line. Co-secondary endpoints are the proportion of patients from whom a conclusive genomic profile can be obtained, the proportion of patients with an AMT, the number of AMTs, overall survival, and therapy response rate. To date, 91 of 200 planned patients have been enrolled.

ESMO GOOD SCIENCE BETTER MEDICINE BEST PRACTICE

ANNALS OF ONCOLOGY driving innovation in oncology

TUMOUR BIOLOGY AND PATHOLOGY

2323P Multi-omic spatial phenotyping of the NSCLC tumour microenvironment for the development of a spatial score associated with immunotherapy resistance

A. Kulasinghe[1], N. Ma[2], A. Pratapa[2], J. Monkman[1], O. Braubach[2], K.J. O'Byrne[3]

[1]Faculty of Medicine, University of Queensland, Herston, QLD, Australia; [2]Commercial Application, Akoya Biosciences - East Coast, Hopkinton, MA, USA; [3]Cancer Services, Princess Alexandra Hospital - Metro South Health, Woolloongabba, QLD, Australia

Background: Non-small cell lung cancers (NSCLC) are the leading cause of cancer morbitidy and mortality globally with a 5-year survival of ∼15-20%. Immunotherapies have shown durable benefit in a subset of patients. There is a growing need to identify better biomarkers able to stratify patients who are likely to respond to therapy. Whilst PD-L1 expression and other assessments such as tumour mutation burden (TMB), microsatellite instability (MSI) have shown associations with patient outcomes, there remains a need to comprehensively characterize the tumour microenvironment (TME).

Methods: In this study, we used high-dimensional spatial transcriptome and proteomic profiling of whole slides from NSCLC patients who had received single-agent immunotherapy. We performed a combination of compartmentalized (tumour/stroma) 1800-plex RNA (Nanostring Technologies, Cancer Transcriptome Atlas) and whole-slide 57-plex Phenocycler Fusion and custom Phenocode Signature Panels (Akoya Biosciences) targeting immune contexture, immune profiles, activation status, metabolic activity and immune checkpoints.

Results: For our transcriptome analysis, we compared the tumour and stromal compartments associations with response to therapy (RECIST). The tumour compartments showed specific enrichment for metabolic pathways in patients that were non-responsive to immunotherapy. These findings were further strengthened at the protein level with a grouping of metabolic signatures, including Glucose Transporter 1 (GLUT-1), Glucose-6-phosphate dehydrogenase (G6PD) and Citrase Synthase (CS). In resistant tumours, there was a clear lack of CD8 and CD68 infiltration and reduction or absence of lymphoid/tertiary lymphoid-like structures highlighting the complementarity of T- and B-cell biology in areas of high metabolic activity.

Conclusions: This study identifies a unique metabolic signature associated with response and resistance to immunotherapy in NSCLC which is mirrored by T- and B-cell biology. Our study demonstrates the utility of high-dimensional spatial multi-omic profiling to delineate new signatures associated with response to therapy and aid in patient stratification.

2324P Trametinib and PD-1 combined blockade impairs tumor growth and improves survival of KRAS-mutant lung cancer through Id1 downregulation

A. Puyalto[1], M. Rodríguez-Remírez[1], I. López[2], M. Olmedo López-Frías[3], A. Vilalta[4], I. Macaya[2], C. Welch[5], S. Vicent[2], A. Calvo[2], D. Ajona[2], I. Gil Bazo[6]

[1]Oncology, Clinica Universidad de Navarra, Pamplona, Spain; [2]Program of Solid Tumors, CIMA Universidad de Navarra, Pamplona, Spain; [3]Oncología Médica, Clinica Universidad de Navarra, Pamplona, Spain; [4]Dept. Medical Oncology, Clinica Universidad de Navarra, Pamplona, Spain; [5]Program of Solid Tumors, University of Navarra, Center for Applied Medical Research, Pamplona, Spain; [6]Medical Oncology Department, IVO - Fundación Instituto Valenciano de Oncología, Valencia, Spain

Background: Although anti-PD-1/PD-L1 antibodies represent a major breakthrough in NSCLC therapy, this treatment's efficacy is highly dependent on tumor PD-L1 expression. We previously reported the role of Id1 in lung adenocarcinoma and the efficacy of a combined blockade of PD-1 and *Id1*, through RNA silencing, in *KRAS*-mutant LUAD murine models. Trametinib, an oral MEK1/2 inhibitor, acts downstream of *KRAS*. Here we evaluate trametinib as a pharmacological *Id1* inhibitor able to enhance immunotherapy efficacy through PD-L1 overexpression.

Methods: To explore whether MEK1/2 inhibition reduces Id1 expression, *in vitro* and *in vivo* experiments were conducted in NSCLC cells and in murine models. RNAseq analysis was performed to elucidate the pathways involved in Id1 inhibition. Apoptosis and PD-L1 expression was measured by flow cytometry. Synergy of trametinib anti-PD1 combo was investigated in *KRAS*-mutant LUAD models.

Results: Experiments in *KRAS*-mutant NSCLC cells and mice models showed Id1 inhibition after MEK1/2 blockade. Blockade of proteasome activity with MG-132, restored Id1 levels. Trametinib-resistant (TR) cells did not show Id1 inhibition, moreover, *Id1* silencing rescued the sensitivity to trametinib in human and murine NSCLC TR cells ($p<0.001$). Flow cytometry analysis showed increased PD-L1 expression ($p<0.001$) in NSCLC cell lines after trametinib administration. In contrast, Id1-overexpressing cells did not show PD-L1 upregulation after trametinib. *In vivo* experiments confirmed a synergistic therapeutic efficacy of the trametinib and anti-PD-1 combo, reducing tumor growth ($p<0.05$) and increasing mice survival ($p<0.05$), compared with either trametinib or immunotherapy alone. Moreover, the immune population's analysis showed a significant increase in $CD8^+$ T and a reduction in Treg cells in tumors of mice receiving combination treatment.

Conclusions: Pharmacological inhibition of MEK1/2 decreased Id1 expression *in vitro* and *in vivo*, replicating the effect of a shRNA against *Id1*, through proteasome activation. PD-L1 upregulation induced by Id1 blockade after trametinib treatment sensitized NSCLC cells to anti-PD-1 immunotherapy, blocking tumor growth and improving overall survival.

2325P Selinexor (XPO1 inhibitor) in combination with tepotinib (MET inhibitor) potentially inhibits SHOC2 and KRAS G12C in KRAS G12C mutant non-small cell lung cancer

R. Rosell[1], A. Jain[2], J. Codony-Servat[3], C. Shivamallu[4], S.P. Kollur[5], A. Prasad[2], P. Vishwanath[6], E. Jantus Lewintre[7], M. Ito[8], A.F. Cardona Zorrilla[9], O.G. Arrieta Rodriguez[10], C. Pedraz-Valdunciel[3], J. González Nieto[1], A. Aguilar[11], M.A. Molina-Vila[3], M. Gonzalez Cao[11]

[1]Cancer Biology & Precision Medicine Program Dept., Institut d'Investigació en Ciències de la Salut Germans Trias i Pujol, Badalona, Spain; [2]Department of Microbiology, JSS Academy of Higher Education and Research, Mysore, India; [3]Laboratory of Molecular Biology, Pangaea Oncology, Barcelona, Spain; [4]Microbiology, JSS Academy of Higher Education and Research, Karnataka, India; [5]Microbiology, Amrita Vishwa Vidyapeetham, Mysuru Campus, Mysuru, India; [6]Microbiology, Center of Excellence in Molecular Biology and Regenerative Medicine, Department of Biochemistry, JSS Medical College, Mysore, India; [7]Laboratory of Molecular Biology, Hospital General Universitario Valencia, Valencia, Spain; [8]Surgical Oncology, Institute of Biomedical & Health Sciences, Hiroshima University, Hiroshima, Japan; [9]Clinical and Traslational Oncology Group, Fundacion Sta Fe de Bogota Instituto de Oncologia, Bogota, Colombia; [10]Medical Oncology Dept., The National Cancer Institute, Mexico City, Mexico; [11]Medical Oncology, IOR, Instituto Universitario Quirón-Dexeus, Barcelona, Spain

Background: In KRAS-mutant NSCLC cells, SHOC2:MRAS:PP1C complex boosted RAS GTP loading and MAPK pathway reactivation after initial MEK suppression. Nuclear export protein exportin 1 (XPO1) is dependent on KRAS-mutant NSCLC cells, making XPO1 a druggable vulnerability. MET and SHOC2 are required for spheroid growth in KRAS-mutant NSCLC cell lines. Using structure-based drug design (SBDD), we looked at whether selinexor and tepotinib could bind into the 1) KRAS G12C His-95 groove like sotorasib (KRAS G12C inhibitor); 2) SHOC2 phosphatase complex in comparison with celestrol (SHOC2 inhibitor).

Methods: We carried out an in silico molecular docking approach with KRAS G12C and the SHOC2 complex against selinexor and tepotinib using SBDD to determine the binding affinity, intermolecular interactions, and ligand structure complementarity. Sotorasib-resistant H358 and parental H358 KRAS G12C NSCLC cells were examined. In vitro growth inhibitory assays determined cell viability after 3-day treatment. Western blot analyses were performed.

Results: The molecular docking results are summarized in the table. Selinexor and tepotinib interacted with all the three proteins of the complex, unlike celestrol interacting with SHOC2 and MRAS. Within the His-95 groove of KRAS G12C, selinexor forms an H bond and tepotinib forms a pi-sulphur and an H bond with the mutant cys12 residue. Selinexor in combination with tepotinib and omeprazole (v-ATPase inhibitor) has been analyzed. Signaling pathway analysis to demonstrate the SHOC2 and KRAS G12C inhibition is ongoing.

Conclusions: In silico modeling predicts that selinexor and tepotinib have more interactions and better binding affinity with the target proteins when compared to the standard inhibitors. In vitro data will be presented on the validation of selinexor and tepotinib for repositioning in KRAS G12C NSCLC.

Table: 2325P

Target proteins	Ligands	Binding affinity (Kcal/mol)	Number of hydrogen (H) bonds	Other interactions
SHOC2 complex	Tepotinib	-10.3	2	3
	Selinexor	-9.6	5	6
	Celestrol	-8.8	3	0
KRASG12C	Tepotinib	-9.1	2	1
	Selinexor	-9.4	6	6

2326P Circulating tumor DNA (ctDNA) dynamics and clinical outcome in metastatic colorectal cancer (mCRC) patients (pts) undergoing front-line chemotherapy

M. Ghidini[1], J.C. Hahne[2], C. Senti[3], G. Tomasello[1], M. Ratti[3], T. Heide[4], O. Garrone[1], A. Cortellini[5], R. Passalacqua[3], N. Valeri[5]

[1]Oncology Unit, Fondazione IRCCS Ospedale Maggiore Policlinico, Milan, Italy; [2]Centre for Molecular Pathology, ICR - Institute of Cancer Research, London, UK; [3]Oncology Unit, ASST Cremona - Azienda Socio-Sanitaria Territoriale, Cremona, Italy; [4]Computational Biology Research Centre, Human Technopole, Milan, Italy; [5]Department of Surgery and Cancer, Imperial College London, London, UK

Background: The potential of monitoring circulating tumor DNA (ctDNA) dynamics to guide clinical decisions in metastatic colorectal cancer (mCRC) patients (pts) treated with I and II line systemic anti-cancer therapy (SACT) has not been widely tested.

Methods: 862 serial plasmas were collected 4-weekly from baseline (BL) until disease progression in 75 mCRC pts undergoing SACT. ctDNA was tested using a custom (20 genes) or a commercial (77 genes) ctDNA next generation sequencing (NGS) panel. Whole exome sequencing (WES) was performed on tissue biopsies. ctDNA normalization was defined as $\geq$99% clearance after 1 month of therapy (Mo1) in the 3 variants with the highest allele frequency in BL ctDNA.

Results: 83 paired samples from 75 pts were available for analysis (for 8 pts, I and II line bloods were available). 12 pairs (14.4%) showed no variants in either BL or Mo1. In the remaining 71 comparisons (65 pts), 37 (52.1%) showed ctDNA normalization at Mo1. Among normalized pts there was a higher proportion of cases with a baseline ECOG performance status (PS) 0-1 (97.3% vs 82.4%, p= 0.0362) in comparison to non-normalized pts. Moreover, normalized pts had significantly longer overall survival (OS), 45.6 months (95% confidence interval [CI]: 30.0 - not reached) and progression-free survival (PFS), 13.9 months (95%CI: 11.2-18.3) compared to non-normalized pts [OS = 22.6 months (95%CI: 16.6-31.2, p= 0.01) and PFS = 10.7 months (95%CI: 7.53-13.8, p= 0.036) respectively]. In addition, pts with normalized ctDNA had higher overall response rate (ORR) of 72.9% (27/37 responses) compared to 38.2% (13/34 responses) in non-normalized pts. In a multivariate model, ctDNA normalization was confirmed as an independent predictor of decreased risk of death (hazard ratio [HR] 0.47, 95%CI: 0.23-0.96; p= 0.04) and higher probability of achieving an objective response from front-line treatment (odds ratio [OR] 3.03, 95%CI: 1.08-8.49; p= 0.0351). Only 23/50 (46%) of variants detected in ctDNA were detected by WES in paired tissues.

Conclusions: ctDNA monitoring represents an early indicator of benefit from systemic therapy in mCRC pts. A significant fraction of variants detected in ctDNA was not detected in paired tissues.

2327P The impact of the microenvironment on the intratumoral cellular heterogeneity in colorectal cancer

I. Carmi, Z. Wiener

Genetics, Cell, and Immunobiology, Semmelweis University, Budapest, Hungary

Background: Colorectal cancer (CRC) is a major public health issue, as it is amongst the most common forms of cancer incidence and mortality worldwide. Lately, intratutmoral cellular heterogeneity has been highlighted for survival and drug response evaluation. In 2015, the consensus molecular subtype system (CMS) surfaced as a potential diagnostic and prognostic tool for CRC. The CMS classification is based on gene expression profiles and recognizes four subtypes. Whereas CMS2/3 is characterized by high Wnt signaling, and Myc activity, CMS4 is defined by its TGF-β signaling, epithelial-mesenchymal transition (EMT), fibroblast accumulation, and overall worst prognosis. I examined the influence of the tumoral microenvironment on the intratumoral cellular heterogeneity of CRC.

Methods: Patient-derived organoids (PDO) model intratumoral heterogeneity of CRC effectively. PDOs were cultured from CRC surgical biopsy samples, and grown alone or with fibroblasts, in Matrigel or in collagen-enriched gel, with growth medium enriched or depleted from amino acids or glucose. The accumulation of collagen in the tumors is negatively correlated with patient survival. The expression levels of markers for CMS2/3 and CMS4 were evaluated with RT-qPCR, immunohistochemistry, and flow cytometry.

Results: We observed a higher rate of CRC cell positivity for CMS2/3 and CMS4 markers, along with their double positivity when co-cultured with fibroblasts. Similarly, the mixed phenotype positivity increased for CRC cells cultured in amino acid or glucose-free conditions compared to standard growth medium. In collagen, only the CMS4 marker positivity was higher compared to those in Matrigel. Furthermore, cocultured organoids demonstrated an increased positivity for the EMT markers.

Conclusions: Altering the microenvironment of CRC significantly modifies the intratumoral cellular heterogeneity, as collagen and fibroblast enrichment shifts the organoids to a CMS4 phenotype with partial EMT activity, both of which are suggestive of worse prognosis.

2328P Alternative molecular mechanisms underpinning breast invasive lobular carcinoma identified by genomics-driven artificial intelligence model

F. Pareja[1], H. Dopeso[1], Y.K. Wang[2], A. Gazzo[1], D. Brown[1], P. Selenica[1], J. Bernhard[2], J. Sue[2], M.C.H. Lee[2], R. Godrich[2], A. Casson[2], B. Weigelt[1], M. Hanna[1], J.D. Kunz[2], B. Rothrock[2], C. Kanan[2], G.J. Oakley[2], D. Klimstra[2], T. Fuchs[2], J.S. Reis-Filho[1]

[1]Department of Pathology and Laboratory Medicine, Memorial Sloan Kettering Cancer Center, New York, NY, USA; [2]Biomarker Development, Paige, New York, NY, USA

Background: A subset of cancers display distinctive phenotypes and harbor pathognomonic genetic alterations. Breast invasive lobular carcinoma (ILC), the most common special histologic subtype of breast cancer (BC), has a distinctive discohesive phenotype, caused by bi-allelic inactivation of *CDH1* (E-cadherin), representing a strong genotypic-phenotypic correlation. Here, we sought to apply an artificial intelligence (AI)-based model trained to detect *CDH1* bi-allelic mutations (i.e. inactivating mutation and loss of heterozygosity (LOH)) using H&E-stained whole slides images (WSI) as input to identify ILCs with alternative mechanisms of *CDH1* inactivation.

Methods: We applied the AI-model trained to detect *CDH1* biallelic mutations using WSIs to a cohort of 1,057 BCs with available targeted sequencing data. To determine the molecular underpinning of cases predicted to harbor *CDH1* bi-allelic mutations but lacking these genetic alterations by targeted sequencing, we conducted the reanalysis of targeted sequencing data, *CDH1* gene promoter methylation assessment and/or whole genome sequencing (WGS) analysis.

Results: We identified 34 cases predicted by the AI-model to harbor a *CDH1* bi-allelic mutations that lacked these alterations by targeted sequencing. Reanalysis of targeted sequencing data and/or promoter methylation assessment revealed *CDH1* promoter methylation (n=20), *CDH1* homozygous deletions (n=3) and *CDH1* intragenic deletion associated with LOH (n=1) in these cases. In addition, WGS of an ILC revealed a translocation t(13;16) predicted to result in a novel deleterious fusion gene affecting *CDH1* with loss of exons 1-2 and the regulatory regions of this gene, associated with LOH. By applying a genomics-driven AI model we detected alternative mechanisms of *CDH1* inactivation in 25/34 (74%) cases.

Conclusions: In the context of genotypic-phenotypic correlations, AI-based methods trained on a genetic ground truth can result in the identification of alternative/convergent molecular mechanisms underpinning histologic entities. This study highlights the potential of combinatorial approaches integrating deep learning methods and genomics in pathology.

2329P Evidence for the utility of artificial intelligence and image analysis in Ki-67 quantification in solid tumors

X. Pichon[1], R. Gaspo[2], S. Iglesias[1], D. Kumar[3], M. Tliba[1], R. Burrer[1], A. Finan[1]

[1]Science, Cerba Research, Montpellier, France; [2]Science, Cerba Research, Montreal, QC, Canada; [3]Science, Aiforia Technologies Plc., Helsinki, Finland

Background: Although it is an important biomarker in oncology, Ki-67 immunohistochemistry analysis has yet to be standardized. Working groups have provided guidelines for Ki-67 scoring in different cancer types to limit pathologist's variability. Digital analysis solutions to assist scoring with image analysis or AI have recently emerged in the evaluation of Ki-67 as rapid and robust solutions. In this context, we compared the results of Ki-67 scoring performed with Aiforia® (AI platform) and Halo® (image analysis supervised software) against two independent pathologists on solid tumors.

Methods: We stained 192 tumors of various origins including breast and prostate with Ki-67 (clone 30-9). Pathologists were trained following the International Ki-67 Working Group recommendations and scored tissues accordingly. Based on deep learning, Aiforia was able to automatically score Ki-67 positive tumor cells within minutes. The random forest classifier from Halo software was used to separate the image into tumor, non-tumor and background. After cell segmentation, Ki-67 positivity was assessed by thresholding.

Results: Our study shows a very high consistency of results obtained for Ki-67 scoring between the image analysis softwares, Aiforia and Halo (r^2=0.94), on all solid tumors. The correlation obtained between the two pathologists was weaker (r^2=0.8), despite the training and guidelines, but remains within an acceptable range. Of the 18 types of primary tumors analyzed, only 2 (thyroid and stomach) showed correlations of less than 0.75 between the image analysis softwares with inter-pathologists' correlation still high (0.73 and 0.86). Depending on the organ, there were significant variations between pathologists, whereas the scores obtained with the image analysis softwares remain very close. For example, with prostate (n=8), a 0.81 correlation for Ki-67 scores between Aiforia and Halo was found while the inter-pathologists' correlation was 0.68.

Conclusions: This work shows that AI based image analysis tools such as Aiforia and image analysis supervised software provide valuable assistance in IHC based clinical analysis, drastically reducing inter-pathologist variability or as an arbitration tool in Ki-67 scoring of solid tumors.

2330P Pre-test prediction of multiple druggable mutations based on H&E image artificial intelligence (AI) analysis may enable more efficient clinical workflow for treatment decisions in non-small cell lung cancer (NSCLC)

J. Lee[1], S. Park[1], S-H. Lee[1], Y-L. Choi[2], Y-D. Choi[3], M-G. Noh[4], J. Park[5], S. Shin[5], T. Lee[5], H. Song[5], J. Ro[5], J. Moon[5], S. Kim[5], C. Ahn[5], S. Pereira[5], D. Yoo[5], C-Y. Ock[5]

[1]Division of Hematology-Oncology, Department of Medicine, Samsung Medical Center, Seoul, Republic of Korea; [2]Pathology, Samsung Medical Center, Seoul, Republic of Korea; [3]Pathology, Chonnam National University Medical School-Gwangju, Gwangju, Republic of Korea; [4]Pathology, Chonnam National University Hwasun Hospital, Hwasun, Republic of Korea; [5]Oncology Group, Lunit, Seoul, Republic of Korea

Background: AI may predict driver mutations from H&E slides, and this prediction may be useful as a screening tool to guide the efficient use of molecular testing. Here, we investigate the prediction performance for mutations in six driver oncogenes and explore the benefits to clinical workflow in NSCLC treatment decisions.

Methods: NSCLC samples from Neogenomics (n=2,161) and TCGA (n=933) were used for model development. Four features were used: two convolutional neural networks trained for cell and tissue, a self-supervised vision transformer, and an AI-based pathology profiling analyzer for semantic contents. A set of classifiers was trained and ensembled for improved robustness. Performance of the model was validated in an independent dataset (n=792), then we simulated real-world impact based on the prevalence of driver mutations from AACR GENIE v13.1 NSCLC (n=19,722).

Results: Table 2330P shows the dataset and performance of the models. Given 2.8% prevalence of *MET* exon skipping mutations (*MET*-ex), 8.5% positive predictive value (PPV) means that a test-positive patient has a 3x higher chance of being true-*MET*-ex positive compared to the overall patient population. Moreover, given 99.2% specificity and 49.4% prevalence, PPV for selecting patients without mutations (All-WT) is 95.2%, enabling avoidance of unnecessary tests with potentially acceptable error (<5%).

Table: 2330P

	Internal set		External set			
	n (%)	AUC	n (%)	AUC	Sensitivity	Specificity
EGFR-mt	384 (12.4)	0.841	224 (28.3)	0.723	75.5%	52.6%
KRAS-mt	516 (16.7)	0.728	130 (16.4)	0.721	86.2%	22.5%
ALK-tr	310 (10.0)	0.795	46 (5.8)	0.738	39.1%	81.8%
ROS1-tr	295 (9.5)	0.793	62 (7.8)	0.609	14.5%	70.6%
RET-tr	307 (9.9)	0.763	11 (1.4)	0.683	18.2%	96.4%
MET-ex	240 (7.8)	0.789	12 (1.5)	0.849	83.3%	74.4%
All-WT	1045 (33.8)	N/A	277 (35.0)	N/A	15.9%	99.2%

AUC, area-under-the-curve; ex, exon skipping; mt, mutation; tr, translocation.

Conclusions: A novel clinical workflow, using AI analysis of H&E to predict genomic profiles and identify which patients would benefit from confirmatory molecular testing, could enable better and more efficient treatment decisions.

2331P Interest of next generation sequencing (NGS) for integrated molecular diagnosis of HER2-low breast cancer

J.L. Merlin[1], M. Husson[1], N. Sahki[2], P. Gilson[1], A. Leroux[1], V. Massard[3], A. Harlé[1]

[1]Biopathology Department, Institut de Cancérologie de Lorraine - Alexis Vautrin, CNRS UMR7039 CRAN Université de Lorraine, Vandoeuvre-les-Nancy, France; [2]Methodology Biostatistics Unit, Institut de Cancérologie de Lorraine - Alexis Vautrin, Vandoeuvre-les-Nancy, France; [3]Medical Oncology Department, Institut de Cancérologie de Lorraine - Alexis Vautrin, Vandoeuvre-les-Nancy, France

Background: Based on HER2 expression using immunohistochemistry (IHC) and HER2 gene amplification using in situ hybridization (ISH), breast cancers (BC) are usually classified, into HER2 positive (IHC 3+ or IHC 2+/ISH+) and HER2 negative (IHC 0, IHC 1+ or IHC 2+/ISH-). Recently, HER2-low breast cancers (HER2-low BC) emerged as a new subtype defined as IHC1+ or IHC2+/ISH- tumors. HER2-low BC represent more than half of all BC. Consistently with the clinical activity of HER2 antibody-directed chemotherapy (ADC) in HER2-low BC, this subtype should be identified to enable early set-up of therapy. Since HER2-low BC identification could be equivocal using conventional IHC and ISH, we evaluated the performance of NGS for integrated diagnostic including HER2 copy number analysis.

Methods: BC tumor specimens were analyzed using IHC and ISH as performed routinely. NGS was performed using a custom capture based 51-gene panel, including BC molecular target genes such as ESR1, PIK3CA, AKT1, ERBB2, TP53, BRCA1 and BRCA2. Gene mutations as well as copy number variation (CNV) and Microsatellite Instability (MSI) were determined.

Results: Thirty-one FFPE BC tumor specimens were classified using IHC and ISH into 11 HER2-positive (IHC2+ ISH+ and IHC3+), 10 HER2-negative (IHC 0) and 10 HER2-low cancers (IHC1+ and IHC2+ ISH-). Using NGS, CNV values for ERBB2 gene were significantly ($p<0.001$) different between HER2 negative, HER2low and HER2- positive tumors with mean CNV values of 2.0 (SD=0.3), 1.9 (SD=0.3) and 7.8 (SD=6.8), respectively. Using 3.25 as cutoff value for CNV, 90% concordance of HER2 amplification status was achieved between ISH and NGS. Using NGS, additional drug-targetable gene mutations as well as amplifications were detected in 68% (21/31) and 19% (6/31) of the cases, respectively. One case of MSI was detected in a HER2-negative and ISH unamplified case.

Conclusions: These results show that in HER2 IHC positive (scores 1+ to 3+) BC, CNV determination using NGS allows the identification of HER2-low status simultaneously with the detection of multiple molecular target genes while sparing tissue samples. This workflow could support molecular board decision between HER2-ADC or other targeted therapies.

2332P Overall survival in breast cancer patients with HER2-low status single- center experience

J. Huszno[1], Z. Kolosza[2], E. Stobiecka[3], D. Ponikiewska[3], B. Szcześniak[3], J. Simek[3], E. Chmielik[3]

[1]Radiotherapy Department, National Oncology Institute Maria Sklodowska-Curie National Research Institute, Gliwice Branch, Gliwice, Poland; [2]Department of Biostatistics and Bioinformatic, Maria Sklodowska-Curie National Research Institute of Oncology Gliwice Branch, Gliwice, Poland; [3]Tumor Pathology Department, National Oncology Institute Maria Sklodowska-Curie National Research Institute, Gliwice Branch, Gliwice, Poland

Background: The HER2/neu (ERBB2) oncogene is amplified and/or overexpressed in approximately 15% of breast cancers (BC), and is a strong prognostic factor for relapse and poor overall survival (OS), particularly in node-positive patients. The aim of this study was to evaluate the prognostic significance of HER2-low status in BC. We also compared HER2-low subgroup with HER2-0 according to clinical, histopathological, laboratory and molecular factors.

Methods: The analysis included medical records of 657 BC patients treated in NIO in Gliwice in years 2002-2018. Human epidermal growth factor receptor 2 overexpression was assessed using an IHC method in postoperative specimens or samples obtained by thick needle biopsy. HER2 gene amplification was additionally assessed by FISH in HER2 (2+) cases.

Results: Median age of all women was 52 years (range from 24 to 81). 176 (27%) tumors were HER2-low BC, 248 (38%) HER2-0 and 233 (35%) HER2-positive tumors. There was no difference according to molecular factors such as *BRCA* gene mutation ($p=0.780$) or patient's age ($p=0.275$) between patients with HER2-low tumors and HER2-0. No differences were also detected between the both groups according to family history of cancer, co-morbid condition, menopausal status, tumor size, lymph nodes with metastases (N+) or higher histologic tumor grade (G3). BC patients with HER2-low tumors more often had positive estrogen receptor status (ER+) (80% vs. 60%, p=0. 0001). There was no reported differences according to OS between patients with HER2-low status and HER2-0 ($p=0.747$). In subgroup of patients with ER-negative receptor status (ER-) OS were insignificantly worse in patients with HER2-low status in comparison to HER2-0 (5-year OS 72.6% vs. 86.7%, $p=0.074$). There was also observed tendency to worse OS in patients with HER2-low status in subgroups with higher T3-4 (61.2% vs. 75.1%, $p=0.217$), G3 (80.7% vs. 89.2%, $p=0.139$) and N+ (81.3% vs. 86.9%, $p=0.599$).

Conclusions: There was no association between HER2 status (HER2-low vs. HER2-0) and *BRCA* gene mutation, tumor size, the presence of metastases in lymph nodes and G. HER2-low status worsens OS in subgroups of patients with negative prognostic factors in comparison to patients with HER2-0.

2333P Associating BRCA1 hypermethylation with clinicopathological and molecular variables in triple-negative breast cancers

A. Karlsson[1], F. Killander[2], D.F. Nacer[3], J. Häkkinen[3], F. Rosengren[3], J. Vallon-Christersson[4], J. Staaf[1]

[1]Translational Cancer Research, Lund University - Faculty of Medicine, Lund, Sweden; [2]Department of Clinical Sciences in Lund, Lund University - Faculty of Medicine, Lund, Sweden; [3]Clinical Sciences, Lund, Lund University, Lund, Sweden; [4]Division of Oncology Department of Clinical Sciences, Lund University, Lund, Sweden

Background: The aim of this study was to investigate the correlation of *BRCA1* promoter methylation status (*BRCA1*met) in patients with triple-negative breast cancer (TNBC) to clinicopathological and molecular variables, patient prognosis, patient response to neoadjuvant chemotherapy (NAC), and potential therapy resistance mechanisms in NAC treated patients.

Methods: 145 patients enrolled 2015-2018 in the Sweden Cancerome Analysis Network - Breast (SCAN-B) study (ClinicalTrials.gov ID NCT02306096) were included. 109 had chemotherapy (>90% with sequential epirubicin + cyclophosphamide and a taxane, EC—T) according to national guidelines either as NAC (32%) or adjuvant (68%) therapy. Pathogenic *BRCA1/2* variants were detected in 11 of 54 cases. Microsatellite instability and *BRCA1*met using pyrosequencing were investigated in all cases, including analyses of pre-treatment biopsies and surgical resections for NAC patients with residual disease (RD). The NAC patient cohort was extended with six additional SCAN-B patients to further explore treatment response in relation to *BRCA1*met. Clinicopathological and molecular variables were obtained through clinical review and complementary RNA-seq data.

Results: MSI and *BRCA1*met was observed in 2% and 17% of patients, respectively. *BRCA1*met was correlated to younger age and the PAM50 Basal phenotype (92%) and was frequent (40%) in women without pathogenic *BRCA1/2* germline variants. No

association was observed between *BRCA1*met and distant recurrence-free interval in adjuvant treated patients (log-rank p=0.77), nor between *BRCA1*met and pathological response in NAC patients (p=0.69). *BRCA1*met NAC cases revealed differences in methylation level and *BRCA1* mRNA expression in pre-treatment versus surgically resected tissue in patients with RD. No *BRCA1* gene fusions were detected. Genetic alterations between pre-treatment vs surgically resected tissue are further analyzed using whole genome sequencing.

Conclusions: *BRCA1*met is associated with young age in TNBC but hold no predictive nor prognostic value in this patient cohort. We observe a difference in *BRCA1*met patterns and *BRCA1* mRNA expression in NAC patients with RD that may potentially be related to treatment resistance.

2334P Pathologic patterns following different neoadjuvant therapies in non-small cell lung cancer (NSCLC)

A. Weissferdt[1], C.H. Leung[2], B. Sepesi[3], W. Nassib William Junior[4], H. Lin[2], R. Mehran[3], D.L. Gibbons[5], A. Vaporciyan[3], J. Heymach[5], S. Swisher[6], J.J. Lee[2], T. Cascone[7], A. Pataer[3]

[1]Pathology, The University of Texas MD Anderson Cancer Center, Houston, TX, USA; [2]Biostatistics, The University of Texas MD Anderson Cancer Center, Houston, TX, USA; [3]Thoracic and Cardiovascular Surgery Department, The University of Texas MD Anderson Cancer Center, Houston, TX, USA; [4]Oncology Center, Beneficencia Portuguesa de Sao Paulo - BP Mirante, São Paulo, Brazil; [5]Thoracic Head and Neck Medical Oncology, UT MD Anderson Cancer Center, Houston, TX, USA; [6]Thoracic and Cardiovascular Surgery, MD Anderson Cancer Center, Houston, TX, USA; [7]Thoracic Head and Neck Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX, USA

Background: Neoadjuvant chemotherapy (CT), immunotherapy (IT) and combination CT/IT are associated with pathologic treatment response (PTR) in NSCLC. Comparison of pathologic patterns following CT, IT or CT/IT and upfront surgical resection is lacking. Recently, neoadjuvant nivolumab (N), N+ipilumumab (NI), N+CT and NI+CT have been investigated in the NEOSTAR trial (NCT03158129). We analyzed and compared the pathologic patterns of CT, IT and CT/IT-treated NSCLC and untreated resected NSCLC (total n=139).

Methods: Pathologic assessment of resected NSCLC from the NEOSTAR cohort (n=79), a CT-treated group (n=30) and an untreated group (n=30) was performed. H&E-stained tumor sections were scored for parameters commonly associated with PTR: percentages of viable tumor (VT), fibrosis and necrosis and rate of major pathologic response (MPR, ≤10% VT); inflammation (INF), foamy macrophages (FM), lymphovascular invasion (LVI), cholesterol clefts (CC), giant cells (GC), non-necrotizing granulomas (NNG), and neovascularization (NV) were scored from 0-3. Values for each variable were expressed as a median, except MPR (%). Cohorts were compared with Chi-squared or Kruskal-Wallis test and post-hoc pairwise comparisons were performed. Significance was defined as a two-sided p-value <0.05.

Results: NI and NI+CT were associated with significantly less VT (p=0.001, <.001) and more fibrosis (p=0.002, 0.008) than untreated tumors. MPR rates were highest in NI and NI+CT. Necrosis was higher in the CT cohort, INF in N and NI, FM in CT and NI+CT, CC in CT, and NNG in NI and N+CT.

Table 2334P Summary of scored parameters

	Untreated (n=30)	CT (n=30)	N (n=21)	NI (n=16)	N+CT (n=22)	NI+CT (n=20)	p-value
VT	65.8%	48.5%	50%	9%	50.5%	4.5%	<.001
Fibrosis	26.3%	26.1%	40.5%	84%	45%	61.4%	<.001
Necrosis	0.31%	1.71%	1.5%	0%	0%	0%	0.029
MPR	-	17%	24%	50%	32%	55%	0.028
INF	1.37	1.29	2	1.66	1	1.09	0.007
FM	0	0.4	0	0.16	0	0.89	0.015
LVI	0.06	0.23	0	0	0.02	0	0.109
CC	0	0.86	0.4	0	0.13	0.47	<.001
GC	0	0.47	0.2	0.49	0.21	0.28	0.080
NNG (min, max)	0 (0, 0.25)	0 (0, 0)	0 (0, 1.1)	0 (0, 2.66)	0 (0, 2.25)	0 (0, 1.57)	0.004
NV	0	0	0	0.57	0.22	0.18	0.166

Conclusions: Neoadjuvant NI and NI+CT regimens were associated with significantly less VT and more fibrosis than untreated tumors and achieved higher rates of MPR compared to CT. Collectively, neoadjuvant IT-based treatments produced higher amounts of INF, FM, and NNG, highlighting the potential impact of dual IT on pathological tumor regression and patterns of immune-mediated features.

Clinical trial identification: NCT03158129.

2335P Spatial whole exome sequencing reveals the genetic features of highly-aggressive components in lung adenocarcinoma

J. Li[1], S. Xiong[1], S. Zhan[2], J. He[3], W. Liang[4]

[1]Thoracic Surgery and Oncology, State Key Laboratory of Respiratory Diseases - The First Affiliated Hospital of Guangzhou Medical University, Guangzhou, China; [2]Thoracic Surgery and Oncology, National Center for Respiratory Medicine, Guangzhou, China; [3]Department of Thoracic Surgery and Oncology, The First Affiliated Hospital of Guangzhou Medical University, Guangzhou, China; [4]Thoracic Oncology, The First Affiliated Hospital of Guangzhou Medical University, Guangzhou, China

Background: In invasive lung adenocarcinoma (LUAD), patients with micropapillary (MIP) or solid (SOL) components had a significantly poorer prognosis than those with only lepidic (LEP), acinar (ACI) or papillary (PAP) components. It is interesting to explore the genetic features of different histologic subtypes especially the highly aggressive components.

Methods: This study comprised four cohorts of patients who underwent complete surgical resection for lung adenocarcinoma (LUAD) and had their medical records reviewed. Cohort 1 depicted the distribution of different histological subtypes across tumor size groups. Logistic regression analysis in cohort 2 investigated the associations between driver mutations and histological subtypes. Cohort 3 utilized spatial whole-exome sequencing with laser-capture microdissection to identify genetic heterogeneity among histological components within the same tumor. Cohort 4, in conjunction with the cBioportal cohort, was employed to validate the findings obtained from cohort 3.

Results: Based on a cohort of 5,933 patients (cohort 1), this study observed varying prevalence of micropapillary (MIP) and solid (SOL) components in different tumor size groups. Furthermore, cohort 2 revealed that patients with ALK fusion or TP53 mutations had a higher probability of developing MIP/SOL components in cohort 2. To account for individual differences, tspatial whole-exome sequencing was performed using laser-capture microdissection on five patients with coexistent components, enabling the identification of genetic features within the same tumor. In tracing the evolution of components, we found that titin mutation might serve as a crucial intratumor potential driver for MIP/SOL components, which was validated by the cohort 4 of 146 LUAD patients undergoing bulk WES. Functional analysis demonstrated that TTN mutations were enriched the complement and coagulation cascades, which correlated with the pathway of cell adhesion, migration, and proliferation.

Conclusions: Collectively, the histologic subtypes of invasive LUAD were genetically different, and certain trunk genotypes might synergize with branching TTN mutation to develop highly aggressive components.

2336P MiR-155 overexpression regulates epithelial-mesenchymal transition through repressing Quaking in lung cancer cells

J-J. Hung

School of Medicine, National Yang Ming Chiao Tung University, Taipei, Taiwan

Background: Epithelial-mesenchymal transition (EMT) is one of the major molecular mechanisms inducing tumor invasion and metastasis. Various MicroRNAs (miRNAs) have been shown to be involved in EMT. MiR-155 is consistently up-regulated in non-small cell lung cancer and is associated with poor overall survival. Whether miR-155 regulates EMT in lung cancer cells remains unclear.

Methods: We first transfected plasmid containing miR-155 into H1299 and A549 cells and established H1299-miR-155 and A549-miR-155 cells. Western blotting was done to demonstrate E-cadherin, vimentin, and Quaking (QKI) expression in H1299-miR-155 and A549-miR-155 cells. Invasion and migration assay were performed in H1299-miR-155 and A549-miR-155 cells. We then constructed p-mcherry plasmids that contain miR-155 and a p-Luc-QKI-3'UTR reporter plasmid. Luciferase assay was done to demonstrate whether miR-155 binds to the QKI 3'UTR.

Results: Quantitative RT-PCR showed that QKI expression was downregulated in H1299-miR-155 and A549-miR-155 cells. Western Blotting showed decreased E-cadherin and increased vimentin expression in H1299 and A549 cells after miR-155 transfection. Western blotting also showed decreased QKI expression in H1299 and

A549 cells after miR-155 transfection. Migration assay showed that the number of migrated cells significantly increased after miR-155 transfection in H1299 and A549 cells. Invasion assay showed that the number of invaded cells also significantly increased after miR-155 transfection in H1299 and A549 cells. We constructed p-mcherry plasmids that contain miR-155 and a p-Luc-QKI-3'UTR reporter plasmid. Luciferase assay showed that miR-155 represses the activity of p-Luc-QKI-3'UTR. We then mutated the miR-155 binding site in the QKI 3'UTR to confirm that repression of the mRNA levels is induced by the binding of miR-155 to the QKI 3'UTR.

Conclusions: MiR-155 overexpression regulates EMT through repressing QKI in lung cancer cells. Repression of QKI is induced by the binding of miR-155 to the QKI 3'UTR.

2337P Feasibility of mutation detection in cytological samples from metastasis in patients with metastatic prostate cancer

M. Mencinger[1], V. Kloboves Prevodnik[2], S. Novakovic[3], B. Seruga[1]

[1]*Department of Medical Oncology, Institute of Oncology Ljubljana, Ljubljana, Slovenia;* [2]*Department of Cytopathology, Institute of Oncology Ljubljana, Ljubljana, Slovenia;* [3]*Department of Molecular Diagnostics, Institute of Oncology Ljubljana, Ljubljana, Slovenia*

Background: Mutations in homologous recombination repair (HRR) genes are actionable targets for poly (ADP-ribose) polymerase inhibitors in cancer. Extraction of DNA from archival paraffin-embedded tissue is challenging. In addition, somatic mutations in HRR genes are more frequent in metastases than in primary tumours. Fine needle aspiration (FNA) of metastases is an alternative method to surgical, core needle and circulating tumour DNA-based liquid biopsy and may provide sufficient DNA for genomic analysis.

Methods: We performed a retrospective analysis on our clinical, cytological and next-generation sequencing (NGS) data based on ultrasound-guided FNA samples of metastases in prostate cancer patients. The aims were to evaluate the success rate of FNA for NGS, identify possible obstacles and optimise it.

Results: From Jan. 2021 to Dec. 2022, 27 FNAs of metastases from 21 patients with metastatic castrate-resistant prostate cancer have been undertaken at the Institute of Oncology Ljubljana. The samples were retrieved from lymph node, liver and bone metastases in 59% (16/27), 30% (8/27) and 11% (3/27) patients, respectively. Six out of 27 (22%) samples were unsuccessful according to cytologists. Of undiagnostic samples, 4/6 were obtained from liver and 2/6 from lymph nodes. A high percentage of liver samples, 75% (3/4), contained less than 10% of tumour cells. All samples from bones (3/3) and 56% (9/16) from lymph nodes had more than 50% of tumour cells. Median percentage of tumour cells per sample was 80% (range 5-100). Altogether, 21/27 (78%) samples were adequate for DNA extraction and successful NGS. *BRCA 2* pathogenic mutation were detected in two patients (2/21); of these two, one had an adjacent mutation in *CDK12* and the other in *FANCL* together with a high tumor mutational burden. In three patients (3/21) *ATM* pathogenic mutations were found, one being adjacent to mutation in *CHECK1* and the other in *BARD1*.

Conclusions: Ultrasound-guided FNA of metastases is a feasible method to obtain good quality DNA for NGS in patients with metastatic prostate cancer when searching for potential molecular targets. Close collaboration between dedicated radiologists and cytopathologists could further improve the success rate of this method.

2338P The phenotype of tumor-associated macrophages in human high-grade serous ovarian carcinoma

I. Larionova[1], E.O. Kazakova[1], P. Iamshchikov[1], M. Rakina[1], J. Kzhyshkowska[2]

[1]*Lab. of Translational Cellular and Molecular Biomedicine, National Research Tomsk State University, Tomsk, Russian Federation;* [2]*Institute of Transfusion Medicine and Immunology, Institute for Innate Immunoscience (MI3), Medizinische Fakultät Mannheim der Universität Heidelberg, Mannheim, Germany*

Background: Ovarian cancer (OC) is one of the most common gynecological cancers, with the worst prognosis and the highest mortality rate. According to the FIGO, the overall five-year survival rate is approximately 50%. Tumor-associated macrophages (TAMs) are one of the most prominent populations of immune cells in both ovarian cancer tissue and malignant ascites. The most relevant task is to identify TAM subpopulations in ovarian cancer, to discover how they interact with chemotherapy and affect the development and outcome of the disease.

Methods: Patients with high-grade serous ovarian carcinoma were included in the study. FFPE samples with tumor were obtained after surgery. The study was carried out according to medical ethics. We applied two technologies of spatial transcriptomics for the analysis of TAM transcriptomic features in patients with ovarian cancer — 10x Genomics Visium and Nanostring GeoMX-DSP. All procedures were performed according to manufacturer`s protocols.

Results: The results of 10x Visium demonstrated that TAM cluster express CCL18, APOC1, GPNMB, LYZ, APOE, C1QC, C1QB, CTCB, SPP1, CTSS, and other genes. Interestingly, according to accumulating data the expression of these macrophage markers is distinctive feature for the potentially targeted population of lipid-associated TAMs. The morphology of macrophages in TAM cluster in clinical samples corresponds to the large lipid-associated TAMs. Nanostring technology allowed us to analyse ROIs with immune cells located in different tumor sites. The transcriptome of TAMs located near the tumor nest correlated to functional activation of extracellular matrix organization, antigen presentation, vascular development and myeloid leukocyte activation. These TAMs have the same morphology of large foamy macrophages and express APOE, SPP1, LYZ, CTSS, and other genes.

Conclusions: We found gene signature specific for the large TAMs in tumor tissue of patients with high-grade serous ovarian carcinoma.

Background: Circulating tumor DNA (ctDNA) tumor fraction (TF) is a promising biomarker for cancer diagnosis, follow-up and prognosis. TF depends on tumor burden (TB) but the correlation is moderate and other biological characteristics may play a role. In this study, we investigate the underlying genomic features affecting the relationship between TF and TB, assessed by PET scan.

Methods: Patients with NSCLC from the prospective STING trial (NCT04932525) who had both profiling with FoundationOne®LiquidCDx (F1LCDx™) and a PET scan performed within 42 days from either baseline (BL) or at treatment progression (PD) were included in this study. Foundation Medicine's ctDNA TF on F1LCDx is a composite algorithm prioritizing aneuploidy at higher levels to avoid germline signal and prioritizing variant allele frequency of canonical alterations at lower levels to maximize dynamic range. Tumor burden was calculated with PET scan-derived total metabolic tumor volume (tMTV) with a semi-automated analysis based on a 42% fixed-relative threshold of standardized uptake value (SUV) SUVmax. Genes altered in at least 2.5% of the cohort were evaluated by a multivariate linear regression using gene mutations and rearrangements as covariates and the logarithm of the TF/tMTV ratio as the dependent variable.

Results: Of 242 liquid biopsies, 38 lacked clinically relevant variants; tissue molecular characterization was used for 17 of these patients. Overall, tMTV was correlated with TF (rho 0.402, $p < 0.0001$). No difference was seen between BL or PD ($p = 0.997$). In the multivariate model, alterations associated with higher TF/tMTV ratio were *MLL2* (ß coefficient = 1.45, $p = 0.03$), *PTEN* (ß = 1.28, $p = 0.045$), *RBM10* (ß = 1.06, $p = 0.046$), *RB1* (ß = 0.91, $p = 0.028$), and *TP53* (ß = 0.87, $p = 0.004$). *ALK* rearrangements (ß = -1.04, $p = 0.049$) and *ATM* alterations (ß = -1.46, $p = 0.002$) were associated with lower shedding. Higher tMTV was seen in patients with *STK11* mutation (117 vs 56 cm^3, $p = 0.001$).

Conclusions: Alterations in genes implicated in cell cycle regulation, proliferation and apoptosis are associated with the ratio of TF to tMTV assessed by PET scan. ctDNA TF may therefore provide additional clinical utility beyond tumor burden surrogacy to design precise treatment strategy.

Clinical trial identification: NCT04932525.

2340P T-cell immunoglobulin and mucin-domain containing molecule-3 (Tim3) in breast cancer and the impact on penetration of blood brain barrier by cancer cells

X. Cao[1], B. Cong[2], W. Jiang[1], T.A. Martin[1]

[1]School of Medicine, Cardiff University, Cardiff, UK; [2]Breast Cancer Center, Shandong Cancer Hospital Affiliated to Shandong University, Jinan, China

Background: Tim3 (T-cell immunoglobulin and mucin-domain containing molecule3) plays an important role in metastatic spread of cancers. The blood brain barrier (BBB) is an essential barrier that breast cancer cells have to overcome to metastasize to the CNS. This study investigated the association/functionality of Tim3 in breast cancer cells and in the invasiveness of cerebral endothelial cells by cancer cells.

Methods: Human cerebral microvessel endothelial cells (hCMEC/D3) were used to model BBB in vitro. Tim3 knockdown was by anti-Tim3 siRNA in MCF-7 and MDA-MB-231 cell lines. Electric cell impedance sensing (ECIS) was used for assessing cellular attachment and migration. Transepithelial resistance (TEER) and paracellular permeability (PCP) were used to test the barrier functions of the cells. Cellular response to docetaxel was evaluated and shown as IC50.The effects of Tim3 knockdown on penetration through the hCMEC/D3 monolayer were also assessed.

Results: Tim3 knockdown (Tim3kd) cell models were successfully established with MCF-7 and MDA-MB-231 cells. Loss of Tim3 in these cells resulted in a decrease in both cell adhesiveness and migration. The knockdown also led to a reduced transepithelial resistance as shown by TEER assay and an increase in paracellular permeability when compared with wild type (WT) cells. It was noted that loss of Tim3 rendered both MCF-7 and MDA-MB-231 cells resistant to docetaxel (IC50 for WT and Tim3kd respectively being 0.86nM vs 2.2nM for MCF7 and 1.35nM vs 11.8nM for MDA-MB-231). In the cerebral endothelial cell invasion assay, we found that Tim3 knockdown in both MCF-7 and MDA-MB-231 resulted in a significantly reduced invasion of the breast cancer cells through the endothelium (31±8 vs 24±8 for MCF7, $p=0.018$; 211±48 vs 142±54 for MDA-MB-231, $p<0.001$, WT and Tim3kd respectively).

Conclusions: Tim3 has a marked influence on the barrier functions, adhesiveness and the sensitivity to docetaxel of breast cancer cells. Loss of Tim3 in breast cancer cells reduces tumour cell's penetration of cerebral endothelium. Collectively, Tim3 plays a key role in the maintenance of barrier functions in breast cancer and their potential breach of the blood brain barrier.

2341P Novel therapeutic opportunities in metaplastic breast cancer

F. Pareja[1], A. Gazzo[1], H. Dopeso[1], D. Brown[1], P. Selenica[1], Y. Zhu[1], J. Blanco Heredia[1], L. Gusain[1], X. Pei[2], A. Marra[3], G. Montagna[4], N. Abuhadra[5], H. Wen[1], E. Brogi[1], N. Riaz[2], S. Chandarlapaty[5], M. Scaltriti[6], S. Powell[2], B. Weigelt[1], J.S. Reis-Filho[1]

[1]Department of Pathology and Laboratory Medicine, Memorial Sloan Kettering Cancer Center, New York, NY, USA; [2]Department of Radiation Oncology, Memorial Sloan Kettering Cancer Center, New York, NY, USA; [3]Medical Oncology, IEO - Istituto Europeo di Oncologia IRCCS, Milan, Italy; [4]Department of Surgery, Memorial Sloan Kettering Cancer Center, Commack, NY, USA; [5]Department of Medicine, Memorial Sloan Kettering Cancer Center, New York, NY, USA; [6]Human Oncology and Pathogenesis Program, Memorial Sloan Kettering Cancer Center, New York, NY, USA

Background: Metaplastic breast cancer (MBC) is a rare and aggressive form of triple-negative breast cancer with limited therapeutic options. Despite being reported to display genomic features of homologous recombination (HR) deficiency (HRD) by whole-exome sequencing, MBCs rarely respond to neoadjuvant chemotherapy/immunotherapy. We sought to assess their HR and immune features using whole-genome sequencing (WGS) of MBCs and evaluated the efficacy of antibody-drug conjugates (ADCs) and DNA damage response (DDR)-targeting agents in preclinical MBC models.

Methods: MBCs were subjected to WGS (n=25) and RNAseq (n=31). HRD was assessed using HRDetect ('gold standard') and mutational signatures using Signal. ADC target expression was assessed transcriptomically. Efficacy of ADCs and DDR agents was assessed *in vitro* using MBC cell models (BT549, Hs578T and HCC1806). T-DXd efficacy was evaluated *in vivo* in HCC1806 xenografts in athymic mice.

Results: Despite most (13/25) MBCs displaying partial features of HRD (mutational signature 3), only 3/25 MBCs had a complete HRD pattern with tandem duplications, deletions with microhomology, dominant SBS/indel/rearrangement HRD mutational signatures and were classified by HRDetect as HRD. These 3 MBCs harbored somatic/germline pathogenic *BRCA1* mutations (n=2) or a *RAD51C* intragenic inversion with LOH (n=1). Exposure to APOBEC mutational signature was detected in 15/25 (60%) MBCs, including the HRD cases. HLA homozygosity/LOH was more frequent in non-chondroid (7/15) than in chondroid (1/10) MBCs. *TROP2* and *ERBB2* expression was detected in MBCs by RNAseq, and MBC cell models were found to be sensitive to T-DXd, Sacituzumab govitecan, and ATR and Wee1 inhibitors *in vitro*, and to T-DXd *in vivo*. Combination of T-DXd and DDR agents in MBC models was found to be synergistic.

Conclusions: Most MBCs display an incomplete HRD phenotype and those with complete HRD harbor bi-allelic inactivation of HR-related genes. MBCs express targets for novel ADCs, and preclinical MBC models are sensitive to anti-HER2 and anti-TROP2 ADCs alone or in combination with novel DDR agents, targeting their incomplete HRD phenotype, other than PARP-inhibitors. These findings provide preclinical evidence for assessing the clinical efficacy of these therapeutic approaches.

2342P Single tumor cells are a novel prognostic criterion in breast cancer patients

L. Tashireva[1], E. Grigoryeva[1], V.V. Alifanov[2], A. Kalinchuk[1], N.O. Popova[3], V. Perelmuter[2]

[1]Laboratory of Molecular Therapy of Cancer, Tomsk National Research Medical Center of the Russian Academy of Sciences, Tomsk, Russian Federation; [2]The Department of General and Molecular Pathology, Tomsk National Research Medical Center of the Russian Academy of Sciences, Tomsk, Russian Federation; [3]Chemotherapy, Tomsk National Research Medical Center, Russian Academy of Sciences Cancer Research Institute, Tomsk, Russian Federation

Background: Single tumor cells (STCs) are a manifestation of intratumor morphological heterogeneity and most likely arise from multicellular tumor structures as a result of cancer invasion. In recent years, the appearance of STCs has been described as tumor budding in the invasive front. However, there are no clear data on the clinical significance of these cells in breast cancer patients.

Methods: The study included 230 patients diagnosed with invasive breast carcinoma of the nonspecific type, luminal molecular subtypes. H&E staining was used to detect STCs in breast tissue. STCs (or detached individual tumor cells) were detected in the entire tumor tissue in contrast to tumor buds located in the invasive front, and were defined as tumor cells located outside multicellular tumor structures but similar to them in cytological features. 7-color immunofluorescence analysis was used to study the population composition of the microenvironment (ME) of STCs. Laser microdissection of STCs ME and sequencing on NextSeq500 (Illumina, USA) was performed.

Results: Patients who had a STCs had a 5.8-fold increased risk (CI95% 2.4-14.1) of developing distant metastases compared to patients who did not have a STCs (p=0.0001). Patients who had no STCs had a better metastatic-free survival (91.8%) than patients who had a STCs (49.1) (p<0.0001). The relative risk of distant metastases in breast cancer patients where only Th2-like immune reaction is found in the ME is 2.37 (CI95% 1.25-4.42) times higher than in patients where only Th1-like immune reaction (p=0.0352). In addition, a Top 10 analysis of up- and downregulated genes in the STCs ME in breast cancer patients depending on the status of distant metastasis was performed. Decrease of CD52 (7-fold), NUDT3 (6-fold), TAP1 (6-fold) (p<0.001) genes expression and increase of LAMA5 (4-fold), LPCAT1 (5-fold), FLVCR1 (5-fold) (p<0.001) genes expression were detected in the STCs ME of breast cancer patients with distant metastases compared to those without.

Conclusions: A novel simple prognostic criterion for predicting breast cancer metastasis has been developed. The microenvironment has been shown to play an important role in the metastatic potential of a single tumour cells. Immunosignatures of the pro-tumour microenvironment have been identified.

2343P Evolution of circulating tumour DNA analysis in France over 5 years

G. Herbreteau[1], E. Rouleau[2], J-P. Bellocq[3], D. Fetique[3], C. Egele[3], S. Taverniers[4], E. Dequeker[4], L. Lacroix[2], M.G. Denis[1]

[1]Biochemistry Department, Nantes University Hospital, Nantes, France; [2]Medical Biology and Pathology Department, Gustave Roussy - Cancer Campus, Villejuif, France; [3]Pathology, French Association of Quality Assurance in Pathology (AFAQAP), Strasbourg, France; [4]Biomedical Quality Assurance Research Unit (BQA), UZ Leuven - University Hospitals Leuven - Campus Gasthuisberg, Leuven, Belgium

Background: The detection of oncogenic mutations in cell-free DNA (cfDNA) may identify therapeutic targets in many cancers, but it requires maximum sensitivity and specificity to avoid any loss of chance. Since 2017, the national Gen&Tiss external quality assessment (EQA) program has been assessing the performance of French laboratories for the detection of *EGFR* mutations in lung cancer patients by providing each year 5 reconstituted plasma samples of known composition. Since 2019, the EQA also provides an evaluation for the genes of interest in colorectal cancer and melanoma, with 5 additional samples for *KRAS* and *NRAS* mutations, and 5 others for *BRAF* mutations.

Methods: The performance of the methods used in France was assessed based on the results of Gen&tiss EQA campaigns conducted from 2017 to 2021.

Results: A total of 1303 EQA samples were analysed over 5 years, including 720, 142, 71 and 103 *EGFR*, *KRAS*, *NRAS* and *BRAF*-mutated samples respectively and 267 WT samples. An average of 39 laboratories were evaluated each year, with no significant change over the period. cfDNA extraction protocols varied widely between laboratories, with a trend towards a diversification of methods: 5 different protocols were used in 2017 compared to 11 in 2021. Analytical methods have also changed over the period: the use of quantitative PCR (qPCR), which predominated in 2017, has decreased over the period (from 43% to 29% of laboratories) to the benefit of NGS (from 39% to 59%). The use of digital PCR (dPCR) has remained stable (from 15% to 12%). The true positive (TP) rate averaged 84% over the period, with no significant change from one campaign to the next one (Wilcoxon signed ranks test: p = 0.776). The TP rate was significantly associated with the extraction kit (Fisher: p = 0.0002) and the analytical method (p = 0.0003) but was independent of the mutated gene (p = 0.075). qPCR was the most sensitive (TP rate = 92%), ahead of NGS (83%) and dPCR (77%). The true negative (TN) rate averaged 99% with no significant change over the period (p = 0.763). The TN rate was independent of extraction kit (p = 0.273), analytical method (p = 0.677) and mutated gene (p = 0.455).

Conclusions: Despite better analytical performance, the use of qPCR for cfDNA analysis is tending to decrease in France in favour of NGS, as the number of target mutations increases.

2345P The possibility of programmed death-ligand 1-related immune modulation in neoadjuvant thermoradiotherapy for rectal cancer

S. You

Radiation Oncology, Yonsei University Wonju College of Medicine, Wonju-si, Republic of Korea

Background: The expression of programmed death ligand 1 (PDL1) and CD8-positive T lymphocytes (CD8T) in tumor tissue is known to be influenced by radiotherapy (RT). This type of immune modulation is likely enhanced by hyperthermia (HT), which has been studied preclinically. We describe the immunogenic effects of additive HT in neoadjuvant treatment for rectal cancer.

Methods: Clinical data were reviewed for consecutive 32 patients who received neoadjuvant treatment and did not achieve total regression considering paired tumor tissue analysis from 2012 to 2017. On obtained pre- and post-treatment tumor tissue for each patient, further immunohistochemistry was done to examine the expression of PDL1 and CD8T. The majority of the patients were male (78.1%) and the median age was 57 years. Sixteen patients (50.0%) received HT twice weekly with 40 Gy RT (RHT group) and the others (50.0%) underwent standard 50.4 Gy RT (RT group). Age, initial clinical stage, and pathologic differentiation did not differ between the two groups. The median follow-up period was 68 months (range, 14−107 months).

Results: Both groups showed no significant difference in T- and N-downstaging ratio. Near total regression was experienced by 4 (25.0%) and 7 (43.8%) patients in the RHT and RT groups, respectively. The increase in PDL1 positivity was 0.95±2.17% (p=0.076) in the RHT group and 0.52±0.95% (p=0.257) in the RT group, while CD8T positivity increase was remarkable in both groups (RHT group: 27.97±18.26% (p<0.001); RT group: 22.50±13.14% (p<0.001)). The RHT group showed a relatively high propensity for both overall survival (median 72.0 versus 63.2 months, p=0.130) and local recurrence-free survival (median 69.1 versus 59.7 months, p=0.136). In multivariate analysis, higher level of post-treatment PDL1 positivity (>0.57%) and its increment (>0.35%) had a greater impact on disease-free survival (p=0.027 and p=0.008) and distant metastasis-free survival (p=0.063 and p=0.020).

Conclusions: Post-treatment PDL1 positivity status may have an effect on the prognosis. Even with relatively poor tumor regression, HT-combined low-dose RT did not impair survival, indicating that HT might be involved in the PDL1-related immune mechanism.

2346P Spatial and quantified molecular characterization of high endothelial venule predictive of immunotherapy response

K. Du, Y. Zhang, Z. Guo, X. Bai

Department of Radiotherapy, Southern Medical University Nanfang Hospital, Guangzhou, China

Background: High endothelial venules (HEVs) are important structures that mediate lymphocyte entry into tumors. However, it remains difficult to identify HEVs in tumor at the transcriptome level. Therefore, defining a molecular signature of HEVs is of great significance for characterizing HEVs in tumor, and identifying potential patients who could benefit from immunotherapy.

Methods: We collected scRNA-seq data of tumor tissues of 11 tumor types, and integrated 19923 endothelial cells. Genes that were specifically highly expressed in post-capillary venule subpopulation and most related to the function of HEVs were identified as the HEV signature. Bulk-seq data of tumor blood vessel and spatial transcriptome sequencing data of tumor tissue were used to verify the specificity of the signature to identify HEVs. Immunohistochemistry and multiplex immunofluorescence were used to characterize the tumor HEVs and immune microenvironment. Cohorts of tumor patients who received immunotherapy were used to explore the relationship between the HEV signature and patients' response to immunotherapy.

Results: Seven genes including *ACKR1*, *SELE*, *SELP*, *IL33*, *MEOX1*, *HAPLN3*, and *CPXM2* were screened out as the HEV signature. HEV and non-HEV endothelial cells can be well distinguished according to the expression level of HEV signature. Spatially, regions with higher expression of HEV signature were associated with the aggregates of lymphocytes. *MEOX1* was chosen as a representative of these genes. Using immunohistochemistry of MEOX1 and multiplex immunofluorescence of the tumor microenvironment, we confirmed its co-localization with MECA79 antigen and found that lymphocyte-rich niches formed around $MEOX^+$ blood vessels. In addition, higher expression of HEV signature was associated with better response to immunotherapy and longer survival in cohorts obtained from other studies as well as our in-house cohort from Nanfang Hospital.

Conclusions: A 7-gene HEV signature we identified, especially *MEOX1*, can be used as a new molecular marker to identify HEV in tumors, and its expression can be used to

locate and quantify HEV in tumors, and help identify potential patients who could benefit from immunotherapy.

2347P Correlation between second primary cancers and first primary cancers: A systematic review and meta-analysis of 9 million cancer patients

X. Wang, M. Zeng, A. Lin, C. Zhou, J. Zhang, P. Luo

Department of Oncology, Zhujiang Hospital of Southern Medical University, Guangzhou, China

Background: Many survivors of first primary cancers (FPCs) are at risk of developing a second primary cancer (SPC), the development of which usually leads to a worse prognosis. The development of SPCs may be closely related to the FPC. Different primary cancers have differentially high frequencies of specific SPC development. Our aim was to explore the possible correlation between the SPCs and FPCs.

Methods: We retrospectively searched and screened relevant literature on SPCs from four databases, namely, PubMed, EMBASE, Web of Science, and PMC. We also collected data on 28 different organ sites and the number of patients with SPC from The Surveillance, Epidemiology, and End Results (SEER) 8 Registry Database and NHANES database.

Results: A total of 9,617,643 patients with a FPC and 677,430 patients with a SPC were included in this meta-analysis. Patients with first primary gynaecological cancer and thyroid cancer developed second primary breast cancer and colorectal cancer more frequently. Patients with first primary head and neck cancer, anal cancer and esophageal cancer developed second primary lung cancer more frequently. Patients with first primary bladder cancer and penile cancer developed second primary lung cancer and prostate cancer more frequently. Patients with second primary bladder cancer accounted for 56% of first primary ureteral cancer patients with SPCs.

Conclusions: We recommend close clinical follow-up, monitoring and appropriate interventions in patients with relevant FPCs for better screening and early diagnosis of SPCs to prolong patient survival.

2348P High-throughput screening reveals GSK1838705A as a potent inhibitor of CAFs-promoted tumor progression in esophageal squamous cell carcinoma

H. Zhang[1], J. Yue[1], H. Jiang[2], L. Qiu[1], K. Zhang[3], R. Zhou[4], B. Xia[3], S. Ma[3]

[1]Hangzhou Cancer Institution, Hangzhou Cancer Hospital, Hangzhou, China; [2]Department of Cardiothoracic Surgery, Affiliated Hangzhou First People's Hospital, Zheijang University School of Medicine, Hangzhou, China; [3]Department of Radiation Oncology, Hangzhou Cancer Hospital, Hangzhou, China; [4]Department of Pathology, Hangzhou Cancer Hospital, Hangzhou, China

Background: Esophageal squamous cell carcinoma is a malignance with high invasiveness. Cancer-associated fibroblasts (CAFs) as one major component of tumor microenvironment (TME), promotes tumor initiation and progression. Our previous studies revealed that CAFs mediated ESCC cells significant resistance to a variety of chemotherapeutic drugs and ionizing irradiation. How to inhibit the tumor-promoting activity of CAFs is of critically important for the radical treatment of ESCC.

Methods: Using high-throughput screening, 157 inhibitors of cytokines/chemokines were tested for their effect on the cell viability of CAFs, matched normal fibroblasts (NFs), ESCC cells as well as normal esophageal epithelial cell Het-1A. We also investigated the effect of the inhibitors on cell cycle distribution, ROS accumulation and cell apoptosis of CAFs. The expressions of α-SMA, a marker of CAFs activation, was detected in CAFs treated with the inhibitors. By establishment of xenograft tumors in BALB/c mice, the effect of the inhibitors on CAFs-promoted ESCC growth was studied.

Results: By high-throughput screening, GSK1838705A, an inhibitor of IGF-1R kinase, was discovered as a potent inhibitor of CAFs activity in ESCC. Compared with NFs, ESCC cells as well as Het-1A, the viability of CAFs was significantly reduced when exposure to GSK1838705A. Furthermore, GSK1838705A arrested the cell cycle of CAFs in G2/M phase, promoted cell apoptosis and ROS accumulation. The expression of α-SMA was signifcantly reduced when CAFs were treated with GSK1838705A. In vivo studies demonstrated that GSK1838705A significantly repressed the tumor-promoting activity of CAFs. Immunohistochemical analysis showed that GSK1838705A significantly reduced the percentage of CAFs in xenograft tumor tissues.

Conclusions: GSK1838705A is a potent inhibitor of CAFs which promote ESCC progression. The combination of GSK1838705A and chemoradiotherapy may be a promising strategy against ESCC.

2349P Patterns and frequency of pathogenic germline variants (PGVs) among non-western young male patients with cancer: The Jordanian exploratory cancer genetics (Jo-ECAG) study

H. Bani Hani[1], H. Abu-Fares[1], S. Abdel-Razeq[1], B.S. Sharaf[1], H. Abu-Jaish[1], I. Hamad[1], Z. Zeidan[1], M. Horani[1], A. Abd Elqader[1], S. Mahafdah[1], S. Young[2], B. Heald[2], H. Abdel-Razeq[1]

[1]KHCC - King Hussein Cancer Center, Amman, Jordan; [2]Medical Affairs, Invitae Corporation, San Francisco, CA, USA

Background: Hereditary cancers have been less well-studied in men, particularly younger ones. The incidence of certain cancers associated with pathogenic germline variants (PGVs), such as breast and prostate, is low among men under the age of 50, while the incidence of other cancers, such as colorectal, is increasing. This study describes patterns and frequency of PGVs in a cohort of young men diagnosed with cancer.

Methods: Male patients aged 50 years or younger, with newly diagnosed solid tumors were included in this prospective study. Patients were classified as in-criteria (IC) or out-of-criteria (OOC) based on the National Comprehensive Cancer Network (NCCN) v.1.2020 guidelines. All patients underwent an 84-gene panel test at a reference lab. Patients with one PGV in a gene associated with autosomal recessive inheritance (carriers), were excluded from analysis.

Results: A total of 397 male patients, mean (range) age at diagnosis 41 (18-50) years, were tested; 48 (12.1%) were 30 years or younger. Family history of any cancer was reported by 315 (79.3%). The most common primary tumor diagnoses were colorectal (n=157, 39.5%), testicular (n=38, 9.6%), pancreatic (n=26, 6.5%), lung (n=26, 6.5%), and sarcoma (n=22, 5.5%). In total, 246 (62.0%) were IC while the other 151 (38.0%) were OOC. PGVs were identified in 48 (19.5%) and 18 (11.9%) patients in IC and OOC groups, respectively, $p<0.001$. PGV rates were highest among patients with colorectal (23.6%) and pancreatic cancers (15.4%). PGV rates were significantly higher among patients <30 years (22.9%) compared to patients aged 41-50 years (13.4%), p=0.048. The majority of PGVs were actionable (therapeutic targets, clinical trials, and/or clinical management guidelines), with the most frequently affected genes were *APC* (n=11), *MLH1* (n=11), *BRCA2* (n=6), *TP53* (n=5) and *MSH2* (n=4).

Conclusions: A significant number of males were diagnosed with cancer at young ages, especially colorectal or pancreatic cancer, with strikingly high PGV rates. Comprehensive genetic testing and counseling for this group of patients is critical to inform treatment options, risks of future cancers, and cascade testing.

2350P Single-cell RNA-seq dissecting the initiating liver metastasis cells in various cancers

S-Y. Zheng, X. Guan

Clinical Oncology Dept., HKU - The University of Hong Kong, Hong Kong, China

Background: Liver metastasis (LM) frequently occurs in patients with various cancers; yet our understanding of the underlying salient biology is preliminary. So far, no studies have found the initiating liver metastasis cells and specific liver metastatic microenvironment in various cancers. Here, we performed single-cell RNA-seq in eight patients with LM of various cancers to solve this scientific blind spot.

Methods: Single cell RNA sequencing was performed on tissues from LM of various cancers (gastric cancer(n=2); esophageal cancer(n=1); breast cancer(n=1); lung cancer(n=3); colorectal cancer(n=1)). Also, we downloaded the single-cell RNA-seq of hepatocellular carcinoma (HCC) and corresponding five types of cancer from GEO database. Seurat were applied to sort single-cell RNA-seq of LM in various cancers and corresponding five types of primary cancer into different clusters via feature dimension reduction. Furthermore, flow cytometry was used to sort those initiating liver metastasis cells, and then those cells was verified by cell metastasis function experiment and caudal vein injection of mice.

Results: The transcriptomes of 90035, 78933, 105340 single cells among LM in various cancers, HCC, and corresponding primary cancers were extracted respectively. There were 14 clusters divided into epithelial cells of liver metastasis single cells. Differential gene analyses and ratio analyses in LM and corresponding primary cancers groups showed that C10 and C12 might be the LM initiating cells clusters. And they were both enriched in the positive regulation of cell migration. $SOX6^+$ $CD52^+$ epithelial cells might be the LM initiating cells in various cancers, of which promoted cancer stem cells migration. Cohorts in TCGA database also showed a worse prognosis for patients with $SOX6^+$ $CD52^+$ markers. The sorting $SOX6^+$ $CD52^+$ epithelial cells will be further verified in metastasis function experiment and caudal vein injection of mice in vitro and in vivo.

Conclusions: The initiating liver metastasis cells in various cancers has been found and verified in this study, which provided a further understanding of the potential biological mechanisms of LM in various cancers and potential target for the novel drugs.

2351P Whole genome sequencing of AYA patients

P. Roepman, J. van Putten, I. Riethorst, M. Baksi, H. Nienhuis, J.J.M. van der Hoeven, E. Cuppen

Medical, Hartwig Medical Foundation, Amsterdam, Netherlands

Background: Cancer in adolescents and young adults (AYAs, aged 18-39 years at first cancer diagnosis) is nowadays considered as a separate entity with specific care needs. However, once the diagnosis has been established, AYA patients are mostly treated as having cancer at an older age. Breakthroughs in treatment options are scarce and AYA patients are underrepresented in clinical trials. To improve healthcare outcomes, there is a large unmet need for obtaining more knowledge and better (genomic) understanding of cancers at AYA age.

Methods: As an independent not-for-profit cancer diagnostics organization and data provider, Hartwig Medical Foundation performs clinical-grade whole genome sequencing (WGS) for cancer patients using a single small fresh-frozen biopsy and a matching blood sample. In addition to comprehensive diagnostic reporting of oncology-related genomics aberrations (including mutations, copy-number alterations, fusions and mutational signatures like MSI, TMB, HRD) all WGS data is (following patient consent) stored in the Hartwig Database. This data (>5500 patients) is available to the academic community to facilitate research and improve future cancer patient care.

Results: The Hartwig Database currently includes WGS and associated clinical data for 192 metastatic AYA cancer patients. Although a fair number in total, the numbers per tumor indication are quite small with n > 30 for only three indications (breast n=49, bone/soft tissue n=33 and GI-tract n=34). Also, the distribution does not follow the AYA cancer type prevalence as registered in the Dutch national cancer registry, with e.g. GI-tract (18% vs 9%) and bone/soft tissue (17% vs 2%) overrepresented and male/female reproductive organs underrepresented (8 vs 18%). Preliminary analysis of the frequency of driver alterations of some of the well-known oncogenes (e.g. PIK3CA, BRAF, KRAS, ERBB2) do not reveal differences between AYA and non-AYA cancers although the low number of AYA samples hamper conclusiveness.

Conclusions: To better facilitate research for AYA patients and to offer all possible treatment options (e.g. clinical trials), more patients will need to be analyzed by WGS. For this purpose, a dedicated project has been initiated that includes tumor-normal WGS of 1000 AYA patients in the next 3 years.

2352P Sex-based differences in genomic alterations and biomarkers in anal squamous cell carcinoma (ASCC)

S. Cereda[1], M. Ronzoni[1], B. Kaplan[2], J. Suh[2], S. Sivakumar[2], S. Foti[1], M. Mariani[1], N. Liscia[1], F. Vitiello[1], G. Basile[3], M. Bandini[3], E. Mazza[1], A. Necchi[1], S. Cascinu[1]

[1]Oncology Department, IRCCS Ospedale San Raffaele, Milan, Italy; [2]Biology, Foundation Medicine, Inc., Morrisville, NC, USA; [3]Urology, IRCCS Ospedale San Raffaele, Milan, Italy

Background: ASCC is a relatively rare malignancy. Several studies reported favourable prognosis in **F**emale to **M**ale patients (pts).Our work aims to identify and quantify sex-based differences in cancer-associated genomic alterations to better inform future precision medicine initiatives and provide insights on potential different survival based on sex.

Methods: A cohort of 1,380 ASCC pts (952 **F**,428 **M**) underwent genomic profiling on tissue biopsies using FoundationOne®/FoundationOne®CDx assays, to examine key differences in mutational patterns based on sex and HPV status.

Results: HPV-16 was prevalent in **F** while HPV-6 in **M**. PD-L1 expression: over 70% positive (1%), ∼20% high (50%) with similar rates in HPV+ vs HPV- (74.5% vs 63.9%; p=0.16) and sex (**F**:74% vs **M**:70.4%; p=0.80). TMB-High (10+mutations/Mb) was found in ∼18% without significant differences by sex (p=0.80); a slightly elevated rate was seen in HPV+ vs HPV- (18.4% vs 14.0%; p=0.16); 34% had PIK3CA alterations (37.1% in HPV+ vs.16.8% in HPV- ; p<.01 with similar rates by sex **F**:37.1% vs 20.8%; **M**:37.1% vs 13.3%); in contrast higher prevalence in HPV- vs HPV+ resulted to TP53 (44.9% vs 5.6% p<.01), TERT(31.3% vs 2.7% p<.01), CDNK2A (29% vs 2.9%p<.01), CDNK2B (11.7% vs 1.6% p<.01) and NOTCH1 (14.5% vs 5.1% p<.01); **F** had higher rates of alterations in PTEN (15.3% vs 8.4%p<.01) ,KMT2D (21% vs 13.1%, p<.01), CBFB (3.3% vs 0.2%; p<.01) and CREBBP (5.4 vs 2.6%; p=0.06),whereas **M** showed higher rates of alterations in TERT(15.2 vs 3.5% p<.01), TP53 (20.3% vs 7.8% p<.01),CDKN2A (14% vs 3.8%p<.01),CDKN2B (5.4% vs 2.2% p=.02), MYC (4.2% vs 1.6% p=.03) as well as amplifications on 11q13 such as CCND1(7%vs3.2%p=0.02), FGF19 (7%vs3.3%p=0.02), FGF3(7.2%vs3.6%,p=0.02), FGF4 (7% vs 3.5% p=0.02). BRCA1 and BRCA2 mutations were in 5% pts with mild **M** predominance (7% vs 4%) regardless HPV expression.

Conclusions: The higher incidence of HPV positivity in F compared to M remains the main hypothesis to justify the better prognosis of ASCC in women. A large proportion of PD-L1+ and TMB-High (∼70%), PIK3CA alterations (∼30%) and BRCA1/2 gene alteration (5%) may predict response to possible new therapeutic approaches for pts with ASCC like immunotherapy, targeted tyrosine kinase inhibitors, platinum chemotherapy and PARP inhibitors.

2353P Anti-cancer effects of HDAC8 specific inhibitors EC-352H and EC-374H in lymphoma

S.Y. Lee[1], M. Kwon[1], K.C. Park[2], B.G. Song[1], H.S. Jung[1], S.I. Hwang[1], R. Jeon[3], M.S. Lee[4], Y. Kim[1]

[1]New Drug R&D Center, EDGC - Eone Diagnomics Genome Center Co., Ltd., Incheon, Republic of Korea; [2]Department of Surgery, Severance Hospital - Yonsei University College of Medicine, Seoul, Republic of Korea; [3]College of Pharmacy, Sookmyung Women's University, Seoul, Republic of Korea; [4]R&D Center, EDGC - Eone Diagnomics Genome Center Co., Ltd., Incheon, Republic of Korea

Background: It was well known histone deacetylase (HDAC)s act as regulators of cancer progression in various cancer cells, but conventional pan-HDAC inhibitors used for clinical patients have shown the limitations such as low selectivity, high toxicity and low clinical anticancer efficacy. However, HDAC8 has recently been reported to emerge as a new target protein for cancer treatment among HDAC family class I. Against this background, studies have been conducted to discover new HDAC8 selective inhibitors as anti-cancer drug.

Methods: To appreciate the novel HDAC8 selective inhibitors (EC-352H and EC-374H) function as an anti-cancer agent in lymphoma, we investigated the viability of lymphoma cells and tumor growth of xenograft mouse model by EC-352H or EC-374H. The apoptotic mechanism of each drug was studies using immunoblotting assay. And the safety of EC-352H was evaluated through single-dose toxicity study in compliance with the Good Laboratory Practice (GLP) regulations.

Results: In the microarray analysis (GSE12453), HDAC8 was highly expressed in lymphomas compared with normal tissues. In cytotoxicity tests, the IC_{50} of EC-352H and EC-374H in p53 mutant lymphoma cell (Daudi) was lower than in p53 wild type (WT) lymphoma cells (OCI-Ly3). These results suggest that EC-352H and EC-374H may be more selective inhibitor in p53 mutant lymphoma than in p53 WT lymphoma. Both drugs downregulated the expression of p53 mutant protein through caspase 3-dependent apoptosis, whereas p53 WT protein was highly expressed by EC-352H or EC-374H. In the Daudi xenograft model, 50 mg/kg administration of each drug significantly inhibited tumor growth compared with vehicle-injected mice. Finally, *in vivo* toxicity study of EC-352H was performed through single-dose oral administration, and approximate lethal dose (ALD) was calculated 500-1000 mg/kg in ICR mice.

Conclusions: EC-352H and EC-374H, novel HDAC8 specific inhibitors, act as anticancer agents and inhibit lymphoma. These can be potential alternatives for overcoming disadvantages of conventional HDAC inhibitors by enhancing HDAC8 selectivity.

2354P Computational pathology-derived features capture varied epithelial-mesenchymal transition (EMT) states

H. Levine[1], C. Kirkup[2], S. Vilchez[3], S. Srinivasan[2], M. Lin[3], J. Abel[2], M. Drage[4], J. Conway[2], A. Khosla[2], A. Taylor-Weiner[2]

[1]Bioengineering, Northeastern University, Boston, MA, USA; [2]Machine Learning, PathAI, Inc., Boston, MA, USA; [3]Translational Research and Algorithm Products, PathAI, Inc., Boston, MA, USA; [4]Pathology, PathAI, Inc., Boston, MA, USA

Background: EMT is a process through which epithelial cells acquire mesenchymal-like traits, such as increased migratory capacity, which facilitate cancer cell metastasis. Here we propose an interpretable, scalable, machine learning (ML)-based method to assess EMT status directly from H&E-stained images. We extracted human interpretable features (HIFs) quantifying cancer cell nuclear morphology and the tumor microenvironment from breast cancer H&E images and confirmed concordance with a known ground-truth EMT expression signature.

Methods: Using a breast cancer-specific EMT signature gene set, we calculated quantile normalized EMT scores for each patient in TCGA-BRCA with RNA-seq data (n = 751). Convolutional neural network models trained using H&E-stained whole slide images were used to extract a set of HIFs across available slides (n = 775). An ordinary least squares regression was run for each HIF against EMT score with tumor purity as a covariate. FDR correction was applied to all p-values.

Results: Lower EMT scores were associated with epithelial attributes, such as high nuclei circularity, while high EMT scores were associated with mesenchymal attributes, such as high nuclei eccentricity and greater variation in nuclei perimeter. Epithelial-type tumors were associated with increased immature stromal content and cancer cell proportion. Mesenchymal-type tumors were associated with increased mature stromal content and stromal cell proportion.

Table: 2354P

HIF	Coefficient	Standard error	p-value	R^2	FDR corrected p-value
Mean cancer cell nuclei circularity	-0.047	0.0087	8.60 E-08	0.65	2.80E-07
Mean cancer cell nuclei eccentricity	0.042	0.0089	2.30 E-06	0.65	5.80E-06
Standard deviation of cancer cell nuclei perimeter	0.073	0.0089	1.20 E-15	0.67	8.30E-15
Area proportion immature stroma over all stroma	-0.035	0.0083	2.50 E-05	0.65	5.20E-05
Area proportion mature stroma over all stroma	0.033	0.0082	8.40 E-05	0.65	0.00016
Count proportion cancer cells over all cells	-0.12	0.0075	6.50 E-51	0.75	9.80E-49
Count proportion stromal cells over all cells	0.098	0.0078	1.20 E-32	0.71	3.60E-31

Conclusions: ML model-generated HIFs effectively capture cancer cell morphology reflective of EMT status, including nuclei eccentricity and circularity. The relationships observed in these results are concordant with previous studies showing increased EMT in tumors with greater extracellular matrix stiffness and large numbers of cancer associated fibroblasts. Overall these results reflect significant agreement between EMT scores and HIFs, indicating potential for quantification of EMT states directly from H&E images.

2355P Carcinoembryonic antigen (CEA) expression in human tumors: A tissue microarray study on 15,413 tumors

K. Jansen, L. Kornfeld, M. Lennartz, N.C. Blessin, S. Rico, S. Kind, V. Reiswich, A.M. Luebke, C. Hube-Magg, E. Bady, F. Büscheck, A. Menz, R. Uhlig, G. Sauter, R. Simon, C. Bernreuther

Institute of Pathology, University Medical Center Hamburg-Eppendorf, Hamburg, Germany

Background: Carcinoembryonic antigen (CEA; CEACAM5) is a cell surface glycoprotein which constitutes an attractive therapeutic target and serum CEA is used for cancer monitoring. CEA is overexpressed in various cancers, but the reported prevalence data vary considerably for many tumor types.

Methods: To comprehensively determine CEA expression in normal and neoplastic tissues, a tissue microarray containing 15,413 samples from 120 different tumor types and subtypes as well as 76 different normal tissue types were analyzed by immunohistochemistry.

Results: CEA positivity occurred in 65 of 120 tumor categories including 49 entities with at least one strongly positive case. CEA positivity was most common in colorectal carcinomas (98.7%), other gastrointestinal adenocarcinomas (61.1%-80.3%), medullary carcinomas of the thyroid (96.3%), pulmonary adenocarcinoma (73.7%), mucinous carcinomas of the ovary (79.8%) and the breast (43.2%), squamous cell carcinomas of various sites (30.2%-69.1%), and small cell carcinomas of the lung (64.3%), the urinary bladder (38.9%), and the prostate (50.0%). High CEA expression was linked to high grade ($p<0.0001$) and invasive growth ($p<0.0001$) in urothelial carcinoma. Reduced CEA expression was associated with mismatch repair deficiency ($p<0.0001$) but not with pT and pN stage in colorectal cancer.

Conclusions: In summary, CEA is abundantly expressed in a broad range of epithelial neoplasms. Our data thus identify various tumor entities where CEA positive cancers might best benefit from CEA serum monitoring and anti-CEA therapies.

Background: RET fusions are observed in 1-2% of patients (pts) with non-small cell lung cancer (NSCLC). Targeted therapies with RET inhibitors (RETi) have proven efficacy, improving survival, whereas data on immune checkpoint inhibitors (ICI) are controversial. Aim of the study was to evaluate if pathologic features could have a role as prognostic markers for RET+ NSCLC.

Methods: In this multicentric observational study of 5 European centers baseline tissue specimens were collected from pts with advanced RET+ NSCLC. Clinical data and treatment outcomes with RETi and ICI were collected. Overall survival (OS) in the overall population and progression-free survival (PFS) for RETi and ICI in pts treated with RETi and ICI were calculated. Tumor grade, histological subtype, presence of fibrosis, necrosis, tumor infiltrating lymphocytes (TILs), tertiary lymphoid structures (TLs), lymphangitis, calcifications, neutrophils were determined on haematoxylin/eosin (HE) coloured tissue slides for each patient. We investigated whether pathological features were correlated with PFS and OS.

Results: 38 pts with advanced NSCLC were included. Median age was 62 (IQR 58-72), 63% were female, median number of metastatic sites was 2 (IQR 1-3), PS ECOG was $\leq$1 in 92%1, 28 were treated with RETi, 18 received ICI. Median OS was 50.7 months (95%CI 28.4-NA). Necrosis was observed in 20% of pts and it was associated with shorter OS (7.67 vs 61.10 vs months, $p<0.001$), both in pts treated or untreated with RETi (7.97 vs 83.7 and 4.78 vs 13.93 months, $p<0.001$). Shorter PFS with RETi (5.23 vs 17.37 months, $p=0.004$) was also observed in presence of necrosis. Histological subtype (92% adenocarcinoma), tumor grade (50% G3), presence of fibrosis (84%), TILs (28%), TLs (10%), lymphangitis (62%), neutrophils (3%), calcifications (17%) did not seem to have a prognostic value.

Conclusions: The presence of necrosis in baseline histological samples from advanced RET+ NSCLC was associated with worse prognosis in pts treated or note with RETi. The role of pathological features as prognostic biomarkers deserves further investigation in this setting.

2357P TRX-221, a 4th generation, mutant-selective, and CNS-active EGFR inhibitor with robust antitumor activity in osimertinib-resistant tumor models harboring C797S mutation

S. Lim[1], S. Choi[2], J. Lee[2], S. Kim[2], E. Choi[2], S. Lee[3], K. Chun[4], K. Lee[5]

[1]R&D Planning, Therapex Co., Ltd., Seoul, Republic of Korea; [2]Translational Research, Therapex Co., Ltd., Seoul, Republic of Korea; [3]Laboratory Animal Research, Therapex Co., Ltd., Seoul, Republic of Korea; [4]Durg Discovery, Therapex Co., Ltd., Seoul, Republic of Korea; [5]Therapex Co., Ltd., Seoul, Republic of Korea

Background: Patients with EGFR-mutant non-small cell lung cancer (NSCLC) can derive significant clinical benefit from EGFR tyrosine kinase inhibitor (TKI) therapy, including 3rd generation EGFR TKIs such as osimertinib. However, most patients will experience disease progression with osimertinib, mainly due to acquired mechanisms of resistance. Mutations in the C797 residue in exon 20 are the most frequent EGFR-dependent mechanism of resistance to osimertinib treatment. TRX-221 is an investigational, broad-spectrum, CNS-active, mutant-selective 4th-generation EGFR-TKI (AACR 2023 #4006). Here we report further preclinical data supporting the clinical development of TRX-221 for patients with EGFR-mutant NSCLC.

Methods: Anti-proliferative activity and inhibitory potency of EGFR phosphorylation were determined in Ba/F3 cell lines using CellTiter-Glo® and EGFR AlphaLISA. In vivo antitumor efficacy of TRX-221 was evaluated in subcutaneous patient-derived cell line xenograft model and an intracranial tumor xenograft model.

Results: TRX-221 showed potent inhibitory activity of cell proliferation as well as EGFR phosphorylation in cellular assays driven by EGFR-mutants while sparing activity in EGFR wild-type. In osimertinib-resistant xenograft tumor models harboring EGFR C797S mutant cells, TRX-221 induced significant tumor regression without body weight loss. However, only moderate tumor growth inhibition was observed in an EGFR wild-type CDX model, demonstrating that in vivo efficacy was selective toward mutant EGFR. Furthermore, TRX-221 resulted in substantial intracranial antitumor activity with prolonged survival in an intracranial tumor model. Good correlation between plasma exposure levels and inhibitory effect on EGFR phosphorylation was observed with TRX-221 in a CDX tumor model PK/PD study.

Conclusions: TRX-221 is a potent, broad spectrum, and selective 4th generation EGFR-TKI. TRX-221 demonstrates strong antitumor efficacy in osimertinib-resistant tumor models, and thus has potential to treat patients who have developed resistance to 3rd generation EGFR TKI treatment. Initiation of first-in human clinical trial is expected in Q4 2023.

2358P Assessing the efficacy of robot-assisted total gastrectomy for advanced proximal gastric cancer: Results from a three-year clinical trial

Z-Y. Liu[1], Q. Zhong[2], Q-Y. Chen[1], C-H. Zheng[2], C. Huang[2]

[1]Gastric Surgery Dept., Fujian Medical University Union Hospital, Fuzhou, China; [2]Department of Gastric Surgery, Fujian Medical University Union Hospital, Fuzhou, China

Background: Robotic total gastrectomy (RTG) is accepted as a safety approach to conventional laparoscopy total gastrectomy (LTG) for locally advanced gastric cancer. However, the long-term oncological efficacy of RTG remains unclear.

Methods: This prospective study included 48 patients with advanced proximal GC underwent RTG combined with spleen-preserving splenic hilar lymphadenectomy between March 2018 and February 2020. Patients who underwent LTG in the FUGES-002 study were enrolled in a 1:2 ratio to compare the outcomes between RTG and LTG. The primary outcome was overall postoperative morbidity rate. The secondary outcomes were three-year overall survival (OS), three-year disease-free survival (DFS), and recurrence patterns.

Results: After 1:2 propensity score matching, a total of 48 RTG and 96 LTG patients were included, with similar clinical and pathological data in both groups. In terms of surgical outcomes, the RTG group had significantly less intraoperative bleeding than the LTG group (66.4 vs. 38.7 ml, $P = 0.042$). With regard to lymph node dissection, the RTG group had a significantly higher number of non-gastric lymph node dissections than the LTG group (20.2 vs. 17.5, $P = 0.039$), and its lymph node metastasis rate was significantly lower than that of the LTG group (27.1% vs. 45.8%, $P = 0.030$); in terms of postoperative outcomes, the RTG group had significantly shorter times for first gas discharge, first out of bed, first liquid diet, first semi-liquid diet, and length of stay than the LTG group ($P < 0.05$). Regarding long-term prognosis, the 3-year DFS of the RTG and LTG groups were 77.1% and 68.8%, respectively, and the 3-year OS were 85.4% and 74.0% ($P > 0.05$ for both). Within 3 years after surgery, 9 (18.8%) and 27 (28.1%) patients in the RTG and LTG groups experienced recurrence, respectively, with similar recurrence patterns in both groups ($P > 0.05$). There was no independent correlation between RTG and recurrence or gastric cancer-specific death ($P > 0.05$ for both).

Conclusions: Among patients with a preoperative clinical stage indicating locally advanced gastric cancer, RTG, compared with LTG, did not result in inferior disease-free survival and overall survival at 3 years.

Clinical trial identification: The FUGES-014 was a prospective, single-arm, open-label study (NCT03524287) that was conducted at Fujian Medical University Union Hospital (FMUUH).

Background: Erda is an oral pan-FGFR tyrosine kinase inhibitor approved to treat locally advanced or mUC in pts with susceptible *FGFR3/2alt* who have progressed after platinum-containing chemotherapy. *FGFRalt* tumors are enriched in luminal 1 subtype and may have limited clinical benefit from anti—PD-(L)1 treatment (tx). This cohort in the randomized, open-label phase 3 THOR study (NCT03390504) assessed erda vs pembro in pts with mUC naive to anti—PD-(L)1.

Methods: Pts ≥18 y with unresectable advanced/mUC with select *FGFR3/2alt*, ECOG PS 0-2, disease progression on 1 prior tx, and naive to anti—PD-(L)1 were randomized 1:1 to receive erda 8 mg QD with pharmacodynamically guided uptitration to 9 mg or pembro 200 mg Q3W. Primary end point: overall survival (OS). Secondary end points: progression-free survival (PFS), objective response rate (ORR), safety.

Results: At 15 Jan 2023 data cutoff, intent-to-treat set (median follow-up 33.2 mo) comprised 175 pts in erda and 176 in pembro arm. The primary end point was not met, with no statistically significant difference in OS between tx arms (Table). Erda had numerically longer PFS and numerically higher ORR but shorter duration of response. Most common tx-related adverse events (TRAEs) of any grade: hyperphosphatemia (73%), stomatitis (45%), diarrhea (45%), and dry mouth (35%) with erda; pruritus (12%), asthenia (10%), hypothyroidism (10%), and fatigue (10%) with pembro. Gr 3-4 TRAEs and serious TRAEs occurred in 43% and 13% in erda and 12% and 10% in pembro arm, respectively. TRAEs leading to death occurred in 0 pts in erda and 3 (2%) in pembro arm. 15% of pts discontinued erda and 5% discontinued pembro due to TRAEs.

Table: 2359O

	Erda (n=175)	Pembro (n=176)
OS, median, mo	10.9 (9.2-12.6)	11.1 (9.7-13.6)
Hazard ratio	1.18 (0.92-1.51) p=0.18	
PFS, median, mo	4.4 (4.1-5.5)	2.7 (1.6-3.0)
Hazard ratio	0.88 (0.70-1.10) p=0.26[a]	
ORR, %	40.0 (32.7-47.7)	21.6 (15.8-28.4)
Relative risk	1.85 (1.32-2.59) p<0.001[a]	
DOR, median, mo	4.3 (3.7-6.9)	14.4 (7.4-27.8)

All data are value (95% CI). [a]Nominal p estimate, due to primary end point not being met.

Conclusions: Erda and pembro had similar OS in this anti—PD-(L)1 naive, *FGFRalt* mUC population, with erda showing a numerically longer PFS and numerically higher ORR rate. Toxicities were manageable with dose modifications.

Clinical trial identification: NCT03390504.

2360O The double antibody drug conjugate (DAD) phase I trial: Sacituzumab govitecan (SG) plus enfortumab vedotin (EV) as ≥ second-line therapy for metastatic urothelial carcinoma (mUC)

B.A. McGregor[1], G.P. Sonpavde[2], L. Kwak[3], X. Gao[4], C. Mantia[5], X.X. Wei[1], J.E. Berchuck[1], P. Ravi[5], M.D. Michaelson[6], T.K. Choueiri[1], J. Bellmunt[1]

[1]Medical Oncology Department, Dana Farber Cancer Institute, Boston, MA, USA; [2]Medical Oncology, Genitourinary Section, AdventHealth Medical Group - Internal Medicine at Orlando, Orlando, FL, USA; [3]Biostatistics, Dana Farber Cancer Institute, Boston, MA, USA; [4]Medical Oncology, Massachusetts General Hospital Cancer Center, Harvard Medical School, Boston, MA, USA; [5]Genitourinary Oncology Department, Dana Farber Cancer Institute, Boston, MA, USA; [6]Medical Oncology, MGH - Massachusetts General Hospital, Boston, MA, USA

Background: Antibody-drug conjugates are a mainstay in treatment of mUC. Given different targets, payloads with non-overlapping toxicities and preclinical synergy of SG with anti-microtubule agents, we evaluated the safety and efficacy of SG+EV in a phase I trial (NCT04724018).

Methods: Patients (pts) with mUC and ECOG ≤1 who progressed on platinum and immunotherapy or were cisplatin ineligible and received one line of therapy were enrolled. SG+EV were dosed D1,8 of a 21-day cycle until progression of unacceptable toxicity. To assess the feasibility and safety of combining SG+EV, doses were adjusted based on the incidence of dose-limiting toxicities (DLTs) during cycle(C) 1 and the total number of pts treated at four pre-specified dose levels (DL) using a Bayesian Optimal Interval design (Table). Adverse events (AE) were assessed using CTCAE 5.0.

Results: 24 pts were enrolled (9 DL1, 9 DL2, 6 DL3) from 5/2021 to 4/2023. At data cutoff on May 1, 2023, 23 pts were evaluable for DLT assessment; one pt in DL3 never started therapy. Median age was 69 years (range 41-88); 22 received ≥ 2 lines of therapy. After 2 pts in DL1 experienced febrile neutropenia (FN) prophylactic granulocyte stimulating factor (GCSF) was permitted; 18 pts received GCSF. 70% pts experienced ≥ grade 3 AE at any DLs with one grade 5 AE (pneumonitis possibly related to EV) during C2 (pt in DL3.) The table summarizes DLTs at corresponding DLs; DL2 has been selected for future studies. Among 21 pts evaluble for response, objective response rate was 71% (15/21, 90% Confidence interval: 51-87) with 2 complete and 13 partial responses; 2 pts had progressive disease. With median follow-up 11.9 months, 11/15 responses are ongoing from 1.1+ to 21.6+ months.

Table: 2360O

DL	SG dose (mg/kg)	EV dose (mg/kg)	N enrolled	DLT
-1	6	1	0	NA
1	8	1	9	2 (FN)
2	8	1.25	9	1 (delay C2D1 > 3 wks)
3	10	1.25	6 (1 not evaluable)	3 (grade 3 mucositis, delay C2D1 > 3 wks, FN)

Conclusions: SG+EV was safe with an ORR of 71% in pts with treatment refractory UC. Further DAD expansion cohorts in treatment refractory and naïve setting are in development; triplet therapy with immunotherapy is being explored.

2361MO Impact of positron emission tomography (PET) imaging on staging of muscle-invasive bladder cancer (MIBC) [PET-MUSE]

S. Sridhar[1], S.D. Mukherjee[2], N. Power[3], R. Breau[4], S. Cheng[5], P. Chung[6], G. Pond[7], U. Metser[8], M. Levine[9]

[1]Department of Medical Oncology, Princess Margaret Cancer Center, Toronto, ON, Canada; [2]Medical Oncology, JCC - Juravinski Cancer Centre - Hamilton Health Sciences, Hamilton, ON, Canada; [3]Urology, London Health Sciences Centre (LHSC) - London Regional Cancer Program (LRCP), London, ON, Canada; [4]University of Ottawa Faculty of Medicine, Ottawa, ON, Canada; [5]Medical Oncology, Sunnybrook Health Sciences Centre - Odette Cancer Centre, Toronto, ON, Canada; [6]Radiation Medicine Program, Princess Margaret Cancer Centre, Toronto, ON, Canada; [7]Oncology, McMaster University Medical Centre - Hamilton Health Sciences, Hamilton, ON, Canada; [8]Medical Imaging, Princess Margaret Cancer Centre, Toronto, ON, Canada; [9]Medical Oncology, McMaster University, Hamilton, ON, Canada

Background: In MIBC standard staging with CT imaging is critical for making treatment decisions about neoadjuvant chemotherapy (NAC), and local treatment with either radical cystectomy (RC) or chemoradiation. However, CT imaging can often underestimate disease extent. The aim of this randomized study was to determine if adding 18F-FDG PET/CT (PET) to baseline CT, changes treatment received.

Methods: Newly diagnosed MIBC pts (T2a-T4, N0-3, M0) without metastases on baseline CT, and predominant urothelial histology, were allocated 2:1 to PET or no further imaging. Enrollment occurred 05/16-11/21 at 6 Ontario centers. At the time of analysis, median duration of follow-up was 2 years. Primary outcome was proportion of pts not receiving expected treatment and secondary outcomes were disease-free survival (DFS) and overall survival (OS).

Results: Of 292 pts, 194 were randomized to PET and 98 to no PET. In the PET and no PET arms respectively: median age was 70 (43-93) and 68 (42-89); T2: 77% and 77%; node negative 88% and 87%; planned RC 66% and 69%; and planned NAC 70% and 64%. On PET, primary bladder tumor was seen in 86 (47%) pts, positive pelvic lymph nodes in 37 (20%), distant nodes in 32 (18%) and distant metastases in 13 (7%). By ITT analysis, 166 (86%) PET pts received expected treatment, 21 (11%) did not and 7 (4%) withdrew/died prior to treatment. In the no PET arm, 90 (92%) received expected treatment, 4 (4%) did not, and 4 (4%) withdrew/died prior to treatment. More PET pts were deemed palliative 18 (9.3%) vs 3 (3.1%). Notably >60% in both arms received NAC. PET pts were more likely to have a change in treatment, odds ratio 2.89 (95% CI 0.96-8.74, p=0.06) compared to CT alone. No statistically significant difference was observed between arms for DFS (HR=0.78, 95% CI 0.55-1.12) or OS (HR=1.02, 95% CI 0.66-1.56).

Conclusions: In this large randomized study, there was a trend towards a change in management in pts having a PET, but this did not reach statistical significance. This trial provides new insights into the clinical utility of PET-CT in MIBC.

Clinical trial identification: NCT02462239.

Background: *FGFRalt* are seen in ∼20% of pts with mUC. Erda is an oral pan-FGFR tyrosine kinase inhibitor for pts with locally advanced or mUC with susceptible *FGFR3/2alt* who have progressed after platinum-containing chemo. THOR (NCT03390504), a randomized phase 3 study, assessed whether erda provided an overall survival (OS) advantage vs chemo in pts with mUC who progressed after 1-2 prior therapies (tx), including anti-PD-(L)1.

Methods: Pts (≥18 y) with unresectable advanced/mUC and select *FGFR3/2alt* (mutations/fusions), ECOG PS 0-2, adequate organ function, progression on/after 1-2 prior lines of systemic tx that included anti-PD-(L)1 were randomized 1:1 to erda (8 mg with pharmacodynamically guided uptitration to 9 mg) QD or investigator's choice of chemo (docetaxel or vinflunine) Q3W until disease progression or intolerable toxicity. Primary end point was OS. Secondary end points included progression-free survival (PFS), objective response rate (ORR), and safety.

Results: 266 pts were randomized (median [m] age 67 y, follow-up 16 mo) to erda (N=136) or chemo (N=130). Primary end point was met: mOS 12.1 vs 7.8 mo in erda vs chemo (HR=0.64; 95% CI, 0.47-0.88). OS benefit was seen across subgroups (Table). Erda improved mPFS (6 vs 3 mo) and ORR (46% vs 12%) vs chemo. Most frequent tx-related adverse events (TRAEs): hyperphosphatemia (79%), diarrhea (55%), and stomatitis (46%) with erda; anemia (28%), alopecia (21%), and nausea (20%) with chemo. 46% in each arm had Gr 3/4 TRAEs. 1 and 6 pts had TRAEs leading to death with erda and chemo, respectively.

Table: 2362MO

Subgroup		Erda (n=136)		Chemo (n=130)		HR (95% CI)
		n	mOS, mo	n	mOS, mo	
Age	<65 y	59	14	45	9	0.46 (0.27-0.79)
	≥65 y	77	11	85	8	0.71 (0.47-1.07)
Baseline ECOG PS	0-1	125	12	119	9	0.65 (0.46-0.90)
	2	11	6	11	3	0.47 (0.16-1.35)
FGFRalt	Fusion	25	16	19	8	0.49 (0.23-1.03)
	Mutation	108	11	107	8	0.67 (0.47-0.95)
Prior lines of tx	1	45	14	33	8	0.61 (0.35-1.09)
	2	90	12	97	8	0.67 (0.45-0.98)
Visceral metastasis	Y	103	12	101	8	0.65 (0.45-0.93)
	N	33	11	29	9	0.61 (0.32-1.14)

	Lower tract	95	11	82	10	0.82 (0.56-1.18)
Chemo	Docetaxel[a]	136	12	69	11	0.76 (0.52-1.11)
	Vinflunine[a]	136	12	43	8	0.60 (0.39-0.92)
PD-L1 status	CPS ≥10	7	10	11	20	1.98 (0.57-6.91)
	CPS <10	89	12	68	9	0.58 (0.38-0.89)

[a]Chemo group tx.

Conclusions: In pts with *FGFRalt* advanced/mUC after prior anti-PD-(L)1 tx, erda significantly improved OS vs chemo. Clinically relevant subgroups showed a consistent OS benefit for erda. No new safety signals were observed. These results support the role of erda to treat pts with *FGFRalt* mUC after anti-PD-(L)1 tx.

Background: Neoadjuvant atezolizumab in muscle invasive urothelial bladder cancer is associated with meaningful pathological complete response (pCR) rates. Serial circulating tumor DNA levels correlate with response and disease-free survival. ABACUS-2 investigates the efficacy and safety of neoadjuvant atezolizumab prior to cystectomy in patients with non-urothelial, bladder cancer.

Methods: This single arm phase 2 study investigated 2 cycles of atezolizumab (1200mg Q3W) prior to cystectomy in non-urothelial muscle invasive bladder cancer (T1-4aN0-1M0). pCR was the primary endpoint. Biomarker analysis on sequential tissue and ctDNA were co-primary endpoints. Cross sectional imaging was performed at baseline and prior to cystectomy which occurred 4-8 weeks after starting atezolizumab. Adverse events and surgical complications were assessed using CTCAE v5 and the Clavien-Dindo classification. The IDMC reviewed the first 23 patients (of 29 enrolled) and supported this interim presentation. The full data on 29 pts will be available at the meeting.

Results: The median age of the 23 pts was 70y (range 42-82). At baseline pT1, pT2, pT3 disease occurred in 2/23 (9%), 17/23 (74%), 4/23 (17%) pts respectively. 22 pts (96%) received the full 2 cycles of treatment (1 due to non-compliance). All patients underwent cystectomy. The pCR rate in pT2 or above pts was 38% (8/21), and 35% (8/23) including pT1 pts. The most common histological subtypes were squamous (35%), sarcomatoid (35%) and adenocarcinoma (13%). pCR is pts with sarcomatoid variant was 75% (6/8) and 33% (1/3) in those with adenocarcinoma. Treatment related grade 3/4 toxicity occurred in 17% (4/23) of patients. No treatment related death occurred.

After a median follow up of 6.6 months (95%CI: 5.9 – 7.4), 2 patients died, one due to subsequent disease progression and one COVID related. Grade 3/4 surgical complications occurred in 2/23 (9%) pts. Sequential biomarker analysis including immunohistochemistry, circulating and urinary tumor DNA will be available.

Conclusions: Neoadjuvant atezolizumab is associated with meaningful pCR rates in patients with non-urothelial, bladder cancer awaiting cystectomy at this interim stage.

Clinical trial identification: NCT04624399.

Background: Neoadjuvant cisplatin-based chemotherapy (NAC) regimen followed by local therapy is the standard of care for MIBC. However, 60-75% of these patients (pts) have residual disease after NAC. Preclinical data suggest that the use of ddMVAC regimen may induce higher immunogenic death and pathological complete response (pCR) in the NAC setting as compared to gemcitabine cisplatin regimen (GC). Thus, we aimed to evaluate the efficacy and safety of ddMVAC + D +/- T combination in a phase I/II trial.

Methods: NEMIO (NCT03549715) is a multicenter open-label randomized non-comparative phase 1/2 trial evaluating neoadjuvant ddMVAC + D +/- T in pts with cT2-4N0-1 eligible for radical cystectomy (RC). The pts received 4 cycles of ddMVAC every 2 weeks with D (1500 mg) +/- T (75 mg) every 4 weeks. The co-primary endpoints were locally assessed pCR rate (ypT0N0) and grade $\geq$ 3 treatment related adverse events (TRAE). We assumed a pCR rate $\geq$ 45% to consider trial as positive.

Results: Between November 2018 and April 2022, 121 pts were enrolled in 16 centers and 119 received at least one dose of ddMVAC + D +/- T. The median age was 64 years (IQR: 58-70) with predominant ECOG PS 0 (74%). Clinical tumor stage at diagnosis was cT2, cT3 and cT4 in 86 (89%), 9 (9%) and 1 (1%), respectively, while 5 (5%) pts were cN1. Only 6 pts (6%) did not undergo RC (4 refusal and 2 progressive disease). Among the 113 pts with RC, the pCR was 47.8% (Table). All pts had at least one TRAE and 41% a G$\geq$3 TRAE including neutropenia (12.6%) anemia (9.2%), and acute kidney injury (6.7%). ddMVAC or D +/- T were discontinued in 21 pts (17.6%), mostly due to TRAE (90.5%).

Table: 2364MO

	ddMVAC + D (N = 55)	ddMVAC + D + T (N = 58)	Pts achieved cystectomy (N = 113)
ypT0N0	27 (49.1%)	27 (46.6%)	54 (47.8%)
ypT1, Ta, TisN0	12 (21.8%)	8 (15.5%)	21 (18.6%)
ypT2-4N0	10 (18.2%)	16 (27.6%)	26 (23.0%)
ypN+	6 (10.9%)	6 (10.3%)	12 (10.6%)

Conclusions: NEMIO is a positive trial showing one of the highest pCR achieved in the neoadjuvant setting with the use of ddMVAC + D. Nonetheless, the benefit of adding T on pathological response appears limited, pending survival outcomes.

Clinical trial identification: NCT03549715.

Background: Current SOC for pts w/ MIBC is neoadjuvant cis-based chemotherapy followed by radical cystectomy and pelvic lymph node dissection (RC+PLND). For pts who are cis-ineligible, SOC is RC+PLND alone but adjuvant therapy may be recommended. Due to high rates of recurrence in cis-ineligible pts, an urgent unmet need remains. Neoadjuvant EV showed promising antitumor activity in MIBC (pathological CR [pCR] of 36%, pathological downstaging [pDS] of 50%) in EV-103 Cohort H (Petrylak 2022). Cohort L examines a perioperative approach.

Methods: Cohort L enrolled pts who are cis-ineligible w/ previously untreated MIBC (cT2-T4aN0M0 or cT1-T4aN1M0) who are medically fit for and agree to undergo curative intent RC+PLND within 12 wks. Pts received 3 cycles of neoadjuvant EV (1.25mg/kg) on Days 1 and 8 of each 3-week cycle followed by RC+PLND and then 6 cycles of adjuvant EV (1.25 mg/kg) on Days 1 and 8 of every 3 week cycle starting 8 weeks post-RC. Primary endpoint is pathological CR (pCR) per central pathology review; secondary endpoints include pathological downstaging (pDS) rate per central pathology review, safety and tolerability. Here we present initial results from the neoadjuvant/RC+PLND phase + 30 days post surgery.

Results: 52 pts were enrolled. 51 pts were treated w/ EV in the neoadjuvant phase w/ a median of 3 cycles; 42 pts (82.4%) completed RC+PLND. One pt achieved clinical CR and elected not to undergo RC+PLND and was excluded from pCR and pDS analyses; 17/50 (34.0%) pts had a pCR. pDS was seen in 21/50 (42.0%) pts. In the neoadjuvant/RC+PLND phase, of 51 treated pts most common EV-related TEAEs were fatigue (52.9%), rash maculo-papular (31.4%), and nausea (29.4%). 39.2% of pts had an EV-related TEAE $\geq$ grade 3; 31.4% pf pts had a RC-related TEAE $\geq$ grade 3. No surgeries were delayed due to EV-related TEAEs. One pt (2.0%) experienced an EV-related death (Stevens-Johnson syndrome) before surgery.

Conclusions: EV continues to show promising activity and was tolerable in cis-ineligible pts w/ MIBC in this ongoing trial. Both the efficacy and safety profiles were consistent with previously reported data from Cohort H. These data support the ongoing phase 3 trials evaluating EV + pembrolizumab in MIBC.

Clinical trial identification: EudraCT 2018-001527-39; Release Date: Amendment 11, 15-Feb-2023.

Background: Niraparib (N) is a (PARP)-1/-2 inhibitor (inh) and Cabozantinib (C) is a receptor tyrosine kinase (RTK) inhibitor that targets multiple RTKs (c-MET, TYRO3, AXL, MER). It has been proposed that aberrant c-MET activation could decrease response to PARP inhibitors (PARPi). Preclinical data show that c-Met inhibition renders cells more sensitive to PARPi. Safety of N + C was explored in advanced clear cell renal cell carcinoma or metastatic urothelial carcinoma (mUC) (Ph I. #GU-ASCO-22). We now report safety and efficacy in an expansion cohort of mUC (Ph II).

Methods: Multicenter, open-label Ph I-II study (NCT03425201). Patients (pts) received N/C 100/40 mg p.o. once daily in 28-day cycles. Pts with confirmed histopathological diagnosis of mUC (Ph II) previously treated with at least 2 previous regimens, one platinum-based, and ECOG PS 0-2, were included. Adequate bone marrow, liver and renal functions were required. No pre-molecular selection was assessed (DDR-gene mut or c-MET mut).

Results: The first interim analysis of 44 mUC pts is presented. Median age was 67 years and 98% of pts were male. All pts had received platinum-based treatment and 80% had received immunotherapy. Median number of administered cycles is 3 (range 1-18) and 13 pts are still on treatment at the time of this analysis. Disease control rate was 47.7% and ORR was 15.9%. With a median follow-up time of 5.9 months (range 1.8-19.5), median progression free survival (PFS) and overall survival were 3.8 and 8.7 months, respectively; 6 months PFS was 31%. Most frequent all grade adverse events (AEs), included: asthenia (71%), hypertension (43%), diarrhea (27%), constipation (27%), anemia (25%) and palmar-plantar erythrodysesthesia (23%). Most frequent grade 3 AEs were: asthenia (11%), hypertension (9%) and decreased appetite (9%).

Conclusions: N 100 mg/d + C 40 mg/d combination can be safely administered and has clinical efficacy (30% of pts are still on treatment) in a biomarker unselected heavily pretreated population.

Clinical trial identification: EudraCT 2017-004367-12, NCT03425201.

Scott Cancer Center, New Orleans, LA, USA; [7]PBS, Cytel Inc., Cambridge, MA, USA; [8]Vaccine and Infectious Disease Division, Fred Hutchinson Cancer Research Center, Seattle, WA, USA; [9]VIDD, Fred Hutchinson Cancer Research Center, Seattle, WA, USA; [10]Division of Cancer Treatment & Diagnosis, National Cancer Institute, Bethesda, MD, USA; [11]Medicine/Oncology Department, Fred Hutchinson Cancer Center and University of Washington, Seattle, WA, USA

Background: Atezolizumab is an anti-PD-L1 antibody that was approved for patients with mUC following platinum-containing regimens. IL-7 (CYT107) is a homeostatic cytokine that supports the proliferation and persistence of T cells. We hypothesized that addition of CYT107 would improve responses to PD-L1 inhibition by atezo. We performed a randomized trial (NCT03513952) in mUC comparing the combination of CYT107 and atezo to atezo alone.

Methods: Patients with mUC who had progressive disease after platinum-containing chemotherapy were screened. Key eligibility criteria included ECOG PS 0-2, measurable disease (by RECIST 1.1), and no prior checkpoint inhibitor or cytokine immunotherapy. A safety run-in using the combination of CYT107 and atezo was performed, followed by randomization 1:1 to atezo 1200 mg IV q3wks +/- CYT107 10 ug/kg IM qwk X 4. The primary endpoint was objective response rate (ORR), with secondary endpoints including clinical benefit rate, PFS, DOR, OS, and safety. Detailed immune response analysis and exploratory correlative analyses are in progress.

Results: A total of 47 patients were enrolled. Patient demographics between arms were well-balanced. ORR was 26.3% for the combination vs 23.8% for atezo alone ($p=0.43$). There were no significant differences in clinical benefit rate, PFS, DOR, or OS. No dose limiting toxicities were seen in the safety run-in cohort ($n=7$). 76.9% (20/26) of patients on the CYT107 arm received all four doses. The combination of CYT107 and atezo was well tolerated compared to the atezo arm, with overall grade 3-4 adverse events (AEs) occurring in 46.2% (12/26) and 63.2% (12/19), respectively. Immune-mediated AEs of any grade occurred in 50% (13/26) vs 68.4% (13/19), respectively. 6.3% vs 17.6% of patients on the combination vs monotherapy arm discontinued therapy due to toxicity.

Conclusions: This is the first randomized trial of atezolizumab +/- IL-7 (CYT107) in mUC. During the trial, the FDA approval for atezo in mUC was withdrawn, which limited enrollment. However, our results show that the addition of CYT107 to atezo is safe/tolerable, although there was no improvement in clinical outcomes compared to atezo monotherapy.

Clinical trial identification: NCT03513952.

Background: Combining multitargeted receptor tyrosine kinase inhibitor (TKI) with checkpoint inhibitors has shown synergistic effect in pts with UC due to the immunomodulatory propriety of VEGFR inhibitors. We investigated if the combination of CABO and DURVA in pts with advanced UC and non-UC histology (VHs) in a phase II study (NCT03824691). Herein the preliminary results of the interim analysis.

Methods: In ARCADIA study, pts with UC or VHs recurred/progressed after failure of platinum-based CT were enrolled. Pts received CABO 40 mg daily orally and DURVA 1500 mg IV q28 days, until disease progression (PD, by RECIST 1.1) or unacceptable toxicity. The primary endpoint of the study was OS. Secondary endpoints: safety, objective response-rate (ORR), progression-free survival (PFS).

Results: Seventy-one pts were enrolled from 11/2019 to 04/2023: this interim analysis was performed after obtaining at least one post-baseline tumor assessment data from 62 pts. The median follow-up was 21.9 mos (interquartile [IQ] range: 15.6 — 27.3 mos): 27.4% female, median age 64 yrs (IQ range: 55— 70 yrs), 21 pts (34%) had a pure/predominant non-UC VH: 10 (48%) squamous differentiation/sarcomatoid, 5 (24%) adenocarcinoma, 4 (19%) small-cell neuroendocrine, 1 (5%) clear-cell, and 1 nested VH (5%). In 62 pts, 12 (19%) CR and 10 (16%) PR were obtained, the ORR being 35.5% (95% CI, 23.7 — 48.7) and disease control rate was 71.0% (95% CI, 58.1 — 81.8). In VHs cohort, the ORR was 42.9% (95% CI, 21.8 — 66.0). Median PFS was 7.4 mos (95% CI, 4.9 — 26.3 mos) and median OS was 13.1 mos (95% CI, 7.23 — NA). The duration of response (DOR) was 8.18 mos (95% CI, 4.0 — 21.2); 42 pts (67.7%) of 62 pts had all-grade treatment-related adverse events (trAE): among them, 7 pts (16.7%) reported grade $\geq$ 3 trAE. Dose-reductions of CABO were needed in 26 pts (41.9%). No treatment-related deaths were reported.

Conclusions: CABO in combination with DURVA showed promising preliminary activity with a manageable safety profile in pts with advanced in VHs and UC after previous chemotherapy exposure. More mature results with longer follow-up will be presented.

Clinical trial identification: NCT03824691.

Background: Patients (pts) with BCVH have poor outcomes. We previously reported an ORR of 37% in 19 patients with BCVH for the combination of nivo+ipi. Herein, we report the analysis of the fully accrued BCVH cohorts. (NCT 03333616).

Methods: Eligible pts had locally advanced unresectable or metastatic BCVH (>90% [JB1] variant histology) and ECOG performance status $\leq$2. Prior immunotherapy was prohibited; no limit on prior chemotherapy. Pts received nivo 3 mg/kg + ipi 1 mg/kg IV q3 weeks for 4 cycles followed by nivo 480 mg IV q4 weeks until unacceptable toxicity or progression. Primary endpoint was objective response rate (ORR) by RECIST 1.1.

Results: 49 patients were enrolled from 4/2018 to 12/2022; including 19 pts previously reported; 30 pts were newly enrolled (including 7 from neuroendocrine cohort). 35 (71%) pts were treatment experienced. 28 (57%) pts received 4 doses of nivo+ipi and 24 pts received nivo maintenance: median number of cycles was 10.5 (range, 1-57). Median follow-up for surviving pts was 14.7 (range 1.4-56.7) months. ORR was 35% (80% CI, 26%-45%, N=17) (Table). Median duration of response was not reached; 9 pts maintained response > 12 months. 17 (35%) pts developed treatment-related grade $\geq$ 3 toxicities with one grade 5 toxicity; 3 pts had treatment unrelated grade 5 toxicities. 16 (33%) required high dose steroids ($\geq$40 mg prednisone or equivalent).

Table: 2369P Response summary by tumor histologies

	CR	PR	SD	PD	NE
Overall (N=49, %)	2 (4)	15 (31)	8 (16)	22 (45)	2 (4)
Squamous (N=12, %)	0 (0)	3 (25)	3 (25)	4 (33)	2 (17)
Small Cell (N=12, %)	1 (8)	5 (42)	0 (0)	6 (50)	0 (0)
Adenocarcinoma (N=8, %)	0 (0)	0 (0)	2 (25)	6 (75)	0 (0)
Urachal (N=9, %)	0 (0)	3 (33)	2 (22)	4 (44)	0 (0)
Other* (N=8, %)	1 (13)	4 (50)	1 (13)	2 (25)	0 (0)

*Plasmacytoid N=2, Spindle Cell/Sarcomatoid N=4, Clear Cell N=2 CR = Complete Response, PR = Partial Response, SD = Stable Disease, PD = Progressive Disease, NE = Not Evaluable

Conclusions: The combination of nivo+ipi resulted in objective and durable responses in a subset of pts with BCVH notably with no responses in adenocarcinoma and 50% ORR in small cell carcinoma; toxicities were manageable. This is targeting an unmet need for these pts.

Clinical trial identification: NCT 03333616.

2370P Updated results of PEANUT trial: Pembrolizumab and nab-paclitaxel as salvage therapy for platinum-treated, locally advanced or metastatic urothelial carcinoma (mUC)

A. Bottiglieri[1], W. Ferrari Bravo[1], A. Rametta[1], L. Provenzano[1], D. Raggi[2], L. Marandino[2], E. Farè[3], V. Longo[1], V. Guadalupi[1], M. Stellato[1], E. Verzoni[1], P. Sepe[1], M. Claps[1], G. Calareso[4], A. Alessi[5], L. Cattaneo[6], M. Colecchia[7], G. Procopio[1], A. Necchi[2], P. Giannatempo[1]

[1]Medical Oncology Department, Fondazione IRCCS - Istituto Nazionale dei Tumori, Milan, Italy; [2]Medical Oncology Department, IRCCS Ospedale San Raffaele, Milan, Italy; [3]Medical Oncology Department, Ospedale Civile di Legnano, Legnano, Italy; [4]Department of Interventional Radiology, Fondazione IRCCS - Istituto Nazionale dei Tumori, Milan, Italy; [5]Nuclear Medicine Department, Fondazione IRCCS - Istituto Nazionale dei Tumori, Milan, Italy; [6]Advanced Diagnostics Department, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy; [7]Department of Pathology, IRCCS Ospedale San Raffaele, Milan, Italy

Background: Pembrolizumab (pembro) is approved for the II-line in mUC. In PEANUT trial (NCT03464734) we investigated the efficacy of the combination of pembro plus nab-paclitaxel after chemotherapy (CT) failure. Herein, a long-term follow-up (FUP) update and a post-hoc analysis are presented.

Methods: In an open-label, single-arm, phase 2 trial pts with mUC after failure of $\leq$2 platinum-based CT were enrolled. Pts received 200 mg pembro on D1, and 125 mg/m^2 nab-paclitaxel on D1 and D8, every 3 weeks, until disease progression (PD) or unacceptable toxicity. The primary endpoint was the progression-free survival (PFS).

Results: As of April 1, 2023, 11/70 (15.7%) pts enrolled are in CR after a median FUP of 45.5 mo (95% CI, 42.3 − 49.8). 5/70 (7.1%) completed 2-yrs of treatment. Median OS was 11.7 mo (95% CI, 8.27 − 17.2) and median PFS was 5.1 mo (95% CI, 4.1 − 7.37). The ORR was 47.1%. For CR or PR pts, median OS was 28.4 mo (95% CI, 16.2 − NA). OS rate was 19 (27.1%) at 46 mo. Treatment was discontinued due to toxicity in 12/70 (17.4%) pts: in 9/70 only nab-paclitaxel, in 3/70 both. After PD, 22/70 (32.4%) patients underwent further therapies. Levels of hemoglobin (HR 0.88; 95% CI, 0.76 − 1; *p* value 0.095) and NLR at baseline (HR 1.2; 95% CI, 1.1 − 1.3; *p* value 0.0032), discontinuation due to toxicity (HR 0.34; 95% CI, 0.14 − 0.79; *p* value 0.012) and subsequent therapy (HR 2.4; 95% CI, 1.3 − 4.4; *p* value 0.0033) appear to have a statistically significant impact in PFS. Instead, the primary (bladder vs UTUC) (HR 2.3; 95% CI, 1.1 − 4.7; *p* value 0.027), liver metastases (HR 2.4; 95% CI, 1.3 − 4.2; *p* value 0.0032), NLR at baseline (HR 1.2; 95% CI, 1.1 − 1.3; *p* value 0.0014) and discontinuation due to toxicity (HR 0.38; 95% CI, 0.16 − 0.89; *p* value 0.026) seem to have a greater influence on OS.

Conclusions: After nearly 4 years, the combination of pembrolizumab and nab-paclitaxel maintained clinically meaningful efficacy in pts with mUC that progressed after platinum-based CT. OS data and post-hoc analyzes are consistent with what has been published in the literature in this disease setting.

Clinical trial identification: NCT03464734.

2371P Avelumab first-line (1L) maintenance for advanced urothelial carcinoma (aUC): Long-term outcomes from the JAVELIN Bladder 100 trial in older patients (pts)

S. Gupta[1], M.A. Climent Duran[2], S. Sridhar[3], T.B. Powles[4], J. Bellmunt[5], K. Tyroller[6], S. Guenther[7], A. di Pietro[8], P. Grivas[9]

[1]Taussig Cancer Institute, Cleveland Clinic Foundation, Cleveland, OH, USA; [2]Instituto Valenciano de Oncología, Valencia, Spain; [3]Princess Margaret Cancer Centre, University Health Network, Toronto, ON, Canada; [4]Barts Cancer Institute, Experimental Cancer Medicine Centre, Queen Mary University of London, St Bartholomew's Hospital, London, UK; [5]Department of Medical Oncology, Dana Farber Cancer Institute, Harvard Medical School, Boston, MA, USA; [6]EMD Serono Research & Development Institute, Inc., Billerica, MA, USA; [7]Merck Healthcare KGaA, Darmstadt, Germany; [8]Pfizer Srl, Milan, Italy; [9]University of Washington; Fred Hutchinson Cancer Center, Seattle, WA, USA

Background: In the phase 3 JAVELIN Bladder 100 trial (NCT02603432), avelumab 1L maintenance therapy + best supportive care (BSC) significantly prolonged overall survival (OS) and progression-free survival (PFS) vs BSC alone in pts with aUC without progression following 1L platinum-based chemotherapy. After ≥2 years of follow-up in all pts, median OS was 23.8 months (95% CI, 19.9-28.8) vs 15.0 months (95% CI, 13.5-18.2), respectively. Avelumab 1L maintenance also had minimal impact on quality of life. Here, we report long-term efficacy and safety outcomes in subgroups based on older age (≥65 years).

Methods: Eligible pts with locally advanced or metastatic UC without progression following 4 to 6 cycles of 1L platinum-based chemotherapy were randomized 1:1 to receive avelumab + BSC (n=350) or BSC alone (n=350). The primary endpoint was OS; secondary endpoints included PFS and safety. For this post hoc analysis, subgroups aged ≥65 to <75 years, ≥75 years, and ≥80 years were analyzed. Pts aged <65 years were not included in this analysis.

Results: At data cutoff (June 4, 2021), median follow-up in both arms was ≥38 months. In the avelumab + BSC and BSC alone arms, age was ≥65 to <75 years in 136 and 163 pts, ≥75 years in 85 and 80 pts, and ≥80 years in 28 and 27 pts, respectively. Across all subgroups, OS and PFS were prolonged with avelumab + BSC vs BSC alone (Table). The table also shows incidence of any-grade and grade ≥3 treatment-related adverse events (TRAEs) in the subgroups.

Conclusions: Long-term outcomes from JAVELIN Bladder 100 confirm prolonged OS and PFS with avelumab + BSC vs BSC alone in older pts. Long-term safety of avelumab 1L maintenance was similar across subgroups, confirming its tolerability. These findings provide further support for avelumab 1L maintenance as standard of care in pts with aUC without progression following 1L platinum-based chemotherapy, including older pts over 65 years old.

Clinical trial identification: NCT02603432; First posted: November 11, 2015.

Background: N is approved in 2L mUC after platinum-based chemotherapy. Studies suggest improved outcomes for dual checkpoint inhibition in particular with high doses of ipilimumab (N 1mg/kg + I 3mg/kg). We report final data of TITAN-TCC, NCT03219775, that used a tailored approach with N and N+I boosts for non-response.

Methods: Pts with mUC started N induction (240mg Q2W x4). Non-responders of cohorts 1 (dose escalation) and 2 (high dose ipilimumab) received N+I boosts as reported in the table. Responders to N induction continued with N maintenance (240mg Q2W), but could receive N+I per the respective schedules for later progression. Repeated boost phases were possible. Primary endpoint was objective response rate (ORR) to N ± N+I per RECIST1.1. Secondary endpoints included ORR to N induction, progression-free survival (PFS), and overall survival (OS).

Results: TITAN-TCC was conducted from 08/2017 to 02/2023. In cohort 1, 42 pts were 1L and 44 2/3L. Cohort 2 recruited 2/3L pts only with 83 being enrolled. For follow-up times see the table. ORR to N induction was 29%, 23%, and 20% for cohort 1 − 1L, cohort 1 − 2/3L, and cohort 2, respectively. In total, 105 pts received any boost doses, 14 had repeated boost phases. Best overall response to N ± N+I was 48% (95% CI 32-64), 27% (95% CI 15-43), and 33% (95% CI 23-44), respectively. 1-, 2-, and 3- year OS

Table: 2371P

Age	≥65 to <75 years		≥75 years		≥80 years	
Arm	Avelumab + BSC (n=136)	BSC (n=163)	Avelumab + BSC (n=85)	BSC (n=80)	Avelumab + BSC (n=28)	BSC (n=27)
Median OS (95% CI), months	28.7 (20.9-35.1)	17.1 (12.9-21.3)	24.0 (18.6-37.0)	13.5 (8.6-18.5)	24.9 (14.1-NE)	10.0 (7.0-26.9)
HR for OS (95% CI)	0.73 (0.543-0.974)		0.59 (0.401-0.877)		0.57 (0.284-1.155)	
Median PFS by investigator (95% CI), months	7.4 (3.7-11.2)	2.8 (1.9-3.7)	9.2 (5.6-13.3)	2.2 (1.9-3.7)	13.8 (5.7-30.3)	1.9 (1.7-3.7)
HR for PFS (95% CI)	0.51 (0.389-0.666)		0.38 (0.266-0.554)		0.27 (0.129-0.560)	
Any-grade TRAE, n (%)*	103 (79.2)	2 (1.2)	70 (82.4)	2 (2.6)	24 (85.7)	0
Grade ≥3 TRAE, n (%)*	24 (18.5)	0	18 (21.2)	0	9 (32.1)	0

NE, not estimable.
*In treated pts.

Table: 2372P

Parameter	Cohort 1 - 1L N=42	Cohort 1 - 2/3 L N=44	Cohort 2 (2/3 L) N=83
Boost schedule	2x N 3mg/kg + I 1mg/kg (Q3W); if no response: 2x N 1mg/kg + I 3mg/kg (Q3W)	2x N 3mg/kg + I 1mg/kg (Q3W); if no response: 2x N 1mg/kg + I 3mg/kg (Q3W)	2x N 1mg/kg + I 3mg/kg (Q3W); if no response: 2x N 1mg/kg + I 3mg/kg (Q3W)
Median age, years (range)	70 (45-84)	68 (45-80)	68 (37-84)
Median follow-up, months (range)	10.4 (0.6-51.8)	7.5 (0.3-60.3)	5.6 (0.3-42.6)
ORR N induction, n (%)	12 (29)	10 (23)	17 (20)
ORR N ± N+I, n (%)	20 (48)	12 (27)	27 (33)
Median OS, months (95% CI)	16.4 (7.3-28.5)	8.3 (5.3-19.3)	7.6 (5.0-14.9)
Median PFS, months (95% CI)	3.0 (1.8-6.8)	1.9 (1.7-5.8)	1.9 (1.8-3.2)

rates were 55%, 37%, and 31% for cohort 1 — 1L, 42%, 31%, and 18% for cohort 1 — 2/3L, and 40%, 34%, and 34% for cohort 2. For median OS and PFS see the table.

Conclusions: Despite meaningful clinical activity of the TITAN-TCC approach in cohort 1 — 1L, starting treatment with N monotherapy appears inadequate given the aggressiveness of mUC. In 2/3L, N+I boosts with escalating dose of ipilimumab (cohort 1 — 2/3L) did not improve ORR vs. N monotherapy as reported in the literature. However, it did for boosts with high dose ipilimumab (cohort 2) with a considerable 3-year OS rate for 2/3L mUC.

Background: The phase 3 KEYNOTE-361 trial (NCT02853305) of 1L pembrolizumab + chemotherapy (chemo) or pembrolizumab vs chemo alone in pts with advanced UC completed enrollment prior to approval of PD-L1 maintenance therapy after 1L chemo. This post hoc exploratory analysis evaluated pts who received chemo by eligibility for post-chemo maintenance therapy.

Methods: Pts who received chemo alone were retrospectively categorized as eligible (received ≥4 cycles of chemo and either did not have PD or died within 0-10 wk after completion of chemo or did have a PD or died >10 wk after completion of chemo) or ineligible (received ≥4 cycles of chemo and had a PD or died while on chemo or within 0-10 wk after completion of chemo) for post-chemo maintenance. Pts who received <4 cycles of chemo, were censored before end of chemo, or had non-evaluable or missing scans within 10 wk of chemo were excluded. Exploratory end points were PFS, landmark PFS (time from last non-PD assessment within 0-10 wk of chemo completion to PD per RECIST v1.1 by BICR), OS, and landmark OS (time from last non-PD assessment within 0-10 wk of chemo completion to death).

Results: Median follow-up was 31.7 mo (range, 22.0-42.3). Among 342 pts in the chemo arm, 172 (50.3%) were eligible for maintenance, 108 (31.6%) were ineligible, and 62 (18.1%) were excluded; 85/172 pts (49.4%) received subsequent anti—PD-1/L1 therapy. Results for pts eligible for post-chemo maintenance are reported (Table). For maintenance-ineligible pts, median (95% CI) PFS and OS were 5.1 mo (4.2-6.0) and 10.2 mo (9.1-11.6), respectively.

Conclusions: This post hoc exploratory analysis demonstrates that pts who are eligible for post-chemo maintenance therapy have a favorable prognosis. About 50% of pts who initiated chemo on a clinical trial were considered eligible for maintenance therapy. To our knowledge, these are the first exploratory data describing outcomes of maintenance-eligible pts from the initiation of chemo.

Table: 2373P	
	Maintenance eligible n = 172
PFS, median (95% CI%), mo	9.0 (8.4-10.4)
PFS rate at 12 mo, % (95% CI)	35.1 (27.3-43.0)
Landmark PFS, median (95% CI), mo	4.1 (2.9-6.1)
Landmark PFS rate at 12 mo, % (95% CI)	25.2 (17.9-33.2)
OS, median (95% CI, mo)	23.3 (19.4-26.1)
OS rate at 24 mo, % (95% CI)	46.8 (39.2-54.1)
Landmark OS, median (95% CI), mo	18.8 (14.6-21.8)
Landmark OS rate at 24 mo, % (95% CI)	39.9 (32.2-47.5)

Clinical trial identification: NCT02853305; Release date: August 2, 2016.

Background: Patients (pts) with aUC have poor prognosis after progression on platinum-based chemotherapy (PCT). Immune checkpoint inhibitors (ICI) post-PCT provide overall response rate (ORR) $\leq$ 21%. TGF-β pathway can mediate resistance to ICI in aUC. BA is a first-in-class bifunctional fusion protein composed of extracellular domain of TGF-βRII receptor ("trap") fused to a human IgG1 mAb blocking PD-L1. We conducted a phase 1b trial evaluating the safety/efficacy of BA in PCT-refractory aUC.

Methods: This open-label multicenter trial enrolled pts with PCT-refractory aUC (ECOG PS $\leq$ 1) with $\leq$2 lines of systemic therapy for aUC (no prior therapy targeting T-cell co-stimulation, ICI, or TGF-β pathway). Pts received BA 1200mg every 2 weeks until progression, unacceptable toxicity, death, withdrawal, or for $\leq$2 years. Primary endpoint: investigator-assessed confirmed ORR (RECIST 1.1); secondary endpoints: duration of response (DOR), PFS, OS. A Bayesian predictive probability design for the primary endpoint had 5.7% alpha (type I error) and 85.4% power to rule out ORR $\leq$21% (target ORR $\geq$40%; target accrual 40 pts).

Results: Accrual was stopped based on available trial data indicating that BA was unlikely to show meaningful benefit beyond current available therapies, also considering the evolving therapy landscape. Between Oct 15, 2020, and Aug 31, 2021, 25 pts (21 men, median age 67) were enrolled. At data cutoff (DOC), confirmed ORR 20% (5 pts; 95%CI 6.8-40.7; 2 CR, 3PR), median DOR N/E; median PFS 1.8 mo (95% CI 1.2-3.4), median OS not reached. Median number of BA doses 4; 24 pts discontinued BA [14 for progression; 8 for treatment-emergent adverse event (TEAE); 1 completed therapy; 1 death]; 1 receiving BA at DOC. All pts experienced TEAE; 7 pts experienced G$\geq$3 treatment-related adverse events (TRAEs). Most common G$\geq$3 TEAEs ($\geq$10% of pts): anemia (32%), urinary tract infection (16%); most common G$\geq$3 TRAEs: colitis (4%), pneumonitis (4%).

Conclusions: Accrual was feasible but further development of BA in this therapy setting was halted. Limitations: relatively small sample size and no randomization. Future studies can assess the role of TGF-β pathway inhibition in UC.

Clinical trial identification: NCT04349280.

Background: To evaluate the safety and efficacy of GP regimen in combination with immune checkpoint inhibitor sintilimab as neoadjuvant therapy for MIBC patients and the feasibility of the following selective bladder sparing surgery.

Methods: Patients with histopathologically confirmed urothelial carcinoma without distant metastases (T2-4a, N≤1, M0, AJCC 8th), and have adequate organ function will be enrolled. The therapeutic regimen were sintilimab 200 mg once on day 8, gemcitabine 1,000 mg/m^2 and cisplatin 35 mg/m^2 once on days 1 and 8, every 21 days for four cycles. Multi-disciplinary Treatment was conducted for surgical plan following neoadjuvant therapy. Radical cystectomy (RC) and bladder sparing strategy including partial cystectomy (PC) and TURBT and surveillance were fully discussed. Salvage surgery would be evaluated after recurrence. The primary endpoint was pathologic complete response (pCR, pT0N0) rate. The secondary end points were pT<2 rate, R0 resection rate, event free survival (EFS) and safety.

Results: From May 4, 2020 to Aug 10, 2022, 37 patients were enrolled. Notwithstanding the poor pathological situation of high T3-T4a proportion (n=14, 37.8%), a promising bladder preservation rate was achieved (73.0%, including 19 patients TURBT, 5 patients PC and 3 surveillance). Among the patients who underwent surgery (n=34), fourteen patients (41.2%) achieved pCR, twenty-seven patients (79%) achieved pT<2 (41% pT0, 9% pTa, 26% pT1, 3% pTis). All patients achieved R0 resection. With a median follow-up of 20.1 months, seven patients relapsed (bladder preservation vs. RC, 22.2% vs. 10%, p=0.321) and 1-year EFS was 89.1%. There was no significant difference between bladder-preserving and radical surgery subgroup to EFS (P=0.569). The most common grade ≥3 treatment-related adverse events (TRAEs) were neutropenia (n=8; 21.6%), which was related to chemotherapy. There were no Grade 3 immune-related AEs.

Conclusions: Neoadjuvant GP plus sintilimab is a promising regimen for MIBC patients, with relatively high pCR rate and triggering the emerging roles for the MDT decision-making for bladder sparing surgery.

2376P Pembrolizumab monotherapy following tri-modality treatment for selected patients with muscle-invasive bladder cancer

S.B. Qin[1], W. Yu[2], Z.S. He[2], X.S. Gao[1], H. Hao[2], Y. Bai[1], H.Z. Li[1]

[1]Department of Radiation Oncology, Peking University First Hospital, Beijing, China; [2]Department of Urology, Peking University First Hospital, Beijing, China

Background: This is a phase 2, single arm, single-site study of Pembrolizumab as maintenance therapy in muscle-invasive bladder cancer (MIBC) participants who has received maximum Transurethral resection of bladder tumor (TURBT) and tri-modality treatment (TMT) and achieved complete response (CR).

Methods: This trial includes Patients with cT2-4N0M0 MIBC who declined or were ineligible for cystectomy (RC), and achieved CR after receiving maximal TURBT then Stereotactic ablative radiotherapy (SABR) boost to bladder tumor or tumor bed and concurrent radio-chemotherapy. During SABR, intravesical installation of isovolumetric saline through urinary catheter ensured adequate bladder filling. After TMT, patients who achieved CR will receive Pembrolizumab as maintenance therapy. Pembrolizumab (200 mg q3w) monotherapy will begin on Day 1 of each 3-week cycle and will continue for up to 17 cycles (approximately 1 year). The primary endpoint was progression-free survival (PFS).

Results: From January 11, 2022 to April 20, 2023, twenty-three patients with MIBC were enrolled. The median age of included patients was 68 years and clinical stage ranged from cT2 (n=20) to cT3 (n=3). TURBT was visibly complete in twelve cases. After a median follow-up time of 6 months, 5/23 (21.7%) patients reported immune-related AEs, which included Grade 2 myositis, hypothyroidism, pneumonitis and cystitis, and had no ongoing toxicity after administration of steroids. The estimated 1-year PFS, overall survival and local control rate was 78%, 94.4% and 94.7%. One patient experienced local recurrence with MIBC and bone metastasis respectively after 7 months of TMT. One patient died from pulmonary infection related to COVID-19, the others are alive with no evidence of cancer and with intact well-functioning urinary bladder at median follow-up of 6 months.

Conclusions: Pembrolizumab maintenance therapy after SABR boost to bladder tumor and concurrent radio-chemotherapy was well-tolerated with promising efficacy in the early analysis. Immune related toxicity was consistent with prior monotherapy trials. Selected correlative analyses from serially collected blood and tissue specimens will be presented.

Clinical trial identification: NCT05072600.

2377P Interim results from a phase II clinical study of tislelizumab combined with gemcitabine and cisplatin as a bladder-sparing therapy for urine tumor DNA (utDNA) defined clinical complete response (cCR) MIBC patients

C. Luo, B. Huang, Z. Wang, L. Chen, J. Chen

The Urology Department, The First Affiliated Hospital, Sun Yat-sen University, Guangzhou, China

Background: In order to precisely select MIBC patients (pts) for bladder preservation, it's necessary to establish strict standard for cCR. Our study was conducted to evaluate the efficacy of tislelizumab combined with gemcitabine and cisplatin (GC) as a bladder-sparing therapy for utDNA-defined cCR pts.

Methods: The study enrolled pts were cisplatin-eligible with no carcinoma in situ. Firstly, pts received maximal TURBT, then received tislelizumab 200 mg in day 1 (D1), cisplatin 70 mg/m^2 D2, and gemcitabine 1000 mg/m^2 D1 and D8 every 3 weeks for 4 cycles. Secondly, pts further received utDNA testing and clinical restaging were performed. Pts who were utDNA-defined cCR (defined as negative for utDNA, normal urine cytology and MRI imaging, plus bladder biopsies≤cTa.) proceeded bladder preservation, while non-utDNA-defined cCR pts underwent radical cystectomy (RC). Finally, all pts received tislelizumab every 3 weeks for 8 cycles followed by surveillance. The primary endpoint was utDNA-defined cCR rate. Secondary endpoints were 1-year bladder intact disease-free survival(BIDFS) rate, OS and safety.

Results: 16 MIBC pts enrolled between Jul. 2021 and Sep. 2022 and 14 pts were analyzed (male 85.7%; median age 62(39-75)). cT2=21.4%, cT3=64.3%, cT4a=14.3%, cN0=78.6%, cN1=21.4%. 100% pts received maximal TURBT. The median number of tislelizumab and GC cycles were 4 (4-4) and 4 (3-4), respectively. Median follow up was 13.2 months (7.9-17.1). The utDNA-defined cCR rate was 35.7% (95% CI, 10.7%-60.7%). Non-utDNA-defined cCR pts received RC and all were≥pT1N0M0. The 1-year BIDFS rate and 1-year OS rate for utDNA-defined cCR pts were 100% (95%CI, 100%-100%) and 100% (95%CI, 100%-100%), respectively. Grade 1-2 immune related adverse events, including rash (n=4), ALT/AST increased (n=3), hyperthyroidism (n=1) and hyperglycaemia (n=1).

Conclusions: The interim results demonstrated the utDNA-defined cCR can successfully select MIBC pts for precise bladder-sparing treatment.

Clinical trial identification: ChiCTR2200067146.

Background: Pembro has shown durable antitumor activity in advanced/metastatic UC across multiple studies. Rechallenging pts who previously responded to pembro and had their disease subsequently progress may be a potential treatment strategy. We conducted a post hoc pooled analysis of outcomes of pembro rechallenge in pts from the phase 3 KEYNOTE-045 (NCT02256436), phase II KEYNOTE-052 (NCT02335424), and phase 3 KEYNOTE-361 (NCT02853305) studies.

Methods: Pts were included in the pooled analysis if they received pembro monotherapy in the course of one of the studies and stopped pembro after CR or had CR, PR, or SD to first-course pembro and completed 2 y of treatment. Protocol-specified pembro rechallenge was administered at a dose of 200 mg Q3W for up to 17 cycles (∼1 y). Outcomes in this exploratory analysis included ORR, DOR, PFS, OS, and safety of second-course pembro.

Results: A total of 49 pts were included (n = 11, KEYNOTE-045; n = 10, KEYNOTE-052; and n = 28, KEYNOTE-361). Best overall response to first-course pembro included 21 CRs, 23 PRs, 3 SDs, and 2 non-CRs/non-PDs (defined as persistence of ≥1 nontarget lesions and/or maintenance of tumor marker level above the normal limits). Median duration of the first response to pembro was 26.7 mo (range, 4.1-54.9+). Median time between first and second course was 10.7 mo (range, 1.0-36.3); median duration of second course was 8.3 mo (0.0-13.2). Seventeen pts (35%) completed second-course pembro; the most common reason for discontinuation was disease progression (n = 19; 39%). ORR to second-course pembro was 41% (8 CR; 12 PR) and median DOR was 14.0 mo (2.1+ to 20.5). From start of second-course treatment, the 12-mo PFS rate was 45% and the 24-mo OS rate was 61%. Treatment-related adverse events (AEs) occurred in 22 pts (45%); 3 pts (6%) experienced grade 3-4 treatment-related AEs. Three pts (6%) discontinued due to a treatment-related AE, and no pts died due to a treatment-related AE.

Conclusions: Consistent with prior reports, pts with advanced/metastatic UC whose disease had prior response to pembro may benefit from pembro rechallenge. The safety profile of pembro rechallenge was consistent with the known safety profile of pembro monotherapy.

Clinical trial identification: KEYNOTE-361: NCT02853305; Release date: August 2, 2016. KEYNOTE-045: NCT02256436; Release date: October 3, 2014. KEYNOTE-052: NCT02335424; Release date: January 9, 2015.

Background: ≈10% of bladder cancers have nonpure UC histology; these tumors are often underdiagnosed and represent an unmet treatment need. AVENANCE (NCT04822350) is evaluating avelumab 1LM in pts with aUC in France and has previously shown clinical activity in a heterogenous population (N=593). We present a subgroup analysis of pts with histological variants.

Methods: Eligible pts had aUC that had not progressed on 1L platinum-based chemotherapy (PBC) and previous, ongoing, or planned avelumab 1LM. The primary endpoint was overall survival (OS); secondary endpoints included progression-free

survival (PFS), duration of treatment (DOT), and safety. Here, pts with nonpure UC (mixed UC with variants [UC-V] and pure variants [PV]) were analyzed.

Results: 44/593 pts had aUC with histological variants; at data cutoff (March 30, 2023), median follow-up was 18.0 mo (range, 12.9-20.4 mo). Tumor histology was UC-V, including micropapillary and epidermoid, in 32 pts (72.7%) and PV in 12 (27.3%). At the start of 1L PBC, most pts had metastatic disease (UC-V, 96.9%; PV, 91.7%) and ECOG PS 0/1 (UC-V, 71.4%; PV, 55.6%). The most common 1L PBC was gemcitabine + carboplatin in 65.6% of pts with UC-V and 75.0% with PV. In pts with UC-V and PV, best response to 1L PBC was complete response in 18.8% and 33.3%, partial response in 59.4% and 58.3%, and stable disease in 21.9% and 8.3%, respectively. In all 44 pts, median DOT was 5.1 mo (95% CI, 2.8-17.4 mo); 34.1% were still receiving treatment at data cutoff. The table shows OS, PFS, and safety data in pts with aUC with histological variants and the overall population.

Conclusions: RW data from AVENANCE provide evidence of the effectiveness and safety of avelumab 1LM in pts with aUC, including histological variants. To our knowledge, this is the first analysis of avelumab 1LM in this pt population. Data are consistent with findings in the overall population.

Table: 2379P

	aUC with histological variant (n = 44)	Overall population (N = 593)
OS, median, mo (95% CI)	NR (13.9-NE)	20.7 (17.1-NE)
12-month OS rate, % (95% CI)	68.6 (51.9-80.5)	65.4 (61.0-69.4)
PFS, median, mo (95% CI)	5.6 (2.8-17.4)	5.7 (5.3-7.0)
Any-grade TRAE, n (%)	18 (40.9)	254 (42.8)
Serious TRAE, n (%)	3 (6.8)	31 (5.2)

NE, not estimable; NR, not reached; TRAE, treatment-related adverse event.

2380P Real-world effectiveness of single agent enfortumab vedotin (EV) in patients (pts) with locally advanced or metastatic urothelial carcinoma (mUC) based on line of therapy and impact of prior platinum (plat) chemotherapy (chemo) and PD-1/PD-L1 inhibitors (PD-1/PD-L1i)

N. Sayegh, Y. Jung Jo, G. Gebrael, N. Tripathi, B. Chigarira, A. Srivastava, B. Nordblad, E. Dal, C. Hage Chehade, B.L. Maughan, S. Gupta, N. Agarwal, U. Swami

University of Utah Health - Huntsman Cancer Institute, Salt Lake City, UT, USA

Background: EV is a Nectin-4-directed antibody and microtubule inhibitor conjugate indicated for the treatment (trt) of pts with mUC who have previously received a PD-1/L1i and plat chemo, or are ineligible for cisplatin-containing chemo and have received $\geq$ 1 prior lines of therapy. However real-world effectiveness of EV based on line of therapy and impact of prior trt is currently not well established.

Methods: This study used the nationwide (US-based) Flatiron Health EHR-derived de-identified database. Inclusion: diagnosis of advanced, recurrent or mUC of upper or lower urinary tract and trt with single agent EV in 2nd line or beyond after 12/18/2019 (FDA accelerated approval date). Exclusion: Pts with no documentation of 1st-line therapy or pts with no evidence of contact for 90 days from diagnosis of mUC at treating institution to ensure pts were actively engaged in care at the institution providing data. Time to next therapy (TTNT) and overall survival (OS) were summarized based on line of therapy and prior plat chemo and PD-1/L1i using Kaplan Meier survival estimates and its 95% confidence interval (CI).

Results: Overall 6,566 pts with mUC received trt of which 431 received EV from 1/17/2020 to 9/30/2022. Baseline pt characteristics for each line of therapy will be presented at the meeting. The table summarizes real world TTNT and OS of pts.

Table: 2380P Median TTNT and OS in months and their 95% CI for EV based on line of trt and receipt of prior plat chemo or PD-1/L1i or not

Line (n)	TTNT Overall	TTNT Prior platinum	TTNT Prior PD-1/LI	OS Overall	OS Prior platinum	OS Prior PD-1/LI
2nd (157)	5.3 (4.4, 6.3)	Y 6.3 (5.4, 7.4) N 4.4 (3.5, 5.8)	Y 4.8 (3.7, 6.3) N 5.8 (5.2, 7.3)	7.8 (6.3, 12)	Y 11 (8.4, -) N 6.0 (5.3, 12)	Y 6.3 (5.4, 20) N 9.8 (6.9, 21)
3rd (132)	4.5 (3.2, 5.7)	Y 5.5 (—, —) N 4.5 (3.2, 5.7)	Y 4.6 (3.5, 5.7) N 4.5 (2.5, —)	11 (9.3, 15)	Y 8.6 (5.8, -) N- 11 (10, 16)	Y 11 (9.4, 16) N 10 (7.9, —)
4th (62)	6.2 (5.3, 8.4)	Y 11 (5.0, —) N 6.2 (5.3, 8.2)	Y 6.8 (5.7, —) N 6.2 (4.9, 8.2)	9.3 (8.4, 14)	Y 14 (8.6, —) N 9.0 (8.3, 13)	Y 8.7 (6.1, —) N 11 (8.4, 14)
5th (20)	4.1 (3.6, 6.7)	Y 3.4 (2.4, —) N 4.6 (3.6, —)	Y 7.4 (1.4, —) N 4.0 (3.0, 6.7)	7.2 (3.6, —)	Y 5.4 (2.4, —) N 7.2 (3.6, —)	Y 8.5 (1.4, —) N 6.1 (3.0, —)

Y, yes; N, No

Conclusions: EV retains activity in pts with mUC, regardless of prior receipt of plat chemo and PD-1/L1i, and line of systemic therapy. These data may further aid with patient counseling, prognostication, and selection of therapy in the clinics.

2381P Perceived unmet needs and challenges faced by patients with advanced bladder cancer (aBC) and their caregivers: Results of a social media listening (SML) study conducted in 5 European countries

S. Schuck[1], P. Loussikian[1], A. Mebarki[1], J. Malaab[1], P. Foulquié[1], M. Talmatkadi[1], M. Kearney[2]

[1]Kap Code, Paris, France; [2]Merck Healthcare KGaA, Darmstadt, Germany

Background: aBC has a very poor prognosis and is associated with physical, emotional, and social challenges that patients and caregivers are increasingly expressing online. This observational study aimed to explore and understand challenges that European patients with aBC and their caregivers encounter and share on social media.

Methods: This retrospective, real-world study evaluated written public posts on geolocated social media in France, Germany, Spain, Italy, and the UK posted from October 2017 to January 2022. Natural language processing methods were used to filter out irrelevant content and identify posts from patients and caregivers. Unmet needs were identified by qualitative analysis (ie, annotation) and a saturation method.

Results: A total of 1,670 posts from 1,396 users discussing aBC in 91 publicly available online sources were identified (699 posts from 546 patients and 971 posts from 850 caregivers). Half of patients were male (272 [49.8%]) and more caregivers were female (474 [55.8%]); average age was 58.2 and 35.2 years, respectively. Most unmet needs and challenges identified belonged to 2 main categories: transversal, ie, arising throughout the patient's care pathway (307 [28.1%]) and disease specific (295 [27.0%]). Main challenges included disease worsening (141 [12.9%]), psychological impact (112 [10.3%]), and the need to share experiences and seek support (94 [8.6%]). The top 8 challenges identified in posts from patients and caregivers are listed in the table.

Conclusions: This SML study showed that European patients with aBC and their caregivers have a real need for support and to express their challenges, especially regarding disease management. These findings highlight the need for improved patient and caregiver education and for effective systemic cancer treatments and palliative care options for aBC.

Table: 2381P

Challenge	Occurrence in all posts combined, n (%)	Occurrence in patient posts, n (%)	Occurrence in caregiver posts, n (%)	Category
Disease worsening	141 (12.9)	40 (10.5)	101 (14.2)	Disease specific
Psychological impact	112 (10.3)	38 (10.0)	74 (10.4)	Transversal
Need for sharing/ support	94 (8.6)	42 (11.0)	52 (7.3)	Transversal
Management of aBC symptoms	82 (7.5)	31 (8.1)	51 (7.2)	Disease specific
Sequelae of aBC or care	60 (5.5)	34 (8.9)	26 (3.7)	Remission-phase specific
Worried about future	46 (4.2)	14 (3.7)	32 (4.5)	Transversal
Difficulty accessing treatment	40 (3.7)	13 (3.4)	27 (3.8)	Treatment specific
Pain management	33 (3.0)	11 (2.9)	22 (3.1)	Disease specific
TOTAL	**608 (55.7)**	**223 (58.4)**	**385 (54.2)**

Oncology, Hospital Provincial Rodriguez Chamorro, Zamora, Spain; [11]Medical Oncology, Hospital San Pedro, Logroño, Spain; [12]Medical Oncology, Hospital Reina Sofia, Tudela, Spain; [13]Oncology, IDIVAL - Instituto de Investigacion Sanitaria Valdecilla, Santander, Spain; [14]Dept. Despacho 271, HUMV - Hospital Universitario Marques de Valdecilla, Santander, Spain

Background: The available real-world (RWD) evidence on the management of la/mUC is limited but of high importance to understand how to incorporate new treatment options in this setting. The present study describes the clinical characteristics, treatment patterns and outcomes in patients (pts) with la/mUC in Northern Spain.

Methods: Retrospective observational analysis from 16 hospitals across 12 provinces. The study population included adult pts diagnosed with la/mUC (January 1,2007-December 31, 2019) followed from the index date until death, loss to follow-up or end of study. Median overall survival (OS) and progression-free survival (PFS) were determined using the Kaplan-Meier method.

Results: We included 1231 pts (median age:68 years;83% men). 74% had $\geq$1 medical comorbidity (hypertension 48%; DM 22.5%; CAD 13%; COPD 12%). Primary tumour locations: bladder (89.2 %), renal pelvis (6.4%), ureter (4.3%), and urethra(0.1%). 70% of the pts had localized disease at diagnosis, cystectomy was the predominant treatment (95%) and 30% received perioperative chemotherapy. Out of 1231 pts, 292 (24%) never received systemic therapy. From 939 pts (76%) treated with 1st-line therapy, 50% were fit for cisplatin. Only 53% (n=493) progressed to receive a second line (2L) and 22% (n=210) received a third line(3L). Chemotherapy was the most common treatment used across all lines (1L[92%], 2L [74%] and 3L[74%]) and immunotherapy represented 3%, 25% and 22%,in 1L, 2L and 3L respectively. 28 pts (3%) were included in clinical trials. Median OS (95% CI) was 12.1(11.3—12.9) months in the overall group and 14.5 in pts who received 1st-line cisplatin-gemcitabine. From the start of the 1L, 2L and 3L treatment, median PFS was 1L:5.0(4.5-5.4);2L: 3.2(2.8-3.5);3L:2.6(2.3-2.9) months. No unexpected toxicity was reported.

Conclusions: The results of this Spanish RWD analysis are comparable to previous studies conducted in other regions of the world and highlight unmet needs such as the proportion of pts who never receive systemic treatment and the notable decrease in the number of pts progressing to second and subsequent lines of therapy hindering the access to new effective treatments developed in this context.

2383P Stereotactic body radiotherapy (SBRT) of patients with oligometastatic urothelial cancer (UC): A single institution experience

F. Jawdat[1], F. Costa Svedman[1], K. Holmsten[2], V. Grozman[3], D. Alm[1], W.S. Hailom[1], A. Ullén[1]

[1]Department of Oncology, Karolinska University Hospital-Solna, Solna, Sweden; [2]Oncology and Pathology, Karolinska Institutet, Stockholm, Sweden; [3]Section of Thoracic Radiology, Department of Imaging and Physiology, Karolinska University Hospital-Solna, Solna, Sweden

Background: Standard of care for treatment-naïve patients with metastatic UC is platinum-based combination chemotherapy followed by maintenance avelumab if disease stabilisation or response is achieved. The best strategy to treat patients with oligometastatic disease is unknown; data on side effects and benefit of SBRT in postponing or avoiding systemic treatments in UC is limited.

Methods: We performed a real-world study to explore local control rate (LCR), progression-free survival (PFS), overall survival (OS) and tolerability of SBRT of all available patients with metastatic UC treated at Karolinska University Hospital between 2009 and 2022 (n=41). Baseline clinical characteristics and treatment outcome data were collected from medical records. Radiological examinations were reviewed by a radiologist, from baseline until progressive disease.

Results: In our cohort 78% of patients were male, the median age was 72 yr (range 54-88) and all patients had performance status 0-2 (0:54%, 1:39%, 2:7%). Most

patients had a primary UC in the bladder (66%) and 24% had metastatic disease at diagnosis. The most common location of metastases receiving SBRT were lungs (44%) and lymph nodes (27%). The number of metastatic sites receiving SBRT were 1, 2 and 3 in 73%, 24% and 2% of patients, respectively. Most patients (90%) achieved local control. The PFS and OS for the complete cohort were 4,4 and 26,2 months, respectively. The only clinical factor significantly associated with favourable outcome was the number of metastases, i.e., ≤ 2 vs > 2 ($p = 0.049$). Only one patient did not complete the planned SBRT (treatment related pain). We found 13 patients (32 %) with OS exceeding 3 years and 6 out of these 13 patients never received systemic treatment after SBRT. A total of 11 patients are still alive, but 4 of these patients have follow-up (FU) shorter than 3 years (16-29 months FU).

Conclusions: In summary, SBRT in UC is associated with high LCR and is well tolerated. Selected patients may achieve long survival, postponing or avoiding systemic treatment. A randomized study to investigate the role of SBRT in this population is warranted.

2384P Platinum rechallenge in the era of immune checkpoint inhibitor in locally advanced/metastatic urothelial carcinoma: Multicenter retrospective study

E. Kim[1], J.H. Kim[2], J. Chu[3], Y-G. Lee[1], H-S. Im[4]

[1]Department of Hematology and Oncology, Kangbuk Samsung Hospital, Sungkyunkwan University School of Medicine, Seoul, Republic of Korea; [2]Department of Oncology-Hematology, Korea University Anam Hospital, Seoul, Republic of Korea; [3]Department of Pathology, Kangbuk Samsung Hospital, Sungkyunkwan University School of Medicine, Seoul, Republic of Korea; [4]Department of Hematology and Oncology, Ulsan University Hospital, Ulsan, Republic of Korea

Background: In locally advanced/metastatic urothelial carcinoma (UC) which progressed after platinum-based chemotherapy (P), treatment with 2nd-line immune checkpoint inhibitor (ICI) is considered. If disease progresses thereafter, there is no domestically approved drug with proven OS benefit in Korea, despite the development of new drugs. Therefore, P rechallenge is common in clinical practice, in spite of little evidence. This study aimed to evaluate efficacy of P rechallenge, and to explore clinical/genetic biomarkers predicting the efficacy of P rechallenge in locally advanced/metastatic UC.

Methods: A total of 66 patients who rechallenged P for locally advanced/metastatic UC from Jan 2017 to Mar 2023 in 3 tertiary referral hospitals was included. Clinical data were retrospectively evaluated. Next generation sequencing was performed for 43 available patients.

Results: Gemcitabine-based regimens (GP, GCb; [G]; n=28), MVAC-based regimens (MVAC/Cb, ddMVAC; [M]; n=35) and other P (n=3) were administered for P rechallenge; ORR, median PFS and OS were 40.9%, 4.5 and 8.7 months. In patients who received [G] for both 1st-line-P and P-rechallenge (n=24), whose ORR (70.8%) and median TTP (7 months) were favorable to 1st-line P, ORR of P rechallenge was 66.7%. On the other hand, in patients who received 1st-line [G] and rechallenged P with [M] (n=35), whose ORR (45.7%) and mTTP (0.5 months) were relatively poor with 1st-line P, ORR of P rechallenge was 22.9%. Median OS of P rechallenge were significantly longer in patients who received ICI between 1st-line-P and P-rechallenge than those who did not receive (12.4 vs 6.5 months, p=.004). In multivariate analysis, poor response to 1st-line P, visceral metastasis and no alterations in DNA damage repair (DDR) genes were significant prognostic factors for poorer OS after P rechallenge.

Conclusions: This study demonstrated favorable efficacy of P rechallenge in era of ICI in locally advanced/metastatic UC, providing a basis for treatment decision after P and ICI failure. P rechallenge showed fair efficacy even in poorly responded patients from 1st-line P. DDR gene alterations and ICI use before P rechallenge may be associated with improved survival after P rechallenge.

Background: Agents targeting programmed cell death (ligand) 1 (α-PD-(L)1) are approved as first- and second-line (1L, 2L) treatment options for mUC. Durable responses have been reported, but clinical trials were often closed before long-term follow-up (FU) could be assessed. C-reactive protein (CRP) and antibiotic (AB) use at start of α-PD-(L)1 have been suggested to be associated with progression. Here, we show 'real-world' long-term survival upon α-PD-(L)1 monotherapy for mUC and correlate outcome to several baseline clinical and laboratory parameters. We expect patients (pts) requiring AB around α-PD-(L)1 start to have poor survival outcomes.

Methods: This is a retrospective, multicenter study, in which data were collected for mUC pts treated with α-PD-(L)1 monotherapy as 1L-4L between 2014-2023. Overall- and progression-free survival (OS, PFS) were estimated with the Kaplan-Meier method. Uni- and multivariate regression models were used to identify independent factors associated with progression, death, PFS and OS.

Table: 2385P Regression analyses

	OS		PFS		Death		Progression	
	Univariate (U)	Multivariate (M)	U	M	U	M	U	M
Lymph node metastasis	**0.000**	**0.038**	**0.000**	0.122	**0.000**	0.776	**0.000**	0.179
Visceral metastasis	**0.000**		**0.000**		**0.000**		**0.001**	
gamma-glutamyltransferase >ULN	**<0.001**	0.198	**<0.001**	0.113	**0.018**	0.883	**0.004**	0.386
Lactate dehydrogenase >ULN	**0.004**	0.429	**0.039**	**0.016**	0.241	0.527	0.107	0.502
CRP>75 percentile	**<0.001**	0.264	**0.010**	0.919	0.274	0.985	0.499	0.237
AB use	0.094	**0.004**	0.618	**0.002**	0.324	0.290	0.945	0.182
Steroid use	0.111	0.178	0.338	0.199	0.512	0.787	0.415	0.477
Platinum fitness	0.676	0.242	0.719	0.147	0.694	0.498	0.087	0.120
Metastasis at cancer diagnosis	0.182	0.070	0.824	**0.020**	0.630	0.157	0.865	0.998

Results: We included 375 pts (median age 67 years (yr) (59-75); 75% male; 68% visceral metastasis; 43% 1L α-PD-(L)1). After a median FU of 55 months (mo), median OS and PFS for all lines combined were 9 (7.448-10.552) and 3 mo (2.525-3.475) respectively. OS and PFS were comparable between treatment lines. For pts who did not progress within 2 yr after α-PD-(L)1 start, PFS and OS were 53.2% and 62.4% respectively at 5 yr after treatment start. Results from the regression analyses are depicted in the table.

Conclusions: Median OS and PFS observed in our cohort is in line with data from clinical trials. Our data suggest that of the patients without progression at 24 mo, half will still be progression-free and alive at 5 yr from treatment start. Our data indicate that AB use around start of α-PD-(L)1 is associated with inferior PFS and OS. We recognize the retrospective nature of our cohort as a limitation. More data will be available and presented at ESMO2023.

2386P Factors associated with not receiving systemic treatment (tx) in patients (pts) with metastatic urothelial carcinoma (mUC): Results of a retrospective observational study in Germany

G. Niegisch[1], M. Kearney[2], J. Krieger[3], U. Osowski[4], C. Weinhold[4], B. Deiters[5], U. Maywald[6], S. Guenther[2], T. Wilke[7], M-O. Grimm[8]

[1]University Hospital and Medical Faculty of the Heinrich-Heine University, Düsseldorf, Germany; [2]Merck Healthcare KGaA, Darmstadt, Germany; [3]Cytel, Berlin, Germany; [4]Merck Healthcare Germany GmbH, Weiterstadt, Germany; [5]GWQ ServicePlus AG, Düsseldorf, Germany; [6]Drug Department, AOK PLUS, Dresden, Germany; [7]IPAM eV; University of Wismar, Wismar, Germany; Cytel, Berlin, Germany; [8]Universitätsklinikum Jena, Jena, Germany

Background: Real-world studies have shown that many pts with mUC do not receive first-line (1L) systemic anticancer tx. With the expanding therapeutic landscape for mUC, identifying factors associated with undertreatment to mitigate outcome disparities is essential.

Methods: This study identified adults with an incident mUC diagnosis (dx; ICD-10 codes C65-68 + C77-79) in 2015-2019 using 2 German statutory health insurance (SHI) claims databases (2013-2020, ≈8 mil. insured). Baseline (BL) characteristics within 24 mo before dx were analyzed. After dx, pts were followed for ≥12 mo or until death. Overall survival (OS) was calculated by Kaplan-Meier estimation. Multivariable logistic regression was performed to determine variables associated with receiving 1L systemic tx.

Results: Overall, 3,226 pts with mUC (mean age, 73.8 y; male, 70.8%; mean Charlson Comorbidity Index [CCI] score, 6.3) were identified. Mean follow-up was 13.8 mo. A large portion of pts with mUC (1,892 [58.6%]) did not receive systemic tx within 12 mo of dx. Median OS after dx was notably shorter in untreated vs treated pts: 3.0 vs 13.7 mo for pts in SHI 1 and 3.6 vs 13.8 mo for pts in SHI 2, respectively. Untreated pts were significantly older (age ≥80 y: untreated, 48.2%; treated, 13.5%); had considerably more comorbidities (mean CCI: untreated, 6.8; treated, 5.5); and had a higher care level (untreated, 37.5%; treated, 11.0%). In regression analysis, older age, no prior UC-related surgery/tx, and earlier dx in the study period were associated with a higher likelihood of not receiving tx (Table).

Conclusions: Untreated pts with mUC seem to have a shorter OS than treated pts. Identified factors associated with undertreatment, such as older age and increased comorbidity, need to be addressed by offering better tolerated mUC tx and educating pts on the benefits of systemic tx.

Table: 2386P Factors associated with receiving mUC tx within 12 mo of mUC dx (multivariable logistic regression using receiving tx as dependent variable)

Variable	Odds ratio (95% CI)	p value
Age at index (continuous)	0.93 (0.92-0.94)	<0.001
Diagnosis year (reference year, 2015; categorical)	1.11 (1.05-1.17)	<0.001
Previous UC-related tx, surgeries, and interventions (24-mo BL; dummy*)	1.65 (1.37-2.00)	<0.001
CCI (24-mo BL; continuous)	0.97 (0.93-1.00)	0.011
Outpatient diagnosis setting (dummy*)	1.28 (1.05-1.54)	0.013
No. of previous all-cause hospitalizations (24-mo BL; continuous)	0.97 (0.94-1.00)	0.027
Female (dummy*)	0.83 (0.69-0.98)	0.032

2387P Avelumab first-line maintenance (1LM) for locally advanced or metastatic urothelial carcinoma (la/mUC): Treatment (tx) patterns and real-world (rw) outcomes in the US

K. Carson[1], H. Mahmoudpour[2], C. Ike[3], S. Monzon[4], S. Fragkogianni[4], J. Ferrer[4], M. Kearney[2]

[1]Northwestern University, Chicago, IL, USA; [2]Merck Healthcare KGaA, Darmstadt, Germany; [3]EMD Serono, Inc., Rockland, MA, USA; [4]Tempus Labs, Inc., Chicago, IL, USA

Background: Avelumab 1LM was approved in the US in June 2020 for patients (pts) with la/mUC without disease progression after 1L platinum-based chemotherapy (PBC). This study describes rw outcomes in pts with la/mUC who received avelumab 1LM.

Methods: Pts with la/mUC diagnosed between Jan 2016 and Mar 2023 were identified in the Tempus database. Pts who completed 1L PBC after avelumab's UC approval were considered eligible for 1LM. 1LM was differentiated from second-line (2L) tx based on recorded clinical intent or algorithmically based on initiation of immuno-oncology tx within 180 d of 1L PBC completion without recorded disease progression. Rw overall survival (rwOS), progression-free survival (rwPFS), time on treatment (TOT), and time to next treatment were estimated using Kaplan-Meier methods.

Results: Of 3,299 pts, 59% (1,939) received 1L systemic tx. Median age at diagnosis was 70 y, 74% were male, 85% were White, 88% had transitional cell carcinoma, and 48% had a smoking history. For the 50.2% (974/1,939) of pts who completed 1L tx, PBC was the most common 1L tx (66% [644/974]). Median follow-up (f/u) from 1L PBC start was 10.2 mo; median rwOS was 13.6 mo. 89% (574/644) of pts had no evidence of disease progression after completion of 1L PBC; of these, 38% (219/574) had a recorded 1LM tx, with 62% (135/219) receiving avelumab. These pts had a median f/u from 1LM start of 8.9 mo. RwOS landmark analysis from 1LM start showed that 80% of avelumab 1LM pts were still alive at 6 mo and 63% were alive at 12 mo. Median rwPFS from 1LM start was 6.4 mo; median TOT was 3.85 mo. After 1LM

avelumab, 35% (47/135) of pts received 2L tx. 70% (33/47) of those received enfortumab vedotin (EV), with a median rwOS from 2L start of 11.6 mo.

Conclusions: Early uptake of avelumab 1LM was observed in pts with la/mUC whose disease had not progressed on 1L PBC. F/u time in avelumab-treated pts was short. Future studies with longer f/u may show increased use and allow further assessment of rwOS. Additionally, rw outcomes are improving with newly available 1L and sequencing options. Our study provides early evidence of the effectiveness of 2L EV following 1L PBC and avelumab 1LM.

2388P Split-dose cisplatin plus gemcitabine use and associated clinical outcomes in the first-line (1L) treatment of locally advanced or metastatic urothelial cancer (la/mUC): Results of a retrospective observational study in Germany (CONVINCE)

K. Schlack[1], T. Kubin[2], M. Ruhnke[3], C. Schulte[4], S. Machtens[5], A. Eisen[6], U. Osowski[7], S. Guenther[8], M. Kearney[8], R. Lipp[9], S. Schmitz[10]

[1]Department of Urology, University Hospital Muenster, Muenster, Germany; [2]Department for Hematology, Oncology and Palliative Care, Klinikum Traunstein, Traunstein, Germany; [3]Clinic for Hematology, Oncology and Palliative Medicine, Helios Clinic Aue, Aue, Germany; [4]Department of Hematology and Oncology, Practice for Hematology and Oncology, Dortmund, Germany; [5]Department of Urology, GFO Hospitals Rhein-Berg, Marien-Hospital, Bergisch Gladbach, Germany; [6]GermanOncology GmbH, Hamburg, Germany; [7]Merck Healthcare Germany GmbH, Weiterstadt, Germany; [8]Merck Healthcare KGaA, Darmstadt, Germany; [9]RWE Research, GermanOncology GmbH, Hamburg, Germany; [10]Department of Oncology and Hematology, Medical Care Center for Oncology and Hematology, Cologne, Germany

Background: Platinum-based chemotherapy (PBC) followed by avelumab 1L maintenance in patients without progressive disease is standard 1L treatment for la/mUC. In patients ineligible for cisplatin at the standard dose schedule (C; 1 day per cycle), carboplatin (Cb) or a split-dose schedule of C (35 mg/m^2 on days 1 + 8) are alternative options. The effectiveness of these regimens compared with standard-dose C has not been extensively examined, especially in a real-world (rw) setting. In this study, we compared clinical outcomes to PBC in patients with la/mUC who received 1L gemcitabine (G) with split-dose C (CG-S) vs standard-dose CG or CbG regimens.

Methods: The CONVINCE study was initiated in Dec 2021 and enrolled 188 patients who received 1L PBC in 2019-2020 at 27 oncology or urology institutions (8 hospitals/19 office-based practices) across Germany. Objective response rates (ORRs) and rw progression-free survival (rwPFS) and overall survival (rwOS) were compared in the following subgroups: CG-S vs CG and CG-S vs CbG.

Results: Of 124 patients who received 1L PBC with G, 27 (21.8%) received CG-S, 75 (60.5%) CG, and 22 (17.7%) CbG. Median follow-up was 16.5 months. A Cox regression analysis including several characteristics (age, sex, Eastern Cooperative Oncology Group performance status [ECOG PS], comorbidities) showed no significant differences in rwPFS between CG-S vs CG and CG-S vs CbG subgroups.

Conclusions: This rw study provides valuable insights into the use of 1L CG-S in routine clinical practice in Germany, where C administered in split-dose schedule showed comparable outcomes to standard-dose C or Cb. The analysis suggests that CG-S can be a viable alternative for administering 1L PBC in patients with la/mUC for whom standard-dose C may be unsuitable, without compromising treatment effectiveness.

Table: 2388P

Parameter	CG-S (n=27)	CG (n=75)	CbG (n=22)	p value CG-S vs CG	p value CG-S vs CbG

2390P Correlation between overall survival and bladder-intact event-free survival in cystectomy-ineligible/refusal muscle-invasive bladder cancer patients in Sweden

K.H. Kwok[1], O. Laurin[2], S. Baculea[3], S. Côté[3], S. Spigelman[4], R. Szulkin[5], F. Schain[1], C.V. Jones[1], M. Aly[2]

[1]Real World Evidence, Schain Research AB, Stockholm, Sweden; [2]Department of Molecular Medicine and Surgery, Karolinska Institutet, Stockholm, Sweden; [3]Global Market Access and Health Policy, Janssen Global Services, Llc, Raritan, NJ, USA; [4]Global Medical Affairs, Janssen Research & Development, Llc, Raritan, NJ, USA; [5]Real World Evidence, SDS Life Science AB, Stockholm, Sweden

Background: Radical cystectomy (RC) is currently the recommended treatment for muscle-invasive bladder cancer (MIBC) in Europe and the US. In Sweden, patients unfit or refusing RC are offered bladder-sparing curative or palliative treatment, such as radiotherapy and/or chemotherapy. Bladder-intact event-free survival (BI-EFS) is defined as survival from treatment initiation until confirmed refractory/recurrent MIBC or nodal/metastatic disease, RC, or death, and has been introduced as a primary endpoint in clinical trials. This study evaluated the correlation between BI-EFS and overall survival (OS) in RC-ineligible/refusal MIBC patients in real world in Sweden.

Methods: Patients diagnosed with T2-T4aN0M0 MIBC who subsequently received radiotherapy and/or chemotherapy during 2006-2017 in Sweden were identified in population-based registers and followed until 2018. Exclusion criteria included other urothelial carcinoma prior to MIBC diagnosis and upfront RC upon diagnosis. An iterative multiple imputation method for censored outcomes was used to measure the normal scores rank correlation between BI-EFS and OS.

Results: A total of 337 patients were included in the study. The median age at diagnosis was 77 (IQR 71-82) years and 76% of patients were men. At diagnosis, 286 patients presented with T2 and 51 with T3/T4a stage. There was no significant difference in age at diagnosis between T2 and T3/T4a patients. Overall, the median OS and BI-EFS were 1.04 (95%CI 0.88-1.27) and 0.77 (95%CI 0.65-0.99) year, respectively. T2 and T3/T4a patients had a median OS of 1.11 (95%CI 0.91-1.33) and 0.76 (95%CI 0.5-1.45) year, respectively; and a median BI-EFS of 0.85 (95%CI 0.71-1.05) and 0.5 (95%CI 0.22-0.98) year, respectively. Overall, the correlation between BI-EFS and OS was 0.82 (95%CI 0.77-0.85); for T2 and T3/4a patients, the correlation was 0.84 (95% CI 0.80-0.87) and 0.65 (95% CI 0.44-0.79), respectively.

Conclusions: BI-EFS was correlated with OS in RC-ineligible/refusal MIBC patients who received radiotherapy and/or chemotherapy. The strong correlation in all subgroups supports the use of BI-EFS as a surrogate endpoint for OS in similar patient populations.

2391P Impact of perioperative chemotherapy on survival and pathological stage in muscle-invasive micropapillary urothelial bladder cancer

A.M. Roy[1], A. Groman[2], V. Muthusamy Kumarasamy[3], A. Patel[1], K. Jatwani[1], K. Attwood[2], K. Guru[4], G. Chatta[1], D. Gopalakrishnan[1]

[1]Medical Oncology, Roswell Park Comprehensive Cancer Center, Buffalo, NY, USA; [2]Biostatistics, Roswell Park Comprehensive Cancer Center, Buffalo, NY, USA; [3]Department of Internal Medicine, University at Buffalo - Jacobs School of Medicine and Biomedical Sciences, Buffalo, NY, USA; [4]Surgical Oncology, Roswell Park Comprehensive Cancer Center, Buffalo, NY, USA

Background: Micropapillary urothelial carcinoma (MUC) is a rare and aggressive histological variant with poor clinical outcomes and limited consensus regarding its management. The mainstay of treatment in muscle-invasive disease is radical cystectomy (RC). Data regarding the role of neoadjuvant chemotherapy (NAC) and adjuvant chemotherapy (AC) in muscle-invasive MUC is limited.

Methods: The United States National Cancer Database was queried for patients (pts) with MUC diagnosed from 2004 to 2018. Pts older than 18 years with cT2-4aN0-1M0 MUC who underwent RC were included. Clinical T4b/N2-3/M1 and receipt of NAC+AC were used as exclusion criteria. The pts were divided into three cohorts based on perioperative therapy- NAC, AC, and no chemotherapy (CX^-). Chi-Square and Kruskal-Wallis tests were used to compare frequency distributions. Cox Proportional Hazards regression was employed to adjust for confounders associated with overall survival (OS). Models were adjusted for age, race, sex, stage, insurance, and comorbidities.

Results: Of the 477 pts included, 80% were males, and 93% were White. 103 (21.6%) and 157 (32.9%) received NAC and AC, respectively, while 217 (45.5%) belonged to the CX^- group. Pts in the NAC & AC groups were younger (66 yrs vs 73 yrs in CX^-, $p<0.001$). OS was longer in the NAC and AC groups (Table). However, on multivariable analysis, NAC was predictive of OS (Hazard Ratio (HR) 0.68, 95% CI 0.47-0.97, $p = 0.03$) while AC was not (HR 0.84, 95% CI 0.63-1.12, $p = 0.22$). In a separate Cox model, pT0-1N0 disease was independently associated with improved OS (HR 0.27, 95% CI 0.12-0.61, $p=0.002$). The NAC group had significantly more pT0N0 (14.8% vs 2.8%, $p<0.001$) & pT0-1N0 (21% vs 5.9%, $p<0.001$) disease at RC compared to the combined cohort of AC+CX^-.

Table: 2391P

Cohort	Median OS (months)	3-year OS (%)	5-year OS (%)	Median follow-up (months)	Log-rank P
CX^-	23.1 (18.1-28.7)	40 (30-47)	34 (27-41)	68.7	0.008
AC	34.0 (25.7-59.2)	49 (40-57)	40 (31-49)	51.5	
NAC	56.4 (30.1-NR)	55 (43-65)	45 (33-57)	46.4	

Conclusions: In this large retrospective analysis, NAC was independently predictive of longer OS in muscle-invasive MUC, while AC was not. NAC was also associated with pathological downstaging.

2392P Tislelizumab combined with gemcitabine/cisplatin in muscle-invasive bladder cancer with selective bladder preservation for clinical complete response (cCR) patients: A real-world multicenter study

B. Huang[1], Z. Wang[1], B. Wang[2], D. Yuan[3], H. Lin[4], A. Xu[5], P. Liu[6], J. Chen[1]

[1]Urology Department, The First Affiliated Hospital, Sun Yat-sen University, Guangzhou, China; [2]Urology Department, The Affiliated Cancer Hospital and Institute of Guangzhou Medical University, Guangzhou, China; [3]Urology Department, Jiangmen Central Hospital, Jiangmen, China; [4]Urology Department, The Second Affiliated Hospital of Shantou University Medical College, Shantou, China; [5]Department of Urology, Zhujiang Hospital of Southern Medical University, Guangzhou, China; [6]Urology Department, The Third Affiliated Hospital of Guangzhou Medical University, Guangzhou, China

Background: Tri-modality Therapy (TMT) was a standard bladder-sparing strategy for MIBC patients (pts). Considering high costs and side-effects, pts may declined radiotherapy in clinical practice. Our study retrospectively evaluated the effectiveness and safety of maximal TURBT followed chemoimmunotherapy as bladder preservation therapy for cCR pts.

Methods: Retrospectively analyzed MIBC pts at 6 sites who declined radiotherapy. Within 2-4 weeks after maximal TURBT, pts received tislelizumab 200 mg in day 1 (D1), cisplatin 70 mg/m^2 D2, and gemcitabine 1000 mg/m^2 D1 and D8 every 3 weeks for 2-4 cycles, followed by clinical restaging. cCR was defined as normal urine cytology and MRI imaging, and bladder biopsies$\leq$cTa. Pts who achieved cCR proceeded

bladder preservation and non-cCR underwent radical cystectomy (RC). Tislelizumab was administered (200mg, Q3W) for the maintenance treatment for all pts. The primary outcome was cCR rate, and secondary outcomes were bladder intact disease-free survival (BIDFS), OS and safety.

Results: Forty-five MIBC pts enrolled between Jun. 2020 and Sep. 2022 were analyzed (median age 64 years (48-87); pure TCC 95.6%; PD-L1 negative 91.1%; cT2=57.8%, cT3=24.4%, cT4a=17.8%; cN0=82.2%, cN1=15.6%). Median follow-up was 20.14 months (5.3-26.3), the mean number of tislelizumab cycles was 3.5 and GC cycles was 3.1. The cCR rate was 64.4% (95%CI, 50.6%-78.2%), and 2-year BIDFS rate in cCR pts was 96.2% (95%CI, 89%-100%). Pts who received bladder-sparing treatment showed favorable OS compared to those underwent RC. The 2-year OS rates in bladder-sparing treatment group and RC treatment group were 100(95%CI, 100%-100%) and 63.1% (95%CI, 41.2%-96.8%), respectively. There was no significant difference between PD-L1 positive and negative pts regarding OS or BIDFS. The most common treatment-related adverse events included anemia (75.6%, 34/45), nausea ((75.6%, 34/45), rash (64.4%, 29/45), vomiting (60.0%, 27/45), and pruritus (57.8%, 26/45).

Conclusions: Maximal TURBT followed chemoimmunotherapy demonstrated the effectiveness and safety in MIBC with selective bladder preservation for cCR pts who declined radiotherapy.

Background: Ephrin ligand (EFN) and receptor (EPH) signalling is increasingly implicated in tumorigenesis. Recently, EFN-B2 and PD-L1 inhibition have demonstrated impressive synergy in metastatic UC. Using data from the ABACUS trial (NCT02662309) in muscle-invasive UC, we explore the relationship between EFN/EPH expression and response to atezolizumab.

Methods: The neoadjuvant ABACUS study design enabled transcriptomic and immunohistochemical (IHC) comparison of paired baseline and cystectomy samples. For multivariate disease-free survival (DFS) analysis, patients were grouped into high and low EFN/EPH using median expression levels. 83 patients were eligible for biomarker analysis. 64 had paired samples. 27 (33%) achieved complete pathological response and/or major pathological response and were deemed responders, and 17 (20%) relapsed.

Results: Following atezolizumab, there was reduced expression of EFN-A1 (log2FC:-0.9, $p<0.05$), EFN-A4 (log2FC:-0.8, $p<0.05$), EFN-A5 (log2FC:-0.8, $p<0.05$) and their cognate receptor EPH-A1 (log2FC:-1.7, $p<0.05$) as well as EFN-B2 (log2FC:-0.82, $p<0.05$) amongst responders, but not relapsed patients. Consequently, apart from EFN-B2, the post-treatment expression of these genes was significantly higher amongst relapsed patients than responders. High post-treatment EFN-A1 (HR: 11.9, 95%CI: 2.2 — 66.0, log-rank $p<0.01$), EFN-A4 (HR: 4.8, 95%CI: 0.9 — 25.3, log-rank $p<0.01$) and EFN-A5 (HR: 13.9, 95%CI: 2.9 — 67.9, log-rank $p<0.05$), and high baseline EFN-B2 (HR: 7.7, 95%CI: 2.1 — 27.7, log-rank $p<0.01$) expression was associated with reduced DFS. EFN-A1, EFN-A4 and EFN-A5 expression post-treatment, but not at baseline, correlated negatively with a cytotoxic T cell transcriptomic signature and granzyme B-positive CD8 T cells on IHC. EFN-B2 expression correlated positively with transcriptomic signatures of hypoxia and pathological angiogenesis.

Conclusions: EFN-A1, EFN-A4 and EFN-A5, likely through EPH-A1 signalling, are associated with reduced immune infiltrate and survival after atezolizumab, and represent promising biomarkers and targets. High baseline EFN-B2 expression is associated with relapse, supporting the addition of EFN-B2 inhibitors to augment response rates.

Clinical trial identification: NCT02662309.

Background: EV is approved in aUC pts, but Tx duration is often limited by toxicity. We investigated pt characteristics and biomarkers associated with EV-related adverse events (EV AEs).

Methods: UNITE is a multi-site retrospective study of EV-treated aUC pts; pts treated with EV alone with available AE and next-generation sequencing (NGS) data were analyzed. EV AEs were assessed per CTCAE v5.0. For univariate analyses (UVA), Wilcoxon rank sum and Chi-squared tests assessed associations between clinical features or somatic gene alterations (GA; tissue or ctDNA) occurring in $\geq$5% of pts and most common AEs and EV Tx modifications (reduction, hold, or discontinuation). Using Cox regression models, GA were evaluated individually in separate multivariate analysis (MVA) models accounting for relevant clinical factors.

Results: Among 607 pts (16 US sites), 275 had EV AEs and NGS data. At EV start: median age 71; 183 (67%) men; 244 (88%) White; 216 (79%) ECOG PS 0-1; 186 (68%) with $\geq$2 prior Tx lines. Median time from initial diagnosis to EV start was 86 weeks [IQR 48, 165]; median time from EV start to AE onset 4 weeks [IQR 2, 11]. Most common all-grade AEs: neuropathy (46%), skin tox (41%), fatigue (25%), GI tox (22%), cytopenias (14%), anorexia (11%). In UVA, diabetes (DM), prior neuropathy, higher Hgb and albumin at EV start were associated with neuropathy (all $p<0.05$); lower white blood cell count and neutrophil:lymphocyte ratio (NLR), GFR $\geq$30 with skin tox (all $p<0.01$); *TERT* GA ($p=0.04$) and lower absolute lymphocyte count with cytopenias ($p<0.01$); male sex ($p=0.03$), liver mets ($p=0.05$) and *KDM6A* GA ($p=0.04$) with anorexia. Hyperglycemia was associated with higher BMI, DM, lower NLR, male sex (all $p<0.01$). Higher BMI and lower NLR were associated with more Tx modifications in 203 pts ($p<0.05$). In MVA, *MLL2* GA was associated with cytopenias ($p=0.05$) and *KDM6A* with anorexia ($p=0.02$).

Conclusions: In EV-treated aUC pts, clinical variables and certain somatic GA were associated with common EV AEs. These hypothesis-generating findings suggest a limited role of somatic GA in predicting EV AEs, warranting further investigation of host and tumor-related factors underlying EV toxicity.

2395P Micropapillary histology (MPUC) and extra-cellular domain ERBB2 (ERBB2 ECD+) mutations in urothelial bladder cancer (UBC)

A. Sood[1], J.M. Jacob[2], G. Bratslavsky[2], P. Grivas[3], P. Spiess[4], R. Li[4], A. Necchi[5], J. Posada[6], E. Yakirevich[7], L. Cheng[8], D.C. Pavlick[9], R. Huang[9], D.I. Lin[10], N.A. Danziger[11], E.S. Sokol[9], S. Sivakumar[10], J.S. Ross[11], A. Kamat[12]

[1]Urology, MD Anderson Cancer Center, Houston, TX, USA; [2]Urology, SUNY Upstate Medical University, Houston, TX, USA; [3]Medical Oncology, University of Washington, Seattle, WA, USA; [4]Urology, H. Lee Moffitt Cancer Center & Research Institute - Magnolia Campus, Tampa, FL, USA; [5]Medical Oncology Dept., IRCCS Ospedale San Raffaele, Milan, Italy; [6]Medical Oncology, Brown University, Providence, RI, USA; [7]Medical Oncology, Lifespan Cancer Institute - Rhode Island Hospital, Providence, RI, US; [8]Pathology, Brown University, Providence, RI, USA; [9]Cancer Genomics Research, Foundation Medicine, Inc, Cambridge, MA, USA; [10]Cancer Genomics Research, Foundation Medicine, Inc., Morrisville, NC, USA; [11]Pathology Department, Foundation Medicine, Inc, Cambridge, MA, USA; [12]Urology, The University of Texas MD Anderson Cancer Center, Houston, TX, USA

Background: Given the early promising data with afatinib in advanced UC and the recent approval in NSCLC for anti-HER2 targeted therapy for activating kinase domain exon 20 *ERBB2* insertion mutations, there is considerable interest in targeting additional locations in the *ERBB2* gene in other tumor types.

Methods: 5,485 UBC were sequenced using a hybrid capture based comprehensive genomic profiling assay to assess all classes of genomic alterations (GA), tumor mutational burden (TMB), microsatellite instability (MSI), genomic loss of heterozygosity (gLOH), trinucleotide mutational signatures and genetic ancestry. PD-L1 tumor cell expression was measured by IHC (Dako 22C3). Statistical comparisons were performed using Fisher's exact tests with a Bonferonni correction.

Results: 548 (10.0%) of UBC featured *ERBB2* gene amplification (amp) and 219 (4.0%) featured an *ERBB2* ECD+ sequence mutation (74% S310F and 26% S310Y). *ERBB2* ECD mutations and *ERBB2* amplification were mutually exclusive. Central pathology review of the 219 *ERBB2* ECD+ UBC revealed that 63 (28.8%) featured a micropapillary histologic appearance (MPUC). *ERBB2* ECD+ UBC featured more patients (pts) with European genetic ancestry than both *ERBB2* WT (90.9% vs 84.2%; $p=.03$) and *ERBB2* amp (90.9% vs 83.2%; $p=.04$). *ERBB2* ECD+ UBC had higher frequency of APOBEC signature than *ERBB2* WT (82.9% vs 72.4%; $p=.03$). TMB $\geq$ 10 mut/Mb was higher in *ERBB2* amp (49.2% vs 31.4%; $p<.0001$) and *ERBB2* ECD+ (59.8% vs 31.4%; $p<.0001$) when compared to *ERBB2* WT. The main genomic differences between *ERBB2* ECD+ MPUC vs non-MPUC were in frequencies of *KMT2D* (6.4% vs 27.6%, $p=0.02$), *RB1*

(33.3% vs 17.3%, p<.0001) and *MTAP* GA (11.1% vs 26.9%, p<.0001). PD-L1 expression and MSI-High status (rare overall, 0 - 0.9%), was similar in all three groups.

Conclusions: *ERBB2* ECD mutation-driven UBC represents a distinct subtype of UBC featuring an enrichment of MPUC histology from 1-2% to 28% incidence in *ERBB2* ECD mutated UBC, and unique clinical and molecular characteristics, including differences in mutational signatures and genetic ancestry. Further exploration of anti-HER2 targeted therapy for non-amp sequence mutations in *ERBB2* in UBC appears warranted.

2396P Relationship of tumor fraction in circulating tumor DNA (ctDNA) with prognosis in patients with advanced urothelial cancer

B. Miron[1], G. Li[2], A. Clark[3], L. Pasquina[2], R.P. Graf[2], G. Oxnard[2]

[1]Department of Hematology/Oncology, Fox Chase Cancer Center, Philadelphia, PA, USA; [2]Clinical Development, Foundation Medicine, Inc., Cambridge, MA, USA; [3]Medical Affairs Department, Foundation Medicine, Inc., Cambridge, MA, USA

Background: Advanced urothelial cancer (aUC) is often characterized by rapid symptomatic disease progression, making early disease control of particular importance. Development of immunotherapy has been particularly challenging due to limited disease control rates in unselected patients. A biomarker to identify patients with a better prognosis and slower tumor growth kinetics would be of significant clinical utility to personalize therapy. Circulating tumor DNA (ctDNA) is a promising biomarker in multiple tumor types including aUC. Recent work shows that a single time-point/measurement of ctDNA tumor fraction (TF) is prognostic in several other tumor types but has not yet been investigated in aUC.

Methods: This study used a cohort of patients in the de-identified Flatiron Health-Foundation Medicine urothelial clinico-genomic database, which originated from approximately 280 US cancer clinics (∼800 sites of care), who underwent ctDNA testing as part of routine care. TF calculation on FoundationOne®LiquidCDx was based on a composite algorithm incorporating multiple factors including aneuploidy, variant allele frequency, and canonical alterations. Patient/disease characteristics, laboratory and treatment data were captured from the electronic health record. Progression-free survival (PFS) and overall survival (OS) were evaluated by TF level while controlling for relevant covariables.

Results: 83 patients with aUC were included. High ctDNA TF (≥1%) was associated with poor prognostic clinical features. High ctDNA TF also correlated with significantly reduced rwPFS in univariable analysis (hazard ratio (HR) 2.01, 1.14-3.56, p=0.01) and after correction for covariates (HR 2.37, 0.99-5.66, p=0.05). There was a trend towards shorter rwOS in univariable and multivariable analysis.

Conclusions: ctDNA TF is a prognostic biomarker in aUC with potential to inform expected longevity of patients. With further prospective validation, TF could be useful in predicting which patients with aUC have particularly aggressive disease and may enable personalized therapeutic decision-making.

2397P A real-world study of longitudinal urinary ctDNA monitoring of minimal residual disease (MRD) in patients with muscle invasive urothelial carcinoma followed in parallel with plasma based ctDNA

A. Tan

Hematology Oncology, Rush University Medical Center, Chicago, IL, USA

Background: Recently, non-invasive urine-based MRD assays have demonstrated the ability to detect deep molecular alterations in bladder cancer patients, which may greatly improve disease monitoring and treatment stratification. In this study, we carried out both tissue-informed blood and urine-informed urine based MRD tests for a cohort of 30 real-world high risk bladder and UTUC patients and studied their concordance to clinical responses.

Methods: 30 real-world bladder and UTUC patients of various subtypes were included in this study. Standard treatment modalities such as neoadjuvant chemotherapy, trimodality therapy (TMT) for bladder preservation, and systemic chemotherapy/immunotherapy were utilized. All patients with sufficient tissue had a Signatera™ blood-based MRD assay, for which FFPE tumor tissues were also tested to establish a baseline. Blood and urine samples were collected at variable intervals depending on the treatment regimens the patients received. The urine samples were tested using the PredicineBEACON™ urine MRD assay, which used the urine PredicineWES+™ whole exome sequencing results of the baseline urine sample for the design of personalize MRD panel tracking up to 50 mutations in addition to a fixed panel of 500 actionable mutations.

Results: The urine based MRD test had over a 90% testing success rate in detection of molecular alterations specific to urinary tract tumors. The tumor fraction (TF) estimate and kinetics from the urine MRD assay were in high concordance with the blood MRD assay results along with treatment responses and progression events in most cases. In several patients, the urine-based MRD assay detected mutations that were not detected in baseline tissue or blood based testing.

Conclusions: Urine-based MRD assays had highly concordance with blood based MRD. Besides its convenience in sample collection, urine-based genomic profiling also has the potential to capture more heterogeneity of urinary tract malignancies as compared to tissue or blood based testing alone. Urine ctDNA monitoring is a useful complementary test to support standard tissue and plasma based assays in high risk bladder and UTUC patients.

2398P Are fibroblast growth factor receptor 3 (FGFR3) alterations a possible predictive factor for platinum-based chemotherapy and immunotherapy in metastatic urothelial carcinoma (MUC)?

L. Ferrer-Mileo[1], A. Rodriguez Hernandez[2], C. Aversa[1], L. Rodríguez-Carunchio[3], I. Ribera[3], I. Trias Puigsureda[3], L. Oliva[4], N. Jimenez Blasco[5], S. García-Esteve[5], M. Álvarez[4], M. Rabella[4], B. Mellado Gonzalez[1], O. Reig Torras[1]

[1]Department of Medical Oncology, IDIBAPS, Hospital Clinic of Barcelona, Barcelona, Spain; [2]Oncology Department, Hospital Clinic y Provincial de Barcelona, Barcelona, Spain; [3]Pathology Department, Hospital Clinic y Provincial de Barcelona, Barcelona, Spain; [4]Oncologia Medica, Fundació Clínic per a la Recerca Biomedica, Barcelona, Spain; [5]Fundació de Recerca Clínic Barcelona - Institut d'Investigacions Biomèdiques August Pi i Sunyer (FRCB-IDIBAPS), Translational Genomics and Targeted Therapeutics in Solid Tumors Lab, Barcelona, Spain

Background: FGFR3 is associated to proliferation, differentiation and cellular growth. FGFR3 alterations are present in 25% of patients (pts) with MUC and FGFR3 inhibition is an active targeted therapy. However, the role of FGFR3 alterations in patients' clinical outcomes and response to conventional treatment is unclear and no preclinical evidence is available.

Methods: Unicenter retrospective study was performed to explore the correlation between FGFR3 alterations and response rate (ORR), progression free survival (PFS) and overall survival (OS) to platinum-based therapies or immunotherapy. Enrolled pts were diagnosed with muscle-invasive urothelial cancer (MIUC) between 2/2009- 3/2022 at Clinic Hospital of Barcelona, Spain. All were screened for FGFR-3 alterations using next-generation sequencing, qualitative real-time polymerase chain reaction-based assays or RNA-ISH in tumour and/or blood. Demographics, pathology, treatments outcomes were collected retrospectively.

Results: 189 pts with MIUC were included: 74.6% were men, median age was 68.5 (37.6-89.7y). Clinical stage at diagnosis was: 10% II, 44% III, 46% IV. Median follow-up since metastatic disease diagnosis was 16.2 months (0.3-91m). 77% of pts had died at data cut-off. 25.4% had FGFR3 alterations (mutation= 36; fusion= 6; double alteration= 3; RNA-ISH amplification =3). FGFR3 altered (FGFR3-alt) tumours were enriched with papillary histology compared with FGFR3 wild type (FGFR3-wt) (33 vs

11%, p<0.05). No statistical differences were detected in other baseline characteristics. 66.5% (N=113) pts received 1st-line platinum-based chemotherapy (1st PT) and 58% (N=69) 2nd-line immunotherapy (2nd IO). No statistically significant differences were detected in OS (15.2 vs 17.5m), PFS (5.6 vs 7.2m), ORR (62 vs 55%) for pts treated with 1st PT according to FGFR3-alt or FGFR3-wt. In 2nd IO, FGFR3-alt had less ORR than FGFR3-wt (9 vs 41%)(p=0.32) and no statistically significant differences in OS (9.7 vs 12.1m) or PFS (3 vs 3.9m) were observed.

Conclusions: In our cohort, FGFR3 alterations are neither predictive nor prognostic for 1st-line platinum or 2nd-line IO. Further investigation is needed.

2399P Circulating tumor DNA and urine tumor DNA detection of minimal residual disease in upper tract urothelial carcinoma with radical nephroureterectomy: A cohort study

W. Xue[1], X. Cui[2], X. Pan[2], Q. Hao[3], L. Guo[3], F. Pang[3], J. Huang[1]

[1]Department of Urology, Renji Hospital Affiliated to Shanghai Jiao Tong University School of Medicine, Shanghai, China; [2]Department of Urology, Xinhua Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, China; [3]Medical Department, Shanghai OrigiMed Co., Ltd, Shanghai, China

Background: Upper tract urothelial carcinoma (UTUC) is an aggressive disease with poor prognosis that is often diagnosed late. At present, circulating tumor DNA-based minimal residual disease (MRD) has been studied in blood from varies solid tumors but its clinical value in monitoring urinary tumor DNA (utDNA) during adjuvant therapy in postoperative UTUC remains unclear.ma va.

Methods: The OriMIRACLE S™ MRD assay (OrigiMed, Shanghai, China) uses whole exome sequencing (WES) for detecting patient-specific somatic alterations from tumor tissues and for blood a personalized panel.

Results: Nineteen patients with stage II UTUC were enrolled in this study, excluding one death due to COVID-19. By monitoring ctDNA and utDNA, the baseline positive rates were 69.2% (9/13) and 88.9% (8/9), respectively. One month after surgery/before adjuvant therapy, the positive rates of ctDNA and utDNA decreased to 46.2% (6/13) and 21.4% (3/14), respectively. During adjuvant chemotherapy/6 months after immunotherapy, the positive rates of ctDNA and utDNA further decreased to 35.7% (4/14) and 21.4% (3/14), respectively. At the end of adjuvant chemotherapy/12 months after immunotherapy, the positive rates of ctDNA and utDNA were 36.4% (4/11) and 11.1% (1/9), respectively. At the 6-month follow-up, the positive rates of ctDNA and utDNA were both 25% (1/4). Three patients experienced disease recurrence. One of them tested negative for ctDNA twice in a row and positive for utDNA. Half a month later, the patient underwent cystoscopy and was found to have a bladder full of hair-like and carpet-like new organisms, indicating intravesical recurrence. A patient tested positive for ctDNA twice in a row, but negative for utDNA, and reexamination suggested recurrence. The third patient had positive results for both ctDNA and utDNA, and PET-CT indicated the possibility of tumor metastasis and recurrence.

Conclusions: Our preliminary results suggest ctDNA combined with utDNA detection can serve as predictive biomarkers for UTUC recurrence and can enable the prediction of adjuvant therapy efficacy.

Clinical trial identification: RenJiH-PDU Trial.

Lee Moffitt Cancer Center & Research Institute - Magnolia Campus, Tampa, FL, USA; [7]Oncology Department, IRCCS Ospedale San Raffaele, Milan, Italy; [8]Urology, The University of Texas MD Anderson Cancer Center, Houston, TX, USA; [9]Cancer Genomics Research, Foundation Medicine, Inc, Cambridge, MA, USA; [10]Pathology Department, Foundation Medicine, Inc, Cambridge, MA, USA; [11]Pathology Department, Foundation Medicine, Inc., Morrisville, NC, USA; [12]Departments of Pathology and Urology, Foundation Medicine, Inc./SUNY Upstate Medical University, Syracuse, NY, USA; [13]University of Washington, Fred Hutchinson Cancer Center, Seattle, WA, USA

Background: *ERBB2* overexpression is an oncogenic driver in many solid tumors, including UBC. Activating mutations (mut) in *ERBB2* gene were shown to play an oncogenic role relatively like *ERBB2* amplification (amp). We describe and compare the frequency and nature of GA of *ERBB2*-altered (mut, amp) and *ERBB2* wildtype (wt) UBC.

Methods: Using a hybrid capture based comprehensive profiling (CGP) assay, 9,518 UBC cases were evaluated for all classes of GA, tumor mutational burden (TMB), microsatellite instability (MSI), genomic loss of heterozygosity (gLOH), and genomic mutational signature. PD-L1 expression was measured by IHC (Dako 22C3). Statistical comparisons were performed using Fisher's exact tests.

Results: 602 (6.3%) UBC featured *ERBB2* extra-cellular domain (ECD) short variant (SV) GA (ECDmut), 253 (2.7%) UBC featured *ERBB2* kinase domain (KD) SV GA (KDmut); 866 (9.1%) had *ERBB2* amp; 7,797 (81.9%) UBC were *ERBB2*wt. The GA/tumor was higher in all *ERBB2* GA groups vs *ERBB2*wt. European genetic ancestry of ECDmut+ was higher than *ERBB2*wt (p=.02). *CDKN2A/MTAP* loss were more frequent in *ERBB2*wt vs ECDmut and amp only (both p<.0001). *ERBB3* GA was more frequent in ECDmut and KDmut than *ERBB2*wt (both p<.0001). *TERT* GA were more frequent in ECDmut, KDmut and amp vs *ERBB2*wt (all p<.0001). *TOP2A* amp and *TP53* SV GA were significantly higher in *ERBB2* amp vs *ERBB2*wt, ECDmut and KDmut (p<.0001). Mean TMB levels were significantly higher in ECDmut, KDmut and amp than in *ERBB2* wt (all comparisons p<.0001). APOBEC signature was more frequent in ECDmut, KDmut and amp vs *ERBB2*wt (p<.0001). No significant differences in PD-L1 status, MSI-high or gLOH between altered & wt subgroups. The table summarizes key findings.

Conclusions: We noted important differences in co-occurrent-GA in *ERBB2*-altered (ECDmut, KDmut, amp) vs wt UBC, and higher mean TMB and higher APOBEC mut signature in the *ERBB2*-altered group. Results can help refine future clinical trial designs and help elucidate possible resistance mechanisms for *ERBB2*-altered UBC.

2401P Detection of molecular recurrence in early-stage bladder cancer patients using a urinary tumor DNA assay after transurethral resection of bladder tumor (TURBT)

R. Zhang[1], H. Tang[2], J. Zang[1], D. Jin[1], L. Qian[1], T. Zhang[1], F. Xie[2], Y. Zhang[2], X. Zhang[2], S. Jia[2], G. Zhuang[1], H. Chen[1]

[1]Department of Urology, Renji Hospital Affiliated to Shanghai Jiaotong University School of Medicine, Shanghai, China; [2]Translational Medicine, Huidu (Shanghai) Medical Technology Co., Ltd., Shanghai, China

Background: Transurethral resection of bladder tumor (TURBT) is the primary treatment for early-stage bladder cancer, and early detection of tumor recurrence is vital for improving patient outcome. Non-invasive and reliable methods for monitoring molecular changes in urine represent a promising avenue to facilitate timely intervention and effective disease management.

Methods: In this ongoing prospective study, 95 patients with early-stage bladder cancer were recruited, whose urine samples were collected prior to TURBT. Afterward, patients were advised to provide urine samples during follow-up visits. PredicineCARE, a targeted next-generation sequencing (NGS) liquid biopsy assay, was employed to identify somatic alterations in urinary tumor DNA (utDNA). Based on these alterations, the tumor fraction was assessed to identify molecular recurrence in the patients.

Results: Out of the 95 patients, 48 were diagnosed with non-muscle invasive bladder cancer (NMIBC) and 47 with muscle invasive bladder cancer (MIBC). The genes that showed the most frequent variations in NMIBC patients were *TP53* (54%), *TERT* (46%), *FGFR3* (31%), *ERCC2* (31%), *ARID1A* (31%), and *CDKN2A* (31%). Meanwhile, in MIBC, the most frequently varied genes were *TP53* (74%), *TERT* (47%), *PIK3CA* (32%), and *KDM6A* (32%). 38.5% of NMIBC patients and 26.3% of MIBC patients harbored *FGFR2/3* variations, suggesting that they could potentially benefit from FGFR inhibitors. Among the 29 patients with follow-up data, longitudinal urine samples of 12 patients (2 NMIBC, 10 MIBC) were tested. Nine patients (2 NMIBC, 7 MIBC) showed a significant decrease in tumor fraction, one (MIBC) remained stable, and two patients (MIBC) exhibited increasing tumor fraction, indicating molecular recurrence of the disease.

Conclusions: The results of this study confirm the validity of utilizing a utDNA assay to detect molecular recurrence in early-stage bladder cancer patients who have undergone TURBT treatment, which can be instrumental in facilitating early detection of tumor recurrence and guiding treatment decisions. These findings underscore the enormous potential of urine-based NGS assays for urothelial cancer detection and disease surveillance.

2402P Urine-based comprehensive genomic profiling reveals mutational landscape in real-world patients with bladder cancer

H. Chen[1], R. Zhang[1], H. Tang[2], J. Zang[1], D. Jin[1], L. Qian[1], T. Zhang[1], F. Xie[2], X. Zhang[2], Y. Zhang[2], S. Jia[2], G. Zhuang[1]

[1]Department of Urology, Renji Hospital Affiliated to Shanghai Jiaotong University School of Medicine, Shanghai, China; [2]Translational Medicine, Huidu (Shanghai) Medical Technology Co., Ltd., Shanghai, China

Background: Bladder cancer is the most prevalent form of urothelial carcinoma. There is an urgent need for timely and accurate identification of molecular alterations to guide tailored therapeutic treatment. Urinary tumor DNA (utDNA) analysis not only holds promise as a valuable tool in bladder cancer diagnosis and monitoring, but also has the potential to identify actionable mutations that can be targeted with personalized therapies.

Methods: This prospective study enrolled 154 patients with bladder cancer in real-world settings, comprising 65 patients with non-muscle invasive bladder cancer (NMIBC) and 89 patients with muscle invasive bladder cancer (MIBC). The cohort included treatment-naive patients as well as those who had received treatment and were at risk of recurrence. Urine samples were collected from each patient. PredicineCARE, a NGS liquid biopsy assay, was applied to detect somatic alterations in urinary tumor DNA (utDNA).

Results: The study detected a total of 368 somatic mutations and 14 copy number variants in 65 NMIBC patients, and 485 somatic mutations and 43 copy number variants in 89 MIBC patients. Among NMIBC patients, the most frequently mutated genes were *TP53* (38%), *TERT* (37%), *ARID1A* (22%), and *BRCA2* (20%). Among MIBC patients, the most frequently mutated genes were *TP53* (57%), *TERT* (39%), *ERBB2* (24%), *ARID1A* (20%), and *PIK3CA* (20%). The prevalence of FGFR2/3 variations was 15% in NMIBC and 13% in MIBC among all patients, while 38.5% of NMIBC patients and 26.3% of MIBC patients who were confirmed to be treatment-naïve harbored FGFR2/3 variations. The prevalence of *ERBB2* and *TP53* mutations was significantly higher in MIBC than in NMIBC (*ERBB2*: 21/89 vs. 4/65, $p<0.01$; *TP53*: 51/89 vs. 25/65, $p<0.05$). Conversely, the prevalence of *RARA* was significantly higher in NMIBC than in MIBC (5/65 vs. 0/89, $p<0.05$).

Conclusions: The present study unveils a comprehensive mutational landscape of non-muscle invasive bladder cancer (NMIBC) and muscle invasive bladder cancer (MIBC) utilizing urine samples from real-world patients. These results demonstrate the promising potential of urine-based next-generation sequencing (NGS) assays to identify tumor-derived variants for clinical diagnosis and targeted treatment.

Background: Deletion of CDKN2A, encoded for the tumor suppressor protein p16, represents a common cause for reduced or absent of p16 expression in tumor cells. In this study, we analyzed the impact of CDKN2A deletion on tumor aggressiveness, patient prognosis, and p16 expression in patients with urothelial bladder carcinomas.

Methods: CDKN2A copy number status was analyzed by fluorescence *in-situ* hybridization (FISH) on more than 2,500 urothelial bladder carcinomas in a tissue microarray format. Data of CDKN2A deletion were compared with p16 expression data measured by immunohistochemistry in a previous study. The results were compared with parameters of tumor phenotype and patient outcome.

Results: CDKN2A deletions occurred in 28% of 1,880 analyzable carcinomas, including 9% heterozygous and 19% homozygous CDKN2A deletions. The CDKN2A deletion rate, especially for homozygous deletions, increased from pTa G2 low (14%), to pTa G2 high (35%) but slightly decreased in pTa G3 (20%) carcinomas ($p<0.0001$). In muscle-invasive urothelial carcinomas, especially homozygous CDKN2A deletions were associated with advanced pT stage ($p<0.0001$), but unrelated to patient prognosis. However, in the subset of pT4 urothelial bladder carcinomas, a tendency for shorter overall survival for patients with CDKN2A deleted tumors was found ($p=0.0828$). CDKN2A deletions were significantly associated with p16 immunostaining ($p<0.0001$). Cancers without p16 immunostaining harbored in 62% of all cases a CDKN2A deletion and 97% of 343 homozygous CDKN2A deleted cancers were p16 negative. Cancers with CDKN2A deletion and negative p16 immunostaining were associated with advanced stage ($p<0.0001$) but unrelated to patient prognosis in muscle-invasive urothelial carcinomas.

Conclusions: CDKN2A deletions were most commonly seen in p16-negative carcinomas, supporting their role for p16 inactivation in urothelial bladder carcinomas. The association of CDKN2A deletion — especially homozygous deletion — with advanced stage may reflect increasing genomic instability going along with stage progression.

2404P Concordance of genomic alterations by next-generation sequencing in tumor tissue versus urinary tumor DNA and circulating tumor DNA in bladder cancer

S. Xue[1], N. Li[2], Y. Qiu[3], J. Qin[3], S. Cao[4]

[1]Department of Urology, General Hospital of Eastern Theater Command, Nanjing, China; [2]Department of General Surgery, General Hospital of Eastern Theater Command, Nanjing, China; [3]Medical Department, Beijing Acornmed Biotechnology Co., Ltd., Beijing, China; [4]President Office, Beijing Acornmed Biotechnology Co., Ltd., Beijing, China

Background: The current gold standard for diagnosing and monitoring bladder cancer is cystoscopy, but its application is restricted due to invasiveness and high cost. Liquid biopsy has gained widespread attention recently because of its non-invasive, convenient access, and convenient for real-time monitoring. This study aimed to explore the consistency of genomic alterations of bladder cancer detected by urine and blood with their paired tissue to evaluate the potential of liquid biopsy in the real world.

Methods: For this analysis, we included 20 bladder cancer patients with all their tissue, blood, and urine samples. The next-generation sequencing technology was used to detect the mutated genes of 60 obtained samples via the Acornmed panel with 808 cancer-related genes. The average sequencing depth was >10,000x, and the coverage was 95%.

Results: A total of 60 samples from 20 patients were tested in this study. In 90% (18/20) of patients, at least one concordance mutation was detected in both tissue DNA and urinary tumor DNA(utDNA), while at least one concordance mutation was detected in both ctDNA and tDNA in 80% (16/20) of patients. A total of 357 mutated genes were detected in all tissue samples, and 202 mutated genes were detected in all urine samples, of which 179 (88.6%) genes were also detected in tissue DNA. A total of 148 mutated genes were detected in all blood samples, of which 109 (73.6%) genes were also detected in tissue DNA. A total of 75 genes were detected in the three samples, of which 12 (16%) were clinically available genes that could be found in the OncoKB database. The Top 5 frequently mutated genes in tDNA were TERT (50%), TP53 (45%), FAT (35%), LRP1B (35%), and PIK3CA (30%), whereas the Top 5 mutant genes detected in utDNA were TERT (40%), TP53 (30%), KMT2D (25%), NOTCH4 (20%), and PIK3CA (15%), in ctDNA were ATRX (15%), IRS2 (15%), NOTCH4 (15%), ZFHX3 (15%), and KMT2D (10%).

Conclusions: Results of this study show that liquid biopsies represented by urine and blood overlap with the genomic results of tissues, suggesting that utDNA and ctDNA may have potential applications in patients with bladder cancer who have no tumor tissue available, offering similar profiles of genomic alterations of tumor tissues.

2405P Prognostic significance of circulating tumor DNA in patients with urothelial carcinoma: A systematic review and meta-analysis

L. Haoyang[1], J. Chen[1], Y. Huang[2], H. Zeng[1]

[1]Urology, West China Hospital, Sichuan University, Chengdu, China; [2]Cardiothoracic Surgery, West China Hospital, Sichuan University, Chengdu, China

Background: At present, the prognostic stratification of urothelial carcinoma(UC) patients heavily relies on tumor staging, which is limited by the quality of the tissue samples assessed. Recently, circulating tumor DNA(ctDNA) has shown potential as a molecular tool for the diagnosis, staging, and prognosis of UC. We aimed to conduct a systematic review and meta-analysis to evaluate the prognostic value of ctDNA in patients with UC.

Methods: The MEDLINE, EMBASE, and the Cochrane Library databases were searched from the inception to March 2023 to identify studies investigating the relationship between detection of ctDNA and clinical outcomes in patients with UC. Hazard ratios (HRs) of disease-free survival (DFS) and overall survival (OS) were extracted and meta-analysis was performed using the R software (version 4.2.1).

Results: Twelve studies with 1844 patients were ultimately included in this meta-analysis. Ten studies assessed the relationship between baseline ctDNA detection and patient outcomes. Patients with an elevated ctDNA level exhibited significantly worse DFS (HR=6.22; 95% CI, 3.78-10.25, p<0.001) and OS (HR=4.09; 95% CI, 3.02-7.96, p<0.001). Similar results were observed in subgroup analyses in patients with muscle-invasive UC and metastatic UC, respectively. Four studies evaluated the prognostic value of ctDNA dynamics during treatment or observation. Patients who exhibited a decrease or clearance in ctDNA levels demonstrated a more favorable DFS (HR=0.31, 95% CI, 0.16—0.59, p=0.0003) and OS (HR=0.24, 95% CI, 0.14—0.43,P<0.001) compared to those who did not.

Conclusions: Our meta-analysis demonstrated a robust correlation between levels of plasma ctDNA at baseline/during treatment and oncologic outcomes in patients with UC. These findings indicate that plasma ctDNA offers substantial clinical utility in the risk stratification and personalized prognosis of patients.

Clinical trial identification: The protocol for this review is registered on PROSPERO (CRD42023414380).

Background: Advanced penile squamous cell carcinoma (PSCC) is a rare disease, with limited treatment options and poor prognosis. Although PD-1 blockade demonstrated some activity in PSCC patients (pts), response rate is modest. Preclinical data suggests that vorinostat (V), an HDAC inhibitor, might improve immunotherapy efficacy by modulating the epigenome.

Methods: PEVOsq is an open-label, non-randomized, multi-center, basket phase II trial, evaluating the efficacy of pembrolizumab (P) in combination with V in pts with recurrent and/or metastatic squamous carcinomas. Pts had to be PD1/PD-L1 antagonist-naïve with no restriction in terms of prior lines of treatments. P dose was 200 mg Q3W IV, and V 400 mg QD PO. Sample size was determined using an A'Hern design with the following hypotheses (alpha=10%, power=85%, p0=5%, p1=30%). Primary endpoint was objective response rate (ORR) according to RECIST 1.1 Secondary endpoints included safety, progression-free survival (PFS), overall survival (OS), and duration of response (DOR).

Results: Among 112 included pts, 11 pts with penis cancer were evaluable for safety and efficacy. Median age was 71 years old [range: 39-82]. Median number of prior lines of therapies was 1 [range: 0-2]. Two pts (18.2%) had an objective response. Median PFS and OS were 2.4 [95%CI: 0.5-4.1] and 4.4 months [95%CI: 1.6-11.0], respectively. Five (45.5%) pts developed G3/4 treatment related adverse events. P and V were stopped for toxicity in 10.0% and 27.3% of pts, respectively. 54.5% of pts had a dose-reduced of V for toxicity including hematotoxicity, gastrointestinal toxicity, asthenia, and creatinine increase. Results according to PDL1, MSI, TMB and HPV will be presented at the meeting.

Conclusions: P combined with V produced limited efficacy in advanced PSCC pts and was associated with substantial toxicity.

Clinical trial identification: NCT04357873; EudraCT 2019-003839-33.

Background: Standard of care for pts with HR NMIBC is transurethral resection of bladder tumor (TURBT; biopsy only for carcinoma in situ pts) followed by intravesical BCG. However, BCG is associated with toxicities and supply shortages and lacks a durable response in a significant proportion of pts. TAR-200 is an intravesical drug delivery system that provides local continuous gemcitabine release within the bladder. Preliminary data from SunRISe-1 (AUA 2023, NCT04640623) support further investigation of TAR-200 with or without CET in pts with BCG-naive HR NMIBC. SunRISe-3 (NCT05714202) is an open-label, multicenter, randomized phase 3 study assessing efficacy and safety of TAR-200 + CET or TAR-200 vs BCG in pts with BCG-naive HR NMIBC.

Trial design: Eligibility: $\geq$18 y, ECOG PS 0, 1, or 2, histologically confirmed HR NMIBC (high grade Ta, any T1 or CIS) in BCG-naive pts (no prior BCG or stopped $>$3 y prior to randomization). All papillary disease must be fully resected prior to randomization. Pts (N$\approx$1050) are randomized 1:1:1 to receive TAR-200 + CET (Group A), TAR-200 (Group C) or BCG (Group B). In Groups A and C, TAR-200 (225 mg gemcitabine) is dosed Q3W during an induction phase, then Q12W during a maintenance phase. In Group B, BCG is dosed QW for 6 wks and QW for 3 wks at Wks 12, 24, 48, 72, and 96. Pts may continue in Y3 at investigator discretion. Disease recurrence or progression assessments are by cystoscopy, urine cytology, TURBT/bladder biopsy, and CT/MR urography. The primary end point is event-free survival (time from randomization to HR disease first recurrence [high grade Ta, any T1 or CIS], progression or any-cause death, persistent disease at 6 mo in CIS pts). Progression is defined as increase of stage (Ta to T1, or CIS to T1) or progression to MIBC (T $\geq$2 or to N+ or M+ disease). Secondary end points include overall complete response rate (CIS only), recurrence-free survival, time to progression, overall survival, cancer-specific survival, safety, and pt-reported outcomes. As of May 3, 2023, 1 pt has been randomized, with 16 in screening; recruitment is planned at 254 sites.

2408TiP DISCUS: A randomised phase II study of 3 vs 6 cycles of chemotherapy followed by maintenance avelumab in advanced urothelial cancer - Wearable devices and circulating biomarkers assessing quality of life and surrogate efficacy endpoints

F. Jackson-Spence[1], A. Pinto Marin[2], J. Puente[3], J. Molina-Cerrillo[4], S.A. Hussain[5], C. Ackerman[6], N. Bonsu[1], J. Kelly[7], Y. Loriot[8], T.B. Powles[9], E. Grande Pulido[10]

Medical Oncology, Hospital Universitario La Paz, Madrid, Spain; [3]Dept. Medical Oncology, Hospital Clinico Universitario San Carlos, Madrid, Spain; [4]Medical Oncology, Hospital Universitario Ramon y Cajal, Madrid, Spain; [5]Medical Oncology, Sheffield Teaching Hospitals NHS Trust, Sheffield, UK; [6]Clinical Research, Barts ECMC, London, UK; [7]Urology, UCLH - University College London Hospitals NHS Foundation Trust, London, UK; [8]Drug Development Department (DITEP), Gustave Roussy - Cancer Campus, Villejuif, France; [9]Experimental Cancer Medicine Centre, Barts Cancer Institute, Queen Mary University of London, St Bartholomew's Hospital, London, UK; [10]Medical Oncology Department, MD Anderson Cancer Center Madrid, Madrid, Spain

Background: DISCUS (EudraCT2021-001975-17) is a randomised phase III trial comparing 3 vs 6 cycles of first-line CT, followed by maintenance avelumab on the QoL of patients with aUC. Fewer cycles of CT may be associated with better quality of life (QoL) and improve efficacy, as more patients will be exposed to immune checkpoint inhibitors. Wearable devices are a novel method of assessment of QoL for patients receiving systemic anticancer therapy (SACT) and may have advantages over existing methods such as EORTC-QLQ-C30 questionnaires. This is being tested in the DISCUS trial. Recent work demonstrates that normalisation of ctDNA is associated with better outcomes in the adjuvant setting. Dynamic changes in ctDNA will also be tested in this study. Tracking ctDNA may be able to identify mechanisms of resistance to SACT.

Trial design: Patients enrolled in the ongoing DISCUS trial can consent this exploratory sub study, investigating the role of ctDNA and digital wearable device data in assessing QOL in aUC patients receiving SACT. Patient reported outcomes (PROs) on QOL will be correlated with biometric data from wearable devices, tracking step counts, heart rate and peripheral oximetry. Participants will be required to wear the device for 8 hours per day, at least once per treatment cycle, between cycle 1-6 (C1-6) and 8-12 weeks after C6. Average daily step counts at C6 will be compared between groups and correlated to adverse events and PROs. ctDNA measurement will occur at baseline, C3,6 and 8-12-weeks after C6. ctDNA assessment will be conducted using a personalised approach, using whole exome sequencing to track $>$2 mutations from the primary tumour (Natera) and will be compared to radiological assessment and correlated with efficacy outcomes. ctDNA may be more accurate in assessing outcomes than radiology. Shorter periods of CT may be associated with better QoL for patients without affecting efficacy. ctDNA and wearable devices is a step towards personalised medicine for these patients.

Background: Platinum-based chemo is the standard of care for the majority of pts with previously untreated mUC. Treatment options for pts ineligible for any platinum are not well defined and include PD-1 or PD-L1 immune checkpoint inhibitors (CPIs) or other regimens such as single-agent chemo, depending on clinical considerations. Because many pts treated with CPIs do not experience durable clinical benefit, additional treatments are needed to mitigate resistance and improve pt outcomes. Combinations targeting novel checkpoints (e.g., LAG3, TIGIT) are attractive as they address distinct resistance mechanisms that could expand the number of pts who respond to CPIs, while also potentially offering a tolerable benefit-risk profile. Tobe is a novel bispecific antibody with monovalent binding to PD-1 and LAG3, and tira is an antibody that binds TIGIT. In this trial, efficacy and safety of atezo (Arm A, control) vs tobe (Arm B) or tobe + tira (Arm C) will be evaluated as first-line (1L) therapy in platinum-ineligible pts with mUC.

Trial design: Approximately 240 pts aged $\geq$18 y with locally advanced or metastatic UC, measurable disease and available tumour sample will be enrolled across 15 countries and 83 sites. Pts must have no prior CPIs or 1L systemic therapy. Pts must be platinum ineligible based on one of the following criteria: (1) ECOG PS 0 with GFR 15-30 mL/min/1.73 m^2; (2) ECOG PS 1-2 with GFR 15-45 mL/min/1.73 m^2; (3) ECOG PS 0-2 with Grade $\geq$2 neuropathy or (4) chemo not deemed appropriate per investigator. Pts will be randomised 1:1:1 to receive atezo 1200 mg IV, tobe 600 mg IV or tobe 600 mg IV + tira 600 mg IV Q3W until loss of clinical benefit or unacceptable toxicity. Randomisation will be stratified by PD-L1 expression per VENTANA SP263 (investigational) (positive [tumour area positivity, TAP$\geq$5% vs negative [TAP$<$5%]), baseline liver metastases (yes vs no; 15% cap), and ECOG PS (0 vs 1 or 2). This study will evaluate the effect of tobe and tobe + tira on investigator-assessed confirmed ORR (primary endpoint) relative to atezo. Secondary endpoints include PFS, OS, DOR, DCR and safety.

Clinical trial identification: NCT05645692.

ESMO GOOD SCIENCE BETTER MEDICINE BEST PRACTICE

ANNALS OF ONCOLOGY driving innovation in oncology

CANCER NURSING: EHEALTH AND DIGITAL INNOVATIONS

CN1 Integrating an electronic patient reported outcome measure (ePROM) into a nurse-led rare cancer pathway

J. Ireson[1], T. Holch[2], D. Greenfield[3], K. Singh[1], S. Gillett[1], S. Rollins[1], S. Radley[4], J. Tidy[1], G. Jones[2]

[1]Sheffield Trophoblastic Screening and Treatment Centre, Weston Park Hospital - Sheffield Teaching Hospitals NHS Foundation Trust, Sheffield, UK; [2]Centre for Psychological Research, Leeds Beckett University, Leeds, UK; [3]Weston Park Hospital, Sheffield Teaching Hospitals NHS Foundation Trust, Sheffield, UK; [4]Royal Hallamshire Hospital, Sheffield Teaching Hospitals NHS Foundation Trust, Sheffield, UK

Background: The use of ePROMs in clinical practice has the potential to generate population level patient-reported outcome data alongside promoting patient-centred care and improving patients' quality of life. Individualised PROMs may be particularly helpful in identifying, prioritising, and discussing health concerns, yet little research in cancer nursing has evaluated this. Gestational Trophoblastic Disease (GTD) is a rare complication of pregnancy that can present as or turn into cancer. This nurse-led research group has recently developed a GTD specific ePROM (ePAQ-GTD) that has been integrated into the GTD pathway to support population level research and deliver tailored virtual nurse-led patient centred care.

Methods: From January 2020, ePAQ-GTD and a new nurse-led virtual clinic were offered to all GTD patients at a regional GTD centre at referral, start of treatment, end of treatment, 6 weeks, 6 months, and yearly post chemotherapy. Feedback of ePAQ-GTD responses were provided ahead of the clinic in the form of an electronic summary report. Reflexive thematic analysis of qualitative interviews with a purposive sample of GTD patients (n=15) and GTD nurses (n=3) was conducted for an in-depth evaluation of ePAQ-GTD's use as an outcome measure used routinely in clinical practice.

Results: The results of the analysis identified three key themes, firstly that patients and staff found ePAQ-GTD demonstrated content validity and was a relevant and acceptable tool to capture the impact of GTD and its treatment from the patient perspective. Secondly, ePAQ-GTD facilitated and enabled important discussions to happen in the virtual nurse-led clinic, especially around taboo subjects such as sexual dysfunction and mental health emphasising its comprehensiveness and patient-centredness. Lastly, the feedback of ePAQ-GTD results in the context of a nurse-led clinic was linked to improvements in wellbeing through improved communication, empowerment and decision making.

Conclusions: Findings suggest ePAQ-GTD has content validity as an outcome measure. The feedback of ePAQ-GTD results in a virtual nurse-led clinic also shows benefits in relation to communication, empowerment and decision making when integrated into a nurse-led cancer pathway for GTD.

CN2 BioVirtualPed: A biofeedback based virtual reality game for pediatric patients

E.H. Savaş[1], R. Semerci[2], A. Sayın[3], B. Dinçer[3], B. Semiz[3], H. Urey[3]

[1]Graduate School of Health Sciences, Koc University, Istanbul, Turkey; [2]Nursing Faculty, Koc University, Istanbul, Turkey; [3]Engineering, Engineering Faculty, Istanbul, Turkey

Background: The management of pain, fear, and anxiety in pediatric oncology patients has always been a significant challenge in the field of healthcare. Medical procedures, especially those involving port catheter needle exchanges, can be distressing and overwhelming for young patients. To address this issue, the initial aim of the study is to develop BioVirtualPed, a cutting-edge virtual reality game designed specifically for pediatric patients undergoing these treatments. Second is the evaluation of the BioVirtualPed's validity and clinical feasibility.

Methods: BioVirtualPed game was made with Unity engine, using ADXL35 accelerometer to collect respiratory data, transferred to the game with ArdunioUno software. Oculus Quest 2 headset monitored the scenario. A feasibility study involved 15 children aged 6-12, data was collected with various forms and scales including the demographic information form, Wong-Baker Pain Rating Scale, Child Fear Scale, Child Anxiety Scale-State, BioVirtualPed Evaluation Form, and Mobile Application Usability Scale.

Results: For validity, detecting respiratory data, enables the game to respond effectively to the user's breath patterns. The Unity game engine successfully integrated the respiratory data, allowing for seamless interaction between the user's breath and the game's bio-responsive elements. For clinical feasibility, the participants found the Oculus Quest 2 headset to be comfortable and easy to wear, with minimal adjustments required for a proper fit. The participants were able to follow the game's instructions and achieve the desired breathing patterns effectively. For User experience, the pediatric patients reported a positive experience with the BioVirtualPed game. They expressed increased relaxation and reduced feelings of pain, fear, and anxiety during the port catheter needle exchange procedure.

Conclusions: By incorporating bio-responsive elements that react to the user's breathing patterns, the game offers an innovative way to teach young patients how to self-regulate their breathing in a fun and engaging manner. This allows them to achieve a relaxed state, which in turn helps to alleviate pain, fear, and anxiety during medical procedures.

Background: PROM platforms, characterized by systematic collection of symptoms and quality of life data, enable timely reactions of health care professionals (HCPs) in trial and routine care settings. The "KAIKU" platform provides a novel algorithm-based approach of converting PROM into safety alerts enabling severity-driven communication between patients and HCPs. In KAIKU's immunotherapy module, patients are interviewed weekly of potential immune-related adverse events. In this study, we investigated if patient adherence to digital PROM is impacted by parameters such as symptom burden, health status, patient characteristics, or device.

Methods: Pooled analyses were performed of retrospective data from six digital PROM pilots in immunotherapies. The study included 243 patients from 6 countries: NO (97), FI (56), NL (37), DE (26), CH (17), and IT (10). Following parameters were analyzed: weekly adherence to questionnaires in correlation to symptom burden, health status (QLQ-C30), age, sex, device (app, browser), messaging, and country for 12-week period.

Results: Mean weekly adherence to PROM on all devices was 80%, ranging from 72.3% (IT) to 84% (FI). Experienced symptom burden (r=-0.46), fatigue level (r=-0.32), physical condition (r=-0.23) or global health status (r= 0.22) did not correlate with adherence. There were no differences between females (79.9%) and males (80.1%) but both had higher adherence using app compared to browser. KAIKU enabled communication with HCPs, but patients' messaging activity did not correlate with adherence (r=0.13). In all age groups, both app and browser-based platform were used. Adherence was highest for ages 60-69. Younger patients (40-59) had a considerable adherence drop when using the desktop browser, whereas in ages 60-89 there weren't such differences between devices.

Conclusions: Digital PROM in cancer patients receiving immunotherapies results in high adherence regardless of country, age, sex, user activity or disease burden, implying it is clinically feasible, and patients stay adherent both in good and worsening health conditions. High adherence to app-based platform across all ages indicates that app-based PROM should be preferred over other methods.

CN4 Enabling patient empowerment through digital symptom monitoring

E.C. Haukland[1], S.G. Aanes[1], V.V. Kataja[2], L. Lang[2]

[1]Department of Oncology and Palliative Medicine, Nordlandsykehuset HF, Bodoe, Norway; [2]Medical Science Department, Kaiku Health, Helsinki, Finland

Background: Patient reported outcomes (PROs) are the golden standard for monitoring symptoms in cancer care and have shown great clinical benefits to patients. New technology enables electronic PROs to be used in clinical practice also with an intent to empower patients and involve them more actively in their treatment. This study aimed to pilot a questionnaire for investigating the ability of ePRO monitoring to enable empowerment of patients with active anticancer treatment.

Methods: Based on the validated Cancer Patient Empowerment Questionnaire (CPEQ) we developed a shorter and more practical questionnaire with eleven questions including intrapersonal, interactional, and behavioural components of patient empowerment. Responders were cancer patients, most receiving palliative treatment for metastatic disease, monitored with an ePRO tool by Kaiku Health as part of their standard of care at a central hospital in Northern Norway. Responses were scored on a Likert scale from 1-5.

Results: Out of 58 patients, 46 (79%) returned the questionnaire in the first round, and 37 (67%) responded in the second round two weeks later. The mean total scores were 3.7 and 3.8, respectively. The patients reported the importance for them to manage their challenges, have a feeling of control, and participating actively in decisions, treatment, and follow-up of their illness to a high degree (mean score 4.2). With mean scores of 4.1 and 4.2, the ePRO monitoring provides patients with a feeling of being listened to/taken seriously and supported their ability to contact healthcare professionals when in doubt or having questions or concerns. There were no significant differences in scores due to age, gender, cancer type, treatment, or length of using the program. A Cronbach Alpha of 0.9 and an interclass correlation coefficient of 0.87 indicates good internal consistency. Test-retest shows good reliability with Pearson's correlation of 0.66.

Conclusions: Cancer patients report that it is very important to them to be in control and actively participate in matters concerning their illness and treatment. Digital monitoring with ePRO enables empowerment by providing a channel to contact healthcare professionals when needed, and a feeling of being listened to and taken seriously.

CN5 Shared decision making in rectal cancer surgery: The way to go?

E. Pape[1], J. Dobbelaer[1], D. Van de Putte[1], K. Geboes[2], A. Van Hecke[3], I. Vlerick[3], G. van Ramshorst[1], Y. Van Nieuwenhove[1]

[1]Gastrointestinal Surgery, UZ Ghent - University Hospital Ghent, Ghent, Belgium; [2]Oncology, UZ Ghent - Universitair Ziekenhuis Ghent, Ghent, Belgium; [3]University Center for Nursing and Midwifery, Ghent University - University Centre for Nursing and Midwifery, Ghent, Belgium

Background: In rectal cancer surgery, there are two surgical options: A low anterior resection with preservation of the anal sphincter and an abdominoperineal resection with resection of the sphincter and formation of a permanent stoma. When the sphincter is not compromised, both surgical options are, from an oncological point of view, comparable. Given the need to take patients' perspective into account, the choice of rectal cancer surgery is a value-based choice. To facilitate this, there is a growing interest in the use of decision aids. It helps patients to participate in weighing the impact of different treatment options on their QoL. The aim of this study was to explore the expectations of healthcare professionals (HCPs) and to evaluate the impact of using a decision aid in daily practice.

Methods: A multi-centre explorative study was conducted. Individual semi-structured interviews with 16 interprofessional HCPs responsible for the care of patients with rectal cancer were performed. Thematic analysis was used during data-analysis and investigators' triangulation was applied during analysis.

Results: First, HCPs felt that a decision aid would enable them to provide information in a more neutral and uniform way. Second, it was believed that the decision aid enhanced the understanding of the different aspects of QoL. Moreover, a shared decision was hypothesised to enable patients to accept consequences of rectal cancer surgery, such as bowel problems or a stoma. Additionally, it was believed to empowering patients and increasing their involvement in the treatment decision. Finally, some key issues for implementation were highlighted, such as reorganising the preoperative consultation, a consensus on the most appropriate moment to use the decision aid and the need for training. Several HCPs mentioned the added value of a nurse-led consultation, complementary to the physician.

Conclusions: Using a decision aid to facilitate preoperative consultations was an added value according to HCPs. Before implementation, several key issues need to be taken into account. A nurse-led consultation could be an added value to facilitate shared decision making. A follow-up study will explore the impact on patients.

CN6 Patient involvement in an eHealth intervention for women with gynecological cancer

M.G. Christiansen[1], H. Pappot[1], M. Jarden[2], M.R. Mirza[1], K. Piil[1]

[1]Department of Oncology, Copenhagen University Hospital, Rigshospitalet, Copenhagen, Denmark; [2]Department of Haematology, Copenhagen University Hospital, Copenhagen, Denmark

Background: Women with ovarian or endometrial cancer experience a significant physical and psychological burden due to the disease and treatment. Patient and public involvement in health research is gaining global popularity, with the potential to improve the quality, relevance, and outcomes of studies. Thus, patient involvement is a central component in this study investigating the feasibility and effect of systematic nurse-led consultations based on electronic Patient-Reported Outcome (ePRO) among women with ovarian- or endometrial cancer. The purpose of patient involvement was to encourage patients to participate in all stages of this study, including the development of an ePRO platform.

Methods: The study design was a four-phase, sequential cohort study with comparisons between non-equivalent groups, with the primary outcome being the difference in global HRQoL (EORTC QLQ-C30) at 9 months. The patient advisory board consisting of women with gynecological cancer has continuously been involved in the development and design of the ePRO platform. After two years of involvement, we used The Patient Engagement in Research Scale (PEIRS-22) to evaluate the level of meaningful involvement in the patient advisory board.

Results: A patient advisory board consisting of patients (n=5) has been established. The board provides feedback on written materials, research development, and capturing the perspectives of women with ovarian and endometrial cancer.

Furthermore, the board has been dedicated and constructive in a systematic process that has resulted in the selection of cancer-specific items, self-management strategies, advice, content, and videos that are included in the ePRO platform. The Danish PEIRS-22 total score was 89,3 (range 0-100), indicating a high level of meaningful involvement. The ePRO intervention is currently ongoing and results are expected in 2024.

Conclusions: Throughout the study, the active involvement, engagement, and collaboration of a patient advisory board have contributed to the development of a patient-centered ePRO platform and model of care. Patient involvement is highly valuable and makes a significant contribution to conducting patient-centered nursing research with clinical impact.

CN7 The effect of using mobile application on supportive care needs, distress and quality of life in hematopoietic stem cell transplant patients: Randomized controlled study

D. Başcı[1], S. Kav[2]

[1]Bone Marrow Transplantation Unit, University of Health Sciences Dr. Abdurrahman Yurtaslan Ankara Oncology Training and Research Hospital, Ankara, Turkey; [2]Nursing, Baskent University Faculty of Health Sciences, Ankara, Turkey

Background: The aim of the study was to develop a mobile application and to examine the effect of using this application on the supportive care needs, distress level, and quality of life in hematopoietic stem-cell transplant patients.

Methods: This randomized controlled study was conducted at the Bone Marrow Transplantation Unit located in Ankara, from February to September 2022. Patient Information Form, the James Supportive Care Screening Scale (JSCS), the Distress Thermometer, and Functional Assessment Scale in Cancer Treatment in Bone Marrow Transplant Patients (FACT-BMT, version 4) were used to collect data. The study was completed with 36 patients (18 in the intervention group and 18 in the control group) and the data was collected at 3 time points pre-transplant, 1st month, and 3rd month after transplantation. The mobile application contents were evaluated by an expert group and piloted (n=7) via Mobile Application Usability Scale. Audio recordings have been added to the application in line with user suggestions. The intervention group was trained with the mobile application and was followed up to the 3rd month after transplantation, and the control group received routine education/follow-up.

Results: In the FACT-BMT scale, there was a significant difference ($p<0.05$) between the groups in the FACT-BMT TOI score at admission, while no difference was found between the groups in other sub-dimensions. There was no difference between the groups in terms of distress levels and FACT BMT total scores ($p>0.05$). A significant difference was found in the 3rd-month follow-up in the spiritual-religious problems sub-dimension of the supportive care needs ($p<0.05$). The patients in the intervention group received counseling mostly on nutrition, social life, medication use, and post-transplant complications.

Conclusions: No significant effect was found of the education given with the mobile application on the supportive care needs, distress levels and quality of life of the patients during the first three months after stem cell transplantation. Further large-scale studies are needed to evaluate the effect of the mobile application longer than the first three months after transplantation.

CN8 A guide to data & artificial intelligence: Co-producing accessible an educational resource with the pubic

K.L.T. Gleason

Surgery and Cancer, Imperial College London, London, UK

Background: Digital innovation is shaping healthcare. Data science & artificial intelligence researchers are seeking public involvement for their projects but do the public have sufficient knowledge of the field to contribute meaningful ways? Our experience at Imperial was that they did not. This led us to develop a guide to data and AI created by the public for the public to help individuals become active decision makers in their health. A diverse group of 20 members of the public worked with experts to create the guide which consists of text/illustrations, podcasts and animated videos. A website is currently in development. Aside from developing the guide, we learned a great deal about co-design. We evaluated our experience of co-production.

Methods: We used creative approaches for the participatory evaluation and embedded reflexivity for a potentially more ethical and accessible involvement of public contributors. Firstly, we utilised the photovoice. For three months, public contributors and team members captured photos alongside a description of how this photo presented their experience. Secondly, using these photos to discuss and analyse the experience of being involved in the project. The professional artist captured this discussion together in the mandala- a geometric configuration of symbols representing the experience.

Results: These experiences were spread into six interconnected layers on the mandala and represented a connected journey. The chosen title "Our Journey into AI", reflected the feeling of ownership among public contributors. Layers 1) represented the opportunity to learn new things and develop confidence in data and AI 2) showed interaction when working as a team 3) is about working digitally throughout the project. From layer four onwards, the issues broaden to include those that underpin public contributors' involvement 4) why they got involved in the project 5) their expectation in the involvement process. The last layer is about the ethics that researchers should follow.

Conclusions: We found that the co-production with public contributors around complex and often abstract topics like data science and AI can be conducted in a meaningful way with the public. Co-production process ensures a sense of co-ownership.

CN9 Communicating with patients in modern cancer care

A. Woods

Breast surgery, UCLH - University College London Hospitals NHS Foundation Trust, London, UK

Background: Following the introduction of breast cancer patients into a women's health ward the Breast CNS team needed to develop teaching sessions to upskill ward nurses in breast cancer care. COVID-19 meant that traditional face to face teaching was not broadly possible in health care (Haslam 2021). A new digital approach was required.

Methods: Electronic survey to establish challenges and learning needs communicating with breast cancer patients pre and post delivery of online teaching to 19 members of nursing ward team. This was followed up with a patient questionnaire.

Results: Pre teaching survey 14/19 nurses identified communicating with cancer patients and supporting them emotionally as a key area of concern. The most frequently identified aspect of concern was how to support patients emotionally, diagnosis and prognosis. 12/19 lacked confidence in drain/wound management. 11/20 nurses were unsure where patients could access support post surgery. Post teaching survey All 15 of the respondents reported increased level of confidence in wound and drain management and communication around discharge planning. However, the majority of nurses still felt unsure around some aspects of communication in supporting patients emotionally. Further a patient questionnaire to 32 inpatients at UCLH echoed the nursing challenges 9/32 listing that their emotional needs were not well identified and 9/32 did not feel confident managing drains at home.

Conclusions: The digital teaching package provided improved skills and confidence in practical aspects of care around wound/drain management and discharge planning. Despite this a number of patients 9/32 report they are still lacking confidence in drain management. Complex communication in highly emotive areas is more challenging and requires further support. Many patients also identified that they were not asked about concerns during their in-patient stay (9/32). It is easier for nurses to access learning from a remote location which helped to reach greater numbers, and information can be accessed on demand for improved flexibility. Actions The teaching package is being adapted and re-evaluated to focus further on challenging communication scenarios. The CNS team are in the process of developing new approaches in building confidence in drain care.

CN10 Development and usability test of an individualized nutrition management application (iNutrition) for post-discharged gastric cancer patients following gastrectomy

X-H. Jiang[1], J-S. Peng[2]

[1]School of nursing, Sun Yat-sen University, Guangzhou, China; [2]Department of Gastric Surgery, The Sixth Affiliated Hospital, Sun Yat-sen University, Guangzhou, China

Background: Malnutrition can be largely reduced by nutrition intervention in post-discharged gastric cancer patients following gastrectomy. However, current nutrition interventions have been unsatisfactory worldwide. This study aimed to develop an individualized nutrition intervention application (iNutrition) and evaluate its usability in post-discharged gastric cancer patients following gastrectomy.

Methods: We developed the iNutrition using the design thinking method, which includes 5 phases: (1) "empathize": conducting qualitative research to develop knowledge about the patient's needs; (2) "define": identifying goals and scope of the iNutrition; (3) "ideation": conducting a focus group interview with a multidisciplinary team to brainstorm potential solutions; (4) "prototype": designing the functions and user interface of the iNutrition; (5) "testing": evaluating the potential usability of the iNutrition through a three-month usability test.

Results: According to the results of qualitative research of 15 patients and 5 clinical staff, the iNutrition should satisfy patients' needs for tailored nutritional plans, evidence-based nutrition knowledge, adjusting to postoperative anatomy change, and communicating with peers and medical staff. The final version of the iNutrition includes four modules: nutrition management, nutrition knowledge, gastrointestinal symptoms management, and communication center. The four modules include eight functions which are nutrition consultation, nutrition courses, symptoms knowledge, experience communication, nutrition status score, dietary calculator, nutritional requirement, and concrete meal plans. For the usability test, 25 patients with 52% male and mean age of 51.76 (SD 10.33) were recruited. 72.0% of the participants were satisfied with iNutrition; 76.0% and 64.0% reported that iNutrition was useful and easy to use, respectively.

Conclusions: The iNutrition has achieved its functions of serving as a tailored mHealth tool to conduct nutrition intervention in post-discharged gastric cancer patients following gastrectomy with satisfactory usability.

CN11 Improving quality of life for patients with prostate cancer: ProstaGYM, a new digital skill

E. Gallardo[1], D. Büchser Garcia[2], L. Regis Placido[3], E. Rios Gonzalez[4], A. Marco Perez[5], C. Moretones Agut[5]

[1]Oncology, Parc Taulí Hospital Universitari, Institut d'Investigació i Innovació Parc Taulí I3PT, Universitat Autònoma de Barcelona, Sabadell, Barcelona, Spain; [2]Radiation Oncology, Hospital Universitario Cruces, Barakaldo, Spain; [3]Urology, Vall d'Hebron University Hospital, Barcelona, Spain; [4]Urology, Hospital Universitario La Paz, Madrid, Spain; [5]Medical Affairs, Bayer Hispania S.L., Sant Joan Despí, Spain

Background: Patients with prostate cancer may experience a worsening in their emotional wellbeing and physical health due to treatments or disease burden. It has been reported that physical activity and lifestyle interventions are associated with improved patient outcomes and a lack of health literacy is perceived by patients as a key burden of their cancer experience, and an improvement in this aspect has been strongly correlated with better overall survival. Voice assistants have emerged as a promising tool to support patients' guided learning and exercises. Here, we report on the development, content, and functionality of the first Amazon Alexa voice assistant for patients living with prostate cancer in Spain.

Methods: A multidisciplinary group of expert physicians on prostate cancer were selected as a scientific committee. Based on their clinical experience and the scientific evidence, the working group agreed on and created the content. The topics for each module were defined through the use of a consensus technique. The digital skill, named ProstaGYM, was endorsed by the national patient association ANCAP and the design and programming was performed by an Amazon developer with support from Bayer Hispania.

Results: The skill contains four content modules: 1) general disease information and healthy lifestyle recommendations, 2) exercise routines to prevent sarcopenia, 3) specific exercises and interventions to manage urinary symptoms, 4) advice on sexual health and psychological support. ProstaGYM is available free of charge on the Spain Amazon Alexa skill store. Since its launch in November 2022, the following information on metrics were obtained (cut-off 30th April 2023): 144 unique customers, 164 user enablements (skill activation) and 182 sessions.

Conclusions: The skill ProstaGYM constitutes an innovative approach to guide patients with prostate cancer to self-manage disease symptoms and treatment side effects and promote physical exercise that may improve their quality of life.

CN12 Integrating weekly symptom monitoring for patients with prostate cancer in radiation oncology: A prospective cohort study using electronic patient-reported outcomes

P.K. Møller[1], H. Pappot[2], T. Schytte[1], U. Bernchou[1], K.B. Dieperink[1]

[1]Department of Oncology, OUH - Odense University Hospital, Odense, Denmark; [2]Department of Oncology, Copenhagen University Hospital, Rigshospitalet, Copenhagen, Denmark

Background: Integrating active symptom monitoring of electronic patient-reported outcomes (ePROs) in a clinical workflow and engaging clinicians in acting on data is challenging. This study aimed to adapt weekly digital symptom monitoring into the prostate radiotherapy (RT) workflow and explore the impact of clinician engagement on patient compliance and satisfaction.

Methods: Patients with prostate cancer (PCa) referred for RT were eligible. Weekly ePROs were reported until four weeks following RT and weeks eight, 12 and 24. Clinicians monitored and used the ePROs for symptom management and 'handled' the response in the electronic patient record. In week four following RT, a validated Patient Feedback Form was distributed to assess patient satisfaction with ePRO, and a nurse-led follow-up (FU) was offered after responding. Health-related quality of life was measured with EQ-5D-5L.

Results: A consent rate of 91.5% (n=161) and an attrition rate of 5% resulted in 156 PCa patients included in the analyses (95% ePRO, 81% mean response rate). Non-participants tended to be older (mean age 72 vs 69 ($p=0.010$)) and have a poorer performance status ($p<0.001$). Patients reported ePROs improved communication and discussions with staff (91-93%) and gave them a greater sense of involvement (93%) (Table). Clinician engagement was high, with 93% of patients having all PROs handled. Among patients who chose to deselect FU (23%), a higher proportion had deteriorated EQ-VAS scores two months later ($p=0.044$) and fewer contacts with the department ($p=0.045$).

Conclusions: Integrating weekly ePROs in the radiotherapy workflow for PCa patients was feasible. When clinicians actively used PROs for symptom management, patients felt more involved and reported an improved quality of care and communication with the clinicians compared to their prior experiences. Further exploration of follow-up based on patient preference is warranted.

CN14 Quality of the abeona health app according to the onco-haematology patient in the Principality of Andorra: Preliminary results

C. de Miguel Barbero[1], E. Gea Rodríguez[2], F. Garcia Cuyàs[3]

[1]Primary Care, Servei Andorra d'Atenció Sanitària (SAAS) University of Andorra, Carrer Dels Escalls, Andorra; [2]Pharmacy, Servei Andorra d'Atenció Sanitària (SAAS) University of Andorra, Escaldes-Engordany, Andorra; [3]Health Sciences and Health Services Research Group, Universitat d'Andorra, Sant Julià De Lòria, Andorra

Background: This study is part of the implementation of m-Health in outpatient Clinical Pharmacy at Hospital of the Principality of Andorra, with the aim of knowing the qualification of the Abeona Health App by the patient when using it for three months. The main objectives are: 1. Determine the general rating of the App according to the patient. 2 and 3. Know if the patient would continue using the App for one year and if they would recommend the App.

Methods: Cross-sectional study in onco-haematological patients under treatment with OAAs. 1. Inclusion criteria: all adult patients treated with OAAs seen from November 2022 to May 2023 (6 months of study). 2. Tool measure: the validated spanish translation of uMars survey was chosen to meet the research objectives. 3. Data collected from the patients: age, sex, type of tumour and type of OAAs. 4. Data collected from the surveys: the uMARS questions that were used to evaluate the

Abeona Health App were: 2.4, 5, 6, 7, 8, 9, 10, 11, 12, 17, 18, and 20. 5. Statistical analysis: descriptive, performed with the Jamovi statistical package. 6. Ethical aspects: before providing the surveys, the patients were informed that their data would be treated anonymously, and they gave their signed informed consent to participate.

Results: 64 patients were visited. 44 participated in the study (4 of them through their children for not knowing how to use an App). 41 were women (64%) and 23 men (36%) with a mean age of 63 years. The most frequent tumor in women was the breast with OAAs Palbocilic and in men the Colon with Capecitabine. The general quality of the App according to the patient's response in the uMars survey was: 7.7% of the patients scored 3, 50% scored 4 and 42.3% scored 5. When referring to the use of the App for a year, 19.2% of the patients responded from 3 to 10 times, 46.2% from 10 to 50 times, and 34.6% more than 50 times. In relation to whether patients would recommend the App, 30.8% of the patients answered that they would recommend it to many people and 69.2% that they would recommend it to everyone.

Conclusions: 1. The Abeona Health App was rated with a score of more than 4 for 92.3% of patients. 2. The 80.8% of patients would continue using it for a year. 3. The 100% of patients would recommend it to people who could benefit from it.

CN15 Real-life clinical and organizational evaluation of telemonitoring and assisted telemonitoring in more than 1500 cancer patients

S. Martin[1], A. Fritsch[1], C. Jouannaud[2], J. Martin-Babau[3], B. Mennecier[4], F. Slimano[5], A. Bordeau[6], L. Guéroult-Accolas[7], B. Delcour[8], E. Raymond[9], S. Renet[10], C. Sonntag[11], A. Morel[12], P. Barthelemy[1]

[1]Medical Oncology Department, ICANS - Institut de Cancérologie Strasbourg Europe, Strasbourg, France; [2]Medical Oncology, Institut Jean Godinot, Reims, France; [3]Medical Oncology Department, Hôpital Privé des Côtes d'Armor, Plérin, France; [4]Medical Oncology Department, Hopitaux Universitaires de Strasbourg - Nouvel Hopital Civil, Strasbourg, France; [5]Pharmacy Department, Reims University, BioSpecT, Reims University Hospital, Reims, France; [6]Oncology and Radiotherapy Department, Chambray Les Tours, France; [7]Direction, Patients en Réseau, Paris, France; [8]Direction, AF3M, Paris, France; [9]Department of Medical Oncology, Centre Hospitalier Paris Saint-Joseph, Paris, France; [10]Pharmacy, Centre Hospitalier Paris Saint-Joseph, Paris, France; [11]Onco-hematology Department, ICANS - Institut de Cancérologie Strasbourg Europe, Strasbourg, France; [12]Breast Cancer Unit, Centre Francois Baclesse, Caen, France

Background: Telemonitoring of patients receiving cancer therapy has been shown to improve patient outcomes in clinical trials. However, telemonitoring must be accessible to all patients, regardless of their digital literacy or vulnerability, and only limited evidence of real-life clinical and organizational impact has been provided.

Methods: We performed a multicenter retrospective observational study of telemonitoring for patients receiving oral anticancer drug and/or immunotherapy in routine practice. Depending on the oncologists' decision, patients were included in either remote monitoring or assisted remote monitoring with a home nurse or their community pharmacist. The tool records graded adverse events (AE) (CTCAE V5.0), vital signs, treatment characteristics, tumor baseline characteristics. Compliance (rated by Girerd questionnaire) was also collected. Reporting intervals and duration were based on the patients' treatment type. Based on alerts and clinical examination, the oncologists implemented interventions if needed.

Results: From January 2019 to September 2022, 1556 patients (median: 69 yo; 67,9% of women) from 57 different healthcare facilities were included: 1097 with home nurse support, 152 with community pharmacist support, and 350 with self-assessment. A total of 4509 healthcare professionals (HCPs) were involved in the remote monitoring of at least one patient, which corresponds to 4,6 different HCPs per patient, with different roles (remote monitoring leads, assistance to patients in the remote monitoring …). Nearly half of the patients had breast cancer (49.1%) followed by renal and lung cancer (16.9% and 14.7% respectively). Most patients were treated with an oral antineoplastic agent (83.3%). 94,8% of patients reported an AE; 27.7% had a grade 3 or 4 AE and 58.5% had at least 1 unexpected/rare AE. The compliance rated in the 668 assessed patients remains high at 3 months (79,9% of patients with a score of 0 at initiation vs 79,6% at 3 months).

Conclusions: Telemonitoring of patients with anticancer treatment allows early detection of AE and maintenance of treatment compliance at 3 months. Besides, it strengthens the community care - hospital network.

CN16 The Mount Vernon Cancer Center non medical prescriber GI oncology clinic experience

M. Blyth[1], R. Quinteros[1], M. Azizi[2], T. Achim[2], S. Prematillaka[1], N. Bhuva[3], M. Harrison[4], V. Michalarea[1]

[1]Oncology, Mount Vernon Cancer Centre, Northwood, UK; [2]Oncology Pharmacy, Mount Vernon Cancer Centre, Northwood, UK; [3]Radiotherapy, Mount Vernon Cancer Centre, Northwood, UK; [4]Oncology, Bioscript Group Ltd, Macclesfield, UK

Background: The majority of healthcare services modified the way they operated during the COVID-19 pandemic. One of the areas that was greatly impacted was the Oncology services worldwide. In our department we increased the telephone consultations of the patients who were actively receiving treatment and the non-medical prescribers undertook a more active role in the on-treatment clinics.

Methods: Retrospective review of the GI clinic lists of all patients receiving systemic anti-cancer treatment (SACT) in 2022. Data was collected on gender, primary site of disease, treatment intent, cycle number, type of SACT.

Results: Three thousand four hundred and forty nine appointments (apts) were scheduled in the GI on-treat clinic in 2022. These were pooled from 3 Consultant lists and 1 pharmacy list. Patients were reviewed by 5 medical prescribers and 3 non medical prescribers (NMPs): there are 2 band 7 nurses and 1 band 7 pharmacist. Of the 3415 apts that took place (34 did not attend) the NMPs performed 792(23%) telephone consultations: 65% were male, 74% of patients received combination treatments, 20% single agent, 6% were given scan results. 15% of the patients were assessed for cycle 1 treatments. 70% were receiving chemotherapy, 7% biological target treatments, 9% immunotherapy, 3% chemotherapy — immunotherapy combinations, 3% chemotherapy- radiotherapy combinations and 2% chemotherapy — biological target combinations. The intent was palliative in 55% of the cases, 10% radical, 10% neo-adjuvant and 25% adjuvant. The primary diagnosis was 60% colorectal cancer, 25% gastroesophageal, 10% pancreatic and 5% GIST and cholangiocarcinoma.

Conclusions: Very experienced NMPs are vital members of the clinical team and can safely perform assessments of patients on a variety of treatments in a wide range of clinical settings. Their input in the telephone clinics has transformed the patient experience providing holistic care maximising their role as key workers in patients' journey. It also increased their to job satisfaction and promoted staff retention. More NMPs should be encouraged to undertake the NMP assessment course and set up their own clinics or work alongside with the medical staff in their respective clinics.

CN17 Use of the ONCO'nect telemonitoring tool by socially deprived outpatients actively treated for a solid cancer: A retrospective quantitative and qualitative analysis of the Re'connect program

C. Boiteau[1], N. Alarcon[1], C. Joly[1], C. Fenioux[1], C. Ganter[2], C. Queval[2], S. Dutendas[2], I. Bartoszczyk[2], M. Bouayed[2], H. Ben Nadji[2], A. Briard[3], N. El Biad[3], C. Agius[4], C. Tournigand[1], E. Kempf[1]

[1]Department of Medical Oncology, Henri Mondor and Albert Chenevier Teaching Hospital, Université Paris Est Créteil, Assistance Publique — Hôpitaux de Paris, Creteil, France; [2]CALIPSSO, Supportive Care Unit, Centre Hospitalier Universitaire Henri-Mondor AP-HP, Creteil, France; [3]Telehealth, Nouveal, Irigny, France; [4]Mission handicap, Strategy and Transformation Department, Assistance Publique - Hopitaux De Paris AP-HP, Paris, France

Background: Telehealth improves the quality of life and overall survival of cancer patients. Social deprivation might lead to unequal access to telehealth. The aim of this study was to evaluate how socially deprived outpatients treated for a solid cancer get a grip on a dedicated telemonitoring program.

Methods: Between February 2021 and June 2022, eligible outpatients with a solid cancer undergoing chemotherapy at the Mondor Teaching Hospital, France, were provided with the ONCO'NECT® telemonitoring tool. It includes a chat system and standardized 24 items questionnaires before/after each treatment administration based on the NCCI Patient-Reported Outcomes of the Common Terminology Criteria for Adverse Events (PRO-CTCAE®), triggering alerts when the threshold of clinical significance was reached. Patients with social deprivation were identified based on the EPICES (evaluation of precariousness and health inequalities in health examination centres) score and were enrolled in the Re'Connect program (lending of a tablet, caregivers, technical and peer-to-peer support). We collected the data on patients' healthcare pathways retrospectively, and we performed semi-structured interviews to assess patients' challenges related to ONCO'NECT®.

Results: We enrolled 22 patients: 15 females, 50% were aged $>$ 70 years (interquartile range (IQR), 64-74), 14 had digestive cancer, 15 patients had metastases, 14 lived alone. Five and three patients completed $>$ 75% and $<$ 25% of questionnaires respectively, during a median treatment duration of 7,5 months (IQR, 4-14). The median number of triggered alerts was 5 per patient (IQR, 1-9,25). The underuse of

ONCO'NECT® went beyond patients' understanding of its interest and their technical competence and was related to borderline health literacy. The related patients' emotional negative experience might explain such an underuse.

Conclusions: Socially deprived cancer outpatients perceived the relevance of a telehealth tool. Beyond technical issues, patients' borderline health literacy and their negative emotional experience should be addressed to ensure equal access to telehealth.

Cancer nursing: Health promotion, prevention and screening

CN18 Impact of the medical record-based frailty index on the health outcomes of elderly patients with colorectal cancer

H. Lee

College of Nursing, Yonsei University, Seoul, Republic of Korea

Background: Preoperative frailty in older patients with cancer is associated with poor health outcomes, such as falls, length of hospital stay, complications and mortality. Simple and clinically detectable frailty measurements are preferred in clinical settings. A laboratory frailty index (FI-Lab) based on routine laboratory tests and vital signs was suggested to assess and predict clinical outcomes in older adults. The purpose of this study was to examine the association between preoperative frailty and postoperative risk of fall and dependence, and mortality in elderly patients with colorectal cancer.

Methods: We retrospectively analyzed 268 geriatric patients (≥65 years) who received a curative resection for colorectal cancer. A 32-item FI-Lab was constructed based on routine blood tests and vital signs, and scores were rated as low (<0.25), moderate (0.25-0.40) and high (>0.40). The skeletal muscle mass was measured with CT images. The Johns Hopkins Fall Risk Assessment Tool and Modified Barthel Index were used to assess fall risk and dependency, and survival rates were evaluated.

Results: The mean age of participants was 72.3 years, 61.9% (n = 166), 33.6% (n = 90), and 4.5% (n = 12) were in the low, moderate, and high FI-Lab groups, respectively. Frailty was associated with old age, poor tumor differentiation, increased fall risk and dependency. The two-year survival rate was very low among the moderate and high frailty groups, and the risk of fall and dependency was significantly associated with the survival rate. The multidimensional Cox proportionate risk model showed that high frailty, age 80 years and older, and hypertension were independent predictors of poor prognosis. There were no significant differences in the skeletal muscle mass and density according to frailty.

Conclusions: The FI-Lab score was used to predict the risk of poor post-operative outcomes as a frailty indicator. The FI-Lab is a potentially useful tool for hospitalized elderly patients who are at higher risk of frailty and helps healthcare professionals implement strategies to improve health outcomes.

CN19 Earkt phone oncogeriatric screening in gynaecological and lung cancer a care units by advance practice nurses

A.I. Hernandez, et al.

Nursing, Catalan Institute of Oncology, Badalona, Spain

Late withdrawal

CN20 Nurse's role in coordinating new cancer screening initiatives: Experiences from an on-going risk-based lung cancer screening feasibility study, among Swedish women

N.M. Nordgren[1], U. Sporre[2]

[1]RCC, RCC - Regionalt cancercentrum Stockholm - Gotland, Stockholm, Sweden; [2]Hälso Sjukvårds Förvaltningen, RCC - Regionalt cancercentrum Stockholm - Gotland, Stockholm, Sweden

Background: Lung cancer is the deadliest cancer form on Sweden. In recent years, the incidence of lung cancer among women has increased. International studies show reduced lung cancer mortality in high-risk populations after screening with low dose computed tomography (LDCT). In the Stockholm region, Sweden, a lung cancer screening program was developed, based on previous research, pilot testing and regional health economic analysis.

Methods: The purpose of this feasibility study is to test processes related to invitation, IT, logistics, resources, follow-up, imaging and smoking cessation. A random population-based sample of women (current smokers or recent quitters) aged 55—74 is invited to participate. The aim is to continue until 1000 women have undergone LDCT. Smoking cessation support is offered to all invited women.

Results: The inclusion started in September 2022, and the inclusion rate is currently 33%. The invitations are sent out via regular post, together with a link to a web-based survey. Once completed, women who meet the study's criteria are invited to LDCT. A specific protocol is developed to manage and follow-up different findings. LDCT imaging are managed, using an Artificial Intelligence protocol. The nurse's role includes managing the study office, information and support to participants, scheduling and booking the LDCT invitations, coordinating the study team and involved health care units, managing quality insurance related the study processes including IT issues. The results of the study will be represented during 2025.

Conclusions: The involved processes seem to work really well. The study provides the basis for a future calculation of resources for a national risk-based screening program. Experiences so far indicate improved early detection rate of lung cancer. The role of nurse coordinator is fundamental for the success of this program.

CN21 Stakeholder perceptions of cervical screening accessibility and attendance in Ireland: A qualitative study

S. Mulcahy Symmons[1], A. Drury[2], A. De Brún[1]

[1]School of Nursing, Midwifery and Health Systems, University College Dublin, Dublin, Ireland; [2]School of Nursing, Psychotherapy and Community Health, Dublin City University, Dublin, Ireland

Background: Screening plays a key role in preventing incidence of cervical cancer. In Ireland, the incidence and screening participation rates are not evenly distributed across the population, and evidence is limited. To provide and equitable service, it is important to understand who is and is not attending screening and why. This study explored the perceptions of expert stakeholders on cervical cancer screening attendance and accessibility in Ireland.

Methods: Semi-structured interviews were conducted with 12 healthcare professionals, policymakers and academics to explore their expert views on cervical

screening accessibility and attendance in Ireland. Interviews were conducted online in 2022. Reflexive thematic analysis was used inductively to generate themes, supported by NVivo.

Results: Three themes were developed from the interview data: Getting the right information out the right way, Acceptability and accessibility of screening, and trying to identify and reach the non-attenders. Participants felt public knowledge of cervical screening and Human Papilloma Virus was low and the communication of this information needed to align better with sources that women engage with. Accessibility and acceptability of screening was thought to be dependent on individual, cultural and structural and service factors. Identifying and reaching non-attenders was considered important by participants but community outreach and public engagement could enhance understanding and address the challenges of non-attendance.

Conclusions: Nurses have a significant opportunity to support uptake and engagement with screening. Nurses are often the first point of contact to provide information regarding health promotion and are therefore well positioned to provide education and support which can address the barriers to screening engagement. Community engagement could support understanding of the distribution of participation and awareness of screening and enhance supports for women to make informed decisions about engagement with cervical screening.

CN22 Survivorship care in melanoma cancer survivors

R. Fadden[1], A. Sorrentino[2]

[1]Ambulatory Oncology Dept., Massachusetts General Hospital Cancer Center, Harvard Medical School, Boston, MA, USA; [2]Oncology - Melanoma, Massachusetts General Hospital Cancer Center, Harvard Medical School, Boston, MA, USA

Background: Survivorship care provides numerous benefits for oncology survivors; however, resources and programing are not routinely implemented in clinical practice. The increasing population of cancer survivors presents the need for improvement in patient centered continuity of care. The Melanoma Survivorship Program aims to improve the experience and outcomes for melanoma survivors who have completed treatment. The goal is to aid patients' transition from the acute phase of treatment to living with a chronic condition while maintaining or improving quality of life.

Methods: Patients submit a survey to evaluate the long term emotional, physical, and financial effects of cancer and cancer therapy. They then meet with a Nurse Practitioner (NP) and a Social Worker to formulate an individual care plan. The survivorship program utilizes referrals to an interdisciplinary care team including cardiovascular health, exercise, nutrition, sexual health and intimacy, psychosocial care, and financial support. Additionally, they provide connection with patients' primary care provider for continuity of care.

Results: This poster provides a recommendation for NPs to promote survivorship referrals in clinical practice. Data was produced through analysis and reporting on the effectiveness of survivorship programs in randomized control trials as part of a systematic review. Protocols providing access to comprehensive survivorship care in previous studies were examined and used to measure the effectiveness of survivorship programs in addressing patient quality of life. Findings support the recommendation of survivorship programs and interventions, specifically those studies which utilized and adapted the National Comprehensive Cancer Network Survivorship Assessment and the European Organization for the Research and Treatment of Cancer Quality of Life Questionnaire.

Conclusions: All forms of interventions were equally beneficial and largely dependent on patient goals. Therefore, NPs should encourage patients to engage in aspects of survivorship care that reflect their priorities. Additional research is needed to assess if survivorship care as described in this poster is effective at improving quality of life among melanoma cancer survivors long term.

CN23 Understand the patients' perspectives based on their profile to improve health-related quality of life assessment in breast cancer

C. Lesbros, E. Pain, L. Radoszycki, C. Odouard

Data Science, Carenity, Paris, France

Background: Patient-Reported-Outcomes (PRO) are widely used to measure patients' perspectives and support health product development, and their selection is a critical step of this process. As breast cancer (BC) profile and other medical or socio-demographic factors can influence patients' treatment choice, quality-of-life (QoL) and global patient journey, they could also impact patients' expectations. PROs selection should thus be personalized and based on the targeted population. This research aims to provide recommendations to better adapt the PROs selection and development to the medical product or service.

Methods: A 4-step method was used, starting by a state-of-the-art to identify the PROs most frequently used to assess BC patients' QoL and unmet needs, and list the covered outcomes. Then, organization guidelines and experts' recommendations were reviewed to complete the initial outcomes list. The next step was to conduct a direct-to-patient survey to generate new data on the most important outcomes for BC patients.

Results: The literature review showed that some outcomes are well covered by existing PROs: QoL, survival vs QoL considerations and healthcare pathway satisfaction. On the other hand, some outcomes are partially covered (copying strategies), and others are not covered (unmet needs, burden of disease). Moreover, experts' groups recommended to consider several profile attributes QoL in BC context (cancer stage, treatment strategy, complementary care, etc.[1]). Then, a direct-to-patient online survey was launched in several countries among the BC Carenity patient communities (objective: 300 respondents, results available in Sept 2023). It contains socio-demographic and medical questions, and questions aiming at ranking the previous outcomes and identifying other non-covered outcomes. Needs and expectations will be analyzed according to BC patients' profile.

Conclusions: The survey will provide a list of the most important outcomes for BC patients based on their profile. Then, a gap analysis will compare these results to experts' recommendations and PROs commonly used. These results could be used to improve PRO selection and orientate future investigations on BC patients' QoL assessments.

Cancer nursing: Palliative and end-of-life care

CN24 The effectiveness of person-centered care (PCC) for children with cancer in palliative and end-of-life care

E. Balasova

Pediatric Oncohematologylogy, Hospital of Lithuanian University of Health Sciences, Kaunas, Lithuania

Background: Person-centered care (PCC) has been a succeeding concept, originally described by Edith Balint in 1969 as "understanding the patient as a unique human being." Since then, there have been many other conceptualizations of patient-centred care thought that has been described as several alternatives including patient and family centered care, relationship centered care, personalized centered care and more. PCC as a holistic and humanistic approach has a connection to quality of care and therefore is essential in palliative and end-of life care of children with cancer. The aim of the study is to evaluate the effectiveness of PCC in palliative and end-of-life care of children with cancer.

Methods: Search strategy located 21 papers about PCC and 17 studies about palliative care and end-of-life care of children with cancer. No studies about implementation PCC into palliative and end-of-life care were found. A narrative summary of the study findings is therefore presented. The interventions described by the studies in the review varied in terms of their key components.

Results: Children with cancer experience pain and physical symptoms, low mood, anxiety, and fear. They feel less resilient, experience low self-worth, and have challenges coping with the illness. The families lead very stressful lives, navigating the hospital environment, and dealing with uncertainties of the future. Implementation of PCC improves physical symptoms, emotional support, and quality of life. It enables communication between families and health care providers. It improves end-of-life care support to children and their families and facilitates less invasive diagnostic and therapeutic interventions at the end of life.

Conclusions: Based on the evidence considered in this review, the results has specified the effectiveness of implementing PCC into daily practice in palliative and end-of-life care of children with cancer. Method to measure the degree of effectiveness of PCC is not clear and in many health care organizations evaluation methods do not exist. On the basis of the evidence considered in the review the effectiveness of PCC can be considered as having a multiple role as directing, coordinating, organising, decision-making, and accumulating devices.

CN25 Psycho-education and telephone counselling on the quality of life of advanced cancer patients undergoing chemotherapy in Indonesia

N. Huda, W.N. Dewi, H. Deli

Nursing Faculty, Universitas Riau, Pekanbaru, Indonesia

Background: Compelling evidence regarding the benefit of psycho-educational interventions (PEIs) on mental health among cancer patients is still limited. However, the effectiveness of PEIs followed by telephone counselling on the quality of life and its subscale among advanced cancer patients remains inconclusive. This study aimed to determine the effect of PEIs followed by telephone counselling among advanced cancer patients undergoing chemotherapy on their quality of life.

Methods: This study applied a randomized controlled trial. Patients with advanced cancer ($N = 151$) were randomly assigned to the experimental or control group. The experimental group participated in PEIs, a brief and highly structured program with one face-to-face and one phone session delivered by a nurse two weeks apart. The control group received only regular education. FACT-G questionnaires measured patient outcomes at baseline before and immediately preceding the next chemotherapy cycle. Independent and Dependent t-tests were used to evaluate the impact of the intervention on quality of life and its subscales.

Results: PEI followed by telephone counselling has a significant effect on the total quality of life ($p < 0.001$) and its subscales, namely physical wellbeing ($p < 0.001$), social wellbeing ($p < 0.001$), emotional wellbeing ($p < 0.001$), and functional wellbeing ($p < 0.001$) among the intervention group. A significant difference was observed between the groups concerning physical wellbeing ($p < 0.001$), social wellbeing ($p < 0.038$), emotional wellbeing ($p < 0.001$), and functional wellbeing ($p < 0.001$) and total quality of life ($p < 0.001$).

Conclusions: The psycho-educational intervention is potentially effective in improving the quality of life among advanced cancer patients undergoing chemotherapy. Those results are essential to evidence-based practice and determining the efficacy and cost-effectiveness of interventions in improving patient outcomes. There is a need to examine further the similar issues that continue during the palliative phase.

CN26 Healthcare professionals' perceptions on palliative care in onco-haematological area: Validation of the palliative care perception instrument

T. Buttiron Webber[1], G. Pegoraro[2], I. Lima[2], G. Catania[2], M. Calzolari[2], M. Zanini[2], L. Sasso[2], A. Bagnasco[2]

[1]Medicina, Ente Ospedaliero Ospedali Galliera, Genoa, Italy; [2]Department of Health Sciences - DISSAL, University of Genoa, Genoa, Italy

Background: Several studies show that integrated early palliative care in onco-hematology improves patients' quality of life, symptoms control, physical and mental health, and use of health resources. To better understand potential barriers and facilitators that may influence the referral of onco-hematological patients to palliative care it is necessary to investigate the perception of healthcare professionals in onco-hematological field on palliative care. This study aims to validate an instrument to assess healthcare professionals' perceptions of palliative care in onco-hematological area.

Methods: This is a validation study. The instrument is a questionnaire developed based on the questions of the study by Tay et al., 2021 . The validation of the instrument is ongoing, according to the COSMIN guidelines, and consists of content validation, face validation, and pilot test. To date, we completed content and face validity, which involved 5 experts in the field and 15 possible volunteer respondents, respectively.

Results: We calculated the Content Validity Index (CVI) for each item (I-CVI) and for the entire questionnaire (S-CVI). Every item obtained an I-CVI above 0.7, except for one item that obtained an I-CVI of 0.6. The item was considered acceptable and maintained since the S-CVI score was 0.95, meaning that the Italian experts found the instrument to be relevant to evaluate the topic investigated. After face validity, the questions that were considered confusing or containing difficult terms were rephrased according to participants' suggestions. None of the items was considered offensive. The final questionnaire consists of 22 items divided into 3 sections: demographics, perception, and professional behavior. The pilot test is ongoing and will allow us to assess reliability, internal consistency, and construct validity.

Conclusions: Validation results up to this point are promising, the completion of the validation process will allow obtaining a valid and reliable instrument that will help future researchers to investigate barriers and facilitators to the integration of palliative care in the onco-hematological field.

CN27 Pain in men with metastatic castration-resistant prostate cancer (mCRPC) starting their first-line of life prolonging treatment: A cross sectional study in Sweden

U. Rönningås[1], M. Holm[2], P. Fransson[3], L. Beckman[4], A. Wennman-Larsen[1]

[1]Clinical Neuroscience, Karolinska Institutet, Stockholm, Sweden; [2]Nursing, Sophiahemmet Universty, Stockholm, Sweden; [3]Nursing, Umea University, Umea, Sweden; [4]Oncology, Sundsvalls Sjukhus, Sundsvall, Sweden

Background: Men with metastatic castration-resistant prostate cancer (mCRPC) have an incurable disease and along with prolonging life, symptom management is one of the main goals in treatment of these men. Most of these men have bone metastases and a high frequency report pain. However, to be able to achieve an effective pain management, and to evaluate effects of treatments on pain in a real-world situation, not only knowledge of frequency is important. Today there are no studies describing different dimensions of pain, such as severity and distress, in men with mCRPC starting life-prolonging treatments in a real-world situation. The aim was to describe the multidimensional aspects of pain from the perspective of frequency, severity and distress, and analgesic use in men with mCRPC, starting a first-line life-prolonging treatment.

Methods: Data was taken from a prospective study (n=143) where 72 men with mCRPC starting their first-line of life-prolonging treatment and reported pain were included. Three dimensions of pain (frequency, severity and distress) were measured using the Memorial System Assessment Scale (MSAS) and the use of analgesics was collected from medical records.

Results: Of the 72 men who reported pain on the MSAS, 63.9% (n=46) used analgesics while 36.1% (n=26) did not. Of the men using analgesics, 55.8 % reported pain "frequently" or "almost constantly" and among the men not using analgesics, 44.0% reported that they had pain "frequently" or "almost constantly". Of those using analgesics, 27.5% reported severe or very severe pain, while none of the men not using analgesics reported very severe pain, and 19% reported severe pain. Of the men using analgesics 51% reported quite a bit/very much distress in contrast to 38% of the men not using analgesics.

Conclusions: Pain management was not sufficient for more than half of the men, even for those receiving analgesics. Men with mCRPC starting life-prolonging treatment may benefit from a structured multidimensional assessment. When the disease has progressed to a mCRPC phase, an early integrated palliative approach with thorough symptom management may be essential in order to obtain the best possible quality of life.

CN28 From difficulty to meaning: Palliative cancer patients experience on advance care planning conversation and having a palliative plan

A. Kolstrøm

Home Care Nursing, Kristiansund Municipality/ NTNU, Kristiansund, Norway

Background: ACP is used as a systematic tool with the aim of helping patients establish decisions about future care. Palliative care plan is a document that aims to ensure the planning and facilitation of measures to give patients and their families safety and the best possible quality of life. The plan was implemented in several municipalities in North-western of Norway in the first half of 2018 and follows the patient at all service levels.

Methods: An exploratory qualitative study was conducted with five palliative cancer patients who had undergone ACP and prepared a palliative plan. Strategic selection was used to choose informants and participants were recruited from four municipalities. Data were collected through individual semi-structured interviews and were analyzed using Malteruds systematic text condensation.

Results: Patients experienced ACP as a process starting from difficult conversations and culminating in a sense of meaning. Having a palliative care plan was felt to be a positive aspect, but they wished they had been prepared for these conversations and had undergone ACP in their own home. The patients' insights were as follows: (1) The starting point was difficult for the patients since they had to talk about cancer and death, which was tough, painful, and rather "taboo" topics. (2) The interactions with the doctor/nurse helped the patients feel valued and involved and underlined their final wishes. The patients wished that their next of kin had been involved by the

doctor/nurse. (3) Preparing a plan for the future and death was a meaningful process for the patients and gave them a sense of security.

Conclusions: Results suggest that advance discussion and a comprehensive plan are shown to give palliative cancer patients much benefit. Although participation in ACP can arouse unpleasant feelings, many patients reported benefits from it. Getting their wishes to be known and the reduced personal information about themselves in a document, gives patients inner peace of mind and increases quality of life. The context and interactions provided by the doctor/nurse, their ability in communicating with the patients, including the patients as persons and taking care of the patient's values and wishes was crucial.

CN29 Euthanasia, not simply early death. Lived experiences of patients, caregivers, and nurses: A systematic review and qualitative meta-synthesis

L. Cadorin[1], M. De Martin[2]

[1]Healthcare Profession Management Office, Centro di Riferimento Oncologico - CRO, Aviano, Italy; [2]Medical Oncology, CRO Aviano - Centro di Riferimento Oncologico - IRCCS, Aviano, Italy

Background: The concept of euthanasia and the desire for a serene death that occurs outside frenetic healthcare environments still raises many questions. Different reasons and pathologies prompt people to make this choice. Particularly, for a person who lives with advanced cancer, choosing euthanasia is motivated by reasons including physical and psychological suffering or the need to maintain personal autonomy and dignity. This review can help provide a better understanding of patients, caregivers, and nurses' lived experiences during this journey.

Methods: We conducted a qualitative systematic review in four databases: Pubmed, Cinahl, Scopus, e Web of Science. The PRISMA method and enhancing transparency in reporting the synthesis of qualitative research (ENTREQ) statement were adopted to report the data and the meta-synthesis approach was used. Of 2040 articles considered, twenty-eight were selected according to the inclusion/exclusion criteria (8 in oncology and palliative care settings). The thematic analysis approach was used to summarize the emerging data in two steps: 1) General, across all data, and 2) specific, considering oncology and palliative care settings.

Results: Five themes emerged from the general data: (1) the desire for early death; (2) autonomy as freedom to determine one's death; (3) end-of-life care as a good death; (4) accompaniment with support and care, and (5) personal experiences and emotions. In addition, three further themes found in the specific contexts were: (1) Methods used to address patient requests; (2) obstacles to meeting demands, and (3) nurses' involvement. These contents summarized both the reasons for requesting early death and the experiences of individuals involved in the complex path of euthanasia.

Conclusions: Euthanasia is not achieved only through an early death. Instead, it is a more complex and articulated pathway in which the suffering and consequences that the disease causes are addressed, and the way that these experiences lead to changes in the meaning of life. Patients perceive that euthanasia is "another option" that puts the person who, despite the illness, continues to have desires and expectations for their future, at the center of the care process.

CN30 Patients', relatives', and healthcare professionals' experiences and perspectives of shared decision-making in palliative cancer care: A systematic review and meta-synthesis

J. Rabben[1], M. Fossum[1], B. Vivat[2], G.E. Rohde[3]

[1]Faculty of Health and Sport Sciences, Department of Health and Nursing Science, University of Agder, Grimstad, Norway; [2]Marie Curie Palliative Care Research Department, Division of Psychiatry, Faculty of Brain Sciences, UCL - University College London, London, UK; [3]Faculty of Health and Sport Sciences, Department of Health and Nursing Science, University of Agder, Kristiansand, Norway

Background: Shared decision-making (SDM) in palliative cancer care can be challenging. Palliative care includes interprofessional teamwork and a family-oriented approach, hereunder decision-making. Qualitative research has been conducted on SDM in advanced cancer, mostly on the patient-physician dyad and some on the perspectives of relatives and nurses. However, a synthesis of SDM research in palliative cancer care integrating the perspectives of patients, relatives, and healthcare professionals has not yet been conducted. The aim of this review was to identify and synthesise qualitative findings on how patients, relatives, and healthcare professionals experience and perceive SDM in palliative cancer care.

Methods: We searched five electronic databases (MEDLINE, Embase, CINAHL, PsycINFO, and Scopus) until August 2022. Included studies were peer-reviewed papers reporting qualitative or mixed methods empirical studies of treatment and care decision-making with adult patients with advanced cancer, relatives, or healthcare professionals, which reported findings relevant to SDM. Our qualitative research synthesis was guided by Sandelowski and Barroso's framework. We synthesised extracted data using inductive thematic analysis, including a meta summary.

Results: The search identified 3,312 titles and abstracts, from which we included 20 studies, reported in 23 papers. The thematic analysis produced nine descriptive themes, which were further analysed to produce four analytical themes: 1) Overwhelming situation of "no choice", 2) Process varies by timings and where decision is required, 3) Patient-physician dyad is key, and 4) Involvement depends on personal qualities.

Conclusions: SDM with patients with advanced cancer is a complex process, involving multiple decisions, in a challenging, multifaceted situation with limited equipoise and choice. More attention to creating awareness of choice and motivating patient involvement is needed. This might require involving more healthcare professionals in the team, and particularly developing the role of cancer nurses in SDM in this context.

CN31 A qualitative study investigating the perception of simultaneous care in nurses

D. Tregnago[1], A. Avancini[1], G. Polato[1], L. Belluomini[1], I. Trestini[1], M. Sposito[1], J. Insolda[1], S. Vincenzi[1], M. Milella[2], S. Pilotto[2]

[1]Department of Engineering for Innovation Medicine, University of Verona, Verona, Italy; [2]Department of Engineering for Innovation Medicine, Section of Oncology, University of Verona, Verona, Italy

Background: The purpose of this study was to investigate features that can influence the incorporation of simultaneous care in the oncological setting by nurses' perspectives.

Methods: A qualitative study, involving structured focus group discussions, was conducted via web conferences (ZOOM platform). A total of two focus groups were performed, involving 9 nurses. Each discussion was audio-recorded, transcribed verbatim, and analyzed with thematic analysis.

Results: According to the Health Belief Model, the transcripts of the focus groups were categorized into: (1) benefits, (2) barriers, and (3) cues to action. Nurses recognized the acquisition of greater awareness of the path of care, a sense of empowerment, and the improvement in the patient's quality of life as the major benefits of simultaneous care activation. The perceived barriers in the simultaneous care activation were related to an increased risk of anxiety levels in patients and their relatives, as well as the precarious culture and lack of knowledge among the public opinion. Different strategies may favor the early activation of simultaneous care, including: a teamwork approach (oncologists, palliativists, and nurses), correct patient education, and the synergy between cancer hospital healthcare professionals and home simultaneous care staff.

Conclusions: This result may help to better implement and activate simultaneous care in the oncological setting with important implications for the patients' quality of life.

CN32 Exploring the content and outcomes of meaning-centered interventions in palliative care: A scoping review

Y. Eskigülek, S. Kav

Nursing, Baskent University Faculty of Health Sciences, Ankara, Turkey

Background: Palliative care patients experience existential suffering in terms of psychosocial and spiritual distress and physical pain. Meaning-Centered Interventions have been proposed to be an effective method for improving patient outcomes, reducing psychological and spiritual distress in advanced cancer patients. The aim of the scoping review was to explore the contents, outcome measures, and results of Meaning-Centered Interventions in Palliative Care.

Methods: The PRISMA-ScR checklist and scoping review recommendations were followed. Related databases searched for studies published in English, including PubMed, Ebsco, PsycINFO, and Scopus. Randomized controlled and interventional studies using meaning-centered interventions published from 2000 to April 2023 involving palliative care or advanced cancer patients were included. Two authors conducted the literature search and study selection process independently on the COVIDENCE system. Studies were assessed for design, sample, randomization, setting, administrators of the intervention, outcome measures, intervention content and duration, control group, and results.

Results: A total of 133 studies were imported for screening and ten studies were included in the scoping review after duplicates and irrelevant articles were removed. Five articles described the pilot study, four randomized controlled trials, and one arm feasibility trial. Six studies were from the USA, two from Spain, one from Australia, and Iran. Interventions were delivered by a psychiatrist, clinical psychologist, social worker, or doctoral student in clinical psychology, mostly 8 (3 to 10) sessions weekly as a group (n=5), individual psychotherapy (n=4); in the outpatient setting (n=6), at home and videoconference.

Conclusions: Patients receiving meaning-centered interventions showed significantly greater improvement in spiritual well-being, quality of life, and sense of meaning, and reductions in levels of depression, demoralization, hopelessness, death anxiety, desire for hastened death, and physical symptom distress compared with those receiving standard care. Meaning-centered interventions can be considered and adopted in other countries for patients receiving palliative care.

CN33 Health care professionals' perceptions regarding shared clinical decision-making in both acute and palliative cancer care, a qualitative study and its clinical implications

H. Ullgren[1], L. Sharp[2]

[1]Theme Cancer/ Regional Cancer Center, Karolinska University Hospital-Solna, Solna, Sweden; [2]Cancer Care Improvements, RCC - Regionalt Cancercentrum Stockholm - Gotland, Stockholm, Sweden

Background: Developments in cancer care have resulted in improved survival and quality of life. Integration of acute and palliative cancer care may be challenging, and there is no golden standard model for integration. Fragmented care is associated with sub-optimal communication, collaboration, and ineffective care. This may lead to unnecessary care transitions, and impact patient safety. We performed a study with the aim to explore how health care professionals, from both acute and palliative care, perceive clinical decision-making when caring for patients undergoing active cancer treatment in parallel with specialized palliative care at home.

Methods: Qualitative explorative design, using online focus-group interviews, based on patient-cases, among health care professionals (physicians and nurses) and Framework Analysis.

Results: Six online focus-group interviews were performed. Few signs of systematic integration between acute and palliative care teams were found, risking fragmented care and putting the patients in vulnerable situations. Different aspects of uncertainty related to mandates and goals-of-care impacted clinical decision-making. Organizational factors and uncertainty related to responsibilities impacted clinical decisions. We found barriers to timely end-of-life conversations and clinical decisions on optimal care. In addition, the appropriateness of transfer to acute care, seemed to be related to lack of knowing which team was responsible.

Conclusions: Lack of integration between acute and palliative care have negative consequences for patients (fragmented care), health care professionals (ethical stress), and the health care system (inadequate use of resources). Clinical implications: We started two main integration projects based on this study, one piloting direct admission to specialized palliative inpatient ward directly from the emergency room. The other on-going project will try digital visits with patient, the oncology, and the palliative team, aiming to discuss goals-of-care. The results and what we learned from those integration projects will be presented.

CN34 Pallium game: The use of a card game in palliative care

B. Magalhães[1], C. Fernandes[2], M. Lourenço[3], M. Belem Vale[4]

[1]Nursing, UTAD - Universidade Tras os Montes e Alto Douro, Vila Real, Portugal; [2]Nurse, Escola Superior de Enfermagem do Porto, Porto, Portugal; [3]Nurse, Nursing School of Porto, Porto, Portugal; [4]Nursing, WeCare Saúde — Unidade de Saúde, Porto, Portugal

Background: Palliative care can improve the quality of life of people and their families when timely and holistic identification of needs is carried out, allowing for the planning of person-centered care that meets their multidimensional needs and includes their wishes (Fernandes et al. 2021 .) In palliative care, strategies are needed to eliminate some barriers to be able to discuss and document the values and preferences of the person and the family member.

Methods: This study aimed to evaluate the use of a card game as a family assessment tool in a palliative care unit. The sample was composed of 13 family members of people with palliative illness admitted to the palliative care unit. Participants were recruited using a convenience sampling method. The "Pallium Game" has 2 "Start" Cards, 23 "Family" Cards, 16 "Support" Cards, 10 "Impact" Cards, 23 "Meaning" Cards, 11 "Belief" Cards, and 8 "Intervention". The game begins with the two "Start" cards, serving as an "Icebreaker" and family assessment tool. Next, the participants choose the themes of the letters they want to answer and take turns reading the letters aloud and answering the respective themes. When the game is over, at least two intervention cards must be collected and discussed. Pallium game is intended to improve communication between people/families/caregivers and health professionals, creating a space that enables the understanding of the behaviour patterns in the family system, extracting meaning from adversity, and promoting better interaction and adaptation.

Results: Using a game was found to be useful and effective. A collaborative game in palliative care should create a space for people and families to express feelings and experiences, meeting the myriad of physical, psychosocial, and spiritual needs. Our findings suggest that using the "*Pallium game*" is a useful and impactful approach to discussing sensitive topics in palliative care.

Conclusions: A collaborative game in palliative care helps to create a space for individuals and families to express feelings and experiences, meeting the myriad of physical, psychosocial, and spiritual needs. The "Pallium game" is a useful and impactful approach to discussing sensitive topics in palliative care.

Cancer nursing: Supportive care

CN35 Educational interventions and strategies that nurses use to support women with gynecological cancer: A narrative review

C. Mazzega Fabbro[1], C. Pavon[2]

[1]Medical Oncology, CRO Aviano - Centro di Riferimento Oncologico - IRCCS, Aviano, Italy; [2]Surgical Oncology, Azienda Sanitaria Universitaria Friuli Centrale, University Hospital of Udine, Udine, Italy

Background: The incidence of cancer is increasing worldwide and is considered to be a serious public health problem. Hysterectomy and or oophorectomy are known to be the primary surgical treatments after cancer of the cervix, uterus, and ovary is diagnosed. In many cultures, the uterus and ovaries are considered to be symbols of femininity, fertility, and particularly motherhood. Indeed, the loss of these organs after surgery ends reproductive capacity. After undergoing radical surgery, gynecological cancer patients become vulnerable to several disorders that affect their quality of life, such as anxiety, depression, body image disorders, and low self-esteem.

Methods: A narrative review was conducted in three databases (PubMed, CINAHL and Scopus). The inclusion criteria were: 1) women with gynecological cancer; 2) papers written in English; 3) papers published between January 2012, and September 2022, and 4) papers that describe the details of educational interventions strategies that nurses use in oncology care. Two independent reviewers assessed each paper independently for methodological validity prior to inclusion in the review using the Prisma statement. A total of 178 articles was retrieved and identified. When the duplicates were removed, 150 studies were screened by title, and 67 by abstract, all of which were excluded, after which the full text of 52 articles were evaluated, of which 15 articles were included in the final review.

Results: A total of 15 findings was extracted and aggregated into 3 categories based upon similarity in meaning. Empowerment: nurses play a stimulating role to overcome fears, prioritize gynecological cancer patients' individual needs, and implement sexual rehabilitation strategies; Psychological sphere: nurses help women learn relaxation techniques and physical exercises for sexual rehabilitation, and Physical well-being: physical exercise, dance, and complementary medicine have positive effects on the patients' quality of life.

Conclusions: Nursing interventions are able to reduce the collateral effects of oncological treatments and strengthen patients' self-confidence in facing their oncological treatments, particularly by decreasing their anxiety, depression, and distress.

CN36 Current care for patients on oral anticancer therapy through a different lens: Assessment from a patient and healthcare professional perspective

A. Van Hecke[1], L-M. Kinnaer[1], V. Foulon[2], I. Kenis[3]

[1]University Centre for Nursing, Ghent University - University Centre for Nursing and Midwifery, Ghent, Belgium; [2]Pharmacy, KU Leuven, Leuven, Belgium; [3]University Centre for Nursing, Ghent University, Ghent, Belgium

Background: Over the last decades, an important shift from a disease-focused to a patient-centered approach has taken place in cancer care. This study examined the quality of patient-centered care for patients treated with oral anticancer drugs (OACD), from the patient and healthcare professional (HCP) perspective.

Methods: Patients and HCPs from 12 Flemish oncology departments completed the CONTACT-Patient-Centered Care Questionnaire (CONTACT-PCCQ) and the CONTACT — Key Elements Questionnare (CONTACT-KEQ) respectively. The questionnaires are based on an evidence-based and validated list of key elements (KEs) considered crucial in patient-centered care for patients on OACD. Patients were asked to indicate how they experienced the performance of each KE on a five-point Likert scale. The HCPs were asked to indicate whether the KE was performed or not. The degree of performance, according to patients and HCPs, was calculated for each KE.

Results: In total, 266 patients and 275 HCPs participated. The degree of performance according to patients ranged from 22% to 95%, with 36 KEs having a degree of performance $<$ 70% (i.e., underperformed). According to HCPs, the degree of performance varied between 23% and 99%, and 15 KEs were underperformed. While HCPs mainly assigned low scores to items related to coordination of care, patients scored low on items regarding counselling at treatment-initiation and during follow-up, and psychosocial support.

Conclusions: This study uncovered gaps in patient-centered care according to patients and HCPs. The differences between the scores of patients and HCPs highlight the importance of including both perspectives when evaluating patient-centeredness of care practices.

CN37 Perceptions and attitudes of healthcare providers towards discussing sexuality and sexual problems in cancer patients (from LGBTQ+ backgrounds)

C. Beyts[1], J.N. Verhelle[1], E. Pape[2], G. van Ramshorst[2]

[1]Medicine and health sciences, Ghent University - Campus Ufo, Ghent, Belgium; [2]Oncology, UZ Ghent - Universitair Ziekenhuis Ghent, Ghent, Belgium

Background: Sexual dysfunction is a consequence of cancer survivorship. Few oncology patients have had a conversation with a HCP about sexuality during or after treatment according to a report by *Kom Op Tegen Kanker* (Neefs, 2022). This study aims to explore the knowledge, perceptions, and attitudes of HCPs towards discussing sexuality with cancer patients, more specifically with LGBTQ+ patients.

Methods: A mixed-method study was conducted. An online questionnaire about attitudes and knowledge towards talking about sexuality with cancer patients was distributed by email among several interprofessional HCPs in March of 2023. The answers were statistically analysed in SPSS using descriptive statistics and Chi^2. Three focus group interviews were conducted with HCPs working at a University Hospital to explore their perceptions and attitudes towards discussing sexuality and sexual problems with cancer patients, as well as with LGBTQ+ patients. Data were analysed using thematic analysis.

Results: The questionnaire was completed by 259 HCPs working in cancer care in Flanders. Those who had an education on sexual health were positively correlated to knowledge ($p \leq 0.001$). There were also correlations ($p < 0.001$) that indicated that HCPs in more specialised functions had more knowledge on the topic and felt more comfortable discussing sexuality with cancer patients. Six themes, for which data saturation was reached, emerged from the focus group interviews: (1) preconditions for discussing sexuality with patients, (2) perceived barriers and (3) facilitators, (4) patients belonging to the LGBTQ+ community, (5) focus points, and (6) recommendations given by HCPs. HCPs reported not having enough knowledge of sexual health and deemed asking about sexual orientation as not important, as LGBTQ+ patients received the same care as the general cancer population.

Conclusions: HCPs have presumptions about patients' needs, while these might differ from their actual needs. This is especially true in minority groups such as LGBTQ+ patients. There is a need for more education and training among HCPs to facilitate the conversation about sexuality, as well as more research to improve care regarding sexual issues in cancer patients.

CN38 To study the effect of evidence-based nutrition management on improving the nutritional status of postoperative patients with esophageal cancer

C. Chen

Thoracic surgery, Fudan University Shanghai Cancer Center, Shanghai, China

Background: To explore the effectiveness of evidence-based nutrition management in improving the nutritional status of postoperative patients with esophageal cancer.

Methods: The evidence-based nursing method was used to obtain evidence and apply it to clinical practice after localization. The nutrition management plan for patients with esophageal cancer surgery was formulated, and the clinical behavior of doctors and nurses was standardized. The body weight and body composition index, standard rate of energy and protein intake, and postoperative hospital stay of patients with esophageal cancer surgery were compared before and after the application of the best evidence.

Results: The improvement of body weight, BMI and skeletal muscle in the intervention group were significantly better than those in the control group (all $P < 0.01$). The compliance rate of energy intake from the first to the fifth day after operation and the compliance rate of protein intake from the first to the sixth day after operation in the intervention group were better than those in the control group (all $P < 0.05$). The median postoperative hospital stay was 9 days in the intervention group and 10 days in the control group, which shortened the length of hospital stay ($p < 0.01$) and accelerated the recovery of patients after surgery.

Conclusions: Evidence-based nutrition management can improve the nutritional status and clinical outcomes of patients with esophageal cancer after surgery, which is conducive to improving the quality of medical care.

CN39 Bibliotherapy in cancer nursing: A systematic review

T. Gašpert

Oncology, University Hospital KBC Rijeka, Rijeka, Croatia

Background: Bibliotherapy is an intervention that uses written or visual materials to promote psychological and emotional well-being. Although bibliotherapy has been used in cancer care, there is limited understanding of its effectiveness in the nursing context. This systematic review aims to synthesize the available evidence on the use of bibliotherapy in cancer nursing.

Methods: A systematic search of electronic databases including MEDLINE, CINAHL, PsycINFO, and Cochrane Library was conducted. Studies that evaluated the use of bibliotherapy in cancer nursing were included. Two reviewers independently screened the studies, extracted the data, and assessed the study quality using the Cochrane risk of bias tool. The extracted data were synthesized using a narrative approach.

Results: Of the 1,238 articles identified in the initial search, nine studies met the inclusion criteria. The studies used various forms of bibliotherapy, including written materials, audio recordings, and videos. The studies reported improvements in psychological and emotional well-being, including decreased anxiety and depression, increased self-esteem, and improved quality of life. However, the studies had methodological limitations, such as small sample sizes and lack of control groups.

Conclusions: The available evidence suggests that bibliotherapy may be an effective intervention to promote psychological and emotional well-being in cancer nursing. However, the methodological limitations of the included studies indicate a need for larger, well-designed randomized controlled trials to provide stronger evidence. Cancer nurses may consider using bibliotherapy as an adjunct intervention to support the emotional needs of their patients.

CN40 Time to identify CAM-users during oncology treatment: The results of a regional survey in Sweden

M. Källman[1], M. Bergqvist[1], S. Bergström[1], G. Holgersson[3], J. Hök Nordberg[4], K. Wode[1]

[1]Radiation Sciences Department, Umea University, Umea, Sweden; [3]Oncology department, Akademiska Sjukhuset Uppsala, Uppsala, Sweden; [4]Department of Physiology & Pharmacology, Karolinska Institute, Stockholm, Sweden

Background: Patients' use of complementary and alternative medicine (CAM) is widespread. However, there is a lack of knowledge regarding the extent and details of patient CAM use in Sweden, and especially in rural Sweden. The aim of this study is to estimate the extent and characteristics of the CAM use of cancer patients in Region Gävleborg.

Methods: Questionnaires were distributed to patients either beginning chemotherapy treatment for curative purposes, or newly enrolled in palliative home care. A total of 631 questionnaires were distributed to which 376 responses were registered, yielding a response rate of 59.6%. The characteristics of the respondents were presented with standard descriptive statistics. A multivariate logistic model was fitted to calculate odds ratios (ORs) and identify potential predictors (Age, Gender, Education, Diagnosis) of CAM use post cancer diagnosis.

Results: The most common CAM methods used after diagnosis are vitamins, health food preparations, herbal tea, prayer, and dietary methods. The most common source of information reported is family and friends. 54% of all participants reported CAM use under lifetime, 34% reported CAM use post-diagnosis. Almost 70% of those who used CAM after their diagnosis stated that they did not discuss their use with health care professionals. Most patients wish that CAM modalities should be offered within conventional care regardless own CAM use.

Conclusions: The use of CAM is common among patients with cancer in the region of Gävleborg and previous studies show a similar use in Sweden in general. Based on the widespread use of CAM, as well as patients' desires for dialogue with health care professionals, attention and focus should be placed on creating a basis for this dialogue. If we in healthcare are to emphasise that we provide patient-centred care, we must recognise the fact that patients use CAM and are seeking a dialogue about this topic.

CN41 Qualitative analysis of school re-entry experiences of turkish childhood cancer survivors: Parental perspective

T. Arpaci[1], N. Altay[2]

[1]Nursing, Karamanoglu Mehmetbey University, Karaman, Turkey; [2]Nursing, Gazi University - Faculty of Health Sciences, Ankara, Turkey

Background: Children with cancer stay away from school for a long time during the treatment process. School re-entry helps normalize the cancer experience for children and their families by enabling the child to participate in activities with peers. The aim of this study was to explore the school re-entry experiences of Turkish childhood cancer survivors.

Methods: In this qualitative study, semi-structured, in-depth interviews were conducted with parents of childhood cancer survivors (n = 20). Survivors who had completed treatment at least two years ago were involved in the study. Interviews were conducted via telephone or video conferencing. Interviews recorded and transcribed verbatim. An inductive thematic approach was used to analyze the data. The study was conducted and reported according to the consolidated criteria for reporting qualitative research (COREQ) guidelines. The components of qualitative rigor were considered to ensure confidence in the methods and data.

Results: The diagnosis of most of the survivors was lymphoma (35%). The ages of survivors were between 11-18 years and the duration of school absenteeism ranges from 1 months to 3 years. According to qualitative analysis, three main themes and sub-themes were identified as follows; 1) "Worry" with five sub-themes; Academic performance, Peer relations, Stigma, Physical problems and Exposure to physical trauma 2) "Challenging Situations" with five sub-themes; Negative body image, Negative perceptions of others about the disease, Parents' protective attitudes, The thought of falling behind from his/her friends and Feeling ostracized 3) "Facilitating Situations" with three sub-themes; Willingness to attend the school, Increased social interaction, and Support from school staff. Parents stated that both children and parents need support during the school re-entry process.

Conclusions: This study revealed that survivors worry about physical, academic, and social issues. They face a range of problems that make school re-entry difficult. With the cooperation of the health team and the school, arrangements should be made to ensure that the survivors have a positive experience on school re-entry.

CN42 A pharmacist-led interprofessional medication adherence program improved adherence to oral anticancer therapies: The OpTAT randomized controlled trial

C. Bandiera[1], E. Cardoso[1], I. Locatelli[2], K. Zaman[3], A. Diciolla[3], A. Digklia[3], A. Stravodimou[3], V. Cristina[3], V. Aedo-Lopez[4], A.M. Dolcan[3], A. Sarivalasis[3], H. Bouchaab[3], J. Pasquier[2], J. Dotta-Celio[2], S. Peters[3], A.D. Wagner[3], C. Csajka[1], M.P. Schneider[1]

[1]School of Pharmaceutical Sciences, University of Geneva, Geneva, Switzerland; [2]Unisanté, Center for Primary Care and Public Health, Lausanne, Switzerland; [3]Oncology Dept., CHUV - Centre Hospitalier Universitaire Vaudois, Lausanne, Switzerland; [4]Oncology Department, Monash Health - Monash Medical Centre, Clayton, VIC, Australia

Background: Protein kinase inhibitors (PKIs) are increasingly prescribed in cancer care. We aimed to evaluate the impact of a pharmacist-led interprofessional medication adherence program on patient implementation (dosing history), persistence (time until premature stop of the PKI) and adherence to 27 PKIs prescribed in different types of solid cancers.

Methods: Patients (n=118) were randomized 1:1 in two arms. All PKIs were delivered in electronic monitors (EM). In the intervention arm, pharmacists supported patient adherence through monthly electronic and motivational feedback including educational, behavioral, and affective intervention for 12 months. The control arm received standard care plus EM without intervention. Medication implementation and adherence were compared between groups using generalized estimating equation models, in which relevant covariables were included; persistence was compared with Kaplan-Meier curves. Oncologists prescribed regular treatment interruptions to help patients recover from side effects; this information was compiled in the analyses.

Results: PKI implementation was constantly higher in the intervention (n=58) than in control arm (n=60), 98.1% and 94.9% (Δ3.2%, 95% confidence interval (CI) 2.6%-3.7%) at 6 months. The probabilities of persistence and adherence were comparable between groups. The intervention benefited most to men (Δ5.4%, 95%CI 4.2-6.5), those who initiated PKI for more than 60 days (Δ4.6%, 95%CI 3.7-5.5), patients without a diagnosis of distant metastasis (Δ4.6%, 95%CI 3.4-5.7), those aged less than 60 years old (Δ4.1%, 95%CI 3.3-4.9) and those who had never used any adherence tools (Δ4.1%, 95%CI 3.4-4.7).

Conclusions: The interprofessional medication adherence program, led by pharmacists in the context of an interprofessional collaborative practice, supports implementation to PKIs in patients with solid cancers. In order to manage side effects, dose adaptations are often mandated, further supporting a proactive strategy aiming at supporting adherence. Longer-term medication adherence interventions, embedded in routine care, should provide results on the impact on progression-free survival.

CN43 Development, implementation and evaluation of a cancer survivorship care program

F. Herman[1], E. Rammant[2], M. Goderis[3], E. Pape[1], E. Decoene[1], J. Demunter[4], M. Quaghebeur[5], K. Geboes[6], M. Daem[7]

[1]Oncology Dept., UZ Ghent - University Hospital Ghent, Ghent, Belgium; [2]Public Health and Primary Care, Ghent University - Campus Ufo, Ghent, Belgium; [3]Medicine and healthcare sciences, Ghent University - Campus Ufo, Ghent, Belgium; [4]Oncology - Hematology, UZ Ghent - Universitair Ziekenhuis Ghent, Ghent, Belgium; [5]Hematology, UZ Ghent - University Hospital Ghent, Ghent, Belgium; [6]Gastroenterology Department, UZ Ghent - University Hospital Ghent, Ghent, Belgium; [7]Cancer center, UZ Ghent - Universitair Ziekenhuis Ghent, Ghent, Belgium

Background: Cancer survivors experience treatment-related long-term and late effects, affecting their quality of life. Survivorship care is currently not adequately organized against these challenges and more understanding is needed. The aim of this project was to improve survivorship care by focusing on health care professionals across ten existing oncology groups at Ghent University Hospital.

Methods: A cancer survivorship care program was developed and implemented using action research. Based on a literature study, observations, focus group interviews, consensus meetings, data were gathered. The screening and development phase took place from 2020 till 2021. Implementation started in 2022 and is ongoing. Semi-structured interviews are being conducted to evaluate the program with the final results in October 2023.

Results: In order to improve and reorganize follow-up, training sessions were organized for health care professionals to increase their knowledge and awareness about survivorship care. Second, nurse consultations, in addition to physicians follow-up, were implemented which allowed clinical nurse specialist and oncology nurse navigators to focus more on psychosocial topics. Third, tools such as the survivorship care passport, the Holistic Need Assessment and a booklet for patients were developed as an aid to structure the consultation. Last, a digital platform was created to support health care professionals in primary and secondary health care with specific information on eight common challenges in survivorship care. This diverse set of tools was offered to all oncology groups. According to their needs, the implemented program was slightly different in every group. Preliminary results show positive experiences of the health care professionals on several levels. They feel more competent to deliver care which suits the need of patients. However, organizational issues and lack of time are common reported barriers.

Conclusions: Through action research, current barriers in survivorship care were identified and tailored solutions were offered to ten oncology groups. Preliminary experiences of health care professionals with this cancer survivorship care program look promising.

CN45 Exercise training following surgery and chemotherapy for ovarian cancer: A realist evaluation of a co-designed implementation process

D.M. Mc Grath

School of Nursing and Midwifery, Queens University Belfast, Belfast, UK

Background: The benefits of exercise for women with ovarian cancer are reasonably well established however uptake is poor. Presently, research exploring a co-designed implementation process is limited and may assist in exercise uptake. Determining the feasibility of exercise training in this population is necessary to improve survivorship.

Methods: This single centre study involved a series of three co-design workshops with contributors including ovarian cancer survivors (n=10) and their informal carers (n=10), followed by implementation of an exercise intervention with women (n=31) following surgery and chemotherapy for ovarian cancer. Following completion of the intervention participants undertook a realist interview. Healthcare professionals (n=3) familiar with the exercise intervention were also interviewed.

Results: Key themes that emerged include; the initial approach should be made by a disease specific health care professional, flexibility in meeting exercise goals, weekly telephone behavioural support, and a home-based approach. This promotes: a shift of mental focus from the disease to exercise and wellness; a sense of control over one's destiny; and a feeling of empowerment to reach exercise goals. A recruitment rate of 73.8% was achieved. 100% achieved the recommended dose of aerobic exercise, with 93.4% achieving the recommended dose of resistance training. The retention rate was 96.7%.

Conclusions: The co-design process facilitated exercise recruitment, adherence and retention. This intervention is feasible and safe for women following surgery and chemotherapy treatment for ovarian cancer. These findings contribute to the evolution of a programme theory in relation of how to successfully implement exercise into the care of this patient population.

CN46 Experiences and sexuality of participants with a permanent colostomy after cancer treatment: A qualitative study

K. Van der Eecken[1], Y. Van Nieuwenhove[1], G. van Ramshorst[2], D. Van de Putte[1], P. Pattyn[3], S. De Meyer[1], E. Pape[2]

[1]Gastrointestinal surgery, UZ Ghent - Universitair Ziekenhuis Ghent, Ghent, Belgium; [2]Oncology, UZ Ghent - Universitair Ziekenhuis Ghent, Ghent, Belgium; [3]Gastrointestinal surgery, AZ Delta Campus Rumbeke, Roeselare, Belgium

Background: Each year, approximately 1.4 million people worldwide are diagnosed with cancer, of which 10% are diagnosed with colorectal cancer. A colostomy can negatively affect quality of life in various ways. The aim of this study was to explore the experience and perception of participants with a permanent colostomy after rectal cancer treatment with a focus on the sexual experience.

Methods: An explorative qualitative study was conducted. Semi-structured interviews were conducted in two hospitals. Fifteen participants with a permanent colostomy after treatment for rectal cancer participated. A thematic analysis was performed and investigators' triangulation was used during data-analysis. Data-saturation was obtained in most of the themes.

Results: Five main themes were retained: (1) living with a definitive colostomy, (2) seeking control through trial-and-error, (3) in relation to the other, (4) the sexual experience, (5) the provision of care. How participants experience life with a permanent colostomy was central to the themes. Participants are often not aware of the possible consequences of a colostomy on their general and sexual experience. In addition to commonly reported sexual functional problems, such as erectile dysfunction and vaginal dryness, the psychosocial aspect plays a major role. Mainly altered self-image and feelings, such as shame and anxiety, were most frequently expressed. Healthcare providers play an essential role in the information, education and training of the ostomy carrier.

Conclusions: Within the current care provision, sexuality is still insufficiently included in the care and treatment plan. This ensures participants feel only to a limited extent informed about the effects of the treatment on their sexual experience. There is need for a proactive approach to discuss sexuality.

CN48 Mobile response and prevention unit: Mobile information and management unit a collaboration between "Care In Adult Cancer Patients" nursing research laboratory and "Cancer Guidance Center" a non-profit organization (Kapa3)

E. Bista[1], A. Kostas[2], I. Tsoukalidis[3], M. Lavdaniti[4]

[1]Non-Profit Organization, KAPA 3, Athens, Greece; [2]Logistic Department, International Hellenic University, Kavala, Greece; [3]Logistic Department, Domi Development PC, Kavala, Greece; [4]Research Laboratory "Care in Adult Cancer Patients", International Hellenic University - Nursing Department, Thessaloniki, Greece

Background: Social support plays a critical role in improving treatment outcomes for cancer patients. Patients with strong social support systems tend to have better adherence to treatment plans and better physical recovery. An innovative cooperation between the non-profit organization Cancer Guidance Center (Kapa 3) and the "Care in Adult Cancer Patients" Nursing research laboratory support cancer patients and inform them of any procedure required to fully exercise their rights. Kapa3 manages the rights and obligations of people with cancer. The organization partners with public and private entities, such as the European Cancer Patient Coalition, in taking action to tackle cancer effectively, highlighting the issues facing Greek cancer patients and survivors. A nurse and a social worker informed patients about this innovative cooperation and how to communicate with welfare services. Many nursing students participated in the project as volunteers. They used digital applications that assist in completing information and supporting cancer patients. These will include all offered welfare services, together with all the required supporting documents for their applications. This study aims to assess how many cancer patients use this service.

Methods: This study was conducted in the oncology departments of selected hospitals in Greece. This research used convenience sampling with 348 cancer patients.

Results: The majority of the patients lived in Northern Greece (Thessaloniki), were female (216, 62.1%), and were married (271, 77.9%). The participants' mean age was 60 ± 14 years. Most had breast cancer (28.4%) and lung cancer (22.4%). The majority of the selected cancer patients (71.3%) communicated with K3 to apply for the welfare service by the Disability Certification Centre, 42.5% for social invoice. About 33.6% (n = 117) of the caregivers communicated with K3. Most of them used mobile phone calls (129, 37.1%) and mobile applications (106, 30.5%).

Conclusions: Using the proposed innovative application will help cancer patients and caregivers develop a better relationship and improve their quality of life.

CN49 Nurse—patient sexual health communication in gynecological cancer follow-up: A qualitative study from nurses' perspectives

A. Paulsen[1], I. Vistad[2], L. Fegran[3]

[1]Department of Research, Sørlandet Sykehus, Kristiansand, Norway; [2]Department of Gynaecology and Obstetrics, Sørlandet Hospital, Kristiansand, Norway; [3]Department of Health and Nursing Science, Faculty of Health and Sport Sciences, University of Agder, Kristiansand, Norway

Background: Globally, over 1.39 million women are living with gynecological cancer, and their sexual health can be adversely impacted by cancer treatments. Therefore, it is crucial for gynecological cancer survivors to have opportunities to openly discuss and exchange information regarding their sexual needs during follow-up care. This study was conducted as part of a broader project in Norway that aimed to enhance traditional follow-up approaches for gynecological cancer. The study specifically focused on gathering insights from nurses who were trained in sexual health communication. The primary research question addressed in this study was: What characterizes the nurse-patient sexual health communication, from the perspectives of nurses trained in addressing sexual health?

Methods: Individual semi-structured interviews with 10 nurses at five different hospitals in Norway were conducted in March and April 2021. A Gadamerian-inspired research method was used in the analysis.

Results: Three main themes with six sub-themes were identified. The three main themes were: (1) building relationships through communication, (2) practice makes perfect—the importance of experience and knowledge, and (3) personal attitudes as promoters or inhibiters of sexual health communication.

Conclusions: This study highlights valuable insights on nurse-patient sexual health communication. The nurses recognized the importance of establishing a strong and respectful nurse-patient relationship as the foundation for effective communication in this domain. Professional confidence, gained through experience and knowledge, was found to be crucial, along with recognizing the influence of attitudes and taboos on sexual health communication. The findings indicate that training in sexual health communication and repeated opportunities to address sexual health enhance nurses' skills and professional confidence for follow-up care. Importantly, this study suggests that sexual health communication can be effectively integrated into clinical settings without excessive resource demands. The results may encourage nurses to expand their knowledge of sexual health in cancer follow-up care.

CN50 Patient-reported outcome measures and supportive care need assessment in patients in a slovenian tertiary oncology centre

M. Causevic[1], A. Grbic[2]

[1]Supportive Care Department, Institute of Oncology Ljubljana, Vrhnika, Slovenia; [2]Head Nurse, Institute of Oncology Ljubljana, Ljubljana, Slovenia

Background: Patient-reported outcome measures (PROMs) are tools usually questionnaires, to assess elements of their experience such as symptom burden, functional status and psychological and emotional well-being from patient 's perspective on how illness or care impacts on their well being. The aim of our study is to analyse the psychophysical social well-being and quality of life of cancer patients prior to treatment, the approach of the multidisciplinary team to identify and manage patient needs, and the barriers and facilitators to the use of PROMs in a Slovenian tertiary oncology centre, in order to inform the wider uptake of PROMs.

Methods: From December 2022 to August 2023, PROMs data collected for patients accessing care at a tertiary cancer centre will be retrospectively analysed. Data will be collected using the standardised EORTC C30 questionnaire.

Results: The results will be used to identify, according to each of the domains, the physical, emotional, cognitive, social functioning and functioning, symptom burden, health status and quality of life of the patients before the start of treatment and the use of a multidisciplinary approach to meet the patient's needs. Perceived risks, barriers and facilitators to the use of PROMS will be presented.

Conclusions: This study will demonstrate the benefits of using systematic PROMs monitoring and follow-up to screen patients' needs and provide holistic approach for cancer patients. It will also highlight opportunities, barriers and facilitators to PROMS implementation occur.

CN51 Psychometric properties of the Turkish version of the nurse spiritual therapeutic scale for oncology patients and caregivers

R. Semerci[1], A. Akdeniz Kudubeş[2], Ö. Uğur[3], Y. Yaşa[3]

[1]Pediatric Nursing, Koc University Hospital, İstanbul, Turkey; [2]Pediatric Nursing, Bilecik Şeyh Edabali, Bilecik, Turkey; [3]Nursing, Dokuz Eylul University, Izmir, Turkey

Background: The need for valid and reliable instruments to assess spiritual care in oncology settings has become increasingly important due to the growing awareness of the holistic needs of patients and caregivers. This study is methodologically designed to evaluate the psychometric properties of the Turkish version of the Nurse Spiritual Therapeutic Scale for oncology patients and caregivers.

Methods: This methodological study was conducted between July 2022 and May 2023 with 200 oncology patients and their caregivers. Data were collected using the Information Form and the Nurse Spiritual Therapeutic Scale. In the data analysis, the number and percentage were used for categorical data, while arithmetic mean ± standard deviation was used for quantitative data. Content validity index was used for the compatibility analysis of expert opinions, Pearson correlation analysis was used for item-total score analysis of the scale and its sub-dimensions, and exploratory and confirmatory factor studies were conducted to determine the factor structure of the scale.

Results: The mean age of the nurses was 58.51 + 14.55, and 56.5% were female. In the compatibility analysis among expert opinions, the item-based content validity index was found to be between 0.88 and 0.99, while the scale-based content validity index was 0.97. The total Cronbach's alpha coefficient of the scale was found to be 0.879. The factor analysis used to test the construct validity of the scale revealed that the scale had a single-factor structure with 20 items. The Kaiser-Meyer-Olkin coefficient of the scale was determined to be 0.847, and the result of the Barlett test was 3797.794 ($p < 0.000$). As a result of the exploratory factor analysis in the study, it was found that the factor loadings obtained ranged between 0.29 and 0.89. The scale item-total score correlations were determined to be between 0.236 and 0.761. GFI, AGFI, and CFI were found > 0.90.

Conclusions: The Nurse Spiritual Therapeutic Scale for Oncology Patients and Caregivers is valid and reliable. It should be used to assess the expectations of oncology patients and caregivers regarding spiritual care from nurses.

CN52 Role of translational oncology research nurse (TORN) in improving patients (pts) adherence to microbiome research projects

A. Garcia Rodriguez[1], G. Castillo[2], I. Baraibar Argota[3], M. Sanchis[4], M. Sanz[1], I. Suarez[5], F. Salvà Ballabrera[6], F.J. Ros Montana[7], N. Saoudi Gonzalez[3], A.A. Valdivia[8], C. Perez Alonso[9], C. Rosales[10], A. Texidor[9], M. Rodriguez Castells[6], M. Marti Gallostra[11], A. Peñuelas Saiz[12], J. Tabernero[7], M.E. Elez Fernandez[6]

[1]Oncology Nurse, VHIO Vall d'Hebrón Instituto de Oncología, Barcelona, Spain; [2]Statistics, VHIO Vall d'Hebrón Instituto de Oncología, Barcelona, Spain; [3]Oncology Department, Vall d'Hebron University Hospital, Barcelona, Spain; [4]VHIO Vall d'Hebrón Instituto de Oncología, Barcelona, Spain; [5]VHIO - Vall d'Hebron Institute of Oncology, Barcelona, Spain; [6]Medical Oncology (Gastrointestinal Unit), Vall d'Hebron University Hospital, Barcelona, Spain; [7]Medical Oncology Dept., Vall d'Hebron University Hospital, Barcelona, Spain; [8]Medical Oncology Dept., Vall d'Hebron Hospital Universitari and Vall d'Hebron Institute of Oncology (VHIO), Barcelona, Spain; [9]Clinical trial coordinator, VHIO - Vall d'Hebron Institute of Oncology, Barcelona, Spain; [10]Medical Oncology (Gastrointestinal Unit), VHIO - Vall d'Hebron Institute of Oncology, Barcelona, Spain; [11]Surgery, Vall d'Hebron University Hospital, Barcelona, Spain; [12]Oncology Nurse, Vall d'Hebron University Hospital, Barcelona, Spain

Background: Currently, multiple studies focus on microbiome's relationship to colorectal cancer (CRC) pathogenesis. Microbiota sampling requires strict protocol for collection. Good communication between pts and professionals is needed to ensure their comfort when participating in these projects. TORN is the reference professional in terms of patient care during the disease process and has the necessary training for the collection of biological samples. Our objective is to analyse the adherence to biological samples collection and completion of quality of life and nutrition questionnaires (QoLN) in CRC pts participating in projects involving microbiome, after the incorporation of the TORN into the medical oncology team.

Methods: Pts who attended the TORN consultation for evaluation of microbiome projects at the Vall d'Hebron Institute of Oncology (VHIO) were included. During the consult, functional status and preferences for participating are discussed. If the patient consents, a QoLN is performed. Subsequently, stool and saliva kit are given, and a blood collection is taken. Pts return kits at the following visit. Sample collection is performed at 3-timepoints: baseline, post cycle 1, and at disease progression (PD).

Results: Between 2020 and 2023, 517 pts were visited by TORN (1009 visits), 375 were eligible for microbiome sample collection. A total of 337 QoLN were given, of which 248 were correctly completed (adherence 72%). All pts were able to have blood drawn at all three time points. A total of 788 stool and saliva kits were given to patients, of which 688 were returned (adherence 87,31%). Adherence was lower in the third time period (PD) due to clinical worsening and return to referral centers (Table).

Table: CN52

STOOL/SALIVE SAMPLES	BASAL	POST CYCLE 1	PD	TOTAL
KIT GIVEN	375	293	120	788
KIT RETURNED	345	255	88	688
ADHERENCE (%)	92,0	87,03	73,33	87,31

Conclusions: By being a direct contact to pts and empowering them in the face of their disease, TORN has increased patient adherence to microbiome translational studies. We need to further develop this model of nursing care to continue improving our patient's wellbeing.

CN53 Sexual function in survivors of hematological malignancy and autologous hematopoietic stem cell transplantation

I. Tsatsou[1], T. Adamakidou[2], T. Konstantinidis[3], M. Lavdaniti[4], E. Vlachou[2], D. Papageorgiou[5], O.D. Govina[2]

[1]Nursing Department, University of West Attica, Egaleo, Greece; [2]Nursing Department, University Of West Attica - Campus 1, Egaleo, Greece; [3]Nursing Department, Hellenic Mediterranean University Nursing Department, Herakleio, Greece; [4]Nursing Department, IHU - International Hellenic University, Thermi, Greece; [5]Nursing Department, University of Peloponnese, Tripolis, Greece

Background: Autologous hematopoietic stem cell transplantation (AHSCT) is one of the treatments for patients with hematological malignancies that improves prognosis and survival. Sexual dysfunction following AHSCT is common and affects survivors' quality of life. The aim of the study was to evaluate the sexual function (SF) of survivors of hematological malignancy and AHSCT and to compare it with the SF of healthy individuals.

Methods: A multicenter, quantitative, and cross-sectional study was conducted. Through convenience sampling,127 adults (56 women and 71 men) and survivors of hematological malignancy, who underwent AHSCT from 6 months to 5 years, were recruited from 5 hospitals in Athens,Greece.Also,134 healthy adults were recruited (60 women and 74 men). Survivors and controls completed demographic and clinical data and a male or female SF assessment tool [International Index Erectile Function (IIEF) and Female Sexual Function Index (FSFI) respectively].

Results: Female survivors had a mean of 44 years of age and male ones, 47 years. The median time from transplant was 3 years and the majority had Hodgkin's lymphoma. According to the FSFI, female survivors had a moderate level of SF, with better functioning area "pain" (mean: 4.0 ± 1.74) and worse "orgasm" (mean: 3.19 ± 1.52). According to the IIEF, male survivors had a high level of SF, with better functioning area "erection" (mean: 22.54 ± 8.70) and worse "overall satisfaction" (mean: 6.94 ± 2.47). When comparing SF in survivors with healthy females, it was found that the healthy ones had statistically significantly higher scores in all FSFI subscales ($p < 0.0005$). Also, healthy males had statistically significantly higher scores on "erection" ($p = 0.003$), "desire" ($p = 0.004$), "intercourse satisfaction" ($p = 0.003$), "overall satisfaction" ($p = 0.012$) and on the total score ($p = 0.013$) of the IIEF, compared to survivors. Although male and female survivors had affected SF, there was no statistically significant differences between SF in the male and female survivor groups.

Conclusions: Survivors of AHSCT had impaired SF to varying degrees and areas of functionality, thus indicating the importance of sexual well-being and the implementation of integrated sexual care plans in survivorship.

CN54 Sexual health in women with breast cancer undergoing hormonal treatment

C. Tebar[1], E. Nuñez[1], S. Coret[1], S. Rodríguez[1], J. Soler[1], C. Hernando Melia[2], M.T.M. Martinez[2], B. Bermejo[3], J.M. Cejalvo[3]

[1]Oncology, INCLIVA Instituto de Investigación Sanitaria, Valencia, Spain; [2]Oncology Department, Hospital Clinico Universitario de Valencia, Valencia, Spain; [3]Medical Oncology Dept., Hospital Clinico Universitario de Valencia, Valencia, Spain

Background: Sexual dysfunction is the most common long-term consequence of cancer treatment in breast cancer survivors (BCS), which have a huge impact on their quality of life (QOL). We pretend to develop a tool to assess these problems, identify the most relevant challenges, and prove the beneficial effect a nursing intervention would have on their QOL.

Methods: This is a prospective study with 51 BCS treated with HT, who were recruited from Hospital Clínico Valencia, from March to April 2023. A questionnaire with 28 related items was developed, including demographical data. These were evaluated by a Likert scale.

Results: Patients were aged under 45 years-old (mean 40.5 ± 3.2). 82.4% of BCS received previous chemotherapy treatment. Regarding the surgery, only 43.1% presented a tumorectomy. 21.6% of BCS were treated with Tamoxifen and 78.4% with aromatase inhibitors plus LH-RH analogues (AI + LHRHA). 70.6% expressed high satisfaction with their previous sexual life; however, only 25.5% of BCS feel satisfied. This study highlights vaginal dryness (72.5%), loss of sensibility in the affected breast (62.5%), loss of femininity (60.8%), loss of desire (60.8%), and fear of penetration pain (60.8%). AI + LHRHA was related to fear of penetration pain ($p=0.003$). The type of surgery impacted sexual satisfaction ($p=0.031$), and breast sensitivity ($p=0.018$). 74.5% of the patients emphasized the importance of sexual health. Nevertheless, 72.6% of BCS stated a decrease in the frequency of their sexual activity. 66.7% of the patients shared these issues with their partners, but only 23.6% talked about it with the oncologist. Furthermore, 72.5% felt that they did not have enough previous information. Interestingly, 80.4% would attend a nursing sexual health counselling and 78.4% considered this would improve their QOL.

Conclusions: HT impacted BCS' sexual health. The most frequent problems were dysfunction due to vaginal dryness, penetration pain, and desire. Mastectomy and AI + LHRHA presented poorer outcomes. Nurses' interventions could be helpful to improve their QOL.

CN55 The impact of psychosocial support on the overall health of cancer patients in the COVID-19 era

G. Catania, M.E. Musio, G. Fassio, G. Corci, L. Lungarotti, M. Zanini, L. Sasso, A. Bagnasco

Department of Health Sciences - DISSAL, University of Genova, Genoa, Italy

Background: COVID-19 mainly affected the elderly and people with chronic illnesses. The SUCCEED questionnaire was developed to assess the psychosocial needs of cancer patients in the era of COVID-19. This study aims to demonstrate how psychosocial support affected the health of cancer patients in large multisite cancer centers.

Methods: A total of 559 cancer patients were involved. We used the SF-36 questionnaire where higher values indicate a better general health status and the SUCCEED Questionnaire assessing psychosocial needs, higher scores indicate greater needs. Divergent validity was examined by comparison with the SF-36 questionnaire and analyses included descriptive and logistic regressions statistics.

Results: Cancer patients were mainly female (55.3%) and the mean age was 66.2 years ($\pm$11.6). The correlation between psychosocial support (SUCCEED score) and health status (SF-36 score) was negatively significantly correlated and negative: as the level of psychosocial support received decreases, general health also decreases (Pearson'r=-0.140, $p < .001$). This negative correlation was even stronger when considering the "Psychological-emotional health" domain of the SF-36, where a one-point increase in the SUCCEED score leads to a 0.8-point decrease in psychological-emotional health (Pearson'r=-0.152, $p < .001$). A negative correlation was found between the SUCCEED domain 'patient concerns' and the SF-36 domain 'psychological-emotional health': when patient concerns decrease, psychological-emotional health improves (Pearson'r =-0.180, $p <.001$). Also, general health and vitality correlation revealed a negative significant relationship (Pearson'r=-0.147, $p<.001$). The domain of patients' perceptions is also negatively correlated with psychological and emotional health (Pearson'r =-0.280, $p<.005$). Age is negatively correlated with SF-36: each additional year corresponds to a decrease of 0.258 points in the total SF-36 score. In contrast, it increases by 11.5 points if the patient receives psychosocial support ($p<.001$).

Conclusions: Poor psychosocial support negatively affected the health status of cancer patients during the COVID-19 pandemic. Cancer nurses should advocate to better respond to psychosocial patient needs.

CN56 Well-being and healthcare concerns of patients with advanced renal cell carcinoma: The RCC PROMs international survey

G. Kotronoulas[1], C. Diez de los Rios de la Serna[1], A. Drury[2], W.H. Oldenmenger[3], D. Kelly[4]

[1]School of Medicine, Dentistry & Nursing, University of Glasgow, Glasgow, UK; [2]School of Nursing, Psychotherapy and Community Health, DCU - Dublin City University, Dublin, Ireland; [3]Medical Oncology, Erasmus MC Cancer Institute, Rotterdam, Netherlands; [4]School of Healthcare Sciences, Cardiff University - School of Healthcare Sciences, Cardiff, UK

Background: Renal cell carcinoma (RCC) is the most common type of kidney cancer, most frequently diagnosed in men over 60 and in higher-income settings. Around 30% of cases are of advanced RCC. Despite progress with targeted therapies and immunotherapy, patients with advanced RCC face difficulties with day-to-day living. Patient-reported outcomes provide crucial information to enhance clinicians' understanding about what issues patients perceive to have the greatest impact on them and can help promote person-centred approaches to treatment and disease management.

Methods: As part of the larger EONS PROMs project (https://cancernurse.eu/research/proms_project/), an international online survey was launched in May 2022. With a sampling confidence level of 95% and a margin of error of 10%, we aimed to involve $\geq$89 patients with advanced RCC. The survey comprised a bespoke demographic/clinical form, the Functional Assessment of Cancer Therapy-Biologic

Response Modifiers (FACT-BRM) questionnaire, and three questions on patients' priority concerns.

Results: The survey included 105 patients. Typically, patients were men (n=62, 59%), on targeted therapy (n=31, 33.7%), middle-aged (median=44 years), and over 3 years since diagnosis (median=37 months). Descriptive analysis of individual FACT-BRM items revealed that patients: were bothered by too frequent an urge to urinate (70%), worried their condition will worsen (68%), worried about their partner or family (67%), felt helpless (60%), were unable to work (59%), and were concerned about end-of-life care (58%). Spontaneously, patients identified major concerns with wages, impact on family, and future response to treatment. Older age was a statistically significant predictor of higher FACT-BRM total scores ($p<0.001$), better physical wellbeing ($p<0.001$), and better emotional wellbeing ($p<0.001$). Receiving radiotherapy or targeted therapy were predictive of poorer physical wellbeing ($p<0.05$).

Conclusions: Identifying, monitoring, and responding to concerns relating to physical, emotional, social, and practical aspects of wellbeing can be meaningful steps towards provision of enhanced person-centred care in advanced RCC.

CN57 Patients, informal caregivers and healthcare professionals experience in adoptive cell therapies: An experience-based co-design study (EBCD-ACT)

N. Canova[1], N. Graber[1], T. Corbière[2], F. Bosisio[3], A. Kaufmann[4], D. Bryant-Lukosius[5], M. Eicher[1], S. Colomer-Lahiguera[1]

[1]Institute of Higher Education and Research in Healthcare and Department of Oncology- IUFRS-UNIL-CHUV, Lausanne University Hospital, Lausanne, Switzerland; [2]Institute of Higher Education and Research in Healthcare - IUFRS-UNIL-CHUV, Lausanne University Hospital, Lausanne, Switzerland; [3]Management and Health System, School of Engineering and Management Vaud, HES-SO University of Applied Sciences and Arts, Yverdon-les-Bains, Switzerland; [4]Le Collaboratoire, Unité de recherche-action, participative et collaborative, UNIL University of Lausanne, Lausanne, Switzerland; [5]School of Nursing and Department of Oncology, McMaster University, Hamilton, ON, Canada

Background: Adoptive cell therapy with tumor-infiltrating lymphocytes (ACT-TIL) is a rapidly growing strategy in the field of cancer therapies that relies on delivering specific autologous anti-tumor immune cells. While ACT-TIL entails a complex treatment procedure, the experience of care in this context remains understudied. Experience-Based Co-Design (EBCD) positions patients as active partners together with healthcare professionals in services quality improvement. EBCD seeks to capture and understand how people experience a health service through the identification of emotional touchpoints - key moments that shape a person's overall experience. We herein present the design of our study which aims to inform and improve the current delivery of supportive care during a Phase I-II clinical trial with ACT-TIL by examining the experiences and perspectives of patients, caregivers, and healthcare professionals.

Trial design: Following the EBCD methodological framework we will (1) observe clinical areas to map care trajectories, (2) interview patients, caregivers and healthcare professionals, (3) analyze and develop a trigger film highlighting themes from patients' interviews, (4) conduct independent patients/caregivers/healthcare professionals' feedback event (focus group), (5) conduct joint patients/caregivers/healthcare professionals' workshop(s), (6) and a consensus meeting. Furthermore, as part of the setting-up stage and in order to enhance the pertinence and scientific quality of the results, an Advisory Board (AB) has been constituted to inform and support the research team in both the development and the identification of issues that might be relevant for the project. The AB includes national and international experts in ACT (oncologists and nurses), the heads of the different units involved, experts in psychiatry, humanities, and laboratory procedures, as well as a patient representative. Results of this innovative study will provide a list of recommendations on how to adapt care delivery within early phases clinical trial of ACT-TIL.

Cancer nursing: Symptom management

CN59 The comparison between two types of educational information in reducing nausea and vomiting in patients undergoing chemotherapy: Randomized controlled trial

C. Mazzega Fabbro[1], J. Polesel[2], M. Manicone[1], L. Brusutti[1], E. Malnis[1], F. Puglisi[1]

[1]Department of Medical Oncology, CRO Aviano - Centro di Riferimento Oncologico - IRCCS, Aviano, Italy; [2]Unit of Cancer Epidemiology, CRO Aviano - Centro di Riferimento Oncologico - IRCCS, Aviano, Italy

Background: Chemotherapy-induced nausea and vomiting (CINV) are common problems in patients undergoing chemotherapy, occurring in up to 70%-80% of patients. Antiemetic drugs are largely used to treat CINV; however, some studies reported that the CINV can be significantly reduced with patient empowerment, and nurses can play a crucial role in the management of this intervention.

Methods: A phase III randomized trial was conducted at the Multidisciplinary Day Hospital at CRO Aviano between December 2018 and November 2022, enrolling 384 consecutive patients undergoing first-line chemotherapy. Inclusion criteria: age 18-80 years; signed informed consent. Exclusion criteria: life expectation <6 months; previous psychiatric or neurologic disease; visual impairment. Prior to first-line chemotherapy, patients were randomized 1:1 to receive written and verbal information on CINV prevention (arm A) or standard verbal information alone (arm B). A brochure describing drugs for CINV prevention and nutritional advice was provided to arm A patients. Antiemetic drugs were allowed as per standard care. The impact of CINV on daily activities was evaluated after one chemotherapy administration through the Functional Leaving Index — Emesis (FLIE) questionnaire.

Results: Fifty-eight patients were excluded after randomization for incomplete data. Arms were balanced with respect to gender, age, cancer type, chemotherapy, and antiemetic drugs use. Nauseas was reported by 30.1% and 39.9% of patients in arm A and B, respectively. Patients in arm A reported a reduction of 5.9% (95% confidence interval: 0.3%-11.5%) of moderate/high impact of nausea on daily activities compared to those in arm B (4.2% and 10.1%, respectively; p=0.038). This effect was consistent across strata by gender, age, and antiemetic drug use. No effect was found on vomiting.

Conclusions: This study demonstrated that nursing education intervention provided through a booklet reduced the occurrence of severe nausea in patients undergoing chemotherapy. Nurses play an important role in patient empowerment, with beneficial effects in patients' quality of life.

CN60 Dynamics and processes in the perception of colorectal cancer patients facing skin toxicity due to an EGFR-inhibitor

M. De Kegel[1], K. Geboes[2], S. De Meyer[2], P. Vandecandelaere[3], E. Pape[4]

[1]University Center of Nursing and Midwifery, Ghent University - Campus Ufo, Ghent, Belgium; [2]Gastroenterology Department, UZ Ghent - University Hospital Ghent, Ghent, Belgium; [3]Digestieve Oncology Department, AZ Delta Campus Rumbeke, Roeselare, Belgium; [4]Oncology, UZ Ghent - Universitair Ziekenhuis Ghent, Ghent, Belgium

Background: Epidermal growth factor receptor inhibitors (EGFR-I), such as cetuximab and panitumumab, are treatments that are frequently used in patients with metastatic colorectal cancer. An important side effect of these treatments is skin toxicity, which has a negative impact on patients' quality of life. The aim of this study is to explore the dynamics and processes in the perception of colorectal cancer patients facing skin toxicity due to an EGFR-I.

Methods: An exploratory qualitative study was conducted, based on the principles of grounded theory. Fifteen semi-structured interviews were performed within two settings, namely a university hospital and a general hospital. The data were analyzed in a cyclical process through thematic analysis and investigator triangulation. For the main themes data saturation was achieved.

Results: The dynamics and processes of the perception of skin toxicity were situated in three impact areas. First, patients described an impact on themselves due to the confrontation with symptoms and a lower self-esteem due to feelings of shame and insecurity caused by the visibility of skin toxicity. This also affected their self-management and the ability to cope with the toxicity. Second, patients outlined an impact of others. For example, comments caused insecurity and the need to hide their skin toxicity or isolate themselves. Additionally, their relatives had to support them in treating the skin toxicity, or skin toxicity sometimes led to an inability to work. Finally, patients stated that healthcare professionals provided emotional support and helped their coping process. In contrast, negative comments of others or from health care professionals could lead to insecurity or frustration.

Conclusions: The side effect of skin toxicity not only has a physical impact but also affects the psychological and social aspects of a colorectal cancer patient's well-being. The digestive oncologist, dermatologist and nurse specialist should take this into account when counselling these patients. Additionally, there is a lack of knowledge about the impact of this side effect by healthcare professionals.

CN61 Recognizing and managing immune checkpoint: Related symptoms with expert advice from dedicated oncology nurse

A. Muratovic, S. Sopaj, U. Janzic

Medical Oncology Department, University Clinic of Respiratory and Allergic Diseases Golnik, Golnik, Slovenia

Background: In order for oncological treatment with immune checkpoint inhibitors (ICI) to go as planned, a tight patient — care giver bond should be established. Patients (pts) are advised to contact dedicated oncology nurse in case of symptom worsening or adverse events (AEs) emerging. Telephone consultations are recorded as passive monitoring in order to keep track of the pts difficulties. Furthermore, an active monitoring from the dedicated nurse is made halfway between 1st and 2nd ICI cycle to check the pt status.

Methods: We retrospectively analysed active and passive consultations with pts with advanced non-small cell lung cancer, receiving ICI, their complaints, further referrals, ICI discontinuation and / or immunosuppressive treatment prescribed and the final outcomes.

Results: Three hundred and fifty-seven pts started ICI treatment from Jan 1st, 2018, to Dec 31st, 2022, and in that time-period we recorded 112 phone calls from 70 different pts with median age of 66 yrs and 61% being male. All of the patients were further referred to their general practitioner, emergency room or to a prior check-up with their oncologist at 78%, 13% and 9%, respectively. Almost half of the complaints (45%) were assessed as disease symptoms worsening, 33% needed temporary ICI discontinuation due to G1/2 ICI AEs, 20% both ICI discontinuation and immunosuppressive therapy due to G2/3 AEs and 3% of patients had life threatening AEs that led to in-hospital management. From June 2020 active monitoring resulted in 281 active inquiries, with 47 newly recognised complaints, 51% due to poor cancer symptoms management and 49% as possible ICI AEs. Out of latter, symptoms were mostly managed with professional advice about supportive treatment, although 8 (17%) of complaints resulted in temporary ICI cessation and immunosupressive treatment. None of the pts in either cohort died due to an AE complication.

Conclusions: About one fifth of pts on ICI therapy experience intractable concerns that need professional guidance and since half of those were later recognized as AE of ICI therapy, it is essential to accept the role of dedicated oncology nurses with special knowledge that can prevent severe complications by swift recognition of pts concerns.

CN62 Experiences and need of cancer patients with cardiovascular problems during systemic cancer treatment: Results of a qualitative study

L-M. Kinnaer[1], A. Lelong[1], K. Van Den Bussche[2], B. Manderlier[2], B. Von Kemp[2], E. De Mulder[3], F. Tromp[4], E. Naert[3]

[1]Public Health and Primary Care - University Centre for Nursing and Midwifery, Ghent University, Ghent, Belgium; [2]Center for Cardiovascular Diseases, Brussels University Hospital, Brussels, Belgium; [3]Department of Medical Oncology, Ghent University Hospital, Ghent, Belgium; [4]Department of Cardiology, Ghent University Hospital, Ghent, Belgium

Background: New or worsening cardiovascular problems during systemic cancer treatment impact a patient's quality of life. It is therefore of interest to gain insight into patient's experiences and needs when confronted with cardiovascular problems during cancer treatment.

Methods: A qualitative phenomenological study using individual semi-structured interviews is being conducted in two university hospitals. Dutch-speaking adult patients with solid or hematological cancers who's systemic treatment is ongoing or has been completed maximum one year ago and who experienced a cardiovascular problem during this treatment or maximum one year after completion, were eligible. Data collection and a thematic analysis is performed iteratively. Over a 3-month time period, 12 patients have been interviewed. Data collection will be finalized at the time of the conference.

Results: Intermediate analysis shows that participants feel worried, given their perception that the heart is a vital organ. Patients feel anxious about any symptom that might be linked to a reduced heart functioning. In case of cancer treatment interruption, patients worry about a potential negative impact on their oncological prognosis and cancer treatment outcome. Patients have mixed needs towards being informed prior to treatment-initiation about the risk of developing cardiotoxicity. Patients mostly need information and support from their oncologist about the consequences of the cardiovascular problem for the oncological disease.

Conclusions: Developing cardiovascular problems during or shortly after cancer treatment induces feelings of worry and anxiety about the consequences for oncological treatment outcomes and disease progression. The results call for tailored counseling strategies to support and meet patient's needs. A dedicated interdisciplinary cardio-oncology care pathway may prove valuable.

CN63 Patient education outcomes in patients receiving oral anticancer agents: Preliminary results of a systematic review

L. Cadorin[1], S. Cedrone[2], I. Sartor[3], F. Fonda[4]

[1]Healthcare Profession Management Office, Centro di Riferimento Oncologico - CRO, Aviano, Italy; [2]Healthcare Profession Management Office, CRO Aviano - Centro di Riferimento Oncologico - IRCCS, Aviano, Italy; [3]Clinical Trial Office, CRO Aviano - Centro di Riferimento Oncologico - IRCCS, Aviano, Italy; [4]Department of Anaesthesia and Intensive Care, Azienda Sanitaria Universitaria Friuli Centrale, University Hospital of Udine, Udine, Italy

Background: The availability of oral anticancer agents has been increasing and home use has created a need for educational interventions; further, some concerns about symptom management or safety issues have been raised. Although, the importance of patient education as an essential aspect of effective care delivery is recognized in the literature, current evidence regarding the outcomes of educational interventions in patients taking oral anticancer agents still needs to be summarized. Accordingly, this systematic review will cover the knowledge gap in this field specifically regarding contents, methodologies, settings, timing/duration, and healthcare professionals involved in patient education.

Methods: A systematic review is underway following the preferred reporting items for systematic reviews and meta-analyses guidelines upon registration in PROSPERO (number CRD42022341797). PubMed/MEDLINE, CINAHL, Embase, and Scopus and gray literature were consulted to seek for studies addressing adult patients ($\geq$ 18 years old) receiving oral anticancer agents in hospital/outpatient/home settings, and patient education outcomes. Two researchers independently screened the search results via title/abstract and evaluated the full-text using the Rayyan AI platform. The critical appraisal tools from The Joanna Briggs Institute was used to guarantee a quality appraisal. A data extraction form was implemented and the results will be summarized in narrative form.

Results: The database search produced 2588 records; of these, 403 were duplicates. Preliminary results will be presented at the conference.

Conclusions: This systematic review will provide crucial information regarding the outcomes of educational programs in patients taking oral anticancer agents. Aspects of establishing effective educational programs will be highlighted and will influence the management and the clinical practice by increasing patient and family members' awareness, safety, and satisfaction.

CN64 Assessment of depression among lung cancer patients with type 2 diabetes using centre for epidemiologic studies depression scale (CES-D)

M. Lavdaniti[1], O.D. Govina[2], E. Mylona[1], P-M. Prapa[3], D. Palitzika[4], A. Kosintzi[5], E. Vlachou[2]

[1]Nursing Department, International Hellenic University - Nursing Department, Thessaloniki, Greece; [2]Nursing Department, University Of West Attica - Campus 1, Egaleo, Greece; [3]Nursing Department, Sotiria Thoracic Diseases Hospital of Athens, Athens, Greece; [4]Nursing Department, General Hospital of Thessaloniki G. Papanikolaou, Pylaia-Chortiatis, Greece; [5]Special Education, Aristotle University of Thessaloniki, Thessaloniki, Greece

Background: Cancer and diabetes both are highly prevalent diseases. Depression often occurs in patients with lung cancer patients and it is a common symptom in individuals with diabetes 2. The purpose of this study was to assess depression in patients with lung cancer and diabetes type 2 undergoing chemotherapy.

Methods: This was a cross-sectional study conducted in a large oncology hospital in a major city in Northern Greece. It involved a convenience sample consisting of 100 lung cancer patients with type 2 diabetes undergoing chemotherapy. Data was collected using the Centre for Epidemiologic Studies Depression Scale (CES-D) and a questionnaire to determine the demographic and clinical characteristics. The CES-D is a self-rating 20-item scale with a recommended threshold score of 16 for indicating the presence of threshold depression.

Results: The mean age of the sample was 59.57±5.04 years. The majority of the patients were males and married (74%) and were freelancers (21%). Regarding clinical characteristics, most of the participants (31%) underwent surgical removal of the tumor, had small −cell lung cancer (51%). The vast majority of patients received carboplatin (74%). Also, oral medication is the treatment for diabetes (49%). The mean score in CES-depression was 39,47 ±6,16, higher than 16. Comparison between demographic and clinical characteristics and the CES −depression score respectively, have shown that gender (p=0.01) and educational status affected the level of depression (p=0.001). The existence of metastases affected the score of depression (p=0.02). In addition, the type of diabetes treatment affected the overall score of depression (p=0.002). There were not statistically significant correlation between depression and clinical characteristics.

Conclusions: Depression is a symptom experienced by Greek lung cancer patients with diabetes type 2. The results of this study support healthcare professionals to manage the symptom effectively and help their patients.

CN65 Assessment of fatigue in elderly hospitalized cancer patients undergoing chemotherapy: A pilot study

M. Lavdaniti[1], E. Vlachou[2], G. Karagiannidou[1], E. Gogou[1], D. Palitzika[3], P-M. Prapa[4], A. Kosintzi[5], O.D. Govina[2]

[1]Nursing Department, International Hellenic University - Nursing Department, Thessaloniki, Greece; [2]Nursing Department, University of West Attica - Campus 1, Egaleo, Greece; [3]Nursing Department, General Hospital of Thessaloniki G. Papanikolaou, Pylaia-Chortiatis, Greece; [4]Nursing Department, Sotiria Thoracic Diseases Hospital of Athens, Athens, Greece; [5]Special Education, Aristotle University of Thessaloniki, Thessaloniki, Greece

Background: Fatigue is one of the most common symptoms experienced by elderly cancer patients. This study aims to assess fatigue in elderly hospitalized cancer patients and the factors influencing it.

Methods: This pilot study was performed in a large hospital in a major city in Northern Greece. Fifty elderly cancer patients were chosen for the research through convenience sampling. Data were collected using the Cancer Fatigue Scale and a questionnaire with demographic and clinical characteristics.

Results: The mean age of patients was 76.16 ± 9.77 years. Most were widowed (n=22, 44%) and retired (n=39, 78%). The mean score of the total Cancer Fatigue Scale was 40.16 ± 11.22. Comparison between fatigue and clinical-demographic characteristics revealed statistically significant differences between previous therapy (surgical removal of the tumor or radiotherapy) and the physical dimension of fatigue ($p = 0.02$) and the existence of metastases and total fatigue ($p = 0.02$). Furthermore, the factors influencing the patients' total fatigue were examined using clinical and demographic characteristics. However, when these variables were added as predictors of fatigue into a regression model ($R^2 = 0{,}29$, $p < 0{,}01$) to assess their predictive power, two of them significantly predicted the depression score [Metastasis existence (b = 0.51) and comorbidity of diabetes (b=0.48)].

Conclusions: Elderly cancer patients experience fatigue during hospitalization. Certain clinical characteristics affect this symptom. Therefore, Greek nurses should take into account the findings of this study and design appropriate care plans and interventions to alleviate the fatigue problem.

CN66 Cancer symptom clusters, nutritional status and quality of life of patients with cancer undergoing outpatient chemotherapy

L.C. Lopes-Júnior[1], K.Z. Nunes[2], R.M.M. Pessanha[2], L.C.B.S. Neto[3], K.C.G. Viana[4], J. Grassi[1], W.R. Grippa[1], R.J.G.S. Silva[2], J.A.C. Marcarini[5], K.N. Gomes[5], A.B. Lopes[2]

[1]Health Sciences Center, Graduate Program in Public Health, Universidade Federal do Espírito Santo, Campus de Maruípe, Vitoria, Brazil; [2]Nursing Department, Universidade Federal do Espírito Santo, Campus de Maruípe, Vitoria, Brazil; [3]Health Sciences Center, Universidade Federal do Espírito Santo, Campus de Maruípe, Vitoria, Brazil; [4]Nursing Department, Hospital Santa Rita de Cássia, Vitoria, Brazil; [5]Graduate Program in Nutrition and Healthn, Universidade Federal do Espírito Santo, Campus de Maruípe, Vitoria, Brazil

Background: Patients with cancer chemotherapy may have different cancer symptom clusters (CSC) that negatively impact their quality of life (QoL). These symptoms can sometimes arise from the disease itself or as a result of their cancer treatment.

Methods: Cross-sectional observational study conducted at Hospital Santa Rita de Cássia, a reference in oncology treatment in the state of Espírito Santo, Brazil. We included a) patients of both sexes and >18 y.o.; b) anatomopathological diagnosis of malignant neoplasm in stage I-III; c) patients (only new cases) undergoing outpatient chemotherapy. The instruments for data collection were: 1) Sociodemographic and clinical instrument; 2) Memorial Symptom Assessment Scale (MSAS) to identify the CSC and 3) The EQ-5D-3L to assess QoL; 4) Nutritional Risk Screening. Each patient donated two blood samples for measurement of biomarkers (troponin I and C-reactive protein). Descriptive and bivariate statistical analyzes were conducted using SPSS v.28.0.

Results: Thirty-eight participants with a mean age of 56.09 y.o. diagnosed with malignant neoplasm were included. Most patients had a diagnosis of breast cancer (n=21; 55.26%), followed by the diagnosis of colorectal cancer (n=7; 18.42%). Most patients was into staging II (n=18; 47.37%). We observed a mean QoL score of 74, with the most affected domain being anxiety/depression (n=28; 73.68%). The most prevalent CSC were, worry (n=25; 65%), followed by pain (n=19; 50%). Three clusters were identified: 1-(difficulty for sleeping-sadness-worry); 2-(fatigue-nervousness-dry mouth) and 3-(pain-nausea-irritable-difficulty concentrating). Regarding nutritional status by we identified that most patients were classified as "normal"(n=22; 55.89%), followed by slightly altered (n=9), only one patient had serius nutritional status. Troponin I correlated with age (*Rhos*=0.31; p=0.033) and gender (*Rhos*= -0.48; p=0.02). C-relative protein showed a moderate and direct correlation with weight (*Rhos*=0.48; p=0.001) and waist circumference (*Rhos*=0.48; p=0.001).

Conclusions: Adequate attention to CSC should be the basis for the accurate planning of effective interventions to manage the symptoms experienced by cancer patients.

CN67 Comparison of existing guidelines for healthcare professionals on the perceived symptoms of breast cancer patients with registered symptoms in the medical records: Preliminary results

T. Lund-Jacobsen[1], P. Schwarz[1], G. Martino[2], H. Pappot[3], K. Piil[3]

[1]Department of Endocrinology, Rigshospitalet, Copenhagen, Denmark; [2]Department of Clinical and Experimental Medicine, University of Messina, Messina, Italy; [3]Department of Oncology, Rigshospitalet, Copenhagen, Denmark

Background: Healthcare professionals (HCPs) may underestimate symptoms experienced by patients with breast cancer (BC). The study aims to gain insight into a potential gap between the symptoms outlined in guidelines versus the symptoms that the HCPs register in the medical records.

Methods: A Mixed-Method study compared symptoms outlined in best practice guidelines with those documented by physicians' inpatients' medical records. Symptoms were classified according to the National Cancer Institute (NIH). BC patients in follow-up with aromatase inhibitors (Letrozole, Exemestane or Anastrozole) were included. Symptom registration was compared with the European Medicines Agency (EMA) and the Food and Drug Administration (FDA) guidelines.

Results: Patients were included over a recruitment period of 3 months (n=23). Single symptoms identified by the NIH definition (n=235). Several symptoms were identified

in the medical records which in the guidelines were described with different frequencies e.g., dry mount. Multiple identified symptoms in the medical journals were only described in a single guideline e.g., scar pain, skin irritation, general physical condition abnormal and nasal dryness. Several symptoms detected from clinical consultations were not mentioned in the guidelines at all e.g., muscular weakness and lack of energy.

Conclusions: The BC population expressed at the consultations several symptoms that are not compatible with the guidelines. Our results indicate that symptoms outlined in the best practice guidelines do not embrace the total patient-experienced symptoms as outlined by the physicians. There seems to be a discrepancy between the frequency of various symptoms. Perspective: As a part of the Mixed-Method design, an exploratory study is now being carried out by using patient- and focus-group interviews. The exploratory study is important, as it seeks to broaden the symptoms experienced by the patients compared to the symptoms identified in this study.

CN68 Experiences and needs of rectal cancer survivors without or with minor low anterior resection syndrome

F. Serroyen[1], A. Van Hecke[2], G. van Ramshorst[3], D. Van de Putte[3], P. Pattyn[4], W. Lybaert[5], Y. Van Nieuwenhove[3], E. Pape[3]

[1]University center for nursing and midwifery, Ghent University, Ghent, Belgium; [2]University center for nursing and midwifery, Ghent University - University Centre for Nursing and Midwifery, Ghent, Belgium; [3]Gastrointestinal surgery, UZ Ghent - University Hospital Ghent, Ghent, Belgium; [4]Gastrointestinal surgery, AZ Delta Campus Rumbeke, Roeselare, Belgium; [5]Medical Oncology, AZ Nikolaas Hospital, Sint-Niklaas, Belgium

Background: After sphincter-saving rectal cancer surgery, many patients experience bowel problems called low anterior resection syndrome (LARS). Especially major LARS (LARS-score $\geq$ 30) has a negative impact on patients' quality of life. Our previous research has shown that these patients have several information and counselling needs towards healthcare professionals. Patients without LARS (LARS score 0-20) or with minor LARS (LARS-score 21-29) experience less bowel problems which has less impact on their quality of life. The aim of this study was to explore the dynamics in experiences, information and counselling needs of patients without or with minor LARS.

Methods: A qualitative study based on the principles of a grounded theory was conducted. Rectal cancer survivors without LARS or with minor LARS were purposefully recruited in three large hospitals. Patients with major LARS, patients who have had an abdominoperineal resection with permanent stoma and patients who do not speak Dutch were excluded. Semi-structured interviews were performed. The constant comparative method and investigators' triangulation were used during data-analysis.

Results: Fourteen patients were interviewed of which six patients without LARS and seven with minor LARS according to the LARS-score. In the first months, all 14 patients experienced LARS which had an impact on their family or working life. However, these symptoms improved over time resulting in a controllable situation. Additionally, patients described that LARS became less dominant and other symptoms such as peripheral neuropathy due to neoadjuvant chemotherapy were perceived worse. Factors such as having previous bowel problems during treatment, comparing themselves to patients experiencing major LARS or feeling euphoria about avoiding a permanent stoma reinforced their coping strategy. The amount of information patients received beforehand varied. Patients who received a high information load experienced anxiety but stated that this information was necessary to be prepared.

Conclusions: The symptoms of patients without or with minor LARS were more controllable and became less dominant compared to major LARS. These insights are important to organize care for patients without or with minor LARS.

Clinical trial identification: BC-11853.

CN69 Experiences of patients after cytoreductive surgery and hyperthermic intraperitoneal chemotherapy: A qualitative study

J. Dobbelaer[1], W. Ceelen[2], E. Pape[3], S. De Meyer[2], S. Cosyns[4]

[1]Digestive Oncology, UZ Ghent - University Hospital Ghent, Ghent, Belgium; [2]Gastrointestinal Surgery, UZ Ghent - University Hospital Ghent, Ghent, Belgium; [3]Oncology, UZ Ghent - Universitair Ziekenhuis Ghent, Ghent, Belgium; [4]Experimental Surgery, Ghent University - University Centre for Nursing and Midwifery, Ghent, Belgium

Background: Cytoreductive surgery (CRS) followed by hyperthermic intraperitoneal chemotherapy (HIPEC) can control the disease state of patients with limited peritoneal carcinomatosis (PC). In spite of the fact that it is an effective and promising treatment, it has a big impact on various aspects of patients' quality of life. The aim of this study is to explore experiences and needs of patients with digestive tumors after CRS/HIPEC (short and long-term).

Methods: An explorative qualitative design was used. Individual semi-structured interviews were performed with 15 patients (2-14 months postoperatively) between December 2020 and May 2021 in one expert university hospital in Belgium. Data-analysis was done using thematic analysis and investigators' triangulation was used.

Results: Before surgery, patients relied on the expertise of the surgeon and saw the surgery as their only hope. After surgery, patients underestimated rehabilitation due to acute and long-term effects of the treatment. They described their relatives as a second victim but experienced their support at the same time. Patients were grateful for the future but also had fear for recurrence. Treatment by an experienced surgeon and the counseling of a clinical nurse specialist was seen as an added value. The need for contact with peers varied among patients.

Conclusions: CRS/HIPEC has a large impact on patients' and their relatives' lives. Patients were confronted with short and long-term effects. The healthcare professionals (HCPs) should adapt the amount and kind of information before surgery to the coping mechanism of the patient. Counseling afterwards is necessary. HCPs should pay attention to the needs of the relatives as well and explore if the patients have a need to meet with peers.

CN70 Out of hours symptom triage and supportive care

K. Mckendry[1], N. Pierce[1], A. Smullen[1], K. Skehan[1], N. Termanini[1], D. Coyle[1], P. Francis[1], E. Buggy[1], M. Saviour[1], S. Meagher[1], E. Babikir[1], O. Kestell[1], A. Comiskey[1], E. Sinagoga[1], O.S. Breathnach[1], K. Egan[2], F.E. barrett[1], L. Keogh[1], L. French[1]

[1]Medical Oncology Department, Beaumont RCSI Cancer Centre, Dublin, Ireland; [2]Cancer Clinical Trials Unit, Beaumont RCSI Cancer Centre, Dublin, Ireland

Background: Cancer-related Emergency Department (ED) presentations are increasing rapidly, leading to increased utilisation and pressure on EDs. This impacts on their ability to provide timely, high-quality patient care. Nurse-led telephone triage (TT) services have been implemented in many oncology centres. Despite this there have been relatively little study of its ability to reduce ED utilisation. This study was conducted in Beaumont Hospital, a tertiary academic centre in Dublin serving a population of one million. The primary aim of this study was to assess the impact of the TT service in preventing ED presentations and the characteristics of patients accessing the service.

Methods: All patients receiving cancer treatment have a 24-hour contact number for specialist advice. Nurses are trained to assess patients by the UKONS Toolkit and to perform autonomous interventions for grade 1-2 events or refer to the oncologist on-call for higher grade events. Data was collected retrospectively from paper logs recorded over the 2022 calendar year. Patient and disease characteristics, presenting symptoms and the timing of calls were compared between those advised to attend and managed successfully over the phone.

Results: The TT service received 383 calls over the study period. The mean (SD) patient age was 56yrs (15.04); 199 (52%) were female. Of the 383 patients, 182 (47%) were referred to ED while 201 (53%) avoided it. Admission demographics, cancer types and treatment modalities were similar between groups. Patients who avoided an ED referral were significantly more likely to have a chemotherapy/ medication, genitourinary or miscellaneous complaint, while those with infectious issues were more likely to be referred. Most phone calls (65%) occurred at the weekend. Calls during working hours were more likely to avoid referral.

Conclusions: The majority of patients avoided attending the ED and the triage service was particularly effective in dealing with chemotherapy/ medication and genitourinary issues. Symptoms related to infectious issues were referred more frequently. Future steps could include increasing weekend staffing and integrating the TT service

with the national oncology electronic health record system to further improve decision making by providing timely access to detailed patient information.

CN71 SensiEx: A randomized pilot trial Sensorimotor training using whole body vibration exercise to reduce chemotherapy-induced peripheral neuropathy after treatment for breast cancer

M. Backman, Y. Wengström

Neurobiology, Care Science Ans Society, Karolinska Institute, Huddinge, Sweden

Background: Approximately 50% of women receiving chemotherapy for breast cancer develop chemotherapy induced peripheral neuropathy (CIPN) and is associated with significant disability and poor recovery. Common symptoms of CIPN include pain, altered sensation, reduced or absent reflexes, muscle weakness, reduced balance control and insecure gait. These symptoms affect activities of daily living and reducing patients' quality of life. CIPN also cause treatment delays, dose reductions, or even discontinuation of therapy, which can affect the outcome and compromise survival. To date, CIPN cannot be prevented and effective treatment options are lacking. Preliminary data indicate that whole body vibration (WBV) exercise may have a preventive effect on the onset of CIPN. However, how WBV compares to conventional cardio and resistance exercise (CAR) exercise for alleviate CIPN has not yet been studied. The aim is to compare the effects of WBV exercise compared to CAR on the primary outcome of CIPN symptoms and secondary outcomes of balance, physical function, and quality of life.

Methods: This prospective, multicenter, two-armed, randomized pilot study will include 44 women, assigned randomly either to the WBV group or the CAR group. Patients will exercise twice per week (at Karolinska) for 12 weeks. Measurements are performed at baseline, 3 and 6 months. *Inclusion criteria:* breast cancer diagnosis, aged 18—65 years, ECOG performance status of 0—2, completed chemotherapy in the past 6 month and remaining CIPN symptoms. *Exclusion criteria*: pre-existing neuropathy of other cause, severe cardiovascular disease, regular intake of analgesics, smoking. Measurement: CIP-NAT, CIPN-R-ODS, QLQ-C30, PainDETECT, Monofilament, Turn fork test, Tendon reflexes, Balance and Muscle strength tests.

Results: Based on previous study findings, we hypothesize that WBV exercise compared to CAR will reduce symptoms to a larger degree, such as the loss of peripheral deep sensitivity, pain, weakened or absent reflexes and loss of balance control.

Conclusions: Hopefully patients will experience an improvement in physical function and quality of life.

Clinical trial identification: NCT05361018.

CN72 Symptom burden, quality of life and emotional status of patients with advanced lung cancer seen at the functional lung unit

Brao Perez[1], M. Arellano[1], C. Lasmarias[2], S. Padrones Sanchez[3], E. Nadal[5], R. Palmero Sanchez[4], M. Jove Casulleras[4], J. Brenes Castro[4], M.A. Mosteiro Lamas[4], J. Saldaña Cañada[5], R.A. Portolés[6]

[1]Lung Funcional Unit, ICO - Institut Català d'Oncologia l'Hospitalet (Hospital Duran i Reynals), Hospitalet De Llobregat, Spain; [2]Research, Institut Catala d'Oncologia - Hospital Duran i Reynals (ICO L'Hospitalet), Hospitalet De Llobregat, Spain; [3]Lung Funcional Unit, Hospital Universitari de Bellvitge, Hospitalet De Llobregat, Spain; [4]Medical Oncology Department, ICO - Institut Català d'Oncologia l'Hospitalet (Hospital Duran i Reynals), L'Hospitalet De Llobregat, Spain; [5]Catalunya, ICO - Institut Català d'Oncologia - Hospital Duran i Reynals, Hospitalet De Llobregat, Spain; [6]Nurse Direccion, ICO - Institut Català d'Oncologia l'Hospitalet (Hospital Duran i Reynals), Hospitalet De Llobregat, Spain

Background: Lung cancer is usually diagnosed at advanced stage with a high burden of symptoms, deterioration in quality of life (QOL) and significant emotional impact. Interventions in these patients are aimed at improving QOL through physical and emotional symptoms management. It is important for the advanced practice nurse (APN) to know baseline health status of patients before treatment initiation to address interventions to improve their outcomes.

Objective: To describe the burden of symptoms, QOL and emotional status of outpatients with lung cancer before starting the antitumor treatment.

Methods: This is an observational study, evaluating consecutive patients with advanced lung cancer from January to April 2023 from the outpatient clinic of the lung functional unit (UFP). The intensity of the symptoms, QOL, anxiety, depression and APN interventions will be measured using validated and ad-hoc constructed questionnaires with Likert-type responses. The analysis was descriptive using percentages, frequencies, and measures of dispersion.

Results: 48 patients, 60.0% men, 75.9% aged 60-75, 83.6% diagnosed with advanced non-small cell lung cancer. Symptoms burden: dyspnea 52.7%, cough 70.4%, pain 65.8%, sleep disturbance 59%, asthenia 63.5%, anorexia 28.2%, constipation 32.2%. The scores for quality of life were 54.2/100, anxiety 5.3/21, and depression 4.3/21. General interventions carried out by the APN consisted of health education on symptoms and toxicity management, treatment and queries about the disease. Specific interventions consisted of placing a peripheral venous access 12.5%, consultation with a psycho-oncologist 6.3%, psychosocial committee 2.08%, social worker 2.08%, smoking cessation 2.08% and referrals to other specialists 2.08%.

Conclusions: The outpatients seen have low QOL scores, a high burden of symptoms and a certain level of anxiety and depression. Knowing the most prevalent symptoms, the QOL and the emotional state of the patients at the beginning of the treatment will allow the APN to optimize the interventions to address the different physical and emotional symptoms and improve the quality of life of these patients.

CN73 Symptom management in patients with chemotherapy-induced hand-foot syndrome: A qualitative study

J. Zhang

Oncology, Ruijin Hospital - Shanghai Jiao Tong University School of Medicine, Shanghai, China

Background: Hand-foot syndrome (HFS), may cause sensory loss, erythema-specific skin syndrome, hand and foot skin pigmentation, swelling in finger, toes, blisters, ulcers, and bleeding with pain. Studies have found that some patients underestimate the potential long-term effects of the disease, which results in suboptimal disease management. The study aimed to explore the self-management of symptoms in patients with chemotherapy-induced HFS and to provide guidance for developing a self-management plan that aligns with patient needs.

Methods: Twenty-two patients who developed chemotherapy-induced HFS were selected by objective sampling from July to Sept 2022 in the Department of Oncology of a tertiary hospital in Shanghai. A semistructured face-to-face in-depth interview was performed to collect the case data, which were analyzed using the content analysis method, and the themes were refined.

Results: Twenty-two patients, were interviewed. Three themes and six subthemes emerged from analysis of the interviews: The first theme was "Patients' attitudes and emotional responses to symptoms," including patients gradually accepted the symptoms of HFS and adapted to some mild manifestations based on the following responses, showed different emotional responses to the HFS, symptoms that affected their daily lives. Patient felt guilty for his family and had a self-image disorder. The second theme was "symptom experience," symptoms varied across patients and had different impacts on individual lives. Including pain and itching feeling peeling. The third theme was "coping strategies," including patients felt the impact of limited social interaction and family relationships. The fourth theme was "expectations for the future," including acquire related knowledge via websites, physicians, and among patients, changed habits and showed improved symptoms and met/exceeded the expectations of the healthcare providers.

Conclusions: Healthcare providers should offer more education and emotional support to patients with chemotherapy-induced HFS to achieve symptom management, elicit positive experiences, and help with more targeted and effective self-management of symptoms.

CN74 The effect of nursing senior's self-efficacy on symptom management in cancer patients on clinical decision-making skills

S. Kutlutürkan[1], I. Öztürk[2]

[1]Faculty of Nursing, Ankara Üniversitesi, Ankara, Turkey; [2]Faculty of Health Sciences, Yalova Üniversitesi, Yalova, Turkey

Background: This study was conducted as a relation-seeking research to determine the effect of nursing senior students' self-efficacy regarding symptom management of cancer patients on their clinical decision-making skills.

Methods: The universe of the research consists of senior nursing students studying at Nursing Faculties and Health Sciences Faculties Nursing Departments of 7 universities affiliated with the Council of Higher Education in the 2022-2023 academic year in Turkey. A Stratified random sampling method was used in the selection of universities. Considering the 7 geographical regions in Turkey, faculties that are the oldest established and have the largest academic staff were selected for each region. The number of participants to be reached from each university was determined using the known universe sampling formula. The data was collected by the Personal Information Form, Clinical Performance Self-Efficacy Scale, Clinical Decision-Making Scale in Nursing. The data of the research were collected online with "Google Forms". T test, one-way analysis of variance, Bonferroni, Tamhane's T2 test were used. Pearson correlation analysis was used for the relationship between numerical measurements and Cronbach's alpha value was used for scale reliability. $P<0,05$ was accepted for significance.

Results: The average score of clinical performance self-efficacy scale of the senior nursing students was determined to be 76,40. In the study, the average score of clinical decision-making scale in nursing was calculated as 142,48. There is a statistically significant positive correlation between clinical performance self-efficacy scale in nursing and clinical decision making scale and sub-dimension scores ($p<0,05$). In line with the data obtained in the study, it is understood that there is a weak positive correlation between the self-efficacy of nursing senior students regarding symptom management of cancer patients and their clinical decision-making skills ($r=0,384$, $p<0,05$).

Conclusions: It is recommended to provide theoretical and practical training to support nursing students' self-efficacy in clinical performance and clinical decision-making skills to improve symptom management in cancer patients.

CN75 Validation of a symptom diary for outpatients with cancer receiving intravenous chemotherapy and/or targeted therapy

J.J. Koldenhof

Medical Oncology Department, UMC - University Medical Center Utrecht, Utrecht, Netherlands

Background: The Utrecht Symptom Diary (USD) is a Dutch validated patient-reported outcome measurement tool (PROM) - based on the Edmonton Symptom Assessment System - to assess and monitor symptoms in cancer patients. This study aimed to evaluate the added items on the treatment specific outpatient USD in cancer patients receiving intravenous chemotherapy and/or targeted therapy.

Methods: Observational longitudinal retrospective cohort study including all adult outpatients with cancer receiving intravenous chemotherapy and/or targeted therapy in an academic hospital in the Netherlands who completed at least one outpatient USD as part of routine care (2012-2021). Content, criterion and construct validation were assessed.

Results: 1733 patients who completed ≥1outpatient USD during intravenous chemotherapy and/or targeted therapy were included for analysis. Content validity (relevance, comprehensiveness) was shown. Criterion validation was confirmed for all added items of the outpatient USD — except for the item on oral pain. Additional analysis showed that mouth problems were detected with both outpatient USD items oral pain and dry mouth. Construct validity was confirmed for the items hair changes and skin and nail problems. Construct validity on eye problems was not tested due to the low number of paired outpatient USDs.

Conclusions: The outpatient USD is a valid PROM in outpatients with cancer receiving intravenous chemotherapy and/or targeted therapy. Since its validity in this broad group of patients we think the outpatient USD is widely applicable. Additionally, to providing tailored supportive symptom care, the USD-data can be used to increase knowledge about symptom burden in daily practice in this population.

Cancer nursing: Workforce and educational issues in cancer nursing

CN76 Consensus views on research priorities for cancer survivorship in older adulthood: A Delphi study

A. Drury[1], A. O'Brien[2], L. O'Connell[3], S. Cosgrave[4], M. Hannan[5], C. smyth[6], K. Fessele[7], S. Sheehan[1], M. Harkin[8], L. Rogers[2]

[1]School of Nursing, Psychotherapy and Community Health, DCU - Dublin City University, Dublin, Ireland; [2]School of Nursing, Midwifery and Health Systems, University College Dublin, Dublin, Ireland; [3]Haematology, Tallaght University Hospital, Dublin, Ireland; [4]Caritas Day Hospital, St. Vincent's University Hospital, Dublin, Ireland; [5]Medical Oncology, University Hospital Waterford, Waterford, Ireland; [6]Community, HSE - Health Service Executive, Dublin, Ireland; [7]Nursing Research, Memorial Sloan Kettering Cancer Center, New York, NY, USA; [8]Age and Opportunity, Dublin, Ireland

Background: Few published research priority setting activities involve older adults living with or after cancer as the primary stakeholders, and those that do originate in primarily continental North American contexts. This study aims to obtain consensus on priorities for future research on cancer survivorship in older adulthood in a European context.

Methods: A modified three-round Delphi study was undertaken with experts by profession and experience in geriatric oncology. Fifty research priorities were pre-identified via a qualitative interview study with older adults living with and after cancer; these priorities were presented to participants in this Delphi study. Between June and October 2022, the Delphi expert panel determined the importance of each proposed priority for future research in geriatric oncology. Consensus was defined by at least 80% agreement on the highest three points of a 9-point Likert scale.

Results: A total of 60 people participated in rounds 1-3 of this study. In round 3, participants were older adults living with or after cancer ($n=22$, 40.7%) family members/carers ($n=8$, 14.8%), and healthcare professionals ($n=17$, 31.4%), advocacy professionals ($n=4$, 7.4%) and academics/researchers ($n=3$, 5.6%) working in the area of geriatric oncology. Following round 3, 37 of 55 topics (67.3%) reached consensus, of which 7 (12.7%) had greater than 95% consensus. Priority areas with highest consensus focused on development of treatment options for older adults (98%), decision-making (96%), promoting awareness of potential cancer symptoms requiring investigation in older adulthood (96%), clinical programmes to address rehabilitation (96%) and management of multimorbidity in cancer (96%) and cancer- (96%) and frailty-related outcomes (96%).

Conclusions: The results of this study provide a framework of research priorities for research in geriatric oncology survivorship, reflecting areas of highest need identified by key stakeholders, including older adults themselves. Development of treatment modalities for older adults was a notably high priority, but research to understand and address unmet needs related to diagnosis, treatment-related decision-making and rehabilitation are also key priorities identified by this expert panel.

CN77 EONS advocacy toolkit: How to let your voice be heard as a cancer nurse

D. Protogiros[1], M.V. van Klinken[2], G. Suchodolska[3], T.A. Theologia[4], G. Catania[5], G. Knötgen[6]

[1]General Secretary of Primary Health Care, Ministry of Health, Athens, Greece; [2]Internal Division/ Palliative Care Department, Netherlands Cancer Institute/Antoni van Leeuwenhoek Hospital (NKI-AVL), Amsterdam, Netherlands; [3]Department of Oncology and Radiotherapy, Medical University of Gdańsk, Gdansk, Poland; [4]Nursing Department, Cyprus University of Technology - Nursing Science, Limassol, Cyprus; [5]Department of Health Sciences - DISSAL, University of Genova, Genoa, Italy; [6]KOK Cancer nursing Society, German Cancer Nursing Society, Munich, Germany

Background: Cancer nurses are at the heart of cancer care and experience the rapidly changing conditions and the influence of health politics in their daily practice. These are some of the reasons why there needs to be leaders who can uniquely and effectively promote policy and social change in cancer. Recognising the lack of a document on cancer nursing advocacy, the European Oncology Nursing Society's (EONS) Advocacy Working Group developed a guide aimed at addressing the need for individuals and organisations in cancer to better understand the advocacy concept and for a successful approach to sustainable advocacy.

Methods: A review of the relevant literature was conducted to identify themes, theoretical perspectives, and other information relevant to the topic. Moreover, authoritative and adaptable resources, advocacy documents from international organisations and EONS' advocacy work, were retrieved.

Results: A toolkit, consisting of two parts, has been created to offer practical advice and guidance regarding advocacy for cancer nurses. The first part includes the theoretical background and is divided into four target groups in advocacy: i) advocacy in general; ii) advocacy for people affected by cancer; iii) advocacy in nursing education to increase quality of care and create awareness among early career cancer nurses; and iv) advocacy for cancer nurses. The second part describes the advocacy tools that can be used for influencing policy; raising awareness; involving the public; developing an advocacy strategy; monitoring and evaluating advocacy activities. It additionally offers a mapping of good practices in cancer nursing advocacy in Europe.

Conclusions: EONS Advocacy Toolkit provides a comprehensive guide to different aspects and the best practices in cancer nursing advocacy. The use of the toolkit is expected to enhance advocacy skills of nurses and cancer nursing societies to influence decisions that improve cancer nursing status and recognition in Europe.

CN78 Chimeric antigen receptor T cell (CAR T) nursing educational pathway: Reporting on participant feedback

A. O'Halloran[1], S. Impey[2], D. Byrne[1], M. Gillespie[1], K. Mc Tague[2]

[1]Oncology / Haematology Department, St. James's Hospital, Dublin, Ireland; [2]School of Nursing and Midwifery, Trinity College Dublin, Dublin, Ireland

Background: New interventions require training programmes or pathways. This project was initiated to provide evidence-based nursing education pathway for CAR T cell therapy. The underpinning standards were the JACIE 8th edition standards and the Irish Nursing Scope of Practice. The aim of this poster is to present participant feedback from this education pathway. CAR T therapy is a treatment that involves removing a patient's own T lymphocytes through apheresis, genetically altering the T lymphocytes in the laboratory, and returning the altered cells to the patient via infusion to detect and destroy cancer cells. The pathway combines self-directed learning, simulation session and clinical practice. Access to the pathway was limited to experienced haematology nurses based at the study site. To date n=15 participants have completed the pathway. N=14 participants agreed to take part in the feedback survey, no reason for the one missing participant was noted. Evaluation of the pathway aimed to identify learning that could be integrated into future courses.

Methods: To gather participant feedback, a survey consisted of 16 item questionnaire using 5-point Likert scale and two open ended questions, was used. The survey was anonymous and distributed to the participants, haematology nurses that had completed the programme. A total of n=14 responses were returned.

Results: Participants agreed that they enjoyed the simulation learning experience but would have liked additional time in the simulation lab practicing skills learned. Overall, participant feedback noted they were confident in caring for a patient receiving CAR T following their engagement with the learning pathway. Feedback found (n=14 strongly agree or agree) that the learning that occurred in step 1 (self-directed) and step 2 (simulated learning) was applied in the third step (clinical practice).

Conclusions: The main finding from the participant survey was that pathway was easy to follow and that learning that occurred in steps 1 and 2 was applied in clinical practice (step 3). Additional simulation sessions were identified as something to consider for future courses.

CN79 Mentoring programs for specialised and advanced practice nurses: A systematic review

I. Vlerick[1], E. Decoene[2], A. Van Hecke[1], B. Delbaere[3], A. Coolbrandt[4], L-M. Kinnaer[1]

[1]Public Health and Primary Care - University Centre for Nursing and Midwifery, Ghent University, Ghent, Belgium; [2]Nursing, Ghent University Hospital, Ghent, Belgium; [3]Nursing, University of Antwerp, Antwerpen, Belgium; [4]Nursing, UZ Leuven - University Hospitals Leuven - Campus Gasthuisberg, Leuven, Belgium

Background: Health systems are facing challenges due to increased complexity of care, also in cancer care. Expert nurses such as specialized nurses (SN) and advanced practice nurse (APN) are ideally positioned to make a positive contribution to high quality cancer care. These nurses often face challenges in their professional transition and lack support by their team. Offering a mentoring program focusing on how to integrate in the interprofessional team and how to fulfill their roles as educator, innovator, professional and clinical leader etc., may have a positive impact on role and leadership development, collaboration, role clarity, job satisfaction and job retention. We aim to identify, evaluate and summarize evidence about the objectives and characteristics of mentoring programs for SN and APN, and to identify their effectiveness.

Methods: A systematic review was performed. We searched PubMed, EMBASE, CINAHL and The Cochrane Library and included studies in English, French or Dutch describing the characteristics of mentoring programs focusing on one or more specific roles of SN and APN. No restrictions on publication date and study design were considered. Studies describing mentoring programs that solely focused on clinical/medical capabilities within a specific specialization domain were excluded.

Results: Twelve studies were included. All studies focused on mentorship programs for APN (nurse practitioners and clinical nurse specialists). Different forms of mentorship (formal, informal, work shadowing, competence development, workshops, reflection sessions) were reported. The studies reported positive outcomes on job retention (n=5), job satisfaction (n=6), skills improvement (n=6) and satisfaction with the program (n=6) among participants of the mentoring programs.

Conclusions: In general, there is a lack of rigorous research on mentoring programs for SN and APN, not focusing on building clinical capabilities within their specialty domain. There is a need to develop a mentoring program that focuses primarily on challenges experienced by both SN and APN related to their role integration in an interprofessional team. This is especially important for oncology SN and APN as they are widely introduced in cancer care.

CN80 Mindfulness-based stress reduction as continuing educational course for oncology team welfare

E. Gianotti[1], G. Razzini[1], R. Ferrari[2], D. Barbieri[1], I. Bernardini[1], M. Bini[1], K. Cagossi[1], T. Cipriano[1], M. Delgaudio[1], V. Fantuzzi[1], U. Ferrari[1], L. Lombardo[1], A. Pietramaggiori[1], R. Porumb[1], C. Mucciarini[1]

[1]Oncologia medica, Ospedale Ramazzini - AUSL Modena, Carpi, Italy; [2]A.S.I.A., Modena, Italy

Background: Oncology care providers are facing work-related stress. We aimed to evaluate if mindfulness based-stress reduction (MBSR) is an effective workplace intervention to reduce risk for burnout syndrome.

Methods: This was a pre-post interventional prospective study conducted at a hospital oncology unit, including 6 medical oncologists, 5 nurses, 1 palliative oncologist, 1 psychologist and 1 clinical researcher. The intervention was offered as a continuing education course based on MBSR that met 2.5 hours a week for 8 weeks plus a 7-hour retreat, including body scan practice, yoga light exercise, mindful movement, walking and sitting meditation, as well as group discussion focusing on the application of mindfulness at work; materials for home practice were provided. A qualified MBSR instructor conducted the program. Feasibility and acceptability were assessed on the 14 participants while 6 nurses and 4 medical oncologists did not attend the course and were tested as control group. Outcome measures were work-related burnout and -engagement measured by the Maslach Burnout Inventory and the UWES-17 questionnaire, respectively. Changes in scores before and after intervention were evaluated within group.

Results: Median age was 47, mainly female. Both groups showed moderate to high risk for burnout syndrome and average to high work engagement. Educational credits have been achieved by 11 out of 14 MBSR participants with overall attendance of 78%. Diary records showed that, 12 participants, on average, practiced 3 times per week for 15 min/session, listening to guided meditations throughout the course, 2 participants did not do any home practice. After MBSR intervention emotional exhaustion, depersonalization and dedition domain improved significantly ($p < 0.01$) while there were no significant changes in the realization, vigor and absorption domain scores. Notably, the control group had no significant changes on any outcome measures.

Conclusions: Mindfulness based stress reduction as a continuing education course for cancer care team is feasible and would help to reduce risk of burnout by improving emotional awareness, empathy and work involvement. A better adherence to MBSR home practice is required.

CN81 Oncology nursing clinical pathway for new graduate nurses: Smooth transition and sustainable retention

Q. Alnasser

Oncology Education/Nursing Development and Saudization, King Faisal Specialist Hospital and Research Center, Riyadh, Saudi Arabia

Background: Undergraduate nursing curriculums in Saudi Arabia offer few subjects about oncology, hematology, and palliative care. Thus, nursing graduates are having weak knowledge and skills relevant to oncology practice. Adding to this, graduates may complete all their training and internship in healthcare facilities that have no oncology services. As a result nursing graduates are reluctant to join oncology services, and healthcare facilities found it difficult to recruit and retain local nursing graduates in oncology. Thus, this project was to ensure a smooth transition process of the new graduate nurses into the oncology services through a clinical education pathway.

Methods: Plan-Do-Study-Act (PDSA) is the method used to guide the project process. Six new graduate nurses were recruited based on their initial preference to join oncology services. Number and percentage of retention was measured at 6 months, 12 months and 24 months post completing the clinical pathway. In addition, nurses narrated their lived experience in a qualitative data format via group discussion method. Five clinical specific rotations (medical oncology, Hematology, Bone Marrow Transplant, Infusion unit and Radiation) were developed to onboard new graduate nurses. Five didactic sessions of eight days were established and 10 competency-based sessions were provided.

Results: Two participants completed the hematology clinical pathway, three participants completed the bone marrow transplant clinical pathway and one participant completed the infusion unit clinical pathway. All participants [100%] completed 24 months working full time in their respected units after finishing the clinical pathway rotations. Participants perceived that the clinical pathway made their onboarding process safe and smooth. Participants reported that the time they were provided to learn about oncology helped them to master oncology skills and knowledge and helped them to safely care for cancer patients. However, the duration of the clinical pathway rotation could be shortened.

Conclusions: Clinical pathway made a remarkable impact on new graduate nurses' retention in oncology services and provided participants with the necessary knowledge and skills to safely care for cancer patients.

CN82 Implementation of a nurse led clinic (NLC) in outpatient cancer care: A growing opportunity for clinical nurse specialists (CNS) in Belgium

I. Decadt[1], A. Courtens[1], A. Van Hecke[2]

[1]Kortrijk Cancer Centre, President Kennedylaan 4, 8500 Kortrijk, AZ Groeninge - Campus Kennedylaan, Kortrijk, Belgium; [2]University Centre for Nursing and Midwifery, Ghent University - University Centre for Nursing and Midwifery, Ghent, Belgium

Background: CNS in oncology enhance delivery of high quality care by detecting and addressing unmet needs of patients, the nursing and interprofessional team. To ensure in-depth insight into these specific needs, integration of CNS in direct patient care is essential. Based on unmet patient needs and the need for systematic integration of CNS in direct patient care, a NLC in a regional hospital in Flanders was set up. Contributing factors were the increase of advanced nursing roles, the rise of nurse led clinics in oncology internationally and an oncologist in need of high-quality clinical support provided by the CNS because of raised complexity of oncology care and workload. This study aimed to describe the developmental process and stakeholders' perspectives involved in this NLC initiative.

Methods: Based on a literature review, brainstorming and good practices of NLC, a framework for the NLC was developed. After implementation of the NLC, interviews with 10 stakeholders involved in the process of development were held (oncologist, head nurse, nurse manager, nurses, specialised nurses, CNS). Interviews were transcribed. Thematic analysis and researcher triangulation were performed.

Results: The NLC framework consisted of a complementary model with a description of the nurse led visit (e.g. assessment, prescribing), clarity in roles and responsibilities, which patients (patients with gynaecological and head-and-neck cancer) and referral criteria. A six-month internship for the CNS was set up prior to the start of the NLC. The CNS was introduced by the oncologist to the patient and family, initiating a relationship of trust and shared decision making. Nurse led visits alternated with medical visits. Preliminary results indicate the physician as important initiator, having trust in the CNS, ensuring no dilution in other nursing roles, enhancement in detection of unmet needs by CNS, optimised patient flows and continuity of care. Analysis is ongoing. Results are expected in September 2023.

Conclusions: The NLC provides a faster, more coordinated service for patients undergoing cancer treatment and their family caregivers ensuring continuity of care and attention to unmet needs and appropriate referrals.

CN83 Low bacterial diet in cancer patients: A systematic review

S. Matteucci[1], G. De Pasquale[2], M. Pastore[3], E. Morenghi[4], V. Pipitone[1], F. Soekeland[5], R. Caccialanza[6], B. Mazzoleni[4], S. Mancin[3]

[1]Cancer Center Haematology Unit, IRCCS Humanitas Research Hospital, Rozzano, Italy; [2]Intensive Care Unit, IRCCS Humanitas Research Hospital, Rozzano, Italy; [3]Cancer Center Clinical Nutrition Unit, IRCCS Humanitas Research Hospital, Rozzano, Italy; [4]Department of Biomedical Sciences, IRCCS Humanitas Research Hospital, Rozzano, Italy; [5]School of Health Professions, University of Applied Sciences, Bern, Switzerland; [6]Clinical Nutrition and Dietetics Unit, Fondazione IRCCS Policlinico San Matteo, Pavia, Italy

Background: The low bacteria diet (LBD) is a widely used dietary regimen to reduce the risk of foodborne infections in neutropenic cancer patients. Despite its frequent use over the years, there is no single definition of LBD diet and its role is widely controversial due to unclear benefits. The purpose of this study was to provide an updated analysis of the current body of evidence available on the efficacy of the LBD diet to reduce the risk of infections, mortality rates and quality of life (QoL) in neutropenic patients with cancer.

Methods: A systematic literature search was conducted in the biomedical databases: CENTRAL and DARE (The Cochrane Library), PubMed, CINHAL and EMBASE (Ovid). The process of screening, selection and inclusion of articles, as well as assessment of risk of bias and methodological quality was conducted independently by two reviewers. Of the 1985 records identified, 12 were included in this review.

Results: The included articles demonstrated heterogeneity in the definition, composition and timing of the LBD diet. The LBD diet did not demonstrate a reduction in infection and mortality rates compared to a free diet and furthermore, it showed a negative correlation with the quality of life.

Conclusions: The LBD diet, in addition to not bringing benefits in terms of reduction of infection and mortality rates, has been shown to worsen the quality of life due to the reduced palatability and limited variety of the food supply, negatively impacting the nutritional status. Healthcare professionals should implement safe food handling and preparation practices in conjunction with a free diet.

CN84 Development of a unit for collection of biological samples and clinical data from cancer patients coordinated by nursing: The translational oncology research project (INTRON)

M.P. Andueza[1], E. Navarcorena Zabalza[1], Y. Iragorri Barberena[1], L. Soria Royo[1], S. Chocarro Martin[1], M. Ayensa Burgui[2], I. Gracia Ilundain[1], I. Navamuel Andueza[1], J.L. Perez Gracia[1], A. Ojer Perea[1], M. Ocon[3]

[1]Oncology, Clinica Universidad de Navarra, Navarra, Spain; [2]Radiation Oncology, Clinica Universidad de Navarra, Navarra, Spain; [3]Neumology, Clinica Universidad de Navarra, Navarra, Spain

Background: Biological samples from patients are critical for developing translational research projects in Oncology. Therefore, it is essential to develop units capable of obtaining samples, meeting all legal, ethical and quality requirements. Nursing plays a fundamental role in coordinating these units. We have developed a Translational Research Unit coordinated autonomously by Nursing, which allows obtaining biological samples and associated clinical data from patients, allowing to perform high-impact translational research projects.

Methods: We developed a protocol for collecting biological samples and clinical data from patients and healthy controls using a universal informed consent, in collaboration with the Ethics Committee, and the Biobank, Biochemistry, Pathology and Oncology Departments. Patients, treated in the routine care setting as well as in clinical trials, authorize the collection of blood and urine samples and clinical data for research purposes; and their biopsies and other biological samples (pleural fluid, etc.) obtained for healthcare purposes, as long as it does not interfere with their diagnosis and treatment. Blood samples are drawn, when possible, simultaneously with routine analyses. Samples are obtained at baseline, at the time of reassessments (CT, PET,...) and at other clinically relevant times.

Results: Between February 2009 and April 2023 we have obtained blood samples from more than 5,600 patients, many of them sequential. Genomic, protein expression and immunological studies among others, have been performed on the samples,

resulting on 50 studies published in international journals and on funding for 38 national and international research projects.

Conclusions: We have developed a Research Unit which allows collecting biological samples from patients treated in the routine setting and in clinical trials that has allowed the development of numerous translational research papers published in prestigious international journals. Nursing has a fundamental role in coordinating translational research projects.

CN85 Dynamics and processes influencing role integration of advanced practice nurses and nurse navigators in oncology teams

I.Vlerick[1], A. Van Hecke[2], S. Akhayad[1], E. Decoene[3], M. Daem[4], L-M. Kinnaer[2]

[1]Nursing, Ghent University Hospital, Ghent, Belgium; [2]Nursing, Ghent University - University Centre for Nursing and Midwifery, Ghent, Belgium; [3]Oncology, Ghent University Hospital, Ghent, Belgium; [4]Cancer center, UZ Ghent - Universitair Ziekenhuis Ghent, Ghent, Belgium

Background: Due to the complexity of cancer care, there is an increased need for expert nurses involved in the care of cancer patients. Although the added value of advanced practice nurses (APN) and oncology nurse navigators (ONN) in interprofessional teams has already been proven, barriers and facilitators at individual, organizational and healthcare system level, related to role integration of mainly APN and to a limited extent of ONN, have been reported. A deeper understanding of these processes and dynamics is important as it might enhance role integration processes in interprofessional cancer teams. The goal of this study was to explore the persisting presence of underlying processes, dynamics, experienced barriers and facilitators of Advanced Practice Nurses (APN) in oncology and Oncology Nurse Navigators (ONN) during their role integration in an interprofessional team over a research period of seven years (2011-2018).

Methods: A qualitative study based on the principles of Grounded Theory was conducted. Individual semi-structured interviews and focus groups with 51 ONN and APN from 11 university and local hospitals in Belgium were performed. Data were analyzed thematically to develop a framework.

Results: ONN and APN experienced a lonely journey during role integration. They were constantly searching for partners, medical knowledge and acknowledgement from the interprofessional team. ONN and APN had a watchful attitude and tried to make themselves visible to ensure they were involved in the team and to preserve their role and responsibilities. They felt powerless when they had the impression that their role was not acknowledged by their team. An unclear role description to the interprofessional team, and a lack of coaching and guidance were influencing factors of the experience of ONN and APN.

Conclusions: ONN and APN in oncology experience difficulties to integrate their role in existing interprofessional teams. Coaching and mentorship of novice ONN/APN, their interprofessional team and healthcare managers are needed to address these issues. These findings could form the basis for a mentorship program for ONN/APN and their interprofessional team to enhance role integration.

CN86 Advanced breast cancer care for nurses (ABC4Nurses): A mixed-methods evaluation of an online educational programme

S. Sheehan[1], C. Díez de los Ríos de la Serna[2], G. Bagcivan[3], M. Dowling[4], G. Kotronoulas[5], A. Shewbridge[6], S. Erdem[7], V. Aroyo[7], B. Radia[8], T. Wiseman[9], A. Drury[1]

[1]School of Nursing, Psychotherapy and Community Health, DCU - Dublin City University, Dublin, Ireland; [2]Vall d'Hebron University Hospital, Barcelona, Spain; [3]School of Nursing, Koc University - School of Nursing, Istanbul, Turkey; [4]School of Nursing and Midwifery, National University of Ireland Galway (NUIG), Galway, Ireland; [5]School of Medicine, Dentistry & Nursing, University of Glasgow, Glasgow, UK; [6]Private Practice, London, UK; [7]Europa Donna, Piazza Amendola, Turkey; [8]Guy's Cancer Academy - Guy's Hospital, London, UK; [9]Applied Health Research, The Royal Marsden Hospital - NHS Foundation Trust, London, UK

Background: For people living with advanced breast cancer (ABC), specialist nursing is recognised as an essential component of care. However, access to specialist education and training in ABC is limited, contributing to variability in the availability of clinical specialist nurse services throughout Europe. The ABC4Nurses education programme was co-designed with experts by experience and profession in ABC and translated into four European languages following a systematic review and Delphi study to determine priority topics for nurse education in ABC. The aim of this study is to evaluate the implementation and perceived impact of the education programme from the perspectives of nurses who have completed the programme.

Methods: A mixed-methods evaluation was undertaken, guided by the Kirkpatrick framework (1967). Questionnaires were administered prior to commencing the programme to evaluate expectations for the programme (T1), and immediately after completion of the programme (T2) to assess overall satisfaction and personal views of the programme. Semi-structured qualitative interviews were held with a smaller number of participants to explore the perceived impact of the programme on ABC care in the participants' place of work.

Results: Of 655 registered participants, 188 (29%) participated in T1, and to date, 53 (30%) of these participants have completed all 6 modules, and the T2 questionnaire. T1 participants (n=188) were from the UK (27%), Spain (26%), Turkey (18%) and the Czech Republic (13%). ABC4Nurses has been evaluated positively by T2 participants (n=53), with 94% reporting that the programme has helped them in their work and would recommend this programme to their co-workers. On average, participants felt prepared to care for people with ABC (Mean: 8.2, SD: 1.5) and were committed to applying learning from the programme in their roles (Mean: 9.1, SD: 1.6).

Conclusions: This study shows that a novel, co-designed online learning programme in ABC was effective in enhancing cancer nurses' confidence and commitment to the delivery of care to people living with ABC. Furthermore, the results demonstrate the potential reach of the programme as a result of the programme being available in an accessible, translated format.

CN87 An accreditation tool towards safe quality cancer nursing care

F. Conceição[1], M. van Klinken[2], J.C. de la Torre-Montero[3], N. Salgado[4]

[1]Surgical Center - Intensive Care and Recovery Area, Champalimaud Foundation - Champalimaud Clinical Center, Lisbon, Portugal; [2]Internal Division/ Palliative Care Department, Netherlands Cancer Institute/Antoni van Leeuwenhoek Hospital (NKI-AVL), Amsterdam, Netherlands; [3]Nursing and Physical Therapy department, Universidad Pontificia Comillas, Madrid, Spain; [4]Ward, Instituto Portugues Oncologia de Coimbra Francisco Gentil E. P. E. (IPO Coimbra), Coimbra, Portugal

Background: Good Clinical Practice in cancer care throughout Europe implies a strong and even development of cancer nursing. The European Oncology Nursing Society (EONS) Advocacy Working Group has been advocating for improvement in those areas as a way to impact the quality of cancer care. One of EONS's projects - European Cancer Nursing Index (ECNI) — made visible asymmetries throughout European countries on domains like patient and occupational safety, workforce and working conditions, educational levels, and recognition. This knowledge is the ground base for an urge to action.

Methods: The recognition tool serves to promote awareness in nurses, patients and families, managers, and boards towards specific measures/processes needed to achieve safer and quality cancer care. Not only it can provide knowledge and awareness but can grow as an aspirational symbol for cancer units and a roadmap to the necessary steps towards achieving quality cancer care. The "EONS Accreditation of Safe Workplace" is a tool developed by EONS advocacy working group. It comprises several domains — general policy, safe environment and worker protection, continuous education, safe patient care, and managing of hazardous drugs and radiation — that serve as a standard basis to promote quality safety cancer care. The accreditation will be a voluntary process, ideally self-proposed by the unit itself, using a questionnaire for managers and nurses. The final score represents the level of the unit's maturity towards EONS standards, leading to the recognition of a safe workplace or a recommendation for improvement. The tool is currently constructed and being tested in three hospitals in Belgium, Sweden, and Portugal for final adjustments.

Results: The implementation of "EONS Accreditation of Safe Workplace" could increase the current EONS advocacy work towards safe and quality care. Every unit could propose the application, leading to a recognition and improvement drive between cancer units and promoting healthy competition towards safe and quality care.

Conclusions: At a political level, could bring awareness to multilevel management and stakeholders that impact on nursing workforce and work conditions. Also, is a tool that could empower nurses, as well as patients and families, to search and advocate for safer places of care.

CN88 Handling cancer drugs: Inventory of the state of knowledge and educational opportunities in Sweden

A. Delin Eriksson[1], C. Lundgren[2], M. Sodell[3], U. Landin[4], A. Walter[5], I. Ekh[6]

[1]Department of Oncology, Sahlgrenska University Hospital, Göteborg, Sweden; [2]Departement of Oncology, Sjukhus Gavle, Gavle, Sweden; [3]RCC Stockholm-Gotland, RCC - Regionalt cancercentrum Stockholm - Gotland, Stockholm, Sweden; [4]RCC Syd, Regionalt Cancercentrum syd, Lund, Sweden; [5]Cancercentrum, Norrland University Hospital, Umea, Sweden; [6]Hospital Pharmacy, Länssjukhuset Ryhov, Jönköping, Sweden

Background: Swedish National Working Group for handling cancer drugs is supportive by the regional cancer center in collaboration. The focus is to develop and ensure the availability of educational activities for the safe handling of cancer drugs from a patient safety and work environment perspective. Handling chemotherapy and other potent cancer drugs requires up-to-date knowledge and effective routines to foster both patient and occupational safety. The risks for exposure, from preparation to excretion, are well documented. The aim of this study was to map knowledge and education levels for registered nurses and nurse assistants handling chemotherapy and other cancer drugs in Sweden, as well as to identify education needs, reported by 1st line managers.

Methods: A digital survey was sent out to first line managers across Sweden. The managers, who responded anonymously, all had employees in their teams, handling antineoplastic agents, for example preparing, administering and/or caring for patients who have received cancer drugs. The survey included questions concerning training for newly employed nurses and assistant nurses, follow-up of training, guidelines related to pregnancy, experiences with risk assessments and swab tests.

Results: Out of 136 responding managers, 22% reported no dedicated training for newly employed nurses and 50% stated that there is no requirement for training for nurses and/or nurse assistant before handling cancer drugs. For newly employed nurse assistant, 79% of the managers responded no requirement for training before caring for patients receiving cancer drugs. The majority of managers stated that guidelines for pregnant women were in place, but not for staff planning a pregnancy. In addition, 58% of the managers stated that there was no regular follow-up of the staff's knowledge levels, 35% performed annual risk assessments and 17% reported performing regular swab tests on the clinical surface's/devices.

Conclusions: Deficiencies in training for newly hired nursing staff and lack of regular follow-up of knowledge identify both patient-, and occupational safety risks. Stronger requirements for education is needed, in addition to improved education possibilities, introduction and refresher training.

CN89 In cancer care nursing, does the use of surface wipe sampling for hazardous drugs lead to a safer occupational environment, in an outpatient and inpatient oncology/haematology setting? An evidence translation proposal

A. O'Halloran

Oncology / Hematology Department, St. James's Hospital, Dublin, Ireland

Background: Optimal occupational safety environments for cancer care nurses, is of critical importance. Over 200 systemic anti-cancer treatments (SACT) are classed as hazardous drugs (HD) and the toxicity of these drugs have been well documented in the literature for over eighty years. Importantly, these HD make occupational exposure a significant problem for cancer care nurses, as exposure to HD is linked to both acute and chronic health consequences. Crucially, there are no known safe occupational levels of SACT exposure. Therefore, all available and necessary measures should be taken to limit the potential occupational exposure risks, for cancer care nurses.

Methods: The evidence translation dissertation begins with the PICO intervention question and a comprehensive background on the topic. In Chapter 2, a full systematic search was completed utilising two databases (CINAHL and PubMed) to retrieve the best available research evidence. Chapter 3, explored the historical, methodological and theoretical intricacies behind implementation and complexity sciences. Chapter 4, provides a comprehensive outline of an evidence based implementation proposal, underpinned by an implementation science framework. Through a process of self-critical reflection of learnings achieved, Chapter 5 draws the dissertation to a close and recommends the next steps in progressing this proposal within the author's hospital.

Results: Despite the exhaustive database search, the research reviewed did not involve nurses completing wipe sampling for hazardous drugs in an outpatient and inpatient oncology/haematology settings. Therefore, did not meet the author's criteria for inclusion. The United States Pharmacopeia (2020) guideline is the best available evidence retrieved, to answer the evidence-based research question.

Conclusions: The next step in advancing this project, is to convene a steering committee and engage key stakeholders to develop a strategic implementation resource plan. The implementation plan will be used as a context-sensitive roadmap resource.

CN90 Managing the increasing capacity pressures in a nurse-led rural, satellite oncology unit in the era of immunotherapy

S.M. Murphy[1], S. Lane[2], D.C. Collins[2], R. Bambury[2], S. Iqbal[3], M.O. Connor[1], P. Hickey[1], M. Pomeroy[4], S.A. Noonan[5]

[1]Oncology, University Hospital Kerry, Tralee, Ireland; [2]Department of Medical Oncology, CUH - Cork University Hospital, Cork, Ireland; [3]Medical Oncology Dept., St James's Hospital, Cork, Ireland; [4]Department of Medical Oncology, University Hospital Kerry, Tralee, Ireland; [5]Medical Oncology Department, CUH - Cork University Hospital, Cork, Ireland

Background: University Hospital Kerry (UHK) Oncology Unit is a satellite unit of Cork University Hospital (CUH), an ESMO designated Centre of Integrated Oncology and Palliative Care. It is led by oncology clinical nurse specialists, tumour-site specific nurse specialists, nurse prescribers and advanced nurse practitioners and serves a population of 180,000 people, providing infusional and oral systemic anti-cancer therapy (SACT) ambulatory units, supportive care, acute oncology service (AOS), survivorship follow-up and consultant-led outpatient clinics. Medical support is provided by two on-site registrars and 3 visiting medical oncologists.

Methods: This was a retrospective review of electronic admissions records correlated with pharmacy records and treatment plans for patients with non-small cell lung cancer (NSCLC), melanoma and breast cancer, the most common tumour types treated with immune checkpoint inhibitors (ICI).

Results: In 2019, 262 new patients were referred to UHK and 55% were treated with SACT. 10% of these patients were treated with ICI. The percentage of patients treated with ICI increased to 16% in 2020, 17% in 2021 & 25% in 2022. In 2019, 93% of patients treated with ICI had lung cancer, either small cell or NSCLC. This reduced to 88% in 2020, 86% in 2021 and to 76% in 2022, accounted for by the relative rise in ICI for melanoma: 0% (2019), 13% (2020), 13% (2021) and 22% (2022). Since the AOS was introduced in 2019 the number of calls have remained stable, however, the percentage related to ICI has increased. Admissions of patients have reduced but the proportion with a ICI related toxicity is increasing.

Conclusions: The delivery of SACT to patients living in rural areas presents unique challenges. The growth in ICI use including its unique toxicity profile is specifically challenging to a nurse-led satellite, a necessitated a review of the service. ICI related toxicities are more complex and do not fit neatly into a single algorithm. Recognition of immune-mediated toxicity and knowledge of treatments is lacking among the rural general medical and emergency department community. A dedicated acute oncology CNS, robust educational sessions, ICI work-up algorithms and structured patient review pathways are pivotal to patient care.

CN91 Mentors' roles and responsibilities expected by nursing students in clinical training at the institute of oncology Ljubljana, Slovenia

M. Matković

Nursing, Institute of Oncology Ljubljana, Ljubljana, Slovenia

Background: Nursing is a scientific discipline as well as a practical one. The study requires at least 4600 hours of theoretical and clinical training, the duration of the theoretical training must be at least one third and the duration of the clinical training at least one half of the minimum duration of the training. Practical training in a clinical setting is an important aspect of learning for students and a major responsibility for staff. Mentoring is seen as guiding a person in their own career. It is understood as the transfer of knowledge and experience from the mentor to the student. The aim of this study was to explore nursing students' perspectives on mentors roles and responsibilities at the Institute of Oncology Ljubljana (OIL) where they undertook their clinical training in oncology nursing.

Methods: A quantitative approach was used to explore nursing students' views on mentoring. Data were collected in academic year 2021/2022 using a questionnaire survey method. The sample included 134 second year nursing students who were undergoing clinical training at the OIL. The number of questionnaires returned was 106, representing 59%. The results were presented using descriptive statistics.

Results: In the results, students highlight the importance of the kindness of the mentors (36), good team attitude and acceptance of the student in the team (32), trust (14), positive atmosphere in the clinical environment (12), knowledge in oncology nursing and professionalism (11), nice reception (9) and appropriate communication (7).

Conclusions: Practical training in clinical settings allows students to learn about their future work, to acquire new professional skills, to relate theoretical content to practice and, last but not least, to meet their potential future employers. Findings showed that students highlight the importance of mentor's personal characteristics, communication skills and a willingness to invest time and energy in building a mentoring relationship. Mentors acquire all these skills not only through formal education, but also through lifelong education in nursing and other scientific disciplines.

CN92 Nursing students' attitude towards care of dying: A cross-sectional study in Italy

M. Veronese, M. Zordan

Department of Molecular Medicine, University of Padua - School of Medicine, Padua, Italy

Background: Palliative care is considered an approach to improving the quality of life of patients with terminal illness and their familiars and the nurse is the largest group of healthcare professionals involved in palliative care. Nursing education plays an important role in preparing future nurses to provide palliative care to patients at the end of their lives. The aim of the study was to explore nursing students' attitudes towards the care of dying patients.

Methods: We conduct a cross-sectional study in Nursing program at the University of Padua (Italy). We administered the Frommelt Attitude Toward Care of the Dying Scale form B (FATCOD-B) and demographic form to 445 third-year nursing students, who accepted to participate in the study, in 2022. This Nursing program has eight different places.

Results: The sample of the study consists of 228 students (48%). Respondents reported a median age of 22 years (range 20-43), the most respondents were female (189-83%). Most students attended a course on care of dying (151- 66%). Median total FATCOD-B scores (118.65) indicated intermediated levels of students' attitudes towards care for dying patients. There was no significant difference between the FATCOD-B score between nursing students who attended a course on palliative care and who did not attend the course (118.47 vs 119.10; p=.688).

Conclusions: This study showed that nursing students have an intermediated level of attitude toward care of dying and end-of-life care. Nurses can meet cancer patients in all hospital settings, so the development of professional skills towards the dying patient is essential. The questionnaire used could be used as a tool to identify the gaps present and to program the university's educational activity in the field of palliative care.

CN93 Strategic patient collaboration, cancer theme Karolinska comprehensive cancer center (CCC)

A-B. Johansson

Karolinska Comprehensive Cancer Center, Karolinska University Hospital-Solna, Solna, Sweden

Background: The "2.0 strategy for patient involvement" aims to involve patients and relatives to become active partners at Karolinska CCC. The strategy is based on involvement on different levels; strategic, operational, individual and in specific projects Involvement of patients and relatives is essential for better research and healthcare. In the strategic patient council, two patient representatives meets with medical and nursing managers regularly. The patient representatives address strategic topics to the council and the aim is also to exchange information about ongoing projects. The Strategic Council maps the level of existing patient involvement at operational level. The mapping resulted in a GAP analysis to identify areas of improvement in relation to the OECI standards for patient involvement.

Methods: The working method for GAP analysis has been questionnaires and focus groups based on areas selected by the authors according to OECI standards. Informants have been expert groups/professionals/managers.

Results: Patient Involvement organization. Strategic level**:** The representatives from the Patient and Relatives Council meets with the management team 4 times a year. Term of office 3-4 years (overlapping). Examples from the agenda; Relevant outcome data to be published, governance and organizational development, continuity of care, access to care. The aim of this collaboration is to involve patients in the development of cancer care at a strategic level. This grouping has an advisory function and reports to the management of the Cancer Theme. Operational level: Collaboration with patient representatives on processes that are important for the outcome of care in the patient flow. 2 Representatives. Term of office — 3-4 years (overlapping). Joint evaluation of collaboration.

Conclusions: Patient representatives' views on patient involvement 2.0; "We observe that Theme Cancer has taken note of this and developed Patient Involvement 2.0 and initiated the implementation. In our role as patient representatives, we have seen the difference patient involvement makes. We can use the experiences of those affected and close relations to make a difference, and that encourages us to continue".

CN94 The effect of a compassion fatigue resiliency program on oncology-hematology nurses' professional quality of life, stress levels and patients' care satisfaction: Nurse, patient and nurse manager's perspectives

T. Pehlivan Sarıbudak, B. Üstün

Faculty of Health Sciences, Istinye University, Istanbul, Turkey

Background: Compassion fatigue adversely affects nurses' physical and mental health, and negatively affect patient outcomes. However, there is no study evaluating the indirect effect of 'Compassion Fatigue Resiliency Program (CFRP)', given to nurses, on patient satisfaction. The aim of this study was to evaluate the effect of the CFRP applied to oncology nurses on the professional quality of life and stress levels of nurses, the satisfaction of cancer patients.

Methods: This experimental embedded mixed methods design study was conducted between 2022-2023 with 15 oncology nurses, 19 cancer patients and 6 nurse managers at a comprehensive oncology center in Istanbul. In the first phase of the three-stage study (pre-intervention phase), in-depth individual interviews were conducted with cancer patients, and instruments were applied to nurses and patients, respectively. In the second phase (intervention phase), CFRP was applied to the nurses. In the third phase (post-intervention phase), individual interviews were conducted with the same cancer patients and focus group interviews were conducted with the nurse managers, and the same measurement tools were reapplied to nurses and patients after the intervention.

Results: The mean compassion satisfaction scores of nurses decreased; patient care satisfaction scores increased statistically significantly after the CFRP intervention ($p<0.05$). 6 themes were identified from interviews with patients: communication of nurses; level of responsiveness to needs; accessibility of nurses; psychological care; informing, suggestions for improving nursing; and 5 themes were identified from interviews with nurse managers: awareness; feeling valued, approach to patients, approach to colleagues, no change.

Conclusions: After the CFRP applied to nurses, patient care satisfaction increased, while nurses' compassion satisfaction levels decreased. The qualitative data of the study showed the positive effects of CFRP for both nurses and patients from the perspective of nurses, patients and nurse managers.

Background: With platinum-based CTX, prognosis of patients (pts) with unfavourable CUP is poor; however, CGP may inform treatment strategies based on cancer genomics. The CUPISCO trial (NCT03498521) compared the efficacy and safety of molecularly guided therapy (MGT) vs standard platinum-based CTX in pts with newly diagnosed, unfavourable, non-squamous CUP.

Methods: Pts had central eligibility review-confirmed CUP with $\geq$1 measurable lesion (investigator-assessed via RECIST v1.1). All had tumour tissue and/or blood CGP (Foundation Medicine, Inc.). After 3 induction CTX cycles, pts with disease control were randomised 3:1 to MGT (investigator's choice from 12 regimens after molecular tumour board advice) or continuation with $\geq$3 more CTX cycles (category 1; shown here), stratified by gender and response to induction CTX. Pts with progressive disease received MGT (category 2). The primary endpoint was progression-free survival (PFS) in category 1 pts. Secondary endpoints included overall survival (OS), objective response rate (ORR), duration of response (DoR) and disease control rate (DCR). Safety was also assessed. Exploratory endpoints included quality of life (QoL).

Results: From Jul 2018—Dec 2022, 436 category 1 pts were randomised: 326 to MGT; 110 to CTX. Median PFS (intent-to-treat population) was 6.1 months (95% confidence interval [CI] 4.7—6.5) with MGT vs 4.4 months (4.1—5.6) with CTX (hazard ratio [HR] 0.72; 95% CI 0.56—0.92; P=0.0079). Median OS was 14.7 (95% CI 13.3—17.3) vs 11.0 months (9.7—15.4), respectively (HR 0.82; 95% CI 0.62—1.09; P=0.1779), though OS data were immature at cutoff. ΔORR was 9.6% (95% CI 2.4—16.8, P=0.0141) in favour of MGT, with similar DoR in each arm (HR 0.95; 95% CI 0.33—2.72). ΔDCR was 4.7% (95% CI —6.4—15.9; P=0.3922) in favour of MGT. Adverse event rates were generally similar with MGT vs CTX; no difference in QoL was observed.

Conclusions: In pts with newly diagnosed, unfavourable, non-squamous CUP who responded to induction CTX, CGP with MGT improved PFS. Early CGP and MGT should be considered the new standard of care for these pts.

Clinical trial identification: NCT03498521 / 13 April 2018.

Breast cancer, early stage

LBA17 Adjuvant abemaciclib plus endocrine therapy for HR+, HER2-, high-risk early breast cancer: Results from a preplanned monarchE overall survival interim analysis, including 5-year efficacy outcomes

Background: Two years (yrs) of adjuvant abemaciclib combined with endocrine therapy (ET) resulted in significant improvement in invasive disease-free survival (IDFS) and distant relapse-free survival (DRFS) that persisted beyond the 2-yr treatment (tx) period in patients (pts) with hormone receptor positive, human epidermal growth factor receptor 2 negative, node-positive, high-risk early breast cancer (EBC). Here, we report 5-yr efficacy results from a prespecified overall survival (OS) interim analysis.

Methods: Pts were randomized (1:1) to receive ET for at least 5 yrs +/- abemaciclib for 2 yrs (tx period). High-risk EBC was defined as either ≥4 positive axillary lymph nodes (ALN) or 1-3 ALN with Grade 3 disease and/or tumor ≥5 cm (Cohort 1). A smaller group of pts were enrolled with 1-3+ ALN and central Ki67 ≥20% (Cohort 2). The intent-to-treat (ITT) population consisted of Cohort 1 (5120 pts) and Cohort 2 (517 pts). OS in the ITT population was tested for statistical significance in the gated strategy. Hazard ratios (HR) were estimated using Cox proportional hazard model.

Results: In the ITT population, with a median follow-up of 54 months, the benefit of abemaciclib was sustained with a HR of 0.680 (95% CI: 0.599, 0.772) for IDFS and 0.675 (95% CI: 0.588, 0.774) for DRFS. This persistence of abemaciclib benefit translated to continued separation of the KM curves resulting in a 5-yr absolute improvement in IDFS and DRFS rates of 7.6% and 6.7%, respectively, compared with IDFS/DRFS rates of 6.0%/5.3% at 4 yrs and 4.8%/4.1% at 3 yrs. Tx benefit in Cohort 1 was consistent with ITT. No new safety signals were observed. There continued to be fewer deaths in the abemaciclib plus ET arm compared to the ET arm (208 vs 234; HR 0.903; p=0.284); significance was not met.

Conclusions: At the pivotal 5-yr mark for adjuvant EBC trials, abemaciclib plus ET continued to reduce the risk of developing invasive and distant disease recurrence well beyond the completion of tx. The increasing absolute improvement at 5 yrs is consistent with a carryover effect and further supports the use of abemaciclib in pts with high-risk EBC. OS data are evolving in favor of abemaciclib arm, and follow-up continues.

Clinical trial identification: NCT03155997.

Background: KEYNOTE-522 (NCT03036488) showed statistically significant and clinically meaningful improvements in pCR and EFS with the addition of pembrolizumab (pembro) to chemotherapy (chemo) in patients (pts) with early-stage TNBC. Here, we present updated EFS results after ∼5 yr median follow-up.

Methods: Eligible pts with previously untreated, non-metastatic, centrally confirmed TNBC (stage T1c N1-2 or T2-4 N0-2 per AJCC) were randomized 2:1 to neoadjuvant pembro 200 mg Q3W or placebo (pbo), both given with 4 cycles of paclitaxel + carboplatin, then with 4 cycles of doxorubicin or epirubicin + cyclophosphamide. After definitive surgery, pts received adjuvant pembro or pbo for 9 cycles or until recurrence or unacceptable toxicity. Dual primary endpoints are pCR (ypT0/Tis ypN0) and EFS (time from randomization to disease progression that precluded definitive surgery, local/distant recurrence, second primary cancer, or death from any cause).

Results: 1174 pts were randomized to pembro (n=784) or pbo (n=390). At data cutoff (March 23, 2023), median follow-up was 63.1 mo. 145 pts (18.5%) in the pembro group and 108 pts (27.7%) in the pbo group had an EFS event (HR 0.63 [95% CI, 0.49-0.81]). The 60-mo EFS rate (95% CI) was 81.3% (78.4-83.9) vs 72.3% (67.5-76.5), respectively; the median was not reached in either group. The most common first EFS event was distant recurrence, in 72 pts (9.2%) in the pembro group vs 55 pts (14.1%) in the pbo group. With 210 distant events, rates of distant disease progression- or distant recurrence-free survival at 60 mo were 84.4% with pembro vs 76.8% with pbo (HR 0.64 [95% CI, 0.49-0.84]). The EFS benefit with pembro was consistent across prespecified subgroups, including PD-L1 expression and nodal status. In a prespecified, non-randomized, exploratory analysis, 5-yr EFS rates in the pembro and pbo groups were 92.2% vs 88.2% in pts with a pCR, and 62.6% vs 52.3% in pts without a pCR. Follow-up for OS is ongoing.

Conclusions: Neoadjuvant pembro + chemo followed by adjuvant pembro continues to show a clinically meaningful improvement in EFS compared with neoadjuvant chemo alone in pts with early-stage TNBC, regardless of the pCR outcome.

Clinical trial identification: NCT03036488.

Background: In NeoTRIP (NCT002620280) addition of atezolizumab to nab-paclitaxel/carboplatin was linked to minor numerical increase of pathologic complete response (pCR) in women with high-risk TNBC (48.6 vs 44.4%, p = 0.48), which was 7.6% higher in PD-L1 positive tumors treated with atezolizumab (Gianni L et al, *Annal Oncol* 2022).

Methods: In the phase III open label NeoTRIP study 280 patients with early high-risk or locally advanced TNBC were randomized to neoadjuvant carboplatin AUC 2 and nab-paclitaxel 125 mg/m^2 iv on d1,8 q3 wks with (138) or w/o (142) atezolizumab 1200 mg iv on d1, for 8 cycles followed by surgery and by 4 cycles of an anthracycline regimen regardless of pCR. The primary endpoint of the study is EFS, defined as time from date of randomization to date of disease progression while on primary therapy, or disease recurrence after surgery or death due to any cause.

Results: At median follow-up of 54 months, the five-year EFS was 70.6% (95% CI 61.6 − 77.9) with atezolizumab and 74.9% (95% CI 66.6 − 81.5) w/o atezolizumab. The stratified analysis (by disease stage, PD-L1, age class) resulted in a p-value = 0.66. The table shows the impact of the stratification factors and pCR on EFS evaluated by a multivariate Cox model.

Table: LBA19

Variable	Effect	Hazard ratio	P value
Treatment	With vs w/o atezolizumab	1.076	0.76
pCR	Yes vs no	0.19	<0.0001
Disease stage	Early vs locally advanced	2.05	0.0039
PD-L1	Pos vs neg	0.61	0.043
Age	> 50 vs ≤ 50	0.94	0.79

Higher baseline stromal TILs were prognostic of better EFS in each arm, but they were not predictive of atezolizumab benefit. No new safety signals possibly related to atezolizumab emerged during follow up.

Conclusions: In NeoTRIP the addition of neoadjuvant atezolizumab to carboplatin/nab-paclitaxel did not improve EFS of patients with TNBC. PD-L1 expression and higher sTILs at baseline were prognostic for better EFS, but not predictive of atezolizumab benefit. Extensive biomarkers analysis by Image Mass Cytometry (Wang XQ et al, *Nature* 2023), RNAseq and WES are ongoing to identify those cases who can derive benefit from atezolizumab.

Clinical trial identification: NCT002620280, EudraCT 2014-005017-23.

Background: High-risk, early-stage ER+ HER2− BC treatment includes NACT and adjuvant ET. CheckMate 7FL (CM-7FL; NCT04109066) is the first prospective, phase 3, randomized trial investigating NIVO + NACT + adjuvant ET in this clinical setting.

Methods: This study enrolled newly diagnosed ER+ HER2− BC pts, stages T1c−2 and N1−2 or T3−4 and N0−2, of grade 2 (ER 1−10%) or 3 (ER ≥ 1%). Pts were randomized 1:1 to NACT + NIVO 360 mg Q3W/NIVO 240 mg Q2W (arm A) or NACT + PBO (arm B). In April 2022, based on external data, the trial was closed to new enrollment; the primary endpoint was amended to only pathological complete response (pCR; ypT0/is ypN0) rate in the modified ITT population (mITTP; database lock 14 Apr 2023). Secondary endpoints included pCR rates in programmed death ligand 1 (PD-L1)-positive (PD-L1+) pts (SP142 ≥ 1%), residual cancer burden (RCB) 0−1 rates (all pts and PD-L1+), adverse event (AE) incidences, and death incidences.

Results: 830 pts were screened, 521 randomized (arm A/B, n = 263/258), and 510 were included in the mITTP. Baseline characteristics were balanced across arms. pCR rate was overall significantly higher in arm A (24.5%) vs B (13.8%; $P = 0.0021$) and in the stage III subgroup (Arm A/B, 30.7%/8.1%). The benefit of NIVO on pCR was higher in PD-L1+ pts (adjusted difference [AD], 24.1%; 44.3% in arm A, 20.2% in arm B). RCB 0−1 rates improved overall and more so in PD-L1+ pts. In the NACT phase, grade 3/4 treatment-related AEs incidence was similar across arms (arm A/B, n = 92[35%]/82 [32%]). Two deaths (pneumonitis, hepatitis) in arm A were study-drug related. Immune-mediated AE (IMAE) incidence was higher in arm A vs B.

Conclusions: CM-7FL met its primary endpoint with significantly improved pCR and RCB 0−1 rates (enhanced in PD-L1+ pts) with NIVO + NACT, with increased IMAE incidence and an overall safety profile consistent with that of NIVO and CT.

Clinical trial identification: NCT04109066.

Background: KEYNOTE-756 (NCT03725059) is a global phase 3 study of neoadjuvant pembro or pbo + chemo followed by adjuvant pembro or pbo + ET in patients (pts) with early-stage high-risk $ER^+/HER2^-$ breast cancer. Here, we report primary pCR results.

Methods: Eligible pts with T1c-2 ($\geq$2 cm) cN1-2 or T3-4 cN0-2, centrally confirmed, grade 3, invasive ductal $ER^+/HER2^-$ breast cancer were randomized 1:1 to neoadjuvant pembro 200 mg Q3W or pbo, both given with paclitaxel QW for 12 wk, then 4 cycles of doxorubicin or epirubicin + cyclophosphamide (neoadjuvant treatment). After definitive surgery ($\pm$ radiation therapy), pts received pembro or pbo for 9 cycles + standard ET. Stratification factors include region (Eastern Europe, China, or Other), tumor PD-L1 status (CPS $\geq$1 [+] vs CPS $<$1 [−]), nodal involvement (+ vs −), ER positivity ($\geq$10% vs $<$10%) and anthracycline schedule (Q3W vs Q2W). Dual primary endpoints are pCR (ypT0/Tis ypN0) and EFS. Secondary endpoints include OS, pCR defined as ypT0 ypN0 and ypT0/Tis and safety.

Results: 1278 pts were randomized to pembro + chemo (n=635) or pbo + chemo (n=643). At the final pCR analysis (May 25, 2023, first interim analysis data cutoff), median follow-up was 33.2 mo (range, 9.7-51.8). In the ITT population, pembro + chemo showed a statistically significant improvement in pCR (ypT0/Tis ypN0) vs pbo + chemo: 24.3% (95% CI, 21.0-27.8) vs 15.6% (95% CI, 12.8-18.6); estimated difference, 8.5 percentage points (95% CI, 4.2-12.8); P=0.00005; results were consistent for the secondary pCR definitions, ypT0 ypN0 (21.3% vs 12.8%) and ypT0/Tis (29.4% vs 18.2%). The benefit of pembro + chemo on pCR was generally consistent in the prespecified subgroups. In the neoadjuvant phase, grade $\geq$3 treatment-related AE rates were 52.5% with pembro + chemo and 46.4% with pbo + chemo, with 1 death in the pembro arm due to acute myocardial infarction. EFS results are still immature and continue to be evaluated.

Conclusions: The addition of pembro to chemo significantly increased the pCR rate in pts with early-stage high-risk $ER^+/HER2^-$ breast cancer. Safety was consistent with the known profiles of each regimen.

Clinical trial identification: EudraCT 2017-004869-27, NCT03725059.

Background: Despite benefits of physical activity (PA) during breast cancer (BC) treatments, successful exercise strategies in routine BC care remain to be determined. The primary objective was to assess the efficacy of two 6-month PA interventions: connected PA program and therapeutic patient education (TPE), concomitant to adjuvant treatments.

Methods: DISCO was a 2x2 factorial, multicenter, phase III, randomized controlled trial. Women with a localized invasive BC and eligible for any adjuvant treatment, were randomized in 1 of the 4 groups: web-based connected device (adaptative program of 2 walking and 1 muscle strengthening sessions/week in autonomy + a connected activity wristband); TPE (2 sessions); combination of both interventions; usual care. All patients received PA recommendations. Assessments (baseline, 6&12 months) included physical fitness, body composition and questionnaires. The primary endpoint was the proportion of patients who reached PA recommendations at 6 months based on the Recent Physical Activity Questionnaire, in each intervention compared to patients who did not receive it. Statistical analyses were performed in the ITT population.

Results: From 2018 to 2021, 436 patients were randomized: 108 patients received the connected device, 108 the TPE program, 110 both interventions, and 110 usual care. At baseline, 66% of patients reached PA recommendations. During the 6-month intervention, 96% of patients wore the connected device, the median number of PA sessions was 45 and 80% of patients attended the TPE program. Overall, 89,3% of patients who received the connected device reached PA recommendations at 6 months vs. 89,4% of patients without the device and 91,9% of patients who benefits from TPE reached PA recommendations vs. 87% of patients without TPE. For the primary endpoint, no statistically significant difference was found for both interventions.

Conclusions: The findings provide new information on the efficacy of innovative interventions to practice PA during routine BC treatment. The 6-month major increase of PA, independently of patient group allocation, highlights the importance of providing PA recommendations and PA assessment to BC patients.

Clinical trial identification: NCT03529383; release date: 05/17/2018.

Background: The NATALEE trial demonstrated a statistically significant iDFS benefit with RIB + NSAI vs NSAI alone in a broad population of pts with stage II or III HR+/HER2− EBC at risk of recurrence (Slamon D, et al. *ASCO* 2023. Oral LBA500). Evaluating iDFS outcomes in clinically relevant subgroups is important for understanding treatment (tx) benefit in specific pts. Here we present a prespecified exploratory subgroup analysis of iDFS in pts enrolled in NATALEE.

Methods: Pts with HR+/HER2− EBC were randomized 1:1 to RIB for 3 y (400 mg/d for 3 wk on/1 wk off) + NSAI for ≥5 y (letrozole 2.5 mg/d or anastrozole 1 mg/d) or NSAI

alone. Premenopausal women and men received goserelin every 28 d. NATALEE included pts with anatomical stage IIA (N0 requiring additional risk factors or N1 [1-3 axillary lymph nodes]) and all pts with stage IIB or III disease per AJCC's Cancer Staging Manual (8th ed). iDFS was evaluated by Kaplan-Meier methods. iDFS analysis was performed according to anatomical stage, menopausal status, nodal status, age, and Ki-67 score (locally tested). This prespecified analysis was not powered for statistical significance.

Results: A total of 5101 pts were included in this analysis (data cutoff: 11 Jan 2023; median follow-up for iDFS, 27.7 mo in both arms). Overall, the iDFS benefit with RIB + NSAI vs NSAI alone was consistent across all clinically relevant subgroups (Table), which in turn was consistent with that observed in the overall trial population.

Table: LBA23

	Tx, n	3-y iDFS rate, %	HR (95% CI)
Menopausal status			
Premenopausal women & men	RIB + NSAI, 1126	91	0.72 (0.53-0.98)
	NSAI alone, 1132	89	
Postmenopausal women	RIB + NSAI, 1423	90	0.78 (0.61-1.00)
	NSAI alone, 1420	86	
Anatomical stage			
II	RIB + NSAI, 1011	94	0.76 (0.53-1.10)
	NSAI alone, 1034	91	
III	RIB + NSAI, 1528	87	0.74 (0.59-0.93)
	NSAI alone, 1512	84	
Nodal status			
N0	RIB + NSAI, 285	94	0.63 (0.34-1.17)
	NSAI alone, 328	89	
N1-N3	RIB + NSAI, 2261	90	0.77 (0.63-0.94)
	NSAI alone, 2219	87	
Age			
<65 y	RIB + NSAI, 2142	90	0.77 (0.62-0.94)
	NSAI alone, 2186	87	
≥65 y	RIB + NSAI, 407	90	0.72 (0.46-1.14)
	NSAI alone, 366	86	
Ki-67			
≤20%	RIB + NSAI, 1199	92	0.80 (0.59-1.08)
	NSAI alone, 1236	90	
>20%	RIB + NSAI, 920	89	0.75 (0.56-1.00)
	NSAI alone, 938	84	

Conclusions: The iDFS benefit with RIB + NSAI was generally consistent with that in the intent-to-treat population of NATALEE and was not driven by any particular subgroup. The results further support RIB + NSAI as a new tx of choice in a broad population of pts with HR+/HER2− EBC.

Clinical trial identification: NCT03701334.

Background: Several analyses have shown prognostic impact of clinical and IHC markers in addition to genomic signatures in HR+/HER2 EBC. However, it remains unclear whether histology (e.g. invasive lobular BC (ILC) or further factors provide additional information. We present outcome from the prospective WSG-ADAPT HR+/HER- trial combining both static and dynamic biomarkers to optimize adjuvant therapy in luminal EBC.

Methods: pN0-1 with clinically high-risk HR+/HER2- EBC pts with RS0-11 OR RS12-25/ $Ki67_{postendocrine}$≤10% after 3 +/- of preoperative ET received ET alone; the remaining high-risk cohort was randomized to the CT trial. Prognostic scores containing clinical factors with and w/out mutational/copy number data were derived retrospectively after splitting the data into training- and validation sets. LASSO and cross validation methods were used to predict iDFS in therapy subgroups. Additionally, multivariate Cox models were adapted using a forward-backward selection approach to identify prognostic markers.

Results: 4491 pts were included (n=2246 ET- and n=2245 CT-treated). In the whole set, tumor and nodal (T/N) stage, RS and PR expression were prognostic for iDFS (Cox model). In ET-treated pts, only T-stage, RS and ER expression by RT-pCR were significant by Cox analysis, but prognostic score could not be determined. In CT-treated patients, T/N stage, G2-3 vs. G1, RS, ILC, and PR expression, but not IHC4 entered the model. In the CT cohort, a prognostic score consisting of T/N stage, age (≤50, >50), RS, ILC, PR expression and baseline and post-ET Ki67 yields a ROC AUC of 66% in the validation set. ILC was associated with lower RS than IDC (RS>25: 5.62% vs. 19.37%).High-risk CT-treated ILC had more frequently ERBB2 (11.6% vs. 2.5%) and a lower frequency of CDH1 mutations (60.5% vs 70.7%). Only CCND1 amplification was associated with worse iDFS in the NGS sub-cohort (n=584).

Conclusions: Use of RS in combination with further clinical and genetic factors improves prognostic ability; however, there is no treatment-independent prognostic model for HR+ HER2- EBC pts. For the first time, we have shown worse prognosis of the ILC high-risk subgroup, associated with distinct biological features.

Background: The TROP2-directed antibody-drug conjugate Dato-DXd demonstrated promising activity in heavily pre-treated patients (pts) with inoperable or metastatic HR+/HER2-BC in the Phase 1 TROPION-PanTumor01 trial (NCT03401385). Here we report primary PFS results from the global, Phase 3 TROPION-Breast01 trial (NCT05104866).

Methods: Adult pts with inoperable or metastatic HR+/HER2-BC, who had experienced progression on endocrine therapy (ET) and for whom ET was unsuitable, and who had received 1-2 prior lines of systemic chemotherapy (CT), were randomised 1:1 to Dato-DXd (6 mg/kg Q3W) or investigator's choice of CT (ICC; eribulin, vinorelbine, capecitabine, or gemcitabine) until progression or unacceptable toxicity. Dual primary endpoints were progression-free survival (PFS) by blinded independent central review (BICR) per RECIST 1.1, and overall survival (OS).

Results: 732 pts were randomised (Dato-DXd: 365; ICC: 367). Median age (range) was 56 (29−86)/54 (28−86) yrs in the Dato-DXd/ICC groups. At data cut-off (17 Jul 2023), 93/39 pts in the Dato-DXd/ICC groups were ongoing treatment. Results are shown in the table. Pts receiving Dato-DXd had significantly improved PFS vs ICC (HR 0.63 [95% CI 0.52−0.76]; p<0.0001). OS data were not mature; a trend for improvement favouring Dato-DXd was observed. Pts receiving Dato-DXd had lower rates of grade ≥3 TRAEs and dose reductions vs ICC (Table).

Table: LBA11

Efficacy	Dato-DXd N=365	ICC N=367
PFS		
Median PFS (BICR), mo (95% CI)	6.9 (5.7−7.4)	4.9 (4.2−5.5)
HR (95% CI)	0.63 (0.52−0.76); p<0.0001	
Median PFS (investigator assessed), mo (95% CI)	6.9 (5.9−7.1)	4.5 (4.2−5.5)
HR (95% CI)	0.64 (0.53−0.76)	
PFS rate (BICR), % (95% CI)		
6 mo	53.3 (47.7−58.5)	38.5 (32.8−44.1)
9 mo	37.5 (31.9−43.2)	18.7 (13.8−24.3)
OS*		
HR (95% CI)	0.84 (0.62−1.14)	
Response		
Confirmed ORR (BICR), % (n)	36.4 (133)	22.9 (84)
Safety	**N=360**	**N=351**
TRAEs, %		
Any grade	93.6	86.3
Grade ≥3	20.8	44.7
AEs associated with dose reduction/ discontinuation, %	23.1/3.1	32.2/2.8

*23% maturity.
AEs, adverse events; mo, months; ORR, objective response rate; TRAEs, AEs possibly related to study treatment.

Conclusions: TROPION-Breast01 met the primary endpoint of PFS; the study continues to final OS. Pts receiving Dato-DXd had statistically significant and clinically meaningful improvement in PFS compared with ICC, along with a favourable and manageable safety profile. Results support Dato-DXd as a novel treatment option for pts with inoperable or metastatic HR+/HER2-BC who have received 1−2 prior lines of CT.

Clinical trial identification: NCT05104866; release date November 3, 2021.

Background: We report the first Phase 3 primary results for sotorasib (soto), a $KRAS^{G12C}$-inhibitor, plus panitumumab (pani), an anti-EGFR antibody, vs standard of care (SOC) in patients (pts) with chemorefractory *KRAS* G12C-mutated mCRC.

Methods: In the CodeBreaK 300 (NCT05198934) global, open label study, 160 pts with chemorefractory *KRAS* G12C-mutated mCRC were randomized 1:1:1 to soto 960 mg daily plus pani 6 mg/kg IV (soto960+pani; n=53), soto 240 mg daily plus pani 6 mg/kg IV (soto240+pani, n=53), or investigator's choice of TAS-102 or regorafenib (n=54). Primary endpoint was progression-free survival (PFS) by blinded independent central review (BICR) per RECIST 1.1. Key secondary endpoints included ORR, DRR, and DCR.

Results: The study met its primary endpoint. Both soto+pani arms demonstrated statistically significant superior PFS compared to SOC: soto960+pani HR=0.49 (95% CI: 0.30, 0.80; p=0.006), and soto240+pani HR=0.58 (95% CI: 0.36, 0.93; p=0.03). Secondary efficacy endpoints are shown in the table. OS was immature at data cutoff. Grade ≥3 TRAEs that occurred in ≥5% pts were dermatitis acneiform (11.3%), hypomagnesaemia (5.7%), and rash (5.7%) for soto960+pani; hypomagnesaemia (7.5%), diarrhoea (5.7%) for soto240+pani; and neutropenia (23.5%), anaemia (5.9%), and hypertension (5.9%) for SOC. There were no fatal TRAEs.

Table: LBA10 Efficacy by BICR

	Soto960+Pani n=53	Soto240+Pani n=53	SOC n=54
Median PFS, months (95% CI)	5.6 (4.21, 6.31)	3.9 (3.71, 5.75)	2.2 (1.94, 3.91)
ORR, % (95% CI)	26.4 (15.3, 40.3)	5.7 (1.2, 15.7)	0 (0.0, 6.6)
Number of responders	14	3	0
Median DOR, months (range)	4.4 (1.9+, 6.0+)	NR (1.8+, 3.8+)	–
DCR, % (95% CI)	71.7 (57.7, 83.2)	67.9 (53.7, 80.1)	46.3 (32.6, 60.4)

CI, confidence interval; DCR, disease control rate; DOR, duration of response; NR, not reached; ORR, objective response rate

Conclusions: In the first phase 3 study for a $KRAS^{G12C}$-inhibitor plus an anti-EGFR antibody in chemorefractory mCRC, the primary endpoint was met and both doses of soto+pani showed superior PFS vs SOC. Soto960+pani demonstrated clinically meaningful benefit across PFS and key secondary endpoints (ORR, DCR, DOR) and was tolerable with lower rates of Grade ≥3 TRAEs vs SOC.

Clinical trial identification: NCT05198934.

Background: Based on the results of pre-clinical research and our phase II study, we conducted a randomized, multicenter, open-label phase III study to compare the efficacy and safety of short-course radiotherapy (SCRT) followed by immunochemotherapy versus long-course chemoradiotherapy (LCRT) followed by chemotherapy for perioperative treatment of locally advanced rectal cancer (LARC).

Methods: Patients (pts) with T3-4 or N^+ rectal adenocarcinoma, where the lower edge of the tumor was $\leq$ 10 cm from the anal verge, were randomly assigned to either Arm A or B in a 1:1 ratio. Stratification was based on clinical T stage ($\leq$ T3 vs. T4) and N stage (N0 vs. N^+), and pts received SCRT or LCRT, followed by 2 cycles of camrelizumab (CAM) + CAPOX or CAPOX, respectively. Total mesorectal excision (TME) was performed subsequently, with an additional 6 cycles of CAM + CAPOX followed by CAM for up to 1 year in Arm A, and 6 cycles of CAPOX in Arm B. Primary endpoint was the independent review committee (IRC)-assessed pCR rate (ypT0N0). Secondary endpoints tested hierarchically were 3-year EFS rate and OS.

Results: Between July 2021 and March 2023, 231 pts were randomly assigned to Arm A (n=113) and Arm B (n=118). In Arm A, 112 pts received SCRT, 107 completed neoadjuvant therapy, and 104 underwent TME. In Arm B, 115 pts received LCRT, 109 completed neoadjuvant therapy, and 99 underwent TME. The IRC-assessed pCR rate in the ITT populations was significantly improved in Arm A (39.8% [95% CI 30.7-49.5]) versus Arm B (15.3% [95% CI 9.3-23.0]), with an odds ratio of 3.7 ([95% CI 2.0-6.9], p<0.001), meeting the primary endpoint. Subgroup analysis showed consistently positive results across all subgroups. In the surgical population, the R0 resection rate was 96.2% in Arm A and 97.0% in Arm B. Postoperative complications occurred in 38.1% of pts in Arm A versus 40.8% in Arm B. Grade $\geq$ 3 TRAEs were observed in 29.2% of pts in Arm A and 27.2% in Arm B throughout the treatment. Long-term survival outcomes are currently being monitored.

Conclusions: SCRT followed by CAM and chemotherapy demonstrated a superior pCR rate with acceptable tolerance compared to LCRT followed by chemotherapy for LARC.

Clinical trial identification: NCT04928807.

Background: Neoadjuvant chemoradiotherapy (nCRT) is a crucial component in the treatment of locally advanced rectal cancer (LARC). However, indiscriminate pelvic radiation in all LARC lacks clear long-term survival benefits while accentuating surgical complications and toxicity. Comparatively, neoadjuvant chemotherapy (nCT) alone shows promise as an alternative treatment for LARC with uninvolved mesorectal fascia (MRF). This trial aimed to assess the the noninferiority of nCT with CAPOX versus nCRT with capecitabine in LARC with uninvolved MRF.

Methods: Patients between June 2014 and October 2020 with LARC within 12 cm from the anal verge and uninvolved MRF were randomly assigned to receive 4 cycles of CAPOX chemotherapy alone (nCT arm) or CRT with capecitabine (nCRT arm). The primary end point is 3-year local-regional recurrence-free survival (LRRFS), defined as time interval between the date of randomization and any local or regional progression/relapse, NI of nCT could be established if the upper limit of the 2-sided 95% confidence interval (CI) of the LRRFS hazard ratio (HR) did not exceed 1.6 (NI margin). Secondary endpoints, such as 3-year disease-free survival (DFS), 3-year overall survival (OS), and long-term toxicity, were also reported.

Results: A total of 663 patients were enrolled and 589 patients received the allocated treatment (nCT, n=300; nCRT, n=289). LRFFA was analyzed after a median follow-up of 48 months. 3-year LRRFS was 97.4 % (95% CI, 95.5 to 99.3) in the nCRT arm and 96.3% (95% CI, 94.0 to 98.6) in the nCT arm, resulting in a HR of 1.08 (95% CI, 0.46 to 2.54).

Table: LBA26

Outcomes	nCRT (n=289)	nCT (n=300)	HR/RR	P value
3-year LRRFS, %	97.4 (95.5-99.3)	96.3 (94.0-98.6)	1.08 (.46-2.54)	not proven for noninferiority
3-year DFS, %	87.9 (84.1-91.8)	89.2 (85.6-92.9)	.88 (.54-1.44)	.62
3-year OS, %	94.1 (91.3-96.9)	95.0 (92.4-97.5)	.86 (.42-1.76)	.68
Long-term toxicity				
Grade2, n (%)	71 (24.7)	47 (15.7)	1.30 (1.08-1.54)	.007
Grade3, n (%)	12 (4.2)	9 (3.0)	1.17 (.75-1.58)	.45
Grade4, n (%)	1 (0.3)	1(0.3)	1.02 (.19-1.87)	.98

Conclusions: The noninferiority of nCT was not confirmed, primarily owing to the remarkably low incidence of local recurrence observed in both arms. But nCT offers comparable DFS and OS while mitigating the burden of toxicity as compared to nCRT. These insights shed light on a potential paradigm shift in the treatment for LARC with uninvolved MRF.

Clinical trial identification: NCT02288195.

Background: CAIRO5 aimed to find the optimal systemic induction regimen to convert initially unresectable CRLM to local treatment.Previously, we showed that for patients with right-sided and/or *RAS/BRAFV600E* mutated tumours PFS was significantly longer and complete local treatment (R0/R1 resection and/or ablation) higher with FOLFOXIRI vs FOLFOX/FOLFIRI, both plus bevacizumab. For patients with left-sided and *RAS/BRAFV600E* wild-type tumours these parameters were not different between adding panitumumab vs bevacizumab to FOLFOX/FOLFIRI.

Methods: Patients with right-sided and/or *RAS/BRAFV600E* mutated tumours randomly received FOLFOX/FOLFIRI-bevacizumab (arm A) or FOLFOXIRI-bevacizumab (arm B), and with left-sided and *RAS/BRAFV600E* wild-type tumours FOLFOX/FOLFIRI-bevacizumab (arm C) or FOLFOX/FOLFIRI-panitumumab (arm D). Resectability was assessed by an expert panel of surgeons and radiologists at baseline and 2-monthly thereafter. Patients were stratified by potentially resectable vs permanently unresectable, serum LDH, irinotecan vs oxaliplatin, and *BRAFV600E* mutation status (arm A/B). Overall survival (OS, secondary endpoint) was compared with a stratified log-rank test and hazard ratios were calculated with a Cox proportional hazards model.

Results: Between November 2014 and January 2022, 530 patients were randomised in 47 centres, 148/146/118/118 in arms A/B/C/D. 9 ineligible patients were excluded. Median follow up was 57 months. Median OS in arm A vs B was 23.6 vs 24.1 months (HR 0.92, 95% CI 0.70 − 1.20, p=0.52) with 229 events. Median OS in arm C vs D was 40.4 vs 38.3 months (HR 1.02, 95% CI 0.72 − 1.46, p=0.89) with 134 events. Recurrence within 6 months after complete local treatment occurred in 26 (49%) vs 29 (39%) patients in arm A vs B (p=0.28), and 28 (42%) vs 26 (39%) patients in arm C vs D (p=0.73).

Conclusions: In patients with initially unresectable CRLM, OS was not different between FOLFOXIRI-bevacizumab and FOLFOX/FOLFIRI-bevacizumab for right-sided and/or *RAS/BRAFV600E* mutated tumours, nor between adding panitumumab vs bevacizumab to FOLFOX/FOLFIRI for left-sided and *RAS/BRAFV600E* wild-type tumours.

Background: Retrospective studies demonstrated an impressive prognostic impact of circulating tumor DNA (ctDNA, LB) positivity on colon cancer (CC) relapse after radical resection as proxy of minimal residual disease (MRD). Initial evidence is accumulating that in some patients (pts) adjuvant treatment does not clear ctDNA and this associates with relapse. With these premises we designed the PEGASUS trial to prove the feasibility of using LB to guide the post-surgical and post-adjuvant clinical management of Stage-IIT4N0/III CC pts.

Methods: LB was performed using Guardant Reveal assay (v L1.2). In the post-surgical phase, LB+ pts received 3 months (mos) of CAPOX and LB- pts 6 mos of CAPE. To mitigate the risk of false negatives a LB was repeated after one cycle of CAPE and treatment escalated to CAPOX if LB+. At the end of adjuvant treatments, LB was repeated: CAPOX-treated pts were switched to FOLFIRI if LB+ or de-escalated to CAPE if LB-; CAPE-treated pts received CAPOX if LB+ or started the standard follow-up phase if LB-. Primary endpoint was the number of post-surgery false negative cases, defined as pts with two consecutive LB- experiencing disease relapse (accepted <14 relapses).

Results: From July 2020 to July 2022, 135 pts were included in 11 cancer centers in Italy and Spain. At data cut-off, median follow-up was 20,8 months, with data completeness of 91% in LB- and 92% in LB+. Post-surgery ctDNA was detected in 35/

135 pts (26%), of which 12 (34%) experienced relapses, while 9 out of 100 LB- pts (9%) relapsed, being defined as false negatives. ctDNA+ was associated with a clear increase in the risk of relapse (HR 4.37, log rank P=0.0003). After 3 months of CAPOX, 11/35 LB+ pts were converted to LB- (31%), but 8/11 relapsed or LB re-positivized. Of the 23 LB+ pts receiving FOLFIRI after CAPOX, 12 remained LB+ (52%) among which 6 relapsed, while 11 were converted to LB- remaining relapse-free at the time of analysis (48%), thus suggesting an effect of FOLFIRI in the MRD setting.

Conclusions: LB may be used to guide the post-surgical clinical management of CC pts by reducing unnecessary toxicity and by improving the response to standard chemotherapy. Ongoing and newly designed randomized trials trials will define the clinical utility of LB for MRD in colon cancer.

Background: Aspirin is an inexpensive, readily available treatment globally with the potential to be an effective adjuvant therapy to prevent recurrence of colorectal cancer (CRC) after completing standard primary treatment. This landmark study conducted entirely in the Asia-Pacific region, where incidence of CRC is increasing, is the first international Phase III double-blind placebo-controlled trial to report the activity of aspirin in the secondary prevention of CRC (NCT 00565708).

Methods: Patients with Dukes' C and high-risk Dukes' B CRC were randomised to Aspirin 200mg daily or placebo for 3 years after surgery and completion of standard adjuvant therapy (including 3+ months of chemotherapy) and followed for 5+ years. The primary endpoint was Disease-Free Survival (DFS). The primary analysis used a stratified Cox model, with those commencing study treatment (modified intention to treat (mITT) and with all events up to 31/03/2023. Secondary endpoints included overall survival (OS) and DFS in the colon cancer group. Translational biomarker studies are ongoing.

Results: Between 25/02/2009 and 31/03/2021, 1587 participants were randomised from 66 centres across 10 Asia-Pacific countries and 1550 were included in the mITT analysis: 791 on aspirin and 759 placebo. Of these, 897 were males; 271 Dukes' B colon cancers, 769 Dukes' C colon cancers and 510 rectal cancers. Estimated DFS at 5 years was 77% (95% CI 74-80%) and 75% (95% CI 71-78%) for aspirin and placebo respectively with an estimated hazard ratio (HR) of 0.91 (95% CI 0.73-1.13, p=0.38). Overall survival showed HR favouring aspirin of 0.75 (95% CI 0.53-1.07, p=0.11). In the colon cancer group, the HR for DFS was 0.86 (95% CI 0.66 - 1.13, p=0.28). Adverse events were low in both arms and aspirin was well tolerated.

Conclusions: Our study did not show a significant DFS or OS benefit of aspirin therapy as an additional adjuvant therapy for patients with colorectal cancer. Nevertheless, results are still consistent with a more moderate, yet still worthwhile benefit for the global populations, and results from ongoing studies are awaited. Analysis of special

subpopulations predicted to benefit from aspirin in ASCOLT and other trials, may also be critical.

Clinical trial identification: NCT00565708.

Background: For shrinkage of RAS/BRAF WT tumors, anti-EGFR antibodies combinated with triplet chemotherapy (CT) regimen have shown promising results in phase I-II trials. Ultrasensitive cirDNA analysis as those with IntPlex® technology might result in better selection of super-responders to anti-EGFR-based therapies. Thus, the aim of PANIRINOX was studying the complete response (CR) rate obtained with P plus a tri-CT regimen (FOLFIRINOX = Arm A) or a standard bi-CT (mFOLFOX6 = Arm B) in pts with cirDNA-based RAS/BRAF V600E WT unresectable mCRC tumors.

Methods: In this randomised non-comparative multicentric phase II trial, pts were assigned in a 2:1 ratio in arm A/B (12 cycles max) in 2 different strata (str) according to disease extent (str 1: liver limited /str2: non-liver-limited). Primary endpoint was the CR rate according to RECIST 1.1 (central review) and CEA normalization (Fleming's one-step design, one-sided a=5%, b=10%, H0: 3%; H1: 12%; 60 pts in Arm A needed with at least 4 successes; Arm B as internal control). Secondary endpoints included progression-free and overall survival (PFS and OS).

Results: From 10/2017 to 07/2022, 78/33 pts were assigned in arm A/B in str2. Main characteristics were (arm A/B): median age 64/62 yo; males 67/45%; PS0 63/42%; left-sided 81/79%; synchronous metastases 85/87%; >1 metastatic site 82/72%. The table lists CR, PFS and OS in evaluable pts. Main grade≥3 treatment-related adverse events were (arm A/B): diarrhea 39/9%, peripheral neuropathy 22/24%, skin 18/24%.

Table: LBA30

	Arm A FOLFIRINOX+P (N=65)	Arm B mFOLFOX6+P (N=27)
Median follow-up (months) [95% CI]	32.0 [28.7; 32.3]	30.4 [23.4; 35.7]
Complete response (number) (%) [95% CI]	5 7.7 [2.5; 17.0]	2 7.4 [0.9; 24.3]
Objective response rate (complete + partial radiological reponse)	75.4%	77.8%
Median PFS (months) [95% CI]	9.1 [8.1; 11.7]	9.0 [7.5; 13.2]
Median OS (months) [95% CI]	NR	20.4 [15.1; NR]

Conclusions: With 5 pts achieving CR in arm A and 95%CI including predetermined hypothesis in arm B, the study met its primary objective in str2. We confirm that genotyping tumors from cirDNA analysis is a relevant alternative to tissue before administrating anti-EGFR-based therapies in first line.

Background: Neoadjuvant immunotherapy has shown promising responses in various tumor types. In the NICHE-2 study, neoadjuvant nivolumab/ipilimumab in MMR deficient (dMMR) colon cancers resulted in 95% major pathologic responses (MPR), including 67% pathologic complete responses (pCR) within 6 weeks of treatment. In melanoma patients, nivolumab/relatlimab has shown a favorable toxicity profile and promising efficacy in the neoadjuvant setting. We investigated this regimen in patients with non-metastatic dMMR colon cancer (NCT03026140).

Methods: In the NICHE-3 study, patients with resectable, locally advanced (at least cT3 and/or N+), dMMR colon cancer were treated with two doses of nivolumab 480 mg plus relatlimab 480 mg at a 4-week interval, followed by surgery within 8 weeks of registration. Pathologic response was defined as 50% or less residual viable tumor (RVT), and MPR as ≤10% RVT. The primary endpoint was pathologic response rate. According to a Simon-2-stage design, ≥15/19 responders are needed in stage 1 to continue accrual in stage 2. Here we present the prespecified analysis of pathologic response from stage 1.

Results: A total of 19 patients were treated and underwent surgery without delays. Grade 1-2 immune-related adverse events (irAEs) were observed in 14/19 patients (74%), with infusion related reactions being the most frequent (43%). Only one patient (5%) experienced a grade 3 irAE (hyperthyroidism). Endocrinopathy for which supplementation was required was observed in 4 (21%) patients and consisted of 1 patient with hypothyroidism and 3 patients with hypophysitis with secondary adrenal and/or thyroid insufficiency. There were no grade 4-5 irAEs. With a median of 7.4 weeks between the first dose and surgical resection, the treatment resulted in a 79% pCR rate, 89% MPR rate and 100% overall pathologic response rate among 19 patients.

Conclusions: Here we present data from NICHE-3, the first study showing the safety and efficacy of neoadjuvant nivolumab/relatlimab in dMMR colon cancer patients, with a pathologic response in all patients, including 79% pCR. Accrual is currently ongoing in stage 2, in which an additional 40 patients will be treated.

Background: In the phase 3 KEYNOTE-177 (NCT02563002) study, pembrolizumab (pembro) vs chemotherapy (chemo) improved PFS and showed a trend towards improved OS in MSI-H/dMMR mCRC, supporting pembro as first-line therapy. We report efficacy and safety at 5 yrs of follow-up.

Methods: Patients (pts) aged ≥18 y with untreated MSI-H/dMMR mCRC measurable per RECIST v1.1 and an ECOG PS of 0 or 1 were enrolled. Pts were randomly assigned 1:1 to receive pembro 200 mg Q3W or chemo (mFOLFOX6 or FOLFIRI Q2W ± bevacizumab 5 mg/kg Q2W or cetuximab weekly), IV. Pts assigned to chemo could receive ≤35 cycles of pembro after centrally confirmed progressive disease (PD). End points at 5 y were OS, PFS, DOR, and safety.

Results: At data cutoff (July 17, 2023), median follow-up duration was 73.3 mo (6.1 y; range, 64.9-89.2 mo). Of 153 pts assigned to pembro, all pts received treatment and 59 (38.6%) completed 35 cycles of treatment; 143/154 pts assigned to chemo received treatment. A total of 94 (61.4%) pts in the pembro arm and 143 (100%) in the chemo arm discontinued treatment most commonly due to PD (32.7% and 60.8%, respectively). 57 (37.0%) pts in the chemo arm met the crossover criteria and received pembro; 21 (36.8%) completed 35 cycles of pembro. An additional 39 (25.3%) pts who received chemo received a PD-1/L1 inhibitor off-protocol. Median OS (95% CI) was 77.5 mo (6.5 y; 49.2 mo-not reached) with pembro vs 36.7 mo (3.1 y; 27.6-65.3 mo) with chemo (HR 0.73 [95% CI 0.53,0.99]). The 5 y OS rate was 54.8% in the pembro arm and 44.2% in the chemo arm. The 5 y PFS rate was 34.0% and 7.6%, respectively. Median (range) DOR was 75.4 mo (6.3 y; 2.3+ to 80.1+ mo) with pembro vs 10.6 mo (2.8 to 71.5+ mo) with chemo; 85.7% and 33.6% of pts had DOR ≥24 mo, respectively. Treatment-related adverse events (TRAEs) occurred in 79.7% of pts who received pembro and 98.6% who received chemo; grade 3-5 TRAEs occurred in 21.6% and 67.1% of pts, respectively.

Conclusions: After 5 y of follow-up, responses to pembro were more durable than those from chemo, and the trend towards improved OS with pembro persisted despite an effective crossover rate of 62% in pts with MSI-H/dMMR mCRC.

Clinical trial identification: NCT02563002.

LBA33 A first-in-human phase I study of a novel KRAS G12D inhibitor HRS-4642 in patients with advanced solid tumors harboring KRAS G12D mutation

C. Zhou[1], W. Li[1], Z. Song[2], Y. Zhang[3], Y. Zhang[4], D. Huang[5], Z. Yang[6], M. Zhou[7], R. Mao[8], C. Huang[8], X. Li[8], J. Wang[8]

[1]Department of Medical Oncology, Shanghai Pulmonary Hospital, Tongji University School of Medicine, Shanghai, China; [2]Phase I Clinical Trial Ward, Zhejiang Cancer Hospital, Hangzhou, China; [3]Phase I Clinical Trial Ward, Zhejiang Cancer Hospital, Hangzhou, Zhejiang, China; [4]Lung Cancer Center, West China Hospital, Sichuan University, Chengdu, China; [5]Internal Medicine Department of Lung Tumor, Tianjin Medical University Cancer Institute & Hospital, Tianjin, China; [6]Department of Cancer Center, The Second Affiliated Hospital of Chongqing Medical University, Chongqing, China; [7]Department of Pulmonary and Critical Care Medicine, Ruijin Hospital, Shanghai Jiaotong University School of Medicine, Shanghai, China; [8]Clinical Research & Development, Jiangsu Hengrui Pharmaceuticals Co., Ltd., Shanghai, China

Background: *KRAS* G12D mutation is one of the most prevalent subtypes in *RAS* mutant cancers. However, no results of KRAS G12D inhibitors from any clinical trials have been reported yet. HRS-4642 is a highly selective KRAS G12D inhibitor. Here, we report preliminary results of the dose escalation part of a first-in-human phase 1 study of HRS-4642 in patients (pts) with advanced *KRAS* G12D mutant solid tumors.

Methods: Pts with histologically confirmed advanced solid tumors harboring *KRAS* G12D mutation who failed prior standard of care were enrolled to receive HRS-4642 i.v. at doses of 15, 50, 100, 200, and 300 mg QW in 21-day cycles. Dose escalation part allowed pts with *KRAS* mutation. An accelerated titration followed by a Bayesian optimal interval design is used to guide dose escalation and determine the maximum tolerated dose (MTD). The primary endpoints were safety, MTD, and recommended phase 2 dose (RP2D).

Results: At data cutoff on Aug 4, 2023, 18 pts were enrolled (lung adenocarcinoma n=10, colorectal adenocarcinoma n=5, appendiceal mucinous adenocarcinoma, ovarian cancer, and pancreatic cancer n=1 each). Pts had received a median of 3 lines of prior treatment (range 2-7). No DLTs were observed and the MTD was not reached yet. Grade ≥3 adverse events (AEs) were observed in 9 pts (50.0%). 6 pts (33.3%) had grade ≥3 treatment-related AEs (TRAEs), being hypercholesterolemia (16.7%), increased lipase (11.1%), and anemia (11.1%). No dose dependent trend was observed in the incidence of AEs. Serious TRAEs were observed in one patient (grade 2 increased ALT and grade 1 increased AST). No pts discontinued treatment or died due to TRAEs. 13 pts with baseline target lesions had at least one post-baseline assessment, and one NSCLC patient at 200 mg had partial response. 11 pts (61.1%) had stable disease and 6 (33.3%) experienced target lesion shrinkage, including lung and colorectal cancers. HRS-4642 exposure was approximately proportional to dose with a half-life of around 40 hours.

Conclusions: HRS-4642 showed a tolerable safety profile and preliminary anti-tumor activity in advanced solid tumors harboring *KRAS* G12D mutation. Dose escalation is ongoing and expected to proceed to dose expansion soon.

Clinical trial identification: NCT05533463.

Background: T-DXd has shown significant survival benefit for pts with HER2-expressing breast and gastric cancers. Interim DP-02 data showed a promising objective response rate (ORR) and duration of response (DOR) in HER2-expressing tumors (ASCO 2023). Here we report the primary analysis including progression-free (PFS) and overall survival (OS).

Methods: This open-label, Phase 2 study (NCT04482309) evaluated T-DXd (5.4 mg/kg Q3W) in pts with HER2-expressing (immunohistochemistry [IHC] 3+/2+ by local or central testing), locally advanced/metastatic disease after ≥1 systemic treatment (Tx), or without alternative Tx options. Primary endpoint was investigator-assessed confirmed ORR. Secondary endpoints included safety, DOR, PFS and OS.

Results: At data cut off (Jun 2023), 267 pts with biliary tract (BTC), bladder (URO), cervical (CC), endometrial (EC), ovarian (OC), pancreatic (PC), or other tumors had received Tx (median [m] follow up: 12.75 [range 0.4–31.6] months [mo]); 72.3% received ≥2 prior lines of therapy. In all pts, investigator-assessed ORR (95% CI) was 37.1% (31.3, 43.2); mDOR (95% CI) was 11.3 mo (9.6, 17.8); mPFS (95% CI) was 6.9 mo (5.6, 8.0); and mOS (95% CI) was 13.4 mo (11.9, 15.5). In pts with IHC 3+ expression (central; n=75) ORR was 61.3% (49.4, 72.4); mDOR was 22.1 mo (9.6, not reached); mPFS was 11.9 mo (8.2, 13.0); and mOS was 21.1 mo (15.3, 29.6). Table shows ORR, PFS and OS by tumor type in all pts and IHC 3+. Grade (G) ≥3 Tx-related adverse events (AEs) occurred in 40.8% of pts; 8.6% discontinued Tx due to Tx-related AEs. Adjudicated Tx-related interstitial lung disease/pneumonitis occurred in 10.5% (n=28) of pts (9.0% [n=24] G≤2; 1.1% [n=3] G5).

Conclusions: We observed durable responses to T-DXd and clinically meaningful PFS and OS in pretreated pts across HER2-expressing tumors, with safety consistent with the known profile. These data support T-DXd as a potential tumor-agnostic treatment in HER2-expressing tumors. (Funded by BioNTech; ClinicalTrials.gov number; NCT04503278).

Clinical trial identification: NCT04482309.

Background: Chimeric antigen receptor (CAR) T cells targeting CLDN6 ± CARVac showed promising activity against relapsed/refractory (r/r) CLDN6+ tumors (*ESMO* 2022 LBA38). We present data from a repeat 3+3 dose escalation trial with CAR T cells manufactured by an automated process and increased CARVac dosage.

Methods: BNT211-01 is recruiting patients (pts) with CLDN6-positive r/r solid tumours and no further treatment options. Following lymphodepletion, CAR T cells are flat dosed at 4 dose levels (DLs, 1×10^6 up to 2-5×10^8 CAR-T cells) ± repeat CLDN6 CARVac dosing (1×50 µg, then 100 µg doses). Primary endpoints are safety and tolerability. Additional endpoints are efficacy and pharmacokinetics.

Results: As of 24.07.2023, 38 pts primarily with ovarian cancer (n=14) and germ cell tumors (n=11) have been treated. Treatment related TEAEs ≥G3 were observed in 23 (61%) pts, including 20 (53%) pts with TEAEs related to CAR T cells. From 21 pts treated with the combination, 9 (43%) pts had TEAEs ≥G3 related to both IMPs, and 2 (10%) to CARVac. Related TESAEs have been observed in 8 pts (21%). DLTs occurred in 2 pts from different cohorts, G4 CRS at 5×10^8 CAR-T cells and G4 pancytopenia at 1×10^8, hence an MTD could not be determined. One death was assessed as treatment-related after the data cut-off. CRS was predominantly (95%) G1-2 and observed in 18 (47%) pts. 2 cases each of G1 ICANS and G1 hemophagocytic lymphohistiocytosis were reported (both 5%). Of 28 efficacy-evaluable patients, 9 pts (32%) had partial responses (PRs) and a further 9 had stable disease ([SD], unconfirmed overall response rate [ORR]: 32%, disease control rate [DCR]: 64%). Of 19 pts treated with ≥ $1x10^8$ CAR T cells, 8 PRs and 8 SDs resulted in an ORR of 42% and a DCR of 84%. CAR-T expansion was dose dependent, with improved persistence by addition of CARVac.

Conclusions: CLDN6 CAR T cells ± CARVac demonstrated encouraging antitumor activity. Addition of CARVac improved CAR-T cell persistence. The safety profile in terms of CRS, ICANS and DLTs observed is in line with previously reported observations. We intend to present data on up to 42 pts, with a data cut-off of 10.09.2023.

Clinical trial identification: NCT04503278.

Background: Locally advanced cervical cancer (LACC) is treated with chemoradiation (CRT). However, many patients relapse and die from metastatic disease. A feasibility study demonstrated a good response rate to short course weekly induction chemotherapy (IC) delivered before standard CRT and the INTERLACE trial investigated whether this approach improves both progression free survival (PFS) and overall survival (OS).

Methods: Women with squamous, adeno or adenosquamous carcinoma FIGO (2008) stage IB1 node positive,IB2,II,IIIB, IVA were eligible. Patients were randomised (1:1) to receive either CRT alone (5 cycles weekly cisplatin) or IC (6 weeks carboplatin AUC2 and paclitaxel 80mg/m^2) followed by the same CRT in week 7. Mandated minimum total EQD2 dose 78Gy to Point A with 3D brachytherapy recommended. All centres underwent radiation quality assurance. Primary endpoints were PFS (target hazard ratio [HR] 0.65) and OS (target HR 0.65-0.70).

Results: 500 patients were recruited from 32 centres in 5 countries (Nov 2012-Nov 2022). Median age 46 (range 24-78) years. Stage distribution was: IB1/2; 9%, II;77%, IIIB;11% and IVA;3%. 57% were node negative and 82% squamous subtype. Arms were balanced. 92% of IC patients had 5/6 cycles carboplatin/paclitaxel. Median interval from IC to CRT was 7 days. 84% (IC/CRT) vs. 89% (CRT alone) had 4/5 cycles cisplatin. In the CRT arm 92% and 89% completed external beam and brachytherapy respectively; corresponding figures in the IC/CRT arm were 97% and 95%. The median overall treatment time for CRT was 45 days in both arms. Grade $\geq$3 adverse events were seen in 59% (IC/CRT) vs. 48% (CRT alone). Median follow up 64 months. 5 year PFS rate is 73% with IC/CRT and 64% with CRT alone (HR 0.65; 95%CI:0.46-0.91, p=0.013). The corresponding 5-year OS rates are 80% and 72% (HR 0.61:95%CI:0.40-0.91, p=0.04).

Conclusions: Induction chemotherapy followed by CRT significantly improves PFS and OS in LACC and should be considered a new standard of care. INTERLACE recruited patients from diverse health care settings demonstrating that IC followed by CRT is feasible in all countries.

Background: Tisotumab vedotin (TV) is an investigational antibody-drug conjugate composed of a tissue factor-directed human monoclonal antibody covalently linked to cytotoxic MMAE. In the US, TV monotherapy received accelerated approval for the treatment of adult pts with recurrent or metastatic cervical cancer (r/mCC) with disease progression on or after chemotherapy. Here, innovaTV 301 (NCT04697628) study results of TV vs investigator's choice of chemotherapy in pts with r/mCC following 1L therapy are presented.

Methods: Eligible pts had r/mCC with disease progression on/after treatment with standard of care chemotherapy doublet ± bevacizumab ± anti-PD-(L)1 therapy, measurable disease per RECIST v1.1, and ECOG PS 0-1. Pts were randomized 1:1 to TV monotherapy or investigator's choice of topotecan, vinorelbine, gemcitabine, irinotecan, or pemetrexed. The primary endpoint was OS. Key secondary endpoints included PFS and confirmed ORR by investigator.

Results: 502 pts were randomized (TV: 253; chemotherapy: 249); median survival follow-up was 10.8 mo (95% CI, 10.3-11.6). Overall, median age was 50 yrs (range: 26-80); arms were balanced for demographics and disease characteristics. 63.9% and 27.5% of pts had prior bevacizumab and prior anti-PD-(L)1 therapy, respectively. The TV arm had a 30% reduction in risk of death vs chemotherapy (HR 0.70; 95% CI 0.54-0.89; P=0.0038), with significantly longer median OS (11.5 mo [95% CI 9.8-14.9] vs 9.5 mo [95% CI 7.9-10.7]). PFS was superior in the TV vs chemotherapy arm (HR: 0.67 [95% CI, 0.54-0.82]; P<0.0001). Confirmed ORR was 17.8% and 5.2% in the TV and chemotherapy arms, respectively (odds ratio: 4.0; 95% CI, 2.1-7.6; P<0.0001). Most pts experienced at least 1 treatment-related adverse event (TV: 87.6% [grade ≥3: 29.2%] vs chemotherapy: 85.4% [grade ≥3: 45.2%]). AEs were consistent with the known TV safety profile, including for ocular, peripheral neuropathy, and bleeding AEs.

Conclusions: In the phase 3 innovaTV 301 study, TV showed a statistically significant and clinically meaningful improvement in OS, PFS, and ORR vs chemotherapy, with a manageable and tolerable safety profile in pts with 2L/3L r/mCC.

Clinical trial identification: SGNTV-003; Amendment 3 (6 April 2022), NCT04697628.

Background: Ovarian cancer (OC) is one of the most lethal gynecologic cancers. Approximately 85% of newly diagnosed advanced OC may experience a relapse after the first line (1L) platinum-based chemotherapy. PARP inhibitors are recommended as maintenance therapy to prolong the benefit of platinum. Senaparib (IMP4297) is a novel, highly potency PARP inhibitor. The phase 3 study FLAMES is to investigate the efficacy and safety of Senaparib in Chinese patients (pts) with newly diagnosed advanced OC as 1L maintenance therapy.

Methods: Eligible pts had newly diagnosed, FIGO stage III–IV, high-grade serous or endometrioid OC, who have completed 1L platinum-based chemotherapy with complete response (CR) or partial response (PR). Pts were randomized (2:1) to receive senaparib (Sena) or placebo (PBO) 100 mg/day orally, stratified by CR/PR and BRCA mutation positive/negative. Primary endpoint was progression-free survival (PFS) evaluated by blinded independent central review (BICR) according to RECIST v1.1.

Results: 404 pts were randomized. As of 16 Mar. 2023, 270 and 133 pts received Sena and PBO with a median follow-up of 22.4 and 22.2 months, respectively. Primary analysis showed Sena significantly improved PFS over placebo (HR 0.43, 95% CI 0.32-0.58, P $<$ 0.0001), irrespective of BRCA mutation status (HR 0.43, P $<$ 0.01). Secondary endpoints support the primary analysis (Table). Incidence rates of grade $\geq$3 adverse events (AEs) were 66.3 % vs 20.3%, AEs leading to dose reduction 63.3 % vs 6.0% and discontinuation 4.4 % vs 0% in Sena and PBO arm. No AE leading to death.

Table: LBA36

	Senaparib (n=271), m	Placebo (n=133), m	HR (95%CI), P value
PFS (BICR)	NR	13.6	0.43 (0.32-0.58) P $<$ 0.0001
PFS (BICR) BRCA +	NR	15.6	0.43 (0.24-0.76) P = 0.0026
PFS (BICR) BRCA-	NR	12.9	0.43 (0.30-0.61) P $<$ 0.0001
PFS (INVR)	NR	11.1	0.43 (0.32-0.57) P $<$ 0.0001
PFS (INVR) BRCA +	NR	11.1	0.33 (0.20-0.56) P $<$ 0.0001
PFS (INVR) BRCA-	NR	11.1	0.48 (0.34-0.67) P $<$ 0.0001
TFST	NR	14.4	0.44 (0.33-0.59) P $<$ 0.0001

BICR, blinded independent central review; INVR, investigator review; HR, hazard ratio; NR, not reached; PFS, progression-free survival; BRCA +, breast cancer susceptibility gene (BRCA) mutation positive; BRCA -, BRCA mutation negative; TFST, time to first subsequent therapy or death; m, month

Conclusions: 1L maintenance Senaparib led to an unprecedented reduction in the risk of progression or death versus placebo in OC, regardless of biomarker status. Senaparib was well tolerated, no new safety signals were identified.

Clinical trial identification: NCT04169997.

Background: Standard therapy for late-relapsing (TFIp >6 mo) rOC includes PARPi maintenance if disease responds to platinum-based CT. ANITA (NCT03598270) is the first-reported phase 3 trial evaluating atezo with platinum-based CT and maintenance PARPi in late-relapsing rOC.

Methods: Eligible pts had measurable high-grade serous, endometrioid or undifferentiated rOC, ≤2 prior CT lines (most recent including platinum) and TFIp >6 mo. Prior PARPi for rOC and/or prior immune checkpoint inhibitor were prohibited. Pts were stratified by carboplatin (carbo) doublet (paclitaxel, gemcitabine or pegylated liposomal doxorubicin [PLD]), TFIp (6–12 vs >12 mo), *BRCA* status (mutated vs non-mutated) and PD-L1 status (PD-L1-expressing immune cells on <1% vs ≥1% tumour area vs non-informative by SP142). Pts were randomised 1:1 to a carbo doublet + atezo or pbo for 6 cycles followed (in pts without progression on CT) by maintenance niraparib at an individualised starting dose + atezo or pbo until disease progression. The atezo dose was 1200 mg q3w or 840 mg q2w depending on the CT regimen. The primary endpoint was investigator-assessed progression-free survival (PFS) per RECIST v1.1.

Results: Between Nov 2018 and Jan 2022, 417 pts were randomised (14% *BRCA*m, 36% PD-L1+, 66% TFIp >12 mo, 11% prior PARPi after front-line CT, 54% prior bevacizumab); most (71%) received carbo–PLD and 74% began maintenance. At the data cut-off (15 Apr 2023), median follow-up was 36 mo. PFS results (Table) were consistent in key subgroups. Overall response to CT was 43% (95% CI 36–49%) and 45% (95% CI 39–52%) in the pbo and atezo arms, respectively. The safety profile was as expected from prior experience of these drugs.

Table: LBA37

PFS		Pbo + CT → pbo + niraparib (n=209)	Atezo + CT → atezo + niraparib (n=208)
All pts	Events, n (%)	174 (83)	170 (82)
	Hazard ratio (95% CI)	0.89 (0.71–1.10); p=0.28	
	Median, mo (95% CI)	10.1 (9.2–11.2)	11.2 (10.1–12.1)
PD-L1-positive subgroup	Events, n/N (%)	60/73 (82)	61/76 (80)
	Hazard ratio (95% CI)	0.87 (0.61–1.25)[a]	
	Median, mo (95% CI)	11.1 (9.7–12.7)	12.8 (10.2–15.4)
PD-L1-negative subgroup	Events, n/N (%)	92/112 (82)	97/117 (83)
	Hazard ratio (95% CI)	0.93 (0.70–1.24)[a]	
	Median, mo (95% CI)	9.2 (8.3–11.1)	10.5 (9.2–11.8)

[a]Unadjusted estimate.

Conclusions: Combining atezo with CT and maintenance niraparib for late-relapsing rOC did not significantly improve PFS or ORR.

Clinical trial identification: NCT03598270, EudraCT 2018-000366-11.

Pascale, Naples, Italy; [18]Gynecologic Oncology Department, University of Virginia School of Medicine, Charlottesville, VA, USA

Background: Pembrolizumab (pembro) has shown efficacy in patients (pts) with cervical cancer. The effect of chemoradiotherapy may be enhanced by immunotherapy. ENGOT-cx11/GOG-3047/KEYNOTE-A18(NCT04221945) assessed the efficacy and safety of pembro + concurrent chemoradiotherapy (CCRT) for locally advanced cervical cancer.

Methods: Eligible pts with newly diagnosed, previously untreated, high-risk locally advanced cervical cancer (FIGO 2014 stage IB2-IIB with node-positive disease or stage

III-IVA) were randomized 1:1 to receive 5 cycles of pembro 200 mg or pbo Q3W + CCRT, then 15 cycles of pembro 400 mg or pbo Q6W. The CCRT regimen included 5 cycles (with optional 6th dose) of cisplatin 40 mg/m^2 Q1W + EBRT then brachytherapy. Pts were stratified by planned EBRT type (intensity-modulated radiotherapy [IMRT] or volumetric-modulated arc therapy [VMAT] vs non-IMRT or non-VMAT), stage at screening (stage IB2-IIB vs III-IVA) and planned total radiotherapy dose. Primary endpoints were PFS per RECIST version 1.1 by investigator and OS.

Results: 1060 pts were randomized to pembro + CCRT (n=529) or pbo + CCRT (n=531). At the protocol-specified first interim analysis (January 9, 2023, data cutoff), median follow-up was 17.9 mo (range, 0.9-31.0). Pembro + CCRT showed a statistically significant improvement in PFS vs pbo + CCRT. 24-mo PFS was 67.8% with pembro + CCRT vs 57.3% with pbo + CCRT; median PFS was not reached in either group (HR=0.70 [95% CI, 0.55-0.89; P=0.0020]); results were consistent across all prespecified subgroups. With only 103 events (42.9% maturity), the addition of pembro to CCRT showed a favorable trend in OS (HR=0.73 [95% CI, 0.49-1.07]); these data have not crossed the boundary of statistical significance. Grade ≥3 TRAE incidence was 67.0% in the pembro + CCRT group and 60.0% in the pbo + CCRT group.

Conclusions: Pembro + CCRT showed a statistically significant and clinically meaningful improvement in PFS and a favorable trend in OS compared with pbo + CCRT in pts with high-risk locally advanced cervical cancer and had a manageable safety profile. These data suggest pembro + CCRT can be considered as a new standard of care for this population.

Clinical trial identification: NCT04221945.

Background: The open-label randomised phase 3 BEATcc academic trial (NCT03556839) evaluated atezo (anti-PD-L1) combined with first-line chemotherapy (CT) + bev for R/M CC, irrespective of PD-L1 status. We report final progression-free survival (PFS) and interim overall survival (OS) results.

Methods: Patients (pts) with previously untreated measurable R/M CC not amenable to curative surgery/radiation were randomised 1:1 to standard therapy (cisplatin 50 mg/m^2 or carboplatin AUC5 + paclitaxel 175 mg/m^2 + bev 15 mg/kg) ± atezo 1200 mg d1 q3w. Cycles were repeated until disease progression or unacceptable toxicity. Stratification factors were prior concomitant chemoradiation (yes vs no), histology (squamous cell carcinoma vs adenocarcinoma) and platinum agent (cisplatin vs carboplatin). Dual primary endpoints were investigator-assessed PFS per RECIST v1.1 and

OS. Secondary endpoints included objective response rate (ORR), duration of response (DoR), time to first subsequent therapy (TFST), PFS2, and safety.

Results: Between Oct 2018 and Aug 2021, 410 pts were randomised. At the data cut-off (median follow-up 32.9 mo), median treatment duration was 8.5 vs 12.7 mo in the control vs atezo arms, respectively; treatment was ongoing in 7% vs 23%, respectively. Both PFS and OS were statistically significantly improved with the addition of atezo to CT + bev (Table). Secondary endpoints and subgroup analyses showed consistent results. Grade ≥3 adverse events (any cause) occurred in 75% vs 79% of the control and atezo arms, respectively. Safety profiles were as expected with bev + platinum-based CT. Grade 1/2 diarrhoea, arthralgia, pyrexia and rash were increased with atezo.

Table: LBA39

Endpoint		CT + bev (n=204)	Atezo + CT + bev (n=206)
PFS	Events, n (%)	166 (81)	138 (67)
	HR	0.62 (0.49–0.78); p<0.0001	
	Median, mo	10.4 (9.7–11.7)	13.7 (12.3–16.6)
	2-year rate, %	19 (14–25)	36 (29–43)

Background: The standard therapy for advanced/recurrent endometrial cancer includes carboplatin and paclitaxel (CP). Robust biological rationale suggested a synergy between immunotherapy and chemotherapy in this setting.

Methods: AtTEnd is an international academic study in endometrial carcinoma/carcinosarcoma patients (pts) with advanced newly diagnosed or recurrent disease with no prior systemic chemotherapy for recurrence. Pts were randomized (2:1 ratio) to receive either CP chemotherapy and atezolizumab (atezo) or placebo, followed by atezo or placebo until disease progression. The mismatch repair (MMR) status was evaluated centrally. Coprimary endpoints with a hierarchical approach were: progression free survival (PFS) in the deficient MMR (dMMR) population, PFS and overall survival (OS) in all comers.

Results: Five hundred and fifty-one pts were enrolled from Oct 2018 to Jan 2022 in 89 sites across 10 countries (median follow-up 28.3 months). Of the 549 pts included in the intention to treat population, 125 (22.8%) had dMMR tumours and 352 (64.1%) had endometrioid carcinoma; 369 (67.2%) had recurrent disease and 148 (82.2%) of newly diagnosed cases had primary stage IV. In the dMMR population, the addition of atezo showed a significant improved PFS (HR 0.36 95% CI:0.23-0.57; p=0.0005; median PFS: not reached vs. 6.9 months for atezo vs placebo). The superiority in PFS was confirmed in all comers (HR 0.74 95%CI:0.61-0.91; p=0.0219; median PFS: 10.1 months vs 8.9 months for atezo vs placebo). Interim analysis of OS in all comers indicated a trend in favor for atezo, despite 45 (24.3%) placebo patients received immunotherapy as subsequent therapy. Second PFS and duration of response in the dMMR population confirmed the efficacy of atezo. Grade≥3 adverse events occurred in 66.9% and 63.8% of pts in atezo vs placebo arm. Safety profile for CP + atezo was manageable and consistent with expected toxicities.

Conclusions: The addition of atezo to standard CP chemotherapy demonstrated a statistically significant improvement in PFS for pts with advanced/recurrent endometrial carcinomas with a substantial benefit in pts with dMMR carcinomas.

Clinical trial identification: EudraCT 2018-001072-37; NCT03603184.

Background: Combination of immunotherapy with CP led to improved progression-free survival (PFS) in patients (pts) with advanced EC. DUO-E (NCT04269200) evaluated addition of durva to standard 1L CP, followed by mtx durva ± ola, in pts with EC.

Methods: Pts with newly diagnosed FIGO Stage III/IV or recurrent EC and naïve to systemic treatment were randomised 1:1:1 to CP (CP + durva placebo [pbo] for 6 cycles followed by mtx durva pbo + ola pbo), CP + durva (CP + durva [1120 mg IV q3w] for 6 cycles followed by mtx durva [1500 mg IV q4w] + ola pbo), or CP + durva + ola (CP + durva for 6 cycles followed by mtx durva + ola [300 mg tablets bid]). Dual primary endpoints were PFS (investigator-assessed RECIST v1.1) in the intent-to-treat (ITT) population for CP + durva vs CP and CP + durva + ola vs CP; overall survival (OS) was a secondary endpoint. A multiple testing procedure with gatekeeping strategy was applied to PFS and OS. PFS by mismatch repair (MMR) status was a prespecified subgroup analysis.

Results: In the ITT population (N=718), CP + durva and CP + durva + ola showed statistically significant and clinically meaningful PFS benefit vs CP (Table). Interim OS data were immature (27.7%) yet with a trend towards benefit (CP + durva vs CP: HR [95% CI] 0.77 [0.56−1.07]; P=0.120; CP + durva + ola vs CP: 0.59 [0.42−0.83]; P=0.003). PFS subgroup analysis showed benefit for both arms vs CP in MMR-

Table: LBA41

Population	Arm	Median follow-up duration,† months	PFS events, n/N (%)	Median PFS, months	HR* (95% CI)	12-/18-month PFS rate, %
ITT	CP	12.6	173/241 (71.8)	9.6		41.1/21.7
	CP + durva	15.4	139/238 (58.4)	10.2	0.71 (0.57–0.89); P=0.003	48.5/37.8
	CP + durva + ola	15.4	126/239 (52.7)	15.1	0.55 (0.43–0.69); P<0.0001	61.5/46.3
dMMR	CP	10.2	25/49 (51.0)	7.0		43.3/31.7
	CP + durva	15.5	15/46 (32.6)	Not reached	0.42 (0.22–0.80)	67.9/67.9
	CP + durva + ola	19.2	18/48 (37.5)	31.8	0.41 (0.21–0.75)	70.0/62.7
pMMR	CP	12.8	148/192 (77.1)	9.7		40.8/20.0
	CP + durva	15.3	124/192 (64.6)	9.9	0.77 (0.60–0.97)	44.4/31.3

*Vs CP; †In censored patients.

deficient (dMMR; n=143) and -proficient (pMMR) pts (n=545). In pMMR pts, mtx ola further enhanced PFS benefit (Table). Safety profiles of the treatment arms were generally consistent with individual components.

Conclusions: DUO-E met both primary endpoints, showing statistically significant and clinically meaningful PFS improvement with the addition of durva to CP followed by maintenance durva ± ola vs CP alone. Mtx ola further improved PFS in pts with pMMR disease.

Clinical trial identification: D9311C00001; NCT04269200.

Background: The TGCA data suggest opportunities to target DNA repair in patients (pts) with endometrial cancer (EC). UTOLA assessed the efficacy of Parp-inhibitor maintenance for advanced/M+ EC pts who achieved disease control after 1st line platinum CT and to analyse efficacy in some molecular subgroups.

Methods: UTOLA is a randomized, double-blind, placebo controlled, phase IIb trial. Adjuvant CT ≥12 mos before inclusion was allowed. Pts were randomized (2:1) to olaparib maintenance arm (ola, 300 mg po BID) or placebo arm (pl) until progression or intolerance with stratification on P53, MMR status, and the response to the previous CT. Molecular profile was assessed by IHC and NGS. Primary endpoint was PFS in ITT. Main secondary endpoints were PFS according to P53 status, CT response, OS, safety. A pre-specified PFS analysis was performed according to HRD status defined by the number of large genomic events. One sided unstratified analyses are presented.

Results: 147 pts were randomized (98 to Ola, 49 to pl). 82% of the pts received at least 6 cycles of CT with 46 CR, 64 PR, 34 stable and 3 NED; tumor classification was 53% $P53_{mut}$, 35% NSMP, 12% MMRd, and 1 tumor $POLE_{mut}$. In total, 52% (73) were HRD positive, 79% in $P53_{mut}$ & 23% in $P53_{WT}$. Median PFS in the ITT population was 5.6 mos (90%CI 3.8-7.4) and 4.0 (3.6-7.4) in ola and pl arms respectively (HR:0.94, p=0.29). Median PFS in $P53_{mut}$ were 5.6 mos (3.6-8.8) vs 3.6 ms (1.8-4.9) in ola and pl arms (HR:0.75, p=0.12) whereas 6.1 mos (3.6-11) vs 7.7 mos (2.9-14.5) (HR=1.13, p=0.3) respectively in the $P53_{WT}$. In the HRD tumors (n=73), median PFS was statistically higher with ola: 5.4 mos (90%CI 3.6-9.6) vs 3.6 mos (1.8-4.9) with pl (HR:0.59, p=0.02) regardless of P53 status. For the 46 pts with CR to previous CT, median PFS in ola arm reached 8.8 mos versus 3.8 mos. No difference for OS was observed in all subgroups. Safety profile was similar and acceptable as seen in other cancers (36% vs 10% of G3/4 toxicities without myelodysplasia with ola).

Conclusions: UTOLA suggests maintenance ola could prolong PFS in HRD-positive advanced/M+ EC. These data should be confirmed and warrants further PARP inhibitor studies in this population.

Clinical trial identification: EudraCT 017-002623-13.

Lauder Breast Center, New York, NY, USA

Background: NRG GY018 identified a 70% and 46% reduction in the risk of disease progression or death in advanced stage or recurrent dMMR and pMMR EC patients treated with pembrolizumab plus CP. The relationship between mechanism of MMR deficiency and clinical outcomes in dMMR EC patients is not well understood.

Methods: 819 pts were randomized 1:1 to pembrolizumab + CP or PBO + CP Q3W for 6 cycles followed by maintenance pembrolizumab or PBO Q6W for up to 2 years. MMR status was assessed by local and central immunohistochemistry (IHC). For patients with measurable disease at enrollment, updated best response (RECIST 1.1) was examined in both patient cohorts. Mechanism of MMR loss was determined by review of local MMR IHC results and presence/absence of MLH1 promoter hypermethylation. The effect of mechanism of MMR loss on PFS was examined in dMMR patients treated with pembrolizumab.

Results: Local and central MMR IHC had strong agreement, kappa 0.88 (95% CI 0.84-0.91). The ORR was improved in the pembrolizumab arm of both patient cohorts (dMMR: 81.5% vs. 70.7%, OR 1.83 (95% CI 0.92-3.66) and pMMR: 70.7% vs. 58.1%, OR 1.74 (95% CI 1.18-2.58)). The CR rate in the dMMR and pMMR EC cohorts was higher when pembrolizumab was added to CP (15% vs 32% dMMR; 8% vs 15% pMMR). Median DOR was significantly improved with addition of pembrolizumab, dMMR 28.7 mo vs 6.2 mo (HR 0.22; 95% CI 0.13-0.37, $p<.0001$) and pMMR 9.2 mo vs 6.2 mo (HR 0.47; 95% CI 0.34-0.64, $p<.0001$). In 223 central-dMMR pts, 72% had MLH1 promoter hypermethylation, 13% had MMR protein loss secondary to gene mutation, and 15% were not evaluable. Mechanism of MMR loss was not a significant predictor of PFS (85% versus 75% progression free at 12 months in mutated vs methylated pts). Median PFS and OS were not reached irrespective of mechanism of MMR loss.

Conclusions: In NRG GY018, no difference in PFS was identified in dMMR EC patients based on mechanism of MMR loss. With more mature clinical follow up, the magnitude of benefit in both patient cohorts treated with pembrolizumab was maintained, with significant improved in ORR, and DOR.

Clinical trial identification: NCT04214067.

Background: Combining immunotherapy and anti-angiogenic agents may enhance immune response by reversing the immunosuppressive microenvironment. We conducted a randomized, open-label, phase 2 trial to assess camrelizumab (CAM, an anti-PD-1 antibody) plus famitinib (FAM, a multi-targeted TKI against VEGFR2/3) versus CAM alone and investigator's choice of chemotherapy (chemo) for recurrent or metastatic cervical cancer (R/M CC).

Methods: Patients (pts) with R/M CC who failed prior platinum-based chemo were enrolled. Prior anti-PD-1/PD-L1/CTLA-4 treatment was not allowed. Pts were randomized to receive CAM 200 mg IV Q3W with (cohort A) or without (cohort B) FAM 20 mg PO QD, or investigator's choice of chemo (cohort C) every 3-week cycle. The primary endpoint was ORR per RECIST v1.1 assessed by blinded independent central review (BICR).

Results: At data cutoff on April 21, 2023, 194 pts were randomized (cohort A n=105, cohort B n=54, cohort C n=35), and 46 pts (23.7%) remained on treatment. 77.8% of pts had squamous CC, 63.9% were PD-L1 positive, 31.4% received prior targeted therapy. The median follow-up duration was 9.9 months (IQR 7.3-15.1). Antitumor activities are shown in the table. Treatment-related adverse events (TRAEs) occurred in 100%, 94.3%, and 100% of pts, respectively. Grade ≥3 TRAEs were reported in 84.8%, 15.1%, and 60.0% of pts, respectively, with the most common ones being decreased neutrophil count (23.8%, 1.9%, 30.0%), hypertension (22.9%, 0, 0), decreased white blood cell count (20.0%, 0, 33.3%), and anemia (20.0%, 1.9%, 13.3%). Dose discontinuation due to AEs occurred in 19.0%, 5.7%, and 0 pts, respectively. Treatment-related death was reported in two pts (1.9%) in cohort A (acute coronary syndrome, infection and sepsis).

Table: LBA44 Summary of efficacy

	Cohort A (n=105)	Cohort B (n=54)	Cohort C (n=35)
BICR-assessed			
CR	9 (8.6)	3 (5.6)	—
PR	34 (32.4)	10 (18.5)	—
ORR	41.0 (31.5-51.0)	24.1 (13.5-37.6)	—
DCR	75.2 (65.9-83.1)	55.6 (41.4-69.1)	—
PFS (mo)	7.2 (6.1-12.4)	4.0 (2.1-6.1)	—
Investigator-assessed			
CR	4 (3.8)	2 (3.7)	1 (2.9)
PR	41 (39.0)	10 (18.5)	4 (11.4)
ORR	42.9 (33.2-52.9)	22.2 (12.0-35.6)	14.3 (4.8-30.3)
DCR	74.3 (64.8-82.3)	53.7 (39.6-67.4)	42.9 (26.3-60.7)
PFS (mo)	8.1 (6.2-12.4)	4.1 (2.1-5.1)	2.9 (2.0-6.2)
12-months OS rate	80.3 (70.7-87.0)	71.9 (55.8-83.0)	59.7 (40.9-74.3)

Conclusions: CAM plus FAM showed improved antitumor activity than CAM alone or investigator's choice of chemo in pts with R/M CC, with a tolerable safety profile.

Clinical trial identification: NCT04680988 (registered on December 23, 2020).

Background: In the NRG-GY004 (NCT02446600) primary analysis, neither olaparib (O) nor combined cediranib and olaparib (C+O) improved progression-free survival (PFS) compared to standard of care (SOC) plat therapy as treatment for relapsed plat sensitive ovca, although median PFS was longer in patients with gBRCAm (Liu et al., J Clin Oncol 2022). We now report the prespecified OS analysis.

Methods: Pts with plat sensitive high-grade serous or endometrioid, or BRCA-related, ovca were randomized 1:1:1 to SOC (carboplatin/paclitaxel; carboplatin/gemcitabine; or carboplatin/liposomal doxorubicin), O (300mg twice daily), or C+O (C 30mg daily + O 200mg twice daily), stratified by gBRCA status, PFI (6-12 vs >12 months), and prior anti-angiogenic therapy. OS was a secondary endpoint; analysis was specified to occur when at least 265 events had occurred cumulatively in the SOC and C+O arms.

Results: Between 4FEB2016 and 13NOV2017, 565 pts enrolled (187 SOC, 189 O, 189 C+O), and 528 pts initiated treatment (166 SOC, 183 O, 179 C+O). 23.7% of patients had gBRCAmt. Median follow-up was 66.5 months; 419 deaths had occurred. The hazard ratio (HR) for OS was 1.27 (95% CI 0.99-1.62, p = 0.06) between O and SOC and 1.12 (95% CI 0.87-1.43, p = 0.38) between C+O and SOC, with median OS of 32.7, 31.0, and 33.5 months for SOC, O, and C+O, respectively. In gBRCA pts, HR for OS was 1.39 (95% CI 0.80-2.42) for O vs SOC and 1.24 (95% CI 0.94-1.63) for C+O vs SOC, with median OS of 43.2, 41.3, and 44.8 mos for SOC, O, and C+O. In non-gBRCA pts, HR for these comparisons was 1.26 (95% CI 0.71-2.21) and 1.07 (0.82-1.40). 46 pts on SOC had non-protocol therapy before disease progression, including 36 pts receiving PARPi. 27.3% of pts on SOC, 7.9% on O, and 10.6% on C+O terminated OS follow-up early prior to death.

Conclusions: In NRG-GY004, neither O nor C+O improved OS compared to SOC as treatment for relapsed plat sensitive ovca. Hazard ratios for OS for both O and C+O exceeded 1 with wide 95% CIs that included 1. These findings must be interpreted with caution given the proportion of pts terminating follow-up early and the number of pts on the SOC arm who received off-protocol PARPi maintenance.

Clinical trial identification: NCT02446600.

Head and neck cancer, excl. thyroid

LBA46 SAKK 11/16, a phase IIa trial evaluating overall survival (OS) for recurrent/metastatic Head & neck squamous cell carcinoma (RMHNSCC) patients (pts) progressing after ≥ 1 line of systemic therapy, treated with MVX-ONCO-1, a novel, first in class cell encapsulation-based immunotherapy

N. Mach[1], E. Fernandez[1], R. Vernet[2], O. Vonrohr[2], M. Urwyler[2], E. Charrier[2], M-C. Belkouch[2], V. Saingier[2], F. Courtout[2], C. de Vito[3], O. Rubin[4], V. Ancrenaz[1], J.N. Grogg[5], J. Renaux[6], K. Gysel[7], G. Müller[8], T. Brezina[9], T. Rordorf[9], M. Joerger[10], O.A. Michielin[2]

[1]Oncology Dept. Clinical Research Unit, Geneva University Hospital HUG, Geneva, Switzerland; [2]Oncology Dept., Geneva University Hospital HUG, Geneva, Switzerland; [3]Pathology, Geneva University Hospital HUG, Geneva, Switzerland; [4]Cell Therapy Core Facility, Geneva University Hospital HUG, Geneva, Switzerland; [5]R&D, MaxiVax SA, Geneva, Switzerland; [6]Clinical Operations, MaxiVAX SA, Geneva, Switzerland; [7]Biostatistics, SAKK - Swiss Group for Clinical Cancer Research, Bern, Switzerland; [8]Clinical Operations, SAKK - Swiss Group for Clinical Cancer Research, Bern, Switzerland; [9]Oncology, University Hospital Zurich (USZ), Zurich, Switzerland; [10]Medical Oncology and Hematology Department, Kantonsspital St. Gallen, St. Gallen, Switzerland

Background: MVX-ONCO-1 is a personalized, subcutaneous (sc) cancer vaccine combining irradiated autologous tumor cells and devices containing allogeneic cells producing the potent adjuvant GM-CSF. Positive clinical data in RMHNSCC pts with evidence of immune education in a Phase I study triggered this multicenter phase IIa trial.

Methods: 16 pts with RMHNSCC, progressing after ≥1 line of systemic therapy, with measurable disease and ECOG PS 0-2 were enrolled. Pts received 6 sc treatments over 8 weeks (wks). Primary endpoint was OS at 26 wks. An unplanned interim review of the first 10 pts revealed 7 had met the 26 wks OS endpoint. Using the conditional power method of Kieser *et al.* sample size was reduced from 39 to 21 pts keeping the same one-sided type 1 error rate of 5% and power of 80%. The null hypothesis in the adaptive design can be rejected if among the 21 pts there are ≥11 survivors at 26 wks. Response and safety were secondary endpoints.

Results: Enrollment was closed early as primary endpoint was met ahead of schedule. Median OS is 11.4 months (mo) and OS at 12 and 18 mo are 49.2% and 31.6% respectively. Partial Response (PR) and Complete Response (CR) were observed, including CR ongoing for >17 mo in a nivolumab refractory pt. Several pts are alive with no active metastatic disease, including long-term survivors (> 3 years). ORR at 26 wks is 12.5% while DCR at 6 wks is 75% of pts. No systemic adverse events related to therapy was reported. Strong correlation between OS and Delayed Type Hypersensitivity (DTH) was observed. At 12 mo, 100% of DTH+ pts are alive compared to only one DTH- pt.

Conclusions: MVX-ONCO-1 is a novel personalized cancer vaccine with very good safety profile. Clinically meaningful prolonged survival, PR and CR were observed in IO refractory RMHNSCC pts. Prolonged OS correlates strongly with immune education, DTH being a potential biomarker to be validated in future studies. MVX-ONCO-1 is the first cancer vaccine associated with prolonged survival in advanced chemo / IO refractory disease in monotherapy without maintenance.

Background: Despite recent advances, prognosis for R/M HNSCC patients (pts) remains poor. *HRAS* mutations are seen in 4-8% of HNSCCs. HRAS is uniquely farnesylation dependent, making m*HRAS* tumors susceptible to farnesyl transferase inhibitors. Tipifarnib has activity in pts with HNSCC harboring high variant allele frequency (VAF, ≥20%) m*HRAS* (Ho et al. JCO 2021). We present data in 50 high VAF pts in AIM-HN.

Methods: Pts received tipifarnib 600 mg BID on days 1-7 and 15-21 of a 28-day cycle. The primary endpoint was objective response rate (ORR) in the high VAF pts by independent review facility (IRF). Histologically confirmed m*HRAS* HNSCC pts with ≥1 prior platinum-containing regimen were eligible. ORR was assessed in the modified intent to treat (mITT) set (≥1 tipifarnib dose).

Results: Of 59 pts treated with tipifarnib, 50 (85%) had high VAF (median VAF: 34% [range 4-89%]). Twenty-six (44%) received immunotherapy in 1st line (1L). By Investigator assessment, ORR was 30% with 1 pt achieving a CR. By IRF, ORR was 20% with 1 CR (Table). Two responders were on treatment at study close (9 and 29 mos). Median progression-free survival by IRF: 2.6 mos (95% CI: 1.9-4.4); median overall survival: 7.0 mos (95% CI: 4.9-11.5). Grade 3+ treatment-related adverse events (TRAEs) were observed in 33 pts (56%): neutropenia (24%), anemia (20%), leukopenia (14%) and febrile neutropenia (7%). However, only 7% discontinued treatment due to TRAEs.

Table: LBA47

	Pts with high VAF in mITT* (N=50)	
	Investigator Assessment	IRF
ORR, n (%) [95% CI]		
Line of Therapy for Tipifarnib Any Line (N=50)	15 (30%) [0.18, 0.45]	10 (20%) [0.10, 0.34]
2L (N=24)	9 (38%) [0.19, 0.59]	7 (29%) [0.13, 0.51]
3L+ (N=20)	4 (20%) [0.06, 0.44]	3 (15%) [0.03, 0.38]
Disease Control Rate, n (%) [95% CI]	32 (64%) [0.49, 0.77]	24 (48%) [0.34, 0.63]
Confirmed responses CR PR SD	1 14 17	1 9 14
mDoR, mo [95% CI]	5.6 [3.88, 9.23]	6.5 [3.88, -]

*1/9 low VAF pt (< 20% VAF) was also a responder

Conclusions: Tipifarnib was safe and tolerable with anti-tumor activity observed in m*HRAS* R/M HNSCC pts post-IO and as later-line therapy. Tipifarnib is the first

targeted therapy for this rare HNSCC subset. Ongoing combination studies are targeting adaptive resistance pathways (PI3K/mTOR/Akt) to further improve outcomes.

Clinical trial identification: NCT03719690.

Background: Primary efficacy results from SWOG S1801 showed an improved event-free survival (EFS) in patients who received neoadjuvant-adjuvant (NAT) PEM compared to adjuvant (AT) PEM. In pooled analyses and smaller neoadjuvant studies, pathologic response has been suggested as an important surrogate marker of clinical outcome.

Methods: S1801 was a randomized phase II trial for clinically detectable, resectable AJCC 8th edition stage IIIB-IV melanoma. Participants were randomized 1:1 to AT PEM (surgery then 18 doses of PEM q3w) or NAT PEM (3 doses pre-operative PEM, surgery, 15 doses PEM q3w). Sites submitted surgical specimens for central review. For determination of pathologic response to NAT, these specimens were assessed for percentage of necrosis and viable tumor by a single pathologist blind to the clinical results.

Results: As of August 31, 2023, 281 participants had surgery (138 NAT, 143 AT). Of those randomized to NAT, 109 specimens were reviewed for pathologic response, 89 were lymph node specimens. Pathologic response and recurrence-free survival (RFS) outcomes for these lymph node specimens are shown in the table. 130 of 138 NAT participants who underwent surgery had RECIST response data; 15 (12%) achieved complete response (CR), 50 (38%) partial response (PR) for an overall response rate of 50%; 50 (38%) experienced stable disease (SD), and 15 (12%) progression of disease (PD).

Table: LBA48

Path response N (%)	NAT N=89
pathologic complete response (pCR)	36 (40%)
pathologic near complete response (pnCR)	10 (11%)
pathologic partial response (pPR)	26 (29%)
pathologic non-response (pNR)	17 (19%)
2-year RFS[1] by path response % (95% CI)	N=89
pCR (n=36)	97% (92-100)
pnCR (n=10)	80% (59-100)
pPR (n=26)	73% (58-92)
pNR (n=17)	48% (28-82)
2-year RFS[1] by RECIST 1.1 response	N=130
CR (n=15)	93% (82-100)
PR (n=50)	89% (81-99)
SD (n=50)	64% (52-80)
PD (n=15)	67% (47-95)

[1]RFS measured from date of surgery

Conclusions: The use of NAT with single-agent PEM in resectable stage IIIB-IV melanoma results in a 51% major pathologic response rate (pCR + pnCR) with 40% pathologic complete responses. 2-year RFS rates are highest in those achieving pathologic or radiographic response.

Clinical trial identification: NCT03698019.

Background: In patients (pts) with resected high-risk stage IIIB–IV melanoma, mRNA-4157 + pembrolizumab (pembro) extended recurrence-free survival (RFS) and distant metastasis-free survival (DMFS) vs pembro alone (phase 2 KEYNOTE-942; NCT03897881). Minimal residual disease (MRD; by plasma circulating tumor DNA [ctDNA]) at treatment onset was associated with shorter RFS. We examined ctDNA longitudinal dynamics and associated clinical outcomes and report impact of ctDNA status on BRAF subgroup.

Methods: Pts were assigned to mRNA-4157 + pembro or pembro alone. RaDaR® (Inivata) was used to measure plasma ctDNA during treatment and at follow-up. The table defines longitudinal ctDNA molecular responders (MRs) and non-responders (MNRs). BRAF status was derived from whole exome sequencing of baseline tumor tissue. Kaplan–Meier method was used to estimate RFS and DMFS. Cox proportional hazards regression was used to estimate HRs.

Results: 142/157 pts were evaluable for longitudinal ctDNA analyses (100/107 mRNA-4157 + pembro; 42/50 pembro alone). Across treatment arms, pts with available ctDNA and recurrence events were limited (n=30). 57% (8/14) of MRs and 94% (15/16) of MNRs had recurrence. Local recurrence was more common in MRs; MNRs had more distant events. This trend was supported by stronger separation in DMFS vs RFS between MRs and MNRs. There was a trend for enhanced efficacy of mRNA-4157 + pembro across BRAF V600E/K WT (n=96) (HR [95% CI]: 0.808 [0.366–1.784]) and MUT (n=61) subpopulations (0.332 [0.130–0.850]); however, considering ctDNA status by focusing on ctDNA-negative subpopulation increased similarity of efficacy across BRAF WT (n=68) and MUT (n=42) subgroups (0.334 [0.121–0.923] vs 0.069 [0.009–0.563]).

Table: LBA49

ctDNA subgroup	Patient criteria
Molecular responders	Patients with MRD at baseline that resolved during treatment (ctDNA positive at treatment initiation became ctDNA negative) OR Patients with no MRD at baseline that became ctDNA positive on treatment (MRec), and then ctDNA negative again
Molecular non-responders	Patients with MRD at baseline that did not resolve during treatment (ctDNA positive at treatment initiation and stayed positive) OR Patients with no MRD at baseline who showed molecular progression (MRec, ctDNA negative at treatment initiation became ctDNA positive and stayed positive)

Conclusions: These results suggest a potential relationship between ctDNA dynamics and treatment outcomes in pts with high-risk resectable melanoma and support further exploration in upcoming planned studies.

Clinical trial identification: NCT03897881.

Background: Metastatic uveal melanoma (mUM) has a historically poor 1-yr overall survival (OS) rate of 52%. Tebentafusp (tebe), a bispecific (gp100 x CD3) ImmTAC, is approved for adult HLA-A*02:01+ patients (pts) with unresectable or mUM. In the primary analysis of the Phase (Ph) 3 IMCgp100-202 study in previously untreated mUM [NCT03070392], tebentafusp significantly improved OS compared to investigator's choice (IC) [HR 0.51] with a 1-yr OS rate of 73% versus 59%, respectively. Deeper ctDNA reductions were associated with longer OS. Here we present the 3-yr updated analyses of the Ph3 study.

Methods: In this randomized, open-label, Ph3 trial, HLA-A*02:01+ first-line mUM pts were randomized 2:1 to receive tebe or IC of pembrolizumab, ipilimumab or dacarbazine, stratified by LDH. Primary endpoint was OS. Secondary endpoints included overall response rate (ORR), progression free survival (PFS) and disease control rate (DCR) and safety. An exploratory endpoint was ctDNA reduction.

Results: 378 pts were randomized to tebe (252) or IC, including pembrolizumab (103), ipilimumab (16) or dacarbazine (7). After a minimum follow-up of 36 months, the estimated 3-yr OS of tebe was 27% (95% CI 22-33%) vs 18% (95% CI 11-25%) for IC with maintained separation of the OS KM curves. The OS benefit of tebe was also observed in pts with known poor prognostic factors in the metastatic setting. 1-yr and 2-yr PFS rates were 17% vs 9% and 8% vs 3%, for tebe vs IC, respectively. ORR remained in favor of tebe vs IC (11% vs 5%). A third of tebe responders were still in response at 18 months. The DCR rates (CR/PR/SD $\geq$12 weeks) were 46% for tebe and 27% for IC. Of 45 ctDNA evaluable pts in the tebe arm who cleared their ctDNA by week 9, 32 (71%) survived $\geq$2 yrs and 17 (38%) survived $\geq$3 yrs. No new safety signals were identified. The rate of treatment discontinuation due to related AEs continued to be lower in the tebe arm (2% vs 5%). There were no treatment related deaths.

Conclusions: This is the longest OS follow-up in a randomized trial in mUM. Tebentafusp continues to provide long-term survival benefit in first line HLA-A*02:01+ pts, with estimated 3-yr OS rate of 27%, further solidifying tebentafusp as first line standard of care in this population.

Clinical trial identification: NCT03070392.

Background: NIVO+RELA demonstrated significant progression-free survival (PFS) benefit vs NIVO in RELATIVITY-047 (NCT03470922). Exploratory biomarker analyses were conducted to elucidate mechanisms underlying NIVO+RELA activity and identify patients (pts) more likely to derive benefit from the combination.

Methods: Blood samples at baseline and 4 weeks post dose were analyzed by flow cytometry for pharmacodynamic changes in immune cell populations, eg lymphocyte activation gene-3 (LAG-3)- or programmed death-1 (PD-1)-expressing CD4+ and CD8+ T cells, natural killer (NK) cells. Baseline tissue samples were analyzed by immunohistochemistry (IHC) for major histocompatibility complex (MHC) class I/II expression and CD8 infiltration. HALO image analysis of LAG-3+ and LAG-3− CD8+ T cells was conducted by multiplex IHC. Association between biomarkers and treatment response was assessed.

Results: Multiple peripheral immune cell types significantly increased with NIVO+RELA vs NIVO (Table). Response to NIVO+RELA was associated with increased LAG-3+ CD4+ T cells at week 4, but on-treatment modulation of peripheral CD8+ T cells was not associated with NIVO+RELA efficacy. Baseline PD-1+ CD8+ and ICOS+ CD8+ T cell numbers were higher in responders to NIVO+RELA but not NIVO. In the tumor microenvironment (TME), higher baseline MHC-I and MHC-II were associated with improved efficacy in both arms. A PFS benefit with NIVO+RELA vs NIVO was observed in pts with low/medium TME CD8 infiltration; benefit of NIVO+RELA vs NIVO was seen for high TME CD8 infiltration only when LAG-3 was also expressed.

Table: LBA51 Select changes in peripheral blood 4 weeks post first dose suggesting RELA-specific activity

	NIVO		NIVO+RELA

sLAG-3+ CD56+ CD16+ (int) NK	9.10	NS	117.4	****
sLAG-3+ NK	0	NS	50.0	****
sLAG-3+ CD56− CD16+ (mature) NK	10.5	NS	40.2	**

[a]Median.

c, cytoplasmic; int, intermediate; NS, nonsignificant; s, surface; TE, terminal effector.
*<0.05; **<0.01; ***<0.001; ****<0.0001 by Wilcoxon test.

Conclusions: TME analysis suggests RELA activity is particularly robust in tumors with lower CD8+ T-cell infiltration; peripheral data suggest CD4+ T-cell modulation may be key to its distinct mechanism of action. Further exploratory biomarker analyses are warranted to identify pts who may derive maximal benefit from NIVO+RELA.

Clinical trial identification: NCT03470922, EudraCT 2017-003583-12.

LBA52 A randomized phase Ib/II study of the selective small molecule AXL inhibitor bemcentinib in combination with either dabrafenib/trametinib or pembrolizumab in patients with metastatic melanoma

O. Straume[1], C. Schuster[1], S. Aziz[2], K. Davidsen[1], J. Karlsen[3], A.J. Rayford[4], M.I. Siraji[4], H. Løvendahl Svendsen[5], L. Reisæter[6], B.T. Gjertsen[7], L. Akslen[8], J. Lorens[4]

[1]Oncology and Medical Physics Dept, Haukeland Universitetssykehus, Bergen, Norway; [2]Pathology, Helse Bergen - Haukeland University Hospital, Bergen, Norway; [3]Cancer Clinic St Olavs Hospital, Trondheim, NTNU - Norwegian University of Science and Technology, Trondheim, Norway; [4]Biomedicine department, University of Bergen, Bergen, Norway; [5]Department of Plastic Surgery, Helse Bergen - Haukeland University Hospital, Bergen, Norway; [6]Radiology, Helse Bergen - Haukeland University Hospital, Bergen, Norway; [7]Centre for Cancer Biomarkers, Dept Clinical Science, University of Bergen, Bergen, Norway; [8]Centre for Cancer Biomarkers, Dept Clinical Medicine, University of Bergen, Bergen, Norway

Background: AXL has been linked with both a reduced response to PD-1 blockade and resistance to BRAF directed therapies in melanoma. Bemcentinib (Bem) is a first-in-class, orally bioavailable, highly selective AXL inhibitor. BGBIL006 (NCT02872259) is an open label Phase Ib/II clinical study designed to explore whether combinations with Bem are safe and improve overall response rate (ORR) relative to standard of care therapies in metastatic melanoma.

Methods: Six patients were enrolled in the dabrafenib/trametinib (D/T) + Bem dose finding part 1. In part 2, 68 patients received D/T or pembrolizumab (Pem) based on BRAF mutation status and tumour load and were randomized 2:1 to receive D/T or Pem with or without Bem. Upon progression, 17 BRAF+ patients switched from D/T to Pem or vice versa in part 3. Safety was assessed by NCI CTCAE v 4.03 and tumour responses were assessed using RECIST v1.1.

Results: Patients were enrolled between 2017 and 2022. At the interim database lock on August 21 2023, median follow time was 53 months (10-78). A daily dose of 200 mg Bem was well tolerated in combinations with Pem or D/T; 24% (18/73) of Grade $\geq$ 3 AEs were regarded as related to Bem. Most frequent Bem-related AEs were rash, diarrhoea, fatigue and increased transaminases. In the efficacy population (n=70), we did not observe significant differences in ORR, PFS or OS between standard treatments and the combinations with Bem. In pre-planned analyses of baseline biomarkers, we did not identify subgroups of patients with increased response to combinations with Bem compared to standard treatment. The following biomarkers predicted improved ORR to Pem; high CD8+ count ($p<0.01$), high FOXP3 count ($p<0.01$), high PD-L1 in TIL ($p=0.02$), high AXL expression in inflammatory cells ($p=0.04$). High FOXP3 count (above median) in tumours, compared with low, predicted increased PFS in Pem treated patients (HR 0.2, $p<0.01$).

Conclusions: Bem was well tolerated in combinations with Pem or D/T in melanoma, but did not increase responses or survival in the efficacy population nor in biomarker defined subgroups. High FOXP3 count in tumour infiltrating inflammatory cells was a strong predictive marker for response to Pem.

Clinical trial identification: NCT02872259.

Background: VEGF pathway inhibitors are active against NET. We assessed the efficacy of cabozantinib (CABO), a multi-kinase inhibitor targeting VEGFR, c-MET, AXL, and RET, in previously treated patients (pts) with advanced extra-pancreatic NET (epNET) or pancreatic NET (pNET).

Methods: Pts with locally advanced or metastatic well or moderately differentiated epNET or pNET were randomized (2:1) in separately powered cohorts to receive CABO 60 mg daily vs placebo (PB). Eligibility included progression by RECIST within 12 months (mo) prior to registration, $\geq$ 1 prior therapy including everolimus, sunitinib or Lu-177 dotatate. Randomization was stratified by concurrent somatostatin analog (SSA) and primary site in epNET and by concurrent SSA and prior sunitinib in pNET. Primary endpoint: progression-free survival (PFS), with preplanned interim analyses for futility after 33% and 66% of events and alpha spending of 0.001 per interim analysis. Secondary endpoints: response rate (RR), overall survival (OS), safety.

Results: 197 pts (129 CABO, 68 PB) with epNET and 93 pts (62 CABO, 31 PB) with pNET were randomized between 10/2018-6/2023. For epNET: 55% midgut/unknown primary; 70% concurrent SSA. For pNET: 55% concurrent SSA; 28% prior sunitinib. Median follow-up: 12.6 mo for epNET; 10.1 mo for pNET. An independent DSMB requested and reviewed interim analyses for PFS based on local radiology assessment (2nd interim for epNET [109 events]; 1st for pNET [50 events]). Efficacy analyses in both cohorts noted significantly improved PFS for pts receiving CABO vs placebo (Table). No new safety signals were noted. DSMB voted to terminate accrual and unblind pts on 7/28/2023. RR, OS data will be presented.

Conclusions: CABO demonstrates statistically significant and clinically meaningful improvement in PFS in epNET and pNET. CABO may be a new treatment option for pts with previously treated, progressive NET.

Clinical trial identification: NCT03375320.

Background: Alkylating agents (ALKY, temozolomide, darcabazine and streptozotocin), and oxaliplatin (Ox) are the main chemotherapies used for advanced neuroendocrine tumours (NETs). O^6-Methylguanine-DNA methyltransferase (MGMT) status, as proficient (p) or deficient (d), may be a predictor of response to ALKY.

Methods: MGMT-NET (NCT03217097) is a randomized phase 2 trial. Main inclusion criteria were confirmed advanced pancreatic, thoracic, or unknown (Uk) primary NETs with an indication for chemotherapy and tissue available. The primary aim was to demonstrate an improvement of the objective response rate (ORR) assessed by RECIST-v1.1 at 3 months from 15% in pMGMT NETs to 50% in dMGMT NETs with ALKY. Secondary aims were the best ORR, progression-free-survival (PFS) and overall survival (OS) of ALKY; oxaliplatin-based chemotherapy (Ox) serves as an internal-control. For the primary aim, dMGMT was defined using pyrosequencing if the *MGMT* was methylated (> 8%) and using immunochemistry if MGMT expression was lost (H-score<50) when pyrosequencing was not available.

Results: From Oct 2018 to Oct 2021, 105 patients (55 pancreas, 38 thoracic, 12 Uk) started either ALKY (n=62) or Ox (n=43, 1:1 for pMGMT or 2:1 for dMGMT NETs). Median age was 63 years (range 30−84), 57% males, NET were G1 (28%), G2 (60%) or G3 (10%). 102 had MGMT status available, 39/91 (43%) and 39/82 (48%) were dMGMT when assessed by pyrosequencing or immunohistochemistry, respectively. The primary aim was not met but best ORR, PFS and OS were greater in ALKY-dMGMT group (Table). Results will be also given by technique of MGMT evaluation during the meeting.

Conclusions: ALKY provides a higher response rate for dMGMT-NET while Ox chemotherapy may be a better option in pMGMT-NET.

Clinical trial identification: NCT03217097.

Legal entity responsible for the study: Hospices Civils de Lyon.

Funding: Supported by Clinical Research Hospital Program grants (PHRC 2016) from the French ministry of health (PHRCK-16-0208).

New diagnostic tools

LBA55 An ultra-sensitive and specific ctDNA assay provides novel pre-operative disease stratification in early stage lung cancer

J.R.M. Black[1], A.M. Frankell[1], S. Veeriah[2], M. Colopi[2], M. Hill[1], C.W. Abbott[3], S.M. Boyle[3], B. Li[3], R. Chen[3], M. Al Bakir[4], C. Martinez Ruiz[2], A. Huebner[2], M. Jamal-Hanjani[5], N. McGranahan[6], C. Swanton[7]

[1]Cancer Evolution and Genome Instability Laboratory, Francis Crick Institute, London, UK; [2]Lung Cancer Centre of Excellence, University College London, London, UK; [3]Research & Development, Personalis, Inc. - Headquarters (Office and Laboratory), Menlo Park, CA, USA; [4]Cancer Evolution, Francis Crick Institute, London, UK; [5]Medical Oncology Dept., UCL Cancer Institute - Paul O'Gorman Building, London, UK; [6]Oncology, UCL Cancer Institute - Paul O'Gorman Building, London, UK; [7]Translational Cancer Therapeutics Department, Francis Crick Institute, London, UK

Background: Circulating tumour DNA (ctDNA) detection has significant promise to inform patient care to predict clinical risk in early-stage tumours, optimise personalised adjuvant treatment regimens, and monitor for relapse in the minimal residual disease (MRD) setting. However, clinical applications, especially in low-shedding tumours such as lung adenocarcinomas (LUADs), are constrained by the limited sensitivity of clinically validated ctDNA detection approaches.

Methods: We developed NeXT Personal, a whole genome based, tumour-informed platform for ultra-sensitive ctDNA detection, and analytically validated detection thresholds consistently within 1-3 parts per million (PPM) of ctDNA with >99.95% specificity. We analysed pre-operative plasma samples from an interim cohort of 171 patients with early stage lung cancer from the TRACERx study.

Results: ctDNA was detected pre-operatively in 81% of patients with lung adenocarcinomas (LUADs), including 52%, 88%, and 100% of those with pathological TNM (pTNM) stage I, II, and III disease, respectively; and in 100% of non-LUAD patients.

Table: LBA54

	Proficient MGMT		Deficient MGMT	
	Oxaliplatin-based	**ALK-based**	**ALK-based**	**Oxaliplatin-based**
Number of patients	23	33	27	19
Pancreas	8	12	18	14
Thoracic/unknown	11/4	16/5	7/2	4/1
ORR at 3 months (central review), n (%)	6 (26)	**4 (12)**	**8 (31)**	6 (32)
Best ORR, n (%)	9 (39)	**6 (18)**	**15 (56)**	4 (21)
Median PFS in months (95%CI)	12.2 (11.7-12.7)	**11.3 (9.4-13.2)**	**14.6 (7.1-22.1)**	12.9 (11.8-14.0)
Median OS in months (95%CI)	34.3 (21.9-46.7)	50.2 (not defined)	Not reached	48.8 (21.0-76.6)

Elevated pre-operative ctDNA levels correlated with poor overall survival (OS; ctDNA low HR=9.1; 95% CI:1·1-72.5; ctDNA high HR=23.6, 95% CI: 2·7-206.0) and relapse-free survival (RFS) in LUADs independent of stage (including in stage I patients). Importantly, this remained true among ctDNA-positive samples when ctDNA level was treated as a continuous variable (HR=1.5; 95% CI: 1.1-2.1), whilst elevated ctDNA levels also correlated with reduced RFS in non-LUADs (HR= 2.1, 95% CI= 1·0 to 4.4), independent of disease stage. Critically, LUAD patients with ctDNA present at below 80 PPM (the 95% limit of detection for our recently published ctDNA detection approach in TRACERx) experienced reduced OS compared to those in which ctDNA was not detected (p=0.002, HR=12.2).

Conclusions: Our ultra-sensitive approach demonstrates superior analytic performance and prognostic prediction compared to other assays previously clinically validated in non-small cell lung cancer and provides an advanced stratification tool to guide adjuvant therapy in early-stage ctDNA-positive disease at high risk of relapse.

Clinical trial identification: NCT01888601.

Background: Neoadjuvant (neoadj) NIVO + chemo provides efficacy benefit vs chemo in patients (pts) with resectable NSCLC. However, the efficacy of perioperative NIVO + chemo has not been evaluated in phase 3 studies. Here, we report prespecified interim analysis results from CheckMate 77T, a randomized, double-blind, phase 3 study evaluating neoadj NIVO + chemo followed by surgery and adjuvant (adj) NIVO (NIVO + chemo/NIVO) compared with neoadj placebo + chemo followed by surgery and adj placebo (chemo/PBO) in resectable stage II–IIIB NSCLC.

Methods: Adults with untreated resectable stage IIA (>4 cm)–IIIB (N2) NSCLC (AJCC v8), *EGFR/ALK* wild-type, and ECOG PS ≤1 were stratified by tumor histology, PD-L1 expression, and disease stage, and randomized 1:1 to NIVO 360 mg Q3W + platinum-doublet chemo (4 cycles) followed by surgery and adj NIVO 480 mg Q4W (1 y), or placebo Q3W + platinum-doublet chemo (4 cycles) followed by surgery and adj placebo Q4W (1 y). Primary endpoint was EFS (RECIST v1.1 per BICR). Secondary endpoints were pCR and MPR (both per BIPR), OS, and safety.

Results: Baseline characteristics were balanced between arms (NIVO + chemo/NIVO, n = 229; chemo/PBO, n = 232). At a minimum follow-up of 15.7 mo, NIVO + chemo/NIVO significantly improved EFS vs chemo/PBO (median [95% CI], not reached [28.9 mo–not reached] vs 18.4 mo [13.6–28.1]; HR [97.36% CI], 0.58 [0.42–0.81]; P = 0.00025). NIVO + chemo/NIVO also improved pCR rates (25.3% vs 4.7%; odds ratio, 6.64 [95% CI, 3.40–12.97]) and MPR rates (35.4% vs 12.1%; odds ratio: 4.01 [2.48–6.49]) vs chemo/PBO. Definitive surgery rates were 78% vs 77% in the NIVO + chemo/NIVO vs chemo/PBO arms; of these, 89% vs 90% were R0 resections, respectively. Grade 3–4 treatment-related AEs were 32% and 25% in the NIVO + chemo/NIVO and chemo/PBO arms; surgery-related AEs were 12% and 12%, respectively.

Conclusions: CheckMate 77T met its primary endpoint with a statistically significant and clinically meaningful improvement in EFS with neoadj NIVO + chemo followed by surgery and adj NIVO vs chemo/PBO in pts with resectable NSCLC. No new safety signals were noted with the NIVO + chemo/NIVO regimen.

Clinical trial identification: NCT04025879.

Background: For patients (pts) with resected, stage IB–IIIA, *ALK*+ NSCLC, the recommended treatment after surgery is platinum-based chemotherapy (CT), which is associated with modest improvements in survival. In advanced *ALK*+ NSCLC, alectinib is a preferred first-line treatment. Here, we report data from the prespecified interim analysis of ALINA (NCT03456076), a global, phase III, open-label, randomised trial assessing the efficacy and safety of adjuvant alectinib compared with CT in pts with completely resected *ALK*+ NSCLC.

Methods: Eligible pts were ≥18 years old, had an ECOG PS of 0/1 and completely resected, stage IB (≥4 cm)–IIIA, *ALK*+ NSCLC (per UICC/AJCC 7th edition). Pts were randomised 1:1 to receive either oral alectinib 600 mg twice daily, or up to four 21-day cycles of IV platinum-based CT. Randomisation was stratified by stage (IB vs II vs IIIA) and race (Asian vs non-Asian). Alectinib was given for up to 24 months or until disease recurrence, unacceptable toxicity, or withdrawal of consent. Primary endpoint: investigator-assessed disease-free survival (DFS), tested hierarchically first in the stage II–IIIA and then in the ITT population (stage IB–IIIA). Other endpoints included: CNS-DFS, overall survival (OS), safety.

Results: A total of 257 pts were randomised to receive alectinib (n=130) or CT (n=127); baseline characteristics were overall well balanced between arms. At data cutoff (26 June 2023), median follow up was 27.8 months. A significant DFS benefit was observed with alectinib vs CT in both the stage II–IIIA (HR 0.24; 95% CI: 0.13–0.45) and ITT populations (HR 0.24; 95% CI: 0.13–0.43; Table). A clinically meaningful CNS-DFS benefit was observed in the ITT population (HR 0.22; 95% CI 0.08–0.58). OS data were immature. No unexpected safety findings were observed.

Conclusions: Alectinib is the first ALK inhibitor to significantly improve DFS compared with CT and provides an effective new treatment strategy for pts with resected *ALK*+ NSCLC.

Clinical trial identification: NCT03456076.

Background: At the protocol-specified first interim analysis of the phase 3 KEYNOTE-671 study of resectable early-stage NSCLC (NCT03425643), neoadjuvant pembrolizumab (pembro) + chemotherapy (chemo) followed by resection and adjuvant pembro significantly improved EFS, mPR, and pCR with an expected safety profile vs neoadjuvant chemo and resection alone. We present results of the protocol-specified second interim analysis of KEYNOTE-671.

Methods: Patients (pts) with resectable stage II, IIIA, or IIIB (N2) NSCLC per AJCC v8 were randomized 1:1 to pembro 200 mg (n = 397) or placebo (n = 400) Q3W. Pts were to receive 4 cycles of neoadjuvant pembro or placebo plus cisplatin-based chemo and ≤13 cycles of adjuvant pembro or placebo. Dual primary endpoints are EFS (time from randomization to local progression precluding planned surgery, unresectable tumor, progression or recurrence per RECIST v1.1 by investigator assessment, or death from any cause) and OS.

Results: Median time from randomization to the 10 July 2023 data cutoff was 36.6 mo (range, 18.8-62.0). With 254 (31.9%) deaths, OS was significantly improved in the pembro arm (HR 0.72 [95% CI 0.56-0.93]; $P = 0.00517$). Median OS was not reached (NR) (95% CI NR-NR) in the pembro arm vs 52.4 mo (95% CI 45.7-NR) in the placebo arm; 36-mo OS rates were 71.3% vs 64.0%. EFS continued to be improved in the pembro arm (HR 0.59 [95% CI 0.48-0.72]; median [95% CI] 47.2 mo [32.9-NR] vs 18.3 mo [14.8-22.1]; 36-mo rate, 54.3% vs 35.4%). Treatment-related AEs were grade ≥3 in 45.2% of pts in the pembro arm vs 37.8% in the placebo arm, led to discontinuation of all treatment in 20.2% vs 9.3%, and led to death in 1.0% vs 0.8% (no new treatment-related deaths since the first interim analysis).

Conclusions: Neoadjuvant pembro + chemo followed by resection and adjuvant pembro provided a statistically significant and clinically important improvement in OS compared with neoadjuvant chemo and resection alone in pts with resectable stage II, IIIA, or IIIB (N2) NSCLC. The OS gains seen in KEYNOTE-671 with the absence of new safety signals establish the perioperative pembro regimen as a new standard of care for resectable early-stage NSCLC.

Clinical trial identification: NCT03425643, first posted February 7, 2018.

Background: In CheckMate 816, neoadjuvant N + C vs C significantly improved the primary endpoints of event-free survival (EFS) and pathological complete response (pCR) in patients with resectable NSCLC; 3-y EFS benefit with N + C vs C was also demonstrated. Here, we report clinical outcomes by baseline tumor PD-L1 expression.

Methods: Adults with stage IB ($\geq$ 4 cm)—IIIA (AJCC v7) resectable NSCLC were randomized 1:1 to receive N 360 mg + C Q3W or C Q3W for 3 cycles. Exploratory analyses included EFS, overall survival (OS), pCR, major pathological response (MPR), surgical outcomes, and safety in patients with tumor PD-L1 $\geq$ 1% or $<$ 1%.

Results: In patients with tumor PD-L1 $\geq$ 1% (N + C, 89; C, 89) and PD-L1 $<$ 1% (78; 77), baseline characteristics were generally similar between PD-L1 subgroups and treatment arms. A higher proportion of patients with tumor PD-L1 $<$ 1% had ECOG PS 1 (both arms). At database lock (14 Oct 2022; median follow-up, 41.4 mo), N + C showed improvement vs C across all efficacy endpoints in patients with tumor PD-L1 $\geq$ 1% (Table); 3-y EFS and OS rates were 72% vs 47% and 85% vs 66%, respectively. Similar efficacy benefit was seen in patients with tumor PD-L1 $\geq$ 1% and stage II—IIIA NSCLC (data to be presented). In patients with tumor PD-L1 $<$ 1%, EFS, OS, pCR, and MPR also favored N + C vs C (Table); 3-y EFS and OS rates were 42% vs 39% and 71% vs 60%, respectively. Definitive surgery rates with N + C vs C were 84% vs 74% in patients with tumor PD-L1 $\geq$ 1% and 81% vs 77% in patients with tumor PD-L1 $<$ 1%; R0 resection rates were 91% vs 82% and 79% vs 76%, respectively. Grade 3—4 treatment-related AE rates with N + C vs C were 34% vs 44% in patients with tumor PD-L1 $\geq$ 1% and 36% vs 34% in patients with tumor PD-L1 $<$ 1%.

Conclusions: These exploratory analyses from CheckMate 816 reinforce the clinical benefit and manageable safety profile of neoadjuvant N + C in patients with resectable NSCLC regardless of tumor PD-L1 expression.

Clinical trial identification: NCT02998528.

Editorial acknowledgement: Editorial assistance in the writing of the abstract was provided by Mallika Kanwar, MD, PhD, Adel Chowdhury, PharmD, and Michele Salernitano of Ashfield MedComms, an Inizio company.

LBA58 Pathological response to neoadjuvant tislelizumab (TIS) plus platinum-doublet (PtDb) chemotherapy (CT) in resectable stage II-IIIA NSCLC patients (pts) in the phase III (Ph3) RATIONALE-315 trial

D. Yue[1], W. Wang[2], H. Liu[3], Q. Chen[4], C. Chen[5], J. Zhang[6], F. Bai[7], C. Wang[8]

[1]Lung Cancer Dept, Tianjin Medical University Cancer Institute and Hospital, Tianjin, China; [2]Hunan Cancer Hospital, Hunan, China; [3]Department of Breast Surgery, Liaoning Cancer Hospital and Institute, Shenyang, China; [4]Department of Thoracic Surgery, Zhejiang Cancer Hospital, Hangzhou, China; [5]Neurology, Fujian Medical University Union Hospital, Fuzhou, China; [6]Director of Biostatistics, BeiGene USA, Inc., San Mateo, CA, USA; [7]Clinical Development, BeiGene (Shanghai) Co., Ltd., Shanghai, China; [8]Lung Cancer, Tianjin Medical University Cancer Institute and Hospital, Tianjin, China

Background: Neoadjuvant (NA) CT with anti-PD-(L)1 mAb has shown promising pathologic response rates (ie, major pathological response [MPR], pathological complete response [pCR]) in pts with resectable NSCLC. The Ph3 RATIONALE-315 study (NCT04379635) investigated the efficacy & safety of NA TIS (anti-PD-1 mAb) or placebo (PBO) + CT, then adj TIS or PBO, in pts with resectable stage II-IIIA NSCLC.

Methods: This study enrolled pts with treatment (tx)-naïve, resectable, confirmed squamous (sq) or non-sq (nsq) stage II-IIIA NSCLC who were eligible for PtDb CT, with ECOG PS ≤1 and no known *EGFR* mutation (nsq) or *ALK* gene translocation (sq & nsq). Pts stratified by histology, disease stage, and PD-L1 expression (≥1% vs <1%) were randomized (1:1) to 3-4 cycles of TIS 200 mg IV Q3W or PBO, plus PtDb CT, followed by surgery + 8 cycles of adj TIS 400 mg IV Q6W or PBO. Primary endpoints: MPR rate after completion of NA tx + EFS per RECIST v1.1 by blinded independent review committee (IRC). Key secondary endpoint: pCR rate.

Results: As of 20 Feb 2023 (median follow-up: 16.8 mo), 453 pts (TIS + CT, n=226; CT, n=227) were randomized to the intention-to-treat (ITT) population and had similar baseline characteristics. Of 452 (99.8%; n=226 both arms) pts treated in the NA phase, 421 (92.9%) completed NA tx (TIS + CT, n=211 [93.4%]; CT, n=210 [92.5%]); 90 (19.9%) did not undergo surgery (TIS + CT, n=36 [15.9%]; CT, n=54 [23.8%]). Efficacy & safety data from the NA phase are summarized in the table; MPR & pCR rates were significantly improved with TIS + CT vs CT ($P<0.0001$). TIS + CT did not impact the feasibility of surgery.

Table: LBA58 Efficacy and safety summary

	TIS+CT	CT
	ITT Analysis Set n=226	n=227
MPR, % (95% CI)[a]	56.2 (49.5-62.8)	15.0 (10.6-20.3)
Difference, % (95% CI); *P* value[b]	41.1 (33.2-49.1); *P*<0.0001

[a]Assessed by IRC.
[b]1-sided.
[c]Randomized pts who received ≥1 dose of any study drug.
OR, odds ratio; TEAE, treatment-emergent adverse event.

Conclusions: TIS + CT showed clinically meaningful and statistically significant improvements in MPR and pCR rates vs PBO + CT as NA tx. The safety profile of TIS + CT was consistent with known risks of each tx and was manageable in pts with resectable stage II-IIIA NSCLC, further supporting this tx combination for these pts.

Clinical trial identification: NCT04379635.

Background: In AEGEAN, perioperative durvalumab (D) + neoadj chemotherapy (CT) significantly improved pathological complete response (pCR), major pathological response (MPR), and event-free survival, with manageable safety, vs neoadj CT alone among pts with resectable (R) NSCLC (modified ITT [mITT] population). We report exploratory analyses of ctDNA, including association of ctDNA clearance (CL) with pCR or MPR.

Methods: AEGEAN is a double-blind placebo (PBO)-controlled study (NCT03800134). Adults with Tx-naïve R-NSCLC (stage II—IIIB[N2]; AJCC 8th ed) were randomised (1:1) to receive neoadj CT + D or PBO IV (Q3W, 4 cycles) prior to surgery (Sx), followed by D or PBO IV (Q4W, 12 cycles), respectively, after Sx. Plasma samples were collected at protocol-specified timepoints, including prior to each neoadj Tx cycle and before Sx. Analysis was performed using patient-specific tumour-informed assays, following identification of mutations in diagnostic tissue by whole exome sequencing. ctDNA variant allele fractions (VAFs) and dynamics were assessed during neoadj Tx, including ctDNA CL and association with pCR or MPR.

Results: ctDNA was evaluated in 831 samples from 186 mITT population pts (D arm, n=90; PBO arm, n=96) in the interim pCR analysis cohort. Baseline characteristics of ctDNA-evaluable pts were generally similar to those in the overall mITT population. In both Tx arms, decreases in median VAFs were observed as early as C2D1 (D arm, 97% decrease; PBO arm, 94% decrease) and, by C3D1, were significantly lower in pts with pCR/MPR vs pts with non-pCR/MPR (P≤0.003). After each cycle of neoadj Tx, higher ctDNA CL rates were observed in the D vs PBO arm (with 66% [95% CI, 54—77] vs 41% [95% CI, 30—52] at pre-Sx). Pts achieving ctDNA CL vs no CL at C2D1 had higher rates of pCR (D arm: 50.0% vs 15.1%; PBO arm: 14.3% vs 3.1%) and MPR (D arm: 66.7% vs 35.8%; PBO arm: 38.1% vs 12.5%). Among pts who were ctDNA+ at baseline, all pts achieving pCR and >90% achieving MPR had ctDNA CL by C4D1.

Conclusions: Neoadj Tx with D + CT resulted in greater ctDNA CL than PBO + CT. Earlier ctDNA CL was associated with higher likelihood of pCR and MPR, highlighting ctDNA CL as a potential early-response biomarker.

Clinical trial identification: NCT03800134 (release date: January 11, 2019).

NSCLC, locally advanced

LBA60 Stereotactic body radiation therapy with sequential immunochemotherapy as neoadjuvant therapy in resectable non-small cell lung cancer

Z-R. Zhao[1], S. Liu[2], T. Zhou[3], G. Chen[3], Z-H. Ye[4], Z-C. Li[1], J-D. Wu[1], Y. Yang[3], M. Xi[2], Y-B. Lin[1], H. Yang[1]

[1]Department of Thoracic Surgery, Sun Yat-sen University Cancer Center, Guangzhou, China; [2]Department of Radiation Oncology, Sun Yat-sen University Cancer Center, Guangzhou, China; [3]Deparment of Medical Oncology, Sun Yat-sen University Cancer Center, Guangzhou, China; [4]Deparment of Clinical Oncology, The University of Hong Kong - Shenzhen Hospital, Shenzhen, China

Background: Phase 3 trials of neoadjuvant immunochemotherapy in patients with resectable non-small-cell lung cancer (NSCLC) have reported major pathological response (MPR) rates ranging from 30.2% to 48.5%. Stereotactic body radiotherapy (SBRT) may have an immunomodulating effect and augment the effect of preoperative immune checkpoint blockade monotherapy. In this single-arm phase 2 trial, we investigated the use of SBRT plus immunochemotherapy in the neoadjuvant setting for patients with resectable NSCLCs.

Methods: Eligiblepatients with resectable NSCLCs (stage II-IIIB as per the 8th edition of the AJCC) without known EGFR/ALK alterations received SBRT (8Gy x 3 fractions) to the primary tumor followed by two cycles of PD-1 inhibitor tislelizumab plus platinum-doublet chemotherapy of each 21-day cycle. Patients without systemic disease progression proceeded to resection 4-6 weeks after treatment. The primary endpoint was MPR defined as 10% or fewer viable tumors in the primary tumor and lymph nodes. The sample size was determined based on Simon's optimal two-stage design, considering a threshold MPR rate of 30% and an expected MPR rate of 50%. If there were 19 or more MPRs in 46 patients, the null hypothesis can be rejected.

Results: Between May 2022, and June 2023, 46 patients were enrolled, with 38 (82.6%) having stage III diseases. Two surgeries were canceled due to disease progression and G5 neutropenia, respectively. Forty-four (95.7%) patients underwent R0 resection and none of them required pneumonectomy. The study met the primary endpoint. The MPR rate was 76.1% (35/46, 95% CI: 61.2-87.4), and pathological complete response rate was 52.2% (24/46, 95% CI: 36.9-67.1). Nodal clearance (ypN0) was found in 35 of 46 cN1/2 cases (76.1%). Grade 3 or greater adverse events related to neoadjuvant treatment occurred in 12 patients (26.1%), the most frequent being neutropenia (13.0% [n=6]), pneumonia (4.3% [n=2]), and anemia (4.3% [n=2]). Two patients had delayed operations due to G3 pneumonia (77 and 134 days after the last cycle of immunochemotherapy). No deaths within 30 days of surgery were reported.

Conclusions: Neoadjuvant SBRT followed by immunochemotherapy is well tolerated, feasible, and yielded a high MPR rate.

Background: In the phase 3, placebo-controlled PACIFIC trial, durva after concurrent CRT (cCRT) significantly improved survival in pts with unresectable Stage III NSCLC, with manageable safety. As many pts are considered unsuitable for cCRT, the phase 2 PACIFIC-6 trial (NCT03693300) assessed safety and efficacy with durva after sequential CRT (sCRT); interim data indicated this approach had a similar safety profile to that with durva after cCRT in PACIFIC with encouraging preliminary efficacy. We report the final analysis from PACIFIC-6.

Methods: Pts with unresectable Stage III NSCLC, ECOG performance status (PS) $\leq$2, and no progression after platinum-based sCRT were enrolled to receive durva 1500 mg IV, every 4 wk for up to 24 mo, or until progression, unacceptable toxicity, or consent withdrawal. The primary endpoint (reported previously) was the incidence of grade 3/4 possibly related AEs (PRAEs) occurring within 6 mo. Secondary endpoints included OS and PFS (investigator-assessed; RECIST v1.1), analysed by Kaplan–Meier method.

Results: As of Mar 20, 2023, 117 pts were enrolled. Most had PS 1/2 (59.8%; PS 1, n=67; PS 2, n=3), were aged $\geq$65 yr (65.8%; age range: 39–85 yr), and had stage IIIB/IIIC NSCLC (63.2%). Nearly all had past/present comorbidities (98.3%), mostly vascular (59.0%), respiratory (53.0%) and metabolic (51.3%) disorders. Median treatment duration was 41.0 wk (range: 4–108). Overall, 4.3% (95% CI: 1.4–9.7) of pts had grade 3/4 PRAEs within 6 mo, and 6.0% had grade 3/4 PRAEs during the entire study period (1 pt had a PRAE with outcome of death). Pneumonitis was the most frequently reported PRAE of any grade (17.1%) and grade 3/4 (1.7%). 27.4% of pts discontinued durva due to AEs of any cause. Median duration of follow-up among pts censored for OS was 32.6 mo (range: 4.4–45.7). Median OS was 39.0 mo (95% CI: 30.6–not calculable), the 3-yr OS rate was 56.5% (95% CI: 46.4–65.5), and median PFS was 13.1 mo (95% CI: 7.4–19.9).

Conclusions: Durva after sCRT maintained a similar safety profile to that seen with durva after cCRT in PACIFIC and demonstrated encouraging efficacy in a frailer population, supporting use of this approach for pts who are considered unsuitable for cCRT.

Clinical trial identification: NCT03693300 (release date: October 02, 2018).

Background: Consolidation durvalumab following chemoradiotherapy (CRT) is SOC for patients (pts) with unresectable Stage III NSCLC. Many pts, however, are ineligible for CT and mainly receive RT alone with unsatisfactory results. We report the primary safety and secondary efficacy analyses of DUART (NCT04249362), a phase 2, open-label international study.

Methods: Pts with unresectable Stage III NSCLC deemed ineligible for CT by a multidisciplinary team with no progression after RT were enrolled into two parallel cohorts per prior RT dose according to local SOC (A: standard RT, 60 Gy ± 10% or bioequivalent dose [BED]; B: palliative RT, 40 to <54 Gy or BED). Pts received durvalumab 1500 mg IV Q4W for 12 mo or until progression, unacceptable toxicity, or consent withdrawal. The primary endpoint was safety/tolerability, defined by the incidence of grade 3/4 possibly-related adverse events (PRAEs) occurring within 6 mo of the first dose.

Results: 102 pts received durvalumab. Median total treatment (Tx) duration was 30.6 wk; Tx is ongoing in 21 pts. Median age was 79.0 yr; 71.6% were male, and 18.8%/73.3%/7.9% had ECOG performance status (PS) 0/1/2. Overall, 9.8% (A: 11.9%; B: 7.0%) had grade 3/4 PRAEs within 6 mo of the first dose (primary endpoint). Median PFS was 8.0 mo and confirmed ORR was 26.5%. The most common PRAE leading to discontinuation was pneumonitis, in 3.9% of pts. 7 pts (A: 5; B: 2) had fatal AEs, including 1 PRAE (A: pneumonitis). Key clinical outcomes are summarized in the table. Additional results, including overall survival, will be presented.

Conclusions: We demonstrate in a prospective trial that pts ineligible for CT, including pts with PS 2, can be safely treated with a combination of thoracic RT followed by immunotherapy. Preliminary efficacy outcomes were encouraging (numerically better in the 60 Gy cohort), making this combination a novel option for this common subset of more fragile pts.

Clinical trial identification: NCT04249362 (release date: January 30, 2020).

Background: Selpercatinib is a highly selective and potent, brain penetrant RET inhibitor, approved for treatment of advanced *RET* fusion-positive (*RET+*) NSCLC. Selpercatinib had not previously been evaluated in a randomized trial.

Methods: LIBRETTO-431 (NCT04194944) is a randomized, open-label, phase 3 trial comparing first-line selpercatinib vs chemotherapy (cisplatin/carboplatin + pemetrexed) +/- pembrolizumab. The primary endpoint of blinded independent central review (BICR)-assessed PFS was tested first in patients stratified by investigator's

Table: LBA62

	Cohort A (standard RT; n=59)	Cohort B (palliative RT; n=43)	Total (N=102)
Any PRAEs, %[a] Gr 3/4 Gr 3/4 (within 6 mo)	67.8 15.3 11.9	48.8 7.0 7.0	59.8 11.8 9.8
PFS Events (%) Median (95% CI), mo[b] 12-mo PFS rate (95% CI), %[b]	26 (44.1) 9.0 (5.6—NC) 40.2 (23.6—56.3)	25 (58.1) 7.6 (5.3—11.0) 29.3 (13.8—46.7)	51 (50.0) 8.0 (7.0—9.7) 34.8 (23.0—46.9)
Confirmed ORR (95% CI),[c] %	28.8 (17.8—42.1)	23.3 (11.8—38.6)	26.5 (18.2—36.1)

Data cutoff: Mar 30, 2023 (median [range] follow-up, 7.4 mo [0.0—24.9] in all censored pts). [a]Investigator-assessed.
[b]Estimated by Kaplan—Meier method. [c]CIs calculated by Clopper-Pearson exact method.
NC, not calculable; ORR, objective response rate; PFS, progression-free survival.

intent to treat with pembrolizumab, if assigned to the control arm, (ITT-pembro) and then in the ITT population. The pre-planned interim efficacy analysis by BICR occurred after 98 PFS events in the ITT-pembro population. Crossover to selpercatinib was allowed following BICR progression on the control arm.

Results: A total of 261 patients were enrolled from 23 countries. Baseline characteristics were balanced across study arms. At a median follow up of approximately 19 months, selpercatinib demonstrated superior PFS vs control in the ITT-pembro (HR: 0.465, 95% CI: 0.309, 0.699; p-value: 0.0002) and ITT populations (HR: 0.482, 95% CI: 0.331, 0.700; p-value: 0.0001). In the ITT-pembro population, median PFS was 24.8 months (95% CI: 16.9, NE) with selpercatinib vs 11.2 months (95% CI: 8.8, 16.8) with control. Clinically meaningful improvements in ORR, DOR, and intracranial response were also observed with selpercatinib vs control. Time to CNS progression was longer with selpercatinib than control (cause-specific HR 0.26; 95% CI: 0.11, 0.59; p=0.0006). Adverse events observed with selpercatinib and the control arm were generally consistent with those previously reported.

Conclusions: Selpercatinib achieved a statistically significant and clinically meaningful improvement in PFS compared to chemotherapy + pembrolizumab in advanced *RET+* NSCLC. LIBRETTO-431 is the first randomized study to demonstrate superior PFS with a targeted therapy vs chemotherapy + a checkpoint inhibitor in a biomarker selected patient population. These data support comprehensive genomic testing at diagnosis and treatment with first-line selpercatinib in patients with advanced *RET+* NSCLC.

Clinical trial identification: NCT04194944.

Background: Amivantamab (ami) is an EGFR-MET bispecific antibody with immune cell—directing activity. Ami combined with carboplatin/pemetrexed (ami-chemo) demonstrated safety and antitumor activity in the phase 1 CHRYSALIS study. PAPILLON (NCT04538664) evaluated ami-chemo vs chemo in first-line *EGFR* Ex20ins advanced NSCLC.

Methods: Treatment-naïve pts were randomized 1:1 to ami-chemo or chemo. The primary endpoint was progression-free survival (PFS) by blinded independent central review. Secondary endpoints included objective response rate (ORR), PFS after first subsequent therapy (PFS2), overall survival (OS), and safety. Crossover to ami monotherapy was allowed for the chemo arm upon progression.

Results: Overall, 308 pts were randomized (ami-chemo, 153; chemo, 155); median age was 61/62 years, 56/60% female, 64/59% Asian, and 23/23% with history of brain metastases for ami-chemo/chemo, respectively. At median follow-up of 14.9 months, the median PFS was 11.4 months (95% CI, 9.8—13.7) for ami-chemo vs 6.7 months (95% CI, 5.6—7.3) for chemo (hazard ratio [HR], 0.40; 95% CI, 0.30—0.53; $P<0.001$). The 18-month PFS rate was 31% for ami-chemo vs 3% for chemo. PFS benefit of ami-chemo was consistent across subgroups. ORR was 73% (95% CI, 65—80) for ami-chemo vs 47% (95% CI, 39—56) for chemo (odds ratio, 2.97; 95% CI, 1.84—4.79; $P<0.001$). Median PFS2 was not estimable for ami-chemo vs 17.2 months for chemo (HR, 0.49; 95% CI, 0.32—0.76; $P=0.001$). Interim OS analysis (33% maturity) showed a favorable trend for ami-chemo vs chemo (HR, 0.67; 95% CI, 0.42—1.09; $P=0.106$), despite 66%, of chemo-randomized pts whose disease had progressed, receiving second-line ami. The most common TEAEs ($\geq$40%) for ami-chemo were neutropenia, paronychia, rash, anemia, infusion-related reactions, and hypoalbuminemia; no new safety signals. Discontinuation of ami due to treatment-related AEs was 7%.

Conclusions: Among pts with *EGFR* Ex20ins advanced NSCLC, ami-chemo achieved superior PFS vs chemo. Safety profile was consistent with that of each individual agent. PAPILLON establishes ami-chemo as the new first-line standard of care in *EGFR* Ex20ins advanced NSCLC.

Clinical trial identification: NCT04538664.

Background: Dato-DXd is a novel TROP2-directed antibody-drug conjugate under clinical investigation in multiple tumor types. This is the first report of TROPION-Lung01 (NCT04656652), a randomized, global, open-label, phase 3 study of Dato-DXd vs docetaxel (DTX) in pretreated patients (pts) with adv/met NSCLC with or without actionable genomic alterations (AGAs).

Methods: Pts were randomized 1:1 to Dato-DXd 6 mg/kg or DTX 75 mg/m^2 Q3W. Dual primary endpoints were progression-free survival (PFS; by blinded independent central review [BICR]) and overall survival (OS). Secondary endpoints included objective response rate (ORR), duration of response (DOR), and safety.

Results: 604 pts were included in the full analysis set (FAS); 43.1% had received $\geq$2 prior lines of systemic therapy. Median age was 64 y (range, 24-88). PFS was significantly improved with Dato-DXd over DTX in the FAS (HR, 0.75; 95% CI, 0.62-0.91; P=.004; median, 4.4 vs 3.7 mo). Confirmed ORRs were 26.4% (Dato-DXd) and 12.8% (DTX), with median DORs of 7.1 and 5.6 mo. Longer median PFS was observed in the prespecified non-squamous histology subgroup (NSQ; 5.6 vs 3.7 mo). Median treatment duration was 4.2 mo (range, 0.7-18.3 mo) for Dato-DXd and 2.8 mo (range, 0.7-18.9 mo) for DTX. The most common treatment-emergent adverse events (TEAEs) seen with Dato-DXd were stomatitis (49.2%, mostly grade [gr] 1/2) and nausea (37%). Adjudicated drug-related interstitial lung disease gr $\geq$3 occurred in 3.4% of pts with Dato-DXd vs 1.4% with DTX. Fewer drug-related gr $\geq$3 TEAEs and AEs leading to dose reduction or discontinuation were seen with Dato-DXd vs DTX.

Conclusions: PFS was significantly improved with Dato-DXd over DTX in pts with pretreated adv/met NSCLC. NSQ patients appeared to derive the most benefit. Dato-DXd was well tolerated, with a manageable safety profile. The trial is continuing until the final OS analysis. Drs. M-J. Ahn and E. Lisberg have equally contributed to the study.

Clinical trial identification: NCT04656652.

Background: Amivantamab (ami), an EGFR-MET bispecific antibody with immune cell-directing activity, plus lazertinib (laz), a CNS-penetrant, 3rd-generation EGFR TKI, have demonstrated antitumor activity in phase 1 studies. MARIPOSA (NCT04487080) evaluated ami+laz vs osimertinib (osi) in the first-line setting.

Methods: Patients (pts) with treatment-naïve, *EGFR*-mutated (Ex19del or L858R) locally advanced or metastatic NSCLC were randomized 2:2:1 to ami+laz, osi, or laz. Primary endpoint was progression-free survival (PFS) of ami+laz vs osi by blinded independent central review. Secondary endpoints included overall survival (OS), objective response rate (ORR), duration of response (DoR), PFS after first subsequent therapy (PFS2), and safety. CNS monitoring was required.

Results: 1074 pts were randomized (ami+laz, 429; osi, 429; laz, 216). Baseline characteristics were balanced; median age was 63 years, 62% were female, 59% Asian, and 41% had a history of brain metastases. At a median follow-up of 22.0 months (mo), ami+laz showed a 30% reduction in the risk for disease progression or death vs osi (HR, 0.70; 95% CI, 0.58–0.85; $P<0.001$), with median PFS of 23.7 mo (95% CI, 19.1–27.7) vs 16.6 mo (95% CI, 14.8–18.5), respectively. ORR was 86% (95% CI, 83–89) for ami+laz vs 85% (95% CI, 81–88) for osi, with median DoR among confirmed responders of 25.8 mo (95% CI, 20.1–NE) vs 16.8 mo (95% CI, 14.8–18.5), respectively. Early PFS2 data favored ami+laz vs osi (HR, 0.75; 95% CI, 0.58–0.98). At interim OS, there was a favorable trend for ami+laz over osi (HR, 0.80; 95% CI, 0.61 to 1.05; $P=0.1$). *EGFR*- and *MET*-related AEs were higher for ami+laz except diarrhea, which was higher for osi. VTEs were increased for ami+laz, mostly grade 1-2, occurred early, and effectively managed with anticoagulants. ILD rates were low and similar across arms.

Conclusions: Ami+laz was statistically superior to osi, providing clinically meaningful improvement in PFS, with higher DoR and a favorable OS trend. The safety profile of ami+laz was consistent with prior reports. MARIPOSA establishes ami+laz as a new first-line, standard of care for *EGFR*-mutated advanced NSCLC.

Clinical trial identification: NCT04487080.

Background: Amivantamab (ami), an EGFR-MET bispecific antibody with immune cell-directing activity, plus carboplatin-pemetrexed (chemo) with and without lazertinib (laz), a CNS-penetrant, 3rd-gen EGFR TKI, have demonstrated antitumor activity in phase 1 studies. MARIPOSA-2 (NCT04988295) evaluated these combinations in *EGFR*-mutated (Ex19del or L858R) advanced NSCLC after disease progression on osimertinib (osi).

Methods: Patients (pts) were randomized 2:2:1 to ami-laz-chemo, chemo, or ami-chemo. Dual primary endpoints were progression-free survival (PFS) of ami-chemo vs chemo and ami-laz-chemo vs chemo by blinded independent central review. Secondary endpoints included objective response rate (ORR), overall survival (OS), intracranial PFS, and safety. During the study, hematologic toxicities in the ami-laz-chemo arm necessitated a regimen change to start laz after carboplatin completion.

Results: In total, 657 pts were randomized (ami-chemo, 131; ami-laz-chemo, 263; chemo, 263). Baseline characteristics were balanced between arms, including the number of pts with a history of CNS metastases (44%–46%). At a median follow-up of 8.7 mo, PFS was significantly improved with ami-chemo (HR, 0.48; 95% CI, 0.36–0.64) and ami-laz-chemo (HR, 0.44; 95% CI, 0.35–0.56) vs chemo (median PFS, 6.3 and 8.3 vs 4.2 mo, respectively; $P<0.001$ for both). ORR was 64% for ami-chemo and 63% for ami-laz-chemo vs 36% for chemo ($P<0.001$ for both). Interim OS was immature; HR of 0.77 (95% CI, 0.49–1.21) for ami-chemo vs chemo and HR of 0.96 (95% CI, 0.67–1.35) for ami-laz-chemo vs chemo. Median intracranial PFS was 12.5 mo for ami-chemo and 12.8 mo for ami-laz-chemo vs 8.3 mo for chemo (HR, 0.55 and 0.58; $P=0.001$ and $P<0.001$, respectively). Predominant AEs in the ami-containing arms were hematologic, *EGFR*, and *MET*-related. Ami-chemo had lower rates of hematologic AEs than ami-laz-chemo. The impact of modifying the ami-laz-chemo regimen on safety and efficacy requires longer follow-up.

Conclusions: Ami-chemo and ami-laz-chemo improved PFS, ORR, and intracranial PFS vs chemo in *EGFR*-mutated advanced NSCLC after progression on osi and may represent a new standard of care.

Clinical trial identification: NCT04988295.

Background: Checkpoint inhibitor (CPI) therapy can lead to antitumor responses and prolonged survival in NSCLC, but most patients (pts) who initially benefit acquire CPI resistance with disease progression. Sitravatinib (sitra) is a receptor tyrosine kinase inhibitor that can resensitize tumors to CPI by shifting the tumor microenvironment towards a less immunosuppressive state and, combined with nivolumab (nivo), may overcome acquired CPI resistance and improve outcomes vs chemotherapy.

Methods: In the Phase 3 SAPPHIRE study, pts with advanced non-squamous (adv nsq) NSCLC (excluding EGFR, ROS1, or ALK alterations) who initially benefited from CPI with/after platinum-based chemotherapy (≥4 months [mos] on CPI without progression) with subsequent disease progression were randomized 1:1 to sitra (100 mg QD orally) plus nivo (240 mg Q2W or 480 mg Q4W IV) [sitra/nivo] or docetaxel monotherapy (doce; 75 mg/m^2 Q3W IV). The primary endpoint was overall survival (OS). Secondary endpoints included objective response rate (ORR), clinical benefit rate (CBR), progression-free survival (PFS); all by blinded independent central review, and safety.

Results: As of 20 March 2023 (median follow-up, 17.1 mos), 577 pts received sitra/nivo (n=284) or doce (n=293). Median OS was not significantly improved by sitra/nivo vs doce (12.2 vs 10.6 mos; HR 0.86 [95% CI, 0.70−1.05]; p=0.144). HR for PFS was 1.08 (95% CI, 0.89−1.32; p=0.452); median PFS for sitra/nivo vs doce was 4.4 vs 5.4 mos. ORR was 15.6% with sitra/nivo vs 17.2% with doce (p=0.597); CBR was 75.5% (sitra/nivo) vs 64.5% (doce; p=0.004). Most common (≥25%) any grade treatment-related adverse events with sitra/nivo were diarrhea (56.2% [7.5% gr ≥3]), nausea (31.3% [1.4%]), decreased appetite (28.5% [1.8%]), hypothyroidism (28.1% [0.4%]), and fatigue (26.3% [6.8%]); and diarrhea (35.5% [3.3%]), fatigue (35.5% [8.4%]), nausea (32.2% [2.6%]), decreased neutrophil count (31.9% [29.3%]), alopecia (30.8% [0.4%]), and neutropenia (26.0% [23.1%]) with doce.

Conclusions: The primary endpoint of OS was not met in pts with previously treated adv nsq NSCLC. Safety profiles for sitra/nivo and doce were consistent with prior reports for each regimen.

Clinical trial identification: NCT03906071.

Background: The Phase II PERLA trial (NCT04581824) was the first global randomized, double-blind, head-to-head study of two programmed death (PD)-1 inhibitors in NSCLC. In the primary analysis, dostar + CT met its primary endpoint of equivalence, with a favorable numerical trend in overall response rate (ORR) and progression-free survival compared to pembro + CT [1]. Here we report overall survival (OS) analyses from PERLA.

Methods: Patients (pts) with metastatic NSCLC, documented PD-L1 status, absence of EGFR, ALK or other actionable genomic aberrations determined locally, ECOG 0—1, and no prior systemic treatment were randomised 1:1 to dostar 500 mg or pembro 200 mg Q3W IV up to 35 cycles, combined with CT (4 cycles pemetrexed [pem; 500 mg/m^2] + carboplatin [AUC 5 mg/mL/min] or cisplatin [75 mg/m^2], followed by pem up to 35 cycles) Q3W IV. The primary endpoint was ORR by blinded independent central review (BICR). OS (secondary endpoint) and duration of response (DoR) by BICR (exploratory endpoint) were determined by Kaplan-Meier method, 95% confidence intervals (CIs) by Brookmeyer-Crowley method and hazard ratio by stratified Cox proportional hazard model.

Results: At data cut-off on 07 July 2023, 121 and 122 pts in the dostar + CT and pembro + CT arms respectively, were randomised and treated. OS maturity was 55% (134/243). Median OS was 19.4 mo (95% CI 14.5, NR) in the dostar + CT arm vs 15.9 mo (95% CI 11.6, 19.3) in the pembro + CT arm (Table), after median follow-up (IQR) of 20.7 (17.3, 24.0) and 21.6 (18.3, 24.1) mo respectively, with a similar trend across PD-L1 subgroups. ORR and DoR are shown in the table. No new safety signals were reported.

Conclusions: In this follow-up analysis, dostar + CT continues to demonstrate strong clinical efficacy with no unexpected safety signals. In addition, a numerical trend in OS favoring dostar + CT vs pembro + CT was observed. 1. Peters, S *et al. IOTECH* 2022;16(S1):100162 Funding:GSK (213403).

Background: Adagrasib (ada) is an irreversible $KRAS^{G12C}$ inhibitor selected for favorable properties, including long half-life (23 hrs), dose-dependent PK, and CNS penetration. Optimized noncovalent binding affinity and minimized cysteine reactivity associated with ada are hypothesized to limit off-target effects in the liver and other organ sites. Preliminary ada plus pembrolizumab (pembro) data showed a manageable safety profile and encouraging clinical activity. We report updated efficacy and safety in more patients (pts) treated with ada plus pembro in KRYSTAL-7 (NCT04613596).

Methods: In the phase 2 KRYSTAL-7 study, pts with treatment-naïve $KRAS^{G12C}$-mutated advanced NSCLC received concurrent ada 400 mg orally BID plus pembro 200 mg intravenously Q3W. Study objectives included efficacy (investigator-assessed objective response rate [ORR], duration of response [DOR], progression-free survival [PFS], and overall survival), and safety.

Results: As of 19 June 2023, 148 pts had received ada plus pembro (median follow-up 8.7 months). Median age was 67 years, 48% were female, 39%/61% were ECOG PS 0/1. In pts with PD-L1 ≥50% (median follow-up 10.1 months), ORR was 63% (32/51 pts), disease control rate was 84%. Median DOR was not reached (NR; 95% CI 12.6—not estimable [NE]); median PFS was NR (95% CI 8.2—NE). In all pts, treatment-related adverse events (TRAEs) of any grade (gr) occurred in 94% (139/148) of pts; 55% gr3, 9% gr4, 1% gr5. TRAEs led to both ada and pembro discontinuation in 4% of pts (6% discontinued ada alone, 11% discontinued pembro alone). No pt discontinued both drugs due to ALT/AST increase or hepatic TRAEs; 1 pt discontinued ada and 3 pts discontinued pembro due to liver transaminase elevation. Additional efficacy and safety analyses will be presented.

Conclusions: After longer follow-up, concurrent ada plus pembro continued to have encouraging preliminary efficacy in pts with PD-L1 ≥50% and a manageable safety profile. These findings support initiation of a phase 3 trial evaluating concurrent ada plus pembro vs pembro for treatment-naïve pts with $KRAS^{G12C}$-mutated NSCLC and PD-L1 ≥50% (NCT04613596).

Clinical trial identification: NCT04613596.

Background: *EGFR* mutations are diverse and include major uncommon and compound mutations. There is no conclusion on whether EGFR-TKI is the optimal treatment for these diverse mutations. Herein we report results on the first phase III ACHILLES trial, where treatment with afatinib and chemotherapy were compared in sensitizing uncommon *EGFR* mutant non-small cell lung cancer (NSCLC).

Methods: In this open-label phase III study, treatment-naïve patients with sensitizing uncommon *EGFR* mutant NSCLC were randomized 2:1 to oral afatinib (30 or 40 mg daily) or the combination of platinum (cisplatin 75 mg/m^2 or carboplatin AUC 5 or 6) and pemetrexed (500 mg/m^2), followed by pemetrexed maintenance therapy every three weeks. The primary endpoint was progression-free survival (PFS) per RECIST 1.1. The sample size (n = 106) was based on 75% power to detect a hazard ratio of 0.6 in PFS with $\alpha = 0.05$, which was preplanned upon completion of enrollment. The analysis was adjusted for multiple testing with the Lan-DeMets alpha-spending function, using the O'Brien and Fleming method.

Results: A total of 109 patients were enrolled between Feb 2019 and Feb 2023. The median follow-up time was 12.5 months. The patient's backgrounds were well-balanced. The median PFS was significantly longer with afatinib treatment than with chemotherapy (10.6 vs. 5.7 months; hazard ratio for death or disease progression, 0.422; 95% confidence interval, 0.256−0.694; p = 0.0007). The data and safety monitoring committee recommended an early study termination. The objective response was similar in both groups: 61.4% with afatinib treatment and 47.1% with chemotherapy (p = 0.2069). The rate of grade ≥3 treatment resulting in adverse events in both groups was 43.8% and 37.1%, respectively. The most common adverse events in the afatinib arm were diarrhea, rash, and paronychia. One treatment related death due to pneumonitis was observed in the afatinib arm.

Conclusions: Afatinib is superior to platinum doublet chemotherapy as an initial treatment for uncommon or compound *EGFR* mutation-positive advanced NSCLC.

Clinical trial identification: jRCTs 031180175.

Background: In the treatment ofnon-small cell lung cancer (NSCLC) with a driver mutation, the role of anti-PD-(L)1 antibody following tyrosine kinase inhibitor (TKI) remains unclear. This randomized, open-label, multicenter, phase 3 study evaluates the efficacy of atezolizumab plus bevacizumab and chemotherapy in *EGFR* or *ALK*-mutated NSCLC that progressed prior to TKI therapy.

Methods: We compared the clinical efficacy of atezolizumab plus bevacizumab/paclitaxel/carboplatin (ABCP arm) followed by maintenance therapy with

atezolizumab plus bevacizumab with pemetrexed plus carboplatin or cisplatin (PC arm) followed by pemetrexed maintenance. The primary endpoint was progression-free survival (PFS).

Results: A total of 228 patients with activating *EGFR* mutation (n=215) or *ALK* translocation (n=13) were enrolled from 16 sites in the Republic of Korea and randomized at 2:1 ratio of either ABCP (n=154) or PC arm (n=74). The median follow-up duration was 26.1 months (95% CI 24.7-28.2). Objective response rates were higher in the ABCP arm than in the PC arm (69.5% vs 41.9%, P <0.001). Median PFS was significantly longer in the ABCP than in the PC arm (8.48 months vs. 5.62 months, hazard ratio [HR] 0.62 [0.45-0.86], P=0.004). PFS benefit increased as PD-L1 expression increased, with HR of 0.47, 0.41, and 0.24 for PD-L1 ≥1%, ≥10% and ≥50%, respectively. Overall survival was similar between ABCP and PC (20.63 months vs. 20.27 months, HR 1.01 [0.69-1.46], P=0.975). The safety profile of the ABCP arm was comparable to that previously reported, with no additional safety signals.

Conclusions: This study is the first randomized phase 3 study to demonstrate the clinical benefit of anti-PD-L1 antibody in combination with bevacizumab and chemotherapy in *EGFR* or *ALK* mutated NSCLC who have progressed on relevant targeted therapy.

Clinical trial identification: NCT03991403.

Background: In FLAURA2 (NCT04035486), osi, a 3rd gen CNS-active EGFR-TKI, combined with platinum-pemetrexed (osi-CTx) showed a statistically significant improvement vs osi-monotherapy (osi-mono) in PFS per investigator (HR [95% CI]: 0.62 [0.49−0.79], p<0.001) with a manageable and tolerable safety profile. Addition of CTx did not affect osi exposure. 76% of pts completed 4 CTx cycles; median duration of pemetrexed exposure was 8.3 mos. 40% of FLAURA2 pts had baseline CNS metastases (mets); we report exploratory analyses of CNS efficacy by CNS blinded independent central review (BICR; conducted by neuroradiologist). Updated safety data will be reported.

Methods: Eligible pts (≥18 y [Japan: ≥20] with EGFRm advanced NSCLC, no prior tx for advanced NSCLC; asymptomatic CNS mets not requiring steroids or stable >2 wks after definitive tx/steroids were allowed) were randomised 1:1 to 1L osi-CTx or osi-mono until progression/discontinuation. Brain imaging (MRI preferred) was performed in all pts at baseline + progression, and at scheduled assessments until progression for pts with baseline CNS mets. CNS endpoints (modified RECIST1.1) included CNS PFS, CNS response and CNS DoR by CNS BICR. Safety was assessed by CTCAE v5. Data cutoff: 3 Apr 2023.

Results: Of 557 pts randomised, 118/279 (osi-CTx) and 104/278 (osi-mono) were included in the CNS BICR full analysis set (cFAS; pts with ≥1 measurable and/or non-measurable lesion); 40/118 (osi-CTx) and 38/104 (osi-mono) were included in the CNS evaluable for response set (cEFR; pts with ≥1 measurable lesion). Demographics were balanced across tx arms. CNS efficacy is shown (Table). Safety profile was similar in the cFAS and overall population. The safety and tolerability profile during the course of tx will be described.

Conclusions: In FLAURA2, pts with CNS mets in the osi-CTx arm had a clinically meaningful reduction in the risk of CNS progression, with high CNS ORR (and high CR) and durable responses, with a manageable and tolerable safety profile.

Clinical trial identification: NCT04035486.

Background: The standard first-line treatment for locally advanced or metastatic EGFR-mutated NSCLC patients (pts) is the third-generation EGFR-TKI alone, which has limitations. Combining EGFR-TKI with a small molecule anti-angiogenic agent may be a potential solution due to synergistic effects. The ATTENTION study aims to evaluate the efficacy and safety of aumolertinib plus apatinib (AUM + APA) versus aumolertinib (AUM) alone as the first-line therapy for EGFR-mutated NSCLC.

Methods: Eligible pts were aged 18-75 years old, stage IIIB or IV NSCLC, with EGFR 19del or 21L858R mutation or EGFR uncommon mutations, ECOG PS of 0 or 1, measurable lesion according to RECIST v1.1. We randomly assigned eligible pts in a 1:1 ratio to receive oral aumolertinib (110 mg PO QD) or adding apatinib (250 mg PO QD) until assessed progressive disease (PD). The primary endpoint was progression-free survival (PFS). Secondary endpoints included objective response rate (ORR), disease control rate (DCR), intracranial ORR (iORR), intracranial DCR (iDCR), overall survival (OS) and safety.

Results: From Jun. 2021 to Nov. 2022, a total of 104 pts were enrolled, 98 included in the efficacy analysis set. Of these, 48 pts received AUM + APA, while 50 pts received AUM. As of Sep. 12, 2023, the overall ORR was 72.9% and 64%, DCR was 100% and 94% in AUM + APA and AUM arms, respectively. In EGFR sensitizing mutation (19 del or L858R) subgroup, ORR was 75% and 68% in AUM + APA and AUM arms, respectively. In brain and liver metastasis subgroup, ORR were 100% and 60%, 60% and 33%, iORR was 82% and 63% in AUM + APA and AUM arms. PFS has beneficial trend in AUM + APA arm. The most common treatment-emergent adverse events (TEAEs) in AUM + APA and AUM arms were diarrhea (31% vs 12%), rash (29% vs 10%), proteinuria (27% vs 6%), platelet count decreased (25% vs 4%), hypertension (25% vs 6%), creatine kinase increase (23% vs 16%), respectively.

Conclusions: The combination of AUM + APA may provide a more effective and well tolerable treatment option for the first line treatment in EGFR mutated NSCLC patients.

Background: Dual inhibition of the EGFR/VEGF pathways has demonstrated superior efficacy with 1st generation EGFR tyrosine kinase inhibitor (TKI) in patients with non small cell lung cancer (NSCLC) harboring EGFR mutations. This study aims to evaluate the efficacy and safety of combining osimertinib (Osi), a 3rd generation TKI considered the standard of care, with ramucirumab (Ram).

Methods: Previously untreated patients with advanced NSCLC and EGFR mutations were randomized to receive Osi daily with or without Ram every 2 weeks. Eligibility included asymptomatic and/or treated brain metastases. Stratification was based on gender and mutation type (exon 19 del, L858R). The primary endpoint was progression free survival (PFS) assessed by central radiologic review.

Results: Between November 2018 and April 2020, 122 patients (Osi+Ram arm: 59, Osi arm: 63) were enrolled. With a median follow up of 36.0 months (m), median PFS was 20.0 m for Osi+Ram arm and 24.0 m for Osi arm, resulting in a hazard ratio of 1.054 (95% CI 0.674-1.648, $p = 0.82$). The overall response rate was 77.2% and 79.3%, with a median duration of response of 24.7 m and 25.1 m in the Osi+Ram and Osi arms respectively. Notable grade 3 or higher adverse events ($\geq$10%) included CK elevation (13%) in Osi arm, neutropenia (10%) and hypertension (17%) in Osi+Ram arm. Pneumonitis of any grade occurred in 9% and 16% of Osi+Ram and Osi arms. Median treatment durations for Osi and Ram were 18.8 (0.5-49.7) and 4.6 (0.5-40.7) m in the Osi+Ram arm, and 17.4 m in the Osi arm. The treatment period of Ram was shorter compared to previous studies. In a post hoc analysis, PFS favored the Osi+Ram combination among patients with brain metastasis (n=34) with a hazard ratio of 0.655 (95% CI 0.296-1.451).

Conclusions: While both treatment arms demonstrated long-term effects with acceptable toxicity, this study did not reveal an advantage of the Osi+Ram combination over Osi monotherapy in improving PFS. It's noteworthy that conducted period during the COVID-19 pandemic, and the suboptimal administration of Ram may have influenced the outcome. jRCT2080224085

Lee Moffitt Cancer Center & Research Institute - Magnolia Campus, Tampa, FL, USA

Background: Osimertinib (osi) is the current first-line therapy for patients (pts) with metastatic EGFR-mutant NSCLC. Combination of anti-VEGF with EGFR inhibitors has a potential to prolong progression-free survival (PFS).

Methods: The RAMOSE trial (NCT03909334, HCRN LUN-18-335) is a randomized, open-label phase 2 study comparing osi 80mg PO daily + ramucirumab 10 mg/kg IV q3 weeks (Arm A) to osi alone (Arm B) for initial treatment of metastatic EGFR-mutant NSCLC with 2:1 randomization. The primary endpoint is PFS by investigators, secondary endpoints include best response rates (BRR), disease control rate (DCR), overall survival (OS), and safety. The stratification criteria for randomization were EGFR mutation type and presence of CNS metastasis.

Results: At data cut-off Aug 29, 2023, 160 pts consented, 147 pts received treatment, and 139 pts had at least one efficacy scan. The median follow up was 16.6 months (range 1.4-46.1). Among the 139 pts, 57 PFS events (37 progressions and 20 progressions followed by death) were observed, 32 in A and 25 in B. The median PFS was 24.8 (A) vs 15.6 (B) months (HR=0.55; 95%CI: 0.32-0.93; Log Rank p=0.023), 12-mon PFS rate was 76.7% (A) vs. 61.9% (B, p=0.026). BRRs and DCRs had no difference. For high risk gorup of 43 (31%) pts with L858R, PFS was 24.8 (A) vs 18.4 months (B, p=0.388); for 64 (46%) pts with CNS metastasis, PFS was 17.9 (A) vs 13.8 months (B, p=0.225). Any-grade (G) AEs occurred in 93% (A) and 87% (B) of pts. There were no G5 treatment-related AE (TRAE), one G4 TRAE (hyponatremia, A), 46% (A) vs. 35% (B) G3 TRAEs, including G3 hypertension at 28% (A) vs 7% (B) and decreased neutrophils at 21% (A) vs 23% (B). AE-related discontinuation was observed in13 pts (9.7% in A, 8.7% in B).

Table: LBA71

		Arm A (n=93)	Arm B (n=46)
Best response: n, %	CR	1 (1.1)	1 (2.2)
	PR	60 (64.5)	31 (67.4)
	SD	29 (31.2)	12 (26.1)
	PD	3 (3.2)	2 (4.4)
Overall response rate (ORR: n, %)		71 (76.3) χ^2 p=0.59	37 (80.4)
Disease control rate (DCR: n, %)		90 (96.8) χ^2 p=0.74	44 (95.7)
Median PFS (months)		24.8; 95% CI (17.9, NA) HR= 0.55; 95%CI (0.32, 0.93); p=0.023	15.6; 95% CI (11.7, 22.8)
12-mon PFS rate (%)		76.7 p=0.026	61.9

Conclusions: Ramucirumab + osi significantly prolonged PFS compared to osi alone in *EGFR*-mutant NSCLC pts. The RAMOSE seems to be as efficacious as FLAURA2. Safety profile was in line with known safety of each drug.

Clinical trial identification: NCT03909334.

Background: Patients with metastatic non−small-cell lung cancer (NSCLC) can receive anti PD-L1/PD-1 immunotherapy as a standard of care. However, prediction of response is challenging with existing biomarkers. Retrospective analyses have identified the clonality of mutations and neoantigens as potential biomarkers. However, the impact of intratumour heterogeneity (ITH) on immunotherapy response in patients with metastatic NSCLC has not been prospectively explored. The DARWIN II trial is a phase II, multicentre molecularly stratified trial for patients with NSCLC to study the effect of ITH on response to treatment. The study is unique as patients were recruited from the TRACERx Lung Cancer observational cohort study, following relapse with metastatic disease.

Methods: A total of 65 patients from the TRACERx study, with spatially separated multi-region sampling of resected early lung cancer, who relapsed with metastatic disease were enrolled between November 2016 and March 2023 and received immunotherapy. Patients were recruited with any PDL1 tumour proportion score. Patients received atezolizumab or atezolizumab with chemotherapy. Multi-omic analysis, including deep (∼500x) whole exome, RNA, RRBS, and TCR sequencing of multi-region primary tumour samples and relapse biopsies was performed on 355 samples. All samples were processed on a uniform bioinformatic analysis pipeline and results corrected for tumour purity variation.

Results: The median PFS and OS were 4.5 and 10.0 months respectively. The proportion of patients with durable clinical benefit was 37.5 percent. A high clonal mutation burden was associated with a statistically significant improvement in response (OR = 5.7, 95% CI [1.1-45.0], p value = 0.04) whereas high total tumour mutation burden (>10 mut/Mb) was not. Additionally, we identified several associations between novel molecular features and immunotherapy response, including ITH of the transcriptome and DNA hyper-/hypo-methylation frequency.

Conclusions: This is the first trial to demonstrate prospectively that clonal mutations are associated with improved patient outcome and identify novel molecular features, related to ITH, as predictors of immunotherapy response in patients with NSCLC.

Clinical trial identification: NCT02314481.

Background: The global, Phase 3, randomised, double-blind, placebo (P)-controlled MATTERHORN study (NCT04592913) assesses perioperative durvalumab (D) with FLOT in participants (pts) with resectable GC/GEJC. Results of a pre-planned interim analysis (IA) are reported.

Methods: Pts with resectable (>T2 N0-3 M0/T0-4 N1-3 M0) GC/GEJC were randomised 1:1 to D 1500 mg or P every 4 weeks (Q4W) on Day 1 plus FLOT Q2W on Days 1 and 15 for 4 cycles (2 doses of D or P and 4 doses of FLOT pre- and post-operative),

followed by D 1500 mg or P on Day 1 Q4W for 10 further cycles. IA was conducted after all randomised pts underwent or were precluded from surgery. Superiority of pCR rate (α=0.1% [2-sided]) by central review (Modified Ryan) was assessed. Surgical and safety outcomes were also assessed.

Results: There were 474 pts randomised to each treatment arm. Baseline characteristics were balanced between arms; 19% of pts in each enrolled in Asia. The majority of pts had GC (68%), cT3 (66%; cT4, 25%) and cLN+ (70%). A statistically significant improvement in pCR was observed with addition of D to FLOT versus P (19% vs 7%; Δ12%; odds ratio [OR], 3.08; p<0.00001; Table). Combined pCR/near-complete pathological response (pnCR) rate was 27% with D vs 14% with P. Surgery rate and R0 resection rate (in pts who underwent surgery) were similar with D (87% and 86%, respectively) vs P (84% and 86%, respectively). Downstaging favoured D vs P (pT0, 21% vs 10%; pN0, 47% vs 33%; by central review). Median D and P exposure was similar. Adverse event rates were similar between arms (Table).

Table: LBA73

	D + FLOT (n=474)	P + FLOT (n=474)
pCR		
n; % (95% CI)	91; 19 (15.8–23.0)	34; 7 (5.0–9.9)
OR (95% CI)	3.08 (2.03–4.67); p<0.00001	
pCR/pnCR		
n; % (95% CI)	127; 27 (22.9–31.0)	68; 14 (11.3–17.8)

R0 resection*		
n; % (95% CI)	369; 86 (82.2–89.0)	362; 86 (82.1–89.0)
OR (95% CI)	1.00 (0.68–1.48)	
AE†, n (%)	470 (99)	463 (99)
Grade 3/4	326 (69)	317 (68)
TRAE	452 (95)	441 (94)
Grade 3/4 TRAE	275 (58)	264 (56)

*In pts with surgery: D + FLOT, n=430, P + FLOT, n=422. †In safety analysis set: D + FLOT, n=475, P + FLOT, n=469. TRAE, treatment-related AE.

Conclusions: The addition of D to perioperative FLOT therapy demonstrated a clinically meaningful and statistically significant improvement in pCR in resectable GC/GEJC, with a tolerable safety profile. The MATTERHORN study is ongoing for the primary endpoint of event-free survival.

Clinical trial identification: NCT04592913.

Background: The phase 3 KEYNOTE-585 study (NCT03221426) evaluated neo-adjuvant/adjuvant pembrolizumab (pembro) or placebo (pbo) + chemotherapy (chemo) followed by adjuvant pembro vs pbo in locally-advanced, resectable gastric or gastroesophageal junction (G/GEJ) cancer. A separate cohort evaluated pembro + FLOT. We report results of the pre-specified third interim analysis (IA3).

Methods: Patients (pts) with untreated, locally-advanced, resectable G/GEJ cancer were randomized 1:1 to neoadjuvant pembro 200 mg IV Q3W or pbo + chemo (cisplatin + capecitabine or cisplatin + 5-FU) for 3 cycles. After surgery, pts received adjuvant pembro or pbo + chemo Q3W for 3 cycles, then adjuvant pembro or pbo Q3W for 11 cycles (main cohort). In the FLOT cohort, pts were randomized 1:1 to pembro + docetaxel, oxaliplatin, leucovorin, and 5-FU, Q2W. Primary end points were pathCR rate (BICR), EFS (RECIST 1.1, by investigator), OS (main cohort), and safety (FLOT cohort).

Results: 804 pts were randomized to the main (402 pembro; 402 pbo) and 1007 to main + FLOT ([502 pembro; 505 pbo) cohorts. Median follow-up was 47.7 mo and 46.3 mo, respectively. In the main cohort, pathCR significantly improved with pembro + chemo (12.9% [95% CI, 9.8-16.6]) vs pbo + chemo (2.0 [95% CI, 0.9-3.9]); Δ (10.9% [95% CI, 7.5-14.8]; P<0.00001). EFS was longer with pembro vs pbo (median 44.4 vs 25.3 mo; HR 0.81; 95% CI, 0.67-0.99; P=0.0198), but was not significant. OS continues to final analysis. Median OS was 60.7 vs 58.0 mo (HR 0.90; 95% CI, 0.73-1.12) at IA3. Grade ≥3 drug-related AE rates were 65% with pembro + chemo and 63% with pbo + chemo. Outcomes in the main + FLOT cohort are in the Table.

Conclusions: Neoadjuvant/adjuvant pembro + chemo followed by adjuvant pembro, significantly improved pathCR rate with no significant improvement in EFS vs placebo + chemo in pts with untreated, locally-advanced resectable G/GEJ cancer.

Clinical trial identification: NCT03221426.

Background: One-third of patients with oesophageal cancer has a pathologically complete response after neoadjuvant chemoradiotherapy (nCRT) plus oesophagectomy. Active surveillance may be an alternative for patients with clinically complete response (CCR).

Table: LBA74 Outcomes in main + FLOT cohort

Efficacy	Pembro + chemo N = 502	Pbo + chemo N = 505	Treatment difference (95% CI)
Path CR[a], %	13.0 (10.2-16.3)	2.4 (1.3-4.2)	10.6% (7.4-14.0) P<0.0001
Median EFS, mo (95% CI)	45.8 (35.9-NR)	25.7 (21.9-33.9)	HR 0.81 (0.68-0.97) P=0.011
Median OS, mo (95% CI)	60.7 (51.5-NR)	NR (45.7-NR)	HR 0.93 (0.76-1.12)
Safety	Pembro + chemo N = 498	Pbo + chemo N = 503	NA
Grade ≥ 3 drug-related AEs	67%	63%	NA

[a]In first 987 pts randomized; HR, hazard ratio; NA, not applicable; NR, not reached

Methods: A noninferiority stepped-wedge cluster randomised trial was performed. Patients with CCR (*i.e.* no residual disease 6 and 12 weeks after nCRT) underwent active surveillance (surgery only when locoregional regrowth was detected) or standard surgery. Primary endpoint was overall survival (OS) from day of CCR. Noninferiority was defined as Hazard Ratio (HR) <1.77 for mortality in active surveillance after two years. Secondary endpoints were operative outcomes, disease-free survival (DFS), distant dissemination rate and quality of life (HRQOL, EORTC QLQ-C30).

Results: Some 198 patients underwent active surveillance and 111 patients underwent standard surgery. Median follow-up was 34 months in active surveillance and 50 months in standard surgery. OS in active surveillance was noninferior to standard surgery (HR 0.88, 95% upper boundary 1.40, p = 0.007). During active surveillance, 69 patients (35%) maintained CCR, 96 patients (48%) developed locoregional regrowths, and 33 patients (17%) developed distant metastases. R1 rate was 2% in both groups and postoperative 90-day mortality was 4% (active surveillance) versus 5% (standard surgery). Median DFS for active surveillance was 35 (95% CI 31 − 41) versus 49 months (95% CI 38 − NA) for standard surgery (HR 1.35, 95% CI 0.89 − 2.03, p = 0.15). At 30 months after nCRT, 43% of patients with active surveillance versus 34% with standard surgery developed distant metastases (OR 1.45, 95% CI 0.85 − 2.48, p = 0.18). HRQOL was statistically significantly better at six (p = 0.002) and nine months (p = 0.007) for active surveillance.

Conclusions: After a follow-up of two years, patients undergoing active surveillance had noninferior OS and improved short-term HRQOL compared to standard surgery. Postponed esophagectomy for locoregional regrowth was safe. Extended follow-up is required to assess long-term efficacy of active surveillance.

Clinical trial identification: NTR6803 8-11-2017.

Background: Ramucirumab is a monoclonal antibody that targets the vascular endothelial growth factor receptor 2 (VEGFR-2) and has been shown to improve survival of patients with advanced gastric cancer. It has been reported that sustained VEGF blockade beyond progression had a survival benefit in various cancers.

Methods: This is a multicenter, open-label, randomized phase III study that enrolled patients with unresectable gastric cancer who had received previously ramucirumab containing chemotherapy. Patients were randomly allocated to either irinotecan plus ramucirumab arm or irinotecan alone arm in a 1:1 ratio. Irinotecan was administered at a dose of 150 mg/m^2, every two weeks, in both arms, and ramucirumab at a dose of 8 mg/kg was added biweekly. The primary endpoint was overall survival (OS), expecting a hazard ratio (HR) of 0.77 (a power of 80% with significance level of one-sided 0.05) for full analysis set (FAS). Secondary endpoints include progression-free survival (PFS), overall response rate (ORR), and safety.

Results: From February 2019 to August 2022, 402 patients from 121 institutions participating 9 Japanese clinical trial groups were recruited. As of the data cutoff, 362 events for OS were observed. Median OS in the combination of irinotecan plus ramucirumab and irinotecan alone were 9.4 months and 8.5 months (adjusted HR 0.909, 95% confidence interval [CI] 0.738 − 1.119; p=0.369). Median PFS were 3.8 months and 2.8 months (HR 0.722, 95% CI 0.590 - 0.884; p=0.001) and ORR were 22.1% (33/149) and 15.0% (25/167), respectively. The safety profile was consistent with the known profiles of both irinotecan and ramucirumab, and there were no new safety findings.

Conclusions: This is the first report of the phase III trial to evaluate sustained anti-angiogenic therapy in advanced gastric cancer. In this study, although the addition of ramucirumab to irinotecan after disease progression of ramucirumab improved PFS and ORR with manageable toxicity, the primary endpoint of OS was not met.

Clinical trial identification: This trial was registered at the University Hospital Medical Information Network (UMIN) Clinical Trials Registry as UMIN000023065 from JUL. 13, 2016, and changed to the Japan Registry of Clinical Trials (jRCT) as jRCTs051180187 from Mar. 26, 2019, in accordance with the change of the regulation for clinical research in Japan.

Background: The perioperative FLOT triplet chemotherapy regimen is the standard of care for localized gastric and GEJ adenocarcinomas. We explored the superiority of a modified FLOT (mFLOT=TFOX regimen) vs FOLFOX in patients with advanced disease.

Methods: The GASTFOX phase III study compared FOLFOX versus a mFLOT/TFOX regimen (FOLFOX + docetaxel 50 mg/m^2, q2w) in the first-line setting of patients with HER2-negative, LA unresectable or metastatic gastric or GEJ adenocarcinoma, with measurable disease, an ECOG PS 0 or 1, adequate organ function, and docetaxel naïve. The primary endpoint was PFS. Secondary endpoints included OS, ORR, safety, and quality of life (QoL). For survival outcomes, HR and 95% CI were estimated by a Cox proportional hazard (PH) model. In case of non-PH, the restricted mean survival time (RMST) was used to evaluate the treatment effect.

Results: Between 12/2016 and 12/2022, 507 patients were randomized 1:1 to FOLFOX (n=253) or mFLOT/TFOX (n=254). Baseline characteristics were similar between arms (overall: male, 78%; median age, 64; PS 1, 57%; GEJ, 56%; previous (neo)adjuvant treatment, 6%). Median follow-up (F/U) was 42.8 months (mo). As compared to FOLFOX, PFS was significantly improved in patients treated with mFLOT/TFOX (median: 7.59 vs 5.98 mo, non-PH / RMST at 12 mo F/U: 7.5 vs 6.6 mo, p=0.007). OS was also significantly improved by using mFLOT/TFOX (median: 15.08 vs 12.65 mo; HR 0.82 [0.68-0.99], p=0.048). ORR was also in favor of mFLOT/TFOX (66.0 vs 56.7%, p=0.038). Most common grade $\geq$3 TRAE were neuropathy (31.7 vs 19.7%), diarrhea (14.5 vs 6.4%) and neutropenia (26.1 vs 18.1%) respectively for mFLOT/TFOX and FOLFOX. Median time to deterioration in QoL ($>$ 5 points loss in EORTC QLQC30) was longer in patients treated with mFLOT/TFOX (17.0 vs 13.7 mo; HR 0.75 [0.59-0.94], p=0.015).

Conclusions: The addition of docetaxel to FOLFOX significantly improved PFS, OS and ORR in first-line treatment of advanced HER2 negative gastric or GEJ adenocarcinomas. mFLOT/TFOX can be considered as a new therapeutic option for patients eligible for a triplet regimen.

Clinical trial identification: NCT03006432.

Background: The RESOLVE study demonstrated a disease-free survival (DFS) benefit from perioperative SOX compared to adjuvant CapOx in patients with gastric or gastro-oesophageal junction (G/GOJ) adenocarcinoma who underwent D2 gastrectomy. Here, we aim to update on the 5-year overall survival (5yOS%) results.

Methods: The phase III, open-label, randomized controlled RESOLVE study (NCT01534546) enrolled patients with stage cT4aN+M0 or cT4bNanyM0 G/GOJ adenocarcinoma. Patients were 1:1:1 randomly assigned to adjuvant CapOx, adjuvant SOX, or perioperative SOX and underwent standard gastrectomy with D2 lymphadenectomy. The adjuvant CapOx group received 8 cycles of oxaliplatin (130 mg/m^2, d1) with capecitabine (1000 mg/m^2, bid, d1-14). The adjuvant SOX group received oxaliplatin and oral S-1 at a dose depending on body surface area (40-60 mg bid, d1-14). The perioperative SOX group received 3 cycles of preoperative SOX plus 5 cycles of postoperative SOX followed by 3 cycles of S-1 monotherapy. The primary endpoint was 3-year DFS, and second endpoints included 5yOS% and safety.

Results: Between 08/2012 and 02/2017, 1022 patients were included in mITT population and analyzed. With a median follow up time of 62.8 months, 495 recurrences and 416 deaths were observed by 07/04/2022. Perioperative SOX improved 5yOS% compared with adjuvant CapOx (60.0% *vs.* 52.1%; HR 0.79, 95%CI [0.62-1.00]; p=0.049). Adjuvant SOX was not inferior to postoperative CapOx (61.0% *vs.* 52.1%; HR 0.77, 95%CI [0.61-0.98]; p=0.033). Perioperative SOX improved 5yDFS% compared with adjuvant CapOx (53.2% *vs.* 45.8%; HR 0.79, 95%CI [0.63-0.98]; p=0.034). Adjuvant SOX was not inferior to adjuvant CapOx (50.8% *vs.* 45.8%; HR 0.86, 95%CI [0.69-1.06]; p=0.164). No additional adverse events were observed.

Conclusions: The update on the RESOLVE survival analysis revealed improved survival in patients with G/GOJ adenocarcinoma undergoing D2 gastrectomy with perioperative SOX therapy compared to adjuvant CapOx, and adjuvant SOX was not inferior to adjuvant CapOx.

Ltd., Shanghai, China

Background: GEMSTONE-303 is a randomized, double-blinded, multi-center phase 3 trial evaluating sugemalimab (suge), a full-length, fully human anti-PD-L1 mAb + CAPOX vs placebo + CAPOX as the first-line treatment for patients (pts) with advanced G/GEJ adenocarcinoma. It is the first reported phase 3 trial of an anti-PD-L1 mAb in this disease that met the dual primary endpoints of PFS and OS. Here, we report the final analysis results of dual primary endpoints.

Methods: Eligible pts with previously untreated, no known HER2-positive status, PD-L1 expression ≥5%, unresectable advanced or metastatic G/GEJ adenocarcinoma were randomized 1:1 to receive suge/placebo (1200 mg, Q3W, IV) + CAPOX (capecitabine, 1000 mg/m^2, PO, BID, D1-14, Q3W; oxaliplatin, 130 mg/m^2, IV, Q3W; max 6 cycles). Stratification factors were ECOG PS (0 or 1) and PD-L1 expression levels (5-9% or ≥10%). Primary endpoints were PFS and OS. Data cutoff dates of the preplanned PFS and OS final analyses were 6 Aug 2022 and 9 Jul 2023, respectively.

Results: A total of 479 pts were randomized to suge+CAPOX (N=241) and placebo+CAPOX (N=238) arms between 9 Apr 2019 and 29 Dec 2021. The PFS and OS final analysis showed a significant improvement of the dual primary endpoints with suge+CAPOX vs placebo+CAPOX. The ORR was 68.6% with suge+CAPOX and 52.7% with placebo+CAPOX. The OS benefits were observed across all subgroups. The incidences of G3-5 suge/placebo-related AEs were 31.1% in suge+CAPOX arm and 28.7% in placebo+CAPOX arm. No new safety signals were observed.

Table: LBA79

PD-L1 Expression Level >=5%	Suge+CAPOX N=241	Placebo+CAPOX N=238
PFS (Months)		
Median (95% CI)	7.62 (6.37, 7.89)	6.08 (5.06, 6.44)
P-value	<0.0001	
HR (95% CI)	0.66 (0.54, 0.81)	
OS (Months)		
Median (95% CI)	15.64 (13.27, 17.81)	12.65 (10.64, 14.06)
P-value	0.0060	
HR (95% CI)	0.75 (0.61, 0.92)	
OS Rate		
12 Months (95% CI)	61.25% (54.77%, 67.08%)	52.02% (45.44%, 58.18%)
24 Months (95% CI)	29.90% (23.79%, 36.23%)	23.28% (17.81%, 29.18%)
PD-L1 Expression Level >=10%	**N=130**	**N=128**
PFS (Months)		
Median (95% CI)	7.79 (6.77, 9.99)	5.52 (4.83, 6.67)
P-value	0.0001	
HR (95% CI)	0.58 (0.43, 0.77)	
OS (Months)		
Median (95% CI)	17.81 (14.36, 21.16)	12.45 (9.89, 13.86)
P-value	0.0022	
HR (95% CI)	0.64 (0.48, 0.85)	

Conclusions: Sugemalimab in combination with CAPOX demonstrates statistically significant and clinically meaningful improvements in PFS and OS, with a manageable safety profile. These findings support suge+CAPOX as new first-line treatment option for pts with PD-L1 expression ≥5%, advanced G/GEJ adenocarcinoma.

Background: TIS (anti-PD-1 antibody) plus (+) chemo demonstrated significant overall survival (OS) benefit vs PBO + chemo as 1L treatment in patients (pts) with advanced GC/GEJC at a pre-specified interim analysis of the PD-L1-positive (tumor area positivity score ≥5%) population in the global, phase 3 RATIONALE-305 study (NCT03777657). Here, we present primary analysis results in the intent-to-treat (ITT) population at the pre-specified final analysis.

Methods: Adults with previously untreated, HER2-negative, locally advanced, unresectable, or metastatic GC/GEJC, regardless of PD-L1 expression status, were randomized (1:1) to receive TIS 200 mg or PBO IV once every 3 weeks plus investigator (INV)-choice of chemo (5-FU + cisplatin or capecitabine + oxaliplatin). The primary endpoints were OS in the PD-L1-positive and ITT populations. Secondary endpoints included progression-free survival, objective response rate, and duration of response by INV per RECIST v1.1, and safety.

Results: At data cutoff, 997 pts were randomized (501 pts to TIS + chemo; 496 pts to PBO + chemo). Minimum study follow-up was 24.6 mo. OS in the TIS arm was significantly improved compared with the PBO arm in the ITT population (median OS: 15.0 mo vs 12.9 mo, respectively; HR=0.80 [95% CI: 0.70, 0.92]; 1-sided P=0.0011). Additional main efficacy results are presented in the Table. Grade ≥3 treatment-related adverse events (TRAEs) occurred in 268 (53.8%) pts in the TIS arm and 246 (49.8%) pts in the PBO arm; TRAEs led to treatment discontinuation in 16.1% vs 8.1% of pts, respectively, and death in 1.2% vs 0.4%, respectively.

Table: LBA80

Endpoint	TIS + Chemo (n=501)	PBO + Chemo (n=496)
OS		
Median, mo (95% CI)	15.0 (13.6, 16.5)	12.9 (12.1, 14.1)
HR (95% CI)	0.80 (0.70, 0.92)	
P-value	0.0011	
PFS		
Median, mo (95% CI)	6.9 (5.7, 7.2)	6.2 (5.6, 6.9)
HR (95% CI)	0.78 (0.67, 0.90)	
ORR, % (95% CI)	47.3 (42.9, 51.8)	40.5 (36.2, 45.0)
mDoR, mo (95% CI)	8.6 (7.9, 11.1)	7.2 (6.0, 8.5)

ITT population.
Data cutoff: 28 February 2023. Chemo, chemotherapy; CI, confidence interval; HR, hazard ratio; ITT, intent-to-treat; mDoR, median duration of response; mo, months; ORR, objective response rate; OS, overall survival; PBO, placebo; PFS, progression-free survival; TIS, tislelizumab.

Conclusions: In the ITT population, TIS + chemo showed statistically significant and clinically meaningful improvement in OS vs PBO + chemo, and was well tolerated. These data support the TIS + chemo combination as a potential 1L treatment option for pts with advanced GC/GEJC.

Clinical trial identification: NCT03777657 (first posted December 17, 2018).

Background: The phase 3 GLOW study showed statistically significant improvement with 1L zolbetuximab + capecitabine + oxaliplatin (CAPOX) vs placebo (PBO) + CAPOX in PFS (final; median 8.2 vs 6.8 mo, HR 0.69 [95% CI 0.54, 0.87], $P = 0.0007$) and OS (interim; median 14.4 vs 12.2 mo, HR 0.77 [95% CI 0.62, 0.97], $P = 0.0118$) in pts with CLDN18.2+, HER2−, LA unresectable or mG/GEJ adenocarcinoma. We present an updated efficacy and safety analysis with 8.7 mo additional follow-up from the primary analysis.

Methods: Pts were randomly assigned 1:1 to zolbetuximab IV 800 mg/m^2 (cycle 1, day [D] 1) followed by 600 mg/m^2 (every 3 weeks) + CAPOX (oral capecitabine BID on D1−14 and oxaliplatin IV on D1) for eight 21-day cycles or to PBO + CAPOX; pts without progressive disease (PD) continued beyond cycle 8 with zolbetuximab or PBO, + capecitabine at investigator's discretion, until PD or discontinuation criteria were met. Primary endpoint was PFS per RECIST v1.1 by IRC; OS was a key secondary endpoint.

Results: At data cutoff (June 29, 2023), 507 pts were assigned to zolbetuximab + CAPOX (n = 254) or PBO + CAPOX (n = 253). In zolbetuximab vs PBO arms, median follow-up was 17.8 vs 15.1 mo for PFS and 26.1 vs 26.2 mo for OS, respectively. Median PFS in zolbetuximab vs PBO arms was 8.3 vs 6.8 mo (HR 0.68 [95% CI 0.55, 0.85], $P = 0.0004$). Median OS in zolbetuximab vs PBO arms was 14.3 vs 12.2 mo (HR 0.77 [95% CI 0.62, 0.95], $P = 0.0079$); 24-mo OS rate was 28.3% vs 18.8%, with follow-up ongoing through final analyses. Most common TEAEs with zolbetuximab + CAPOX were nausea (zolbetuximab arm: 68.9% vs PBO arm: 50.2%), vomiting (66.1% vs 31.3%), and decreased appetite (41.3% vs 34.5%); incidences of serious TEAEs were similar between arms (48.0% vs 50.6%).

Conclusions: Zolbetuximab + CAPOX continued to demonstrate statistically significant improvement in PFS and OS compared with PBO + CAPOX, with no new safety signals, supporting zolbetuximab + CAPOX as a potential new option for 1L treatment of patients with CLDN18.2+, HER2−, LA unresectable or mG/GEJ adenocarcinoma.

Clinical trial identification: NCT03653507.

Background: The phase 3 SPOTLIGHT study showed statistically significant improvement with 1L zolbetuximab + a modified folinic acid, 5-FU, and oxaliplatin regimen (mFOLFOX6) vs placebo (PBO) + mFOLFOX6 in PFS (final; median 10.6 vs 8.7 mo, HR

0.75 [95% CI 0.60, 0.94], $P = 0.0066$) and OS (interim; median 18.2 vs 15.5 mo, HR 0.75 [95% CI 0.60, 0.94], $P = 0.0053$) in patients (pts) with CLDN18.2+, HER2−, LA unresectable or mG/GEJ adenocarcinoma. We present an updated efficacy and safety analysis with 9.7 mo additional follow-up from the primary analysis.

Methods: Pts were randomly assigned 1:1 to zolbetuximab IV 800 mg/m^2 (cycle 1, day [D] 1) followed by 600 mg/m^2 (every 3 weeks) + mFOLFOX6 IV (D1, 15, 29) for four 42-day cycles or to PBO + mFOLFOX6; pts without progressive disease (PD) continued with zolbetuximab or PBO, + folinic acid and 5-FU at investigator's discretion, until PD or discontinuation criteria were met. Primary endpoint was PFS per RECIST v1.1 by IRC; OS was a key secondary endpoint.

Results: At data cutoff (June 29, 2023), 565 pts were assigned to zolbetuximab + mFOLFOX6 (n = 283) or PBO + mFOLFOX6 (n = 282). In zolbetuximab vs PBO arms, median follow-up was 17.9 vs 15.2 mo for PFS and 31.1 vs 29.6 mo for OS, respectively. Median PFS was 11.0 vs 8.9 mo (HR 0.73 [95% CI 0.59, 0.91], $P = 0.0022$). Median OS was 18.2 vs 15.6 mo (HR 0.78 [95% CI 0.64, 0.95], $P = 0.0067$), with follow-up ongoing until final analysis; 24-mo OS rate was 37.7% vs 29.1%. Most common TEAEs with zolbetuximab + mFOLFOX6 were nausea (zolbetuximab arm: 82.4% vs PBO arm: 61.5%), vomiting (67.4% vs 36.3%), and decreased appetite (48.7% vs 34.9%); incidences of serious TEAEs were similar between arms (47.0% vs 46.4%).

Conclusions: With longer follow-up, zolbetuximab + mFOLFOX6 continued to demonstrate statistically significant improvement in PFS and OS compared with PBO + mFOLFOX6, with no new safety signals—supporting zolbetuximab + mFOLFOX6 as a potential new option for 1L treatment of pts with CLDN18.2+, HER2−, LA unresectable or mG/GEJ adenocarcinoma.

Clinical trial identification: NCT03504397.

Background: The PREOPANC trial demonstrated an overall survival (OS) benefit of neoadjuvant gemcitabine-based chemoradiotherapy compared with upfront surgery in patients with borderline resectable and resectable pancreatic cancer (PDAC). FOLFIRINOX may further improve OS in the neoadjuvant setting.

Methods: This multicenter, phase 3, randomized trial included patients with borderline resectable and resectable PDAC from 19 Dutch centers. Patients received FOLFIRINOX every 14 days for 8 cycles followed by surgery without adjuvant treatment (FFX arm) versus 3 cycles of neoadjuvant gemcitabine with hypofractionated radiotherapy (36 Gy in 15 fractions during the second cycle), followed by surgery and 4 cycles of adjuvant gemcitabine (CRT arm). Randomization was stratified by center and resectability status. Primary endpoint was OS. Secondary endpoints included resection rate and serious adverse event (SAE) rate. To demonstrate a hazard ratio (HR) of 0.70 with two-sided $\alpha = 0.05$ and 80% power, 368 patients (252 events) were needed. HR and 95% CI were estimated using a stratified Cox model.

Results: Between June 2018 and January 2021, 375 patients were randomized to the FFX arm (n=188) or the CRT arm (n=187). Six patients (3 per arm) were excluded because of ineligibility (n=4) or withdrawal of informed consent immediately after randomization (n=2). After a median follow-up of 41.7 months with 254 events, median OS was 21.9 months in the FFX arm and 21.3 months in the CRT arm (HR 0.87; 95% CI 0.68-1.12, p=0.28). Resection rates were 77% in the FFX arm and 75% in the CRT arm (p=0.69). SAE rates were 49% in the FFX arm and 43% in the CRT arm (p=0.26).

Conclusions: Neoadjuvant chemotherapy with FOLFIRINOX did not improve OS compared with neoadjuvant gemcitabine-based chemoradiotherapy in patients with borderline resectable and resectable PDAC.

Prostate cancer

LBA13 Phase III trial of [177Lu]Lu-PSMA-617 in taxane-naive patients with metastatic castration-resistant prostate cancer (PSMAfore)

Background: [^{177}Lu]Lu-PSMA-617 (^{177}Lu-PSMA-617) prolongs rPFS and OS in patients (pts) with mCRPC and prior ARPI and taxane therapy. PSMAfore (NCT04689828) examined ^{177}Lu-PSMA-617 in taxane-naive pts.

Methods: Eligible adults had mCRPC, were candidates for ARPI change after one progression on prior ARPI, and had $\geq$1 PSMA+ and no exclusionary PSMA− lesions by [^{68}Ga]Ga-PSMA-11 PET/CT. Candidates for PARP inhibition and pts with prior systemic radiotherapy (<6 months ago), immunotherapy (except sipuleucel-T), or chemotherapy (except [neo]adjuvant >12 months ago) were ineligible. Randomization was 1:1 to open-label ^{177}Lu-PSMA-617 (7.4 GBq q6w; 6 cycles) or ARPI change (abiraterone/ enzalutamide). Pts randomized to ARPI could crossover to ^{177}Lu-PSMA-617 following centrally reviewed radiographic progression (rPD). Endpoints included: rPFS (PCWG3/ RECIST v1.1; primary), OS (key secondary) (both overall α=0.025, one-sided), FACT-P (secondary) and ORR/DOR (exploratory). Primary analysis was to occur at ~156 rPFS events and second OS interim analysis (IA) at ~125 deaths. Crossover-adjusted analysis was the prespecified method for OS by rank-preserving structural failure time (RPSFT).

Results: 468 pts were randomized. At primary analysis (median follow-up, 7.3 months; N = 467), the primary endpoint of rPFS was met (HR, 0.41; 95% CI: 0.29, 0.56; p<0.0001); this was similar at second IA (table). At second IA (45.1% of target deaths), 123/146 (84.2%) pts with rPD who discontinued ARPI crossed over; there was a positive OS trend in favour of ^{177}Lu-PSMA-617 per RPFST but not per unadjusted OS analysis. FACT-P and ORR/DOR favoured the ^{177}Lu-PSMA-617 arm (table). For ^{177}Lu-PSMA-617 vs ARPI change, incidence of grade $\geq$3 AEs was 34% (most common: anaemia, dry mouth) vs 44%, serious AEs 20% vs 28%, and AEs leading to discontinuation 5.7% vs 5.2%.

Table: LBA13

Second OS IA (DCO, 21 Jun 2023; median follow-up, 15.9 months)	^{177}Lu-PSMA-617 (N=234)	ARPI change (N=234)
Cycles, median (range)	6.0 (1–6)	–
rPFS[a]		
Events, n (%)	115 (49.1)	168 (71.8)
Median (95% CI), months	12.02 (9.30, 14.42)	5.59 (4.17, 5.95)
HR (95% CI), *p*	0.43 (0.33, 0.54), <0.0001	
TTW in FACT-P Total[b]		
Events, n (%)	167 (71.4)	187 (79.9)
Median (95% CI), months	7.46 (6.08, 8.51)	4.27 (3.48, 4.53)
HR (95% CI)	0.59 (0.47, 0.72)	
	N=105	**N=103**
ORRc, % (95% CI)	41.9 (32.3, 51.9)	12.6 (6.9, 20.6)
	N=44	**N=13**
DORc, median (95% CI), months	17.1 (11.6, NE)	10.1 (4.6, NE)

[a]Radiographic progression or death [b]Time to worsening in FACT-P Total, clinical disease progression, or death [c]Soft tissue only NE, not estimable.

Conclusions: ^{177}Lu-PSMA-617 prolonged rPFS vs ARPI change in taxane-naive pts with PSMA+ mCRPC, with a favourable safety profile.

Background: Enzalutamide (ENZA) and Lutetium-177-prostate-specific membrane antigen-617 (LuPSMA) both improve overall survival (OS) in mCRPC. Preclinical and clinical data suggest synergy for LuPSMA with androgen receptor pathway inhibitors (ARPI) in mCRPC. We evaluated the activity and safety of combining ENZA with adaptive-dosing of LuPSMA vs ENZA alone as first-line treatment for mCRPC.

Methods: Participants (pts) had mCRPC not previously treated with chemotherapy or ARPI (prior abiraterone and/or docetaxel for hormone-sensitive disease were allowed), ^{68}Ga-PSMA-positive disease on positron emission tomography (PET), and at least 2 risk factors associated with early progression on ENZA. Pts were randomised (1:1) to either ENZA 160 mg daily (ENZA-alone), or ENZA 160 mg daily plus adaptive dosing LuPSMA 7.5 GBq on days 15 and 57, with 2 further doses of LuPSMA if persistent PSMA-positive disease on interim ^{68}Ga-PSMA PET (day 92) (ENZA+LuPSMA). The primary endpoint was PSA-progression free survival (PSA-PFS). Secondary endpoints include radiological PFS (rPFS), PSA50% and PSA90% response rates (PSA50RR, PSA90RR), adverse events (AE), and OS.

Results: We randomised 162 pts from Aug 2020 to Jul 2022: median age 71 (range 45-96), prior docetaxel in 54%, and prior abiraterone in 13%. Imaging screen failure rate was 18% (40/220). 16% (13) of pts received between 2-3 doses of LuPSMA and 81% (67) received 4 doses. The median follow up was 20 months (IQR 18-21). PSA-PFS was longer with ENZA+LuPSMA vs ENZA-alone (median 13 vs 7.8 months; HR 0.43 [95%CI 0.29-0.63], $p<0.001$). PSA50RR and PSA90RR were higher with ENZA+LuPSMA vs ENZA-alone: 93% (77/83) vs 68% (54/79) ($p<0.001$) and 78% (65/83) vs 37% (29/79) ($p<0.001$) respectively. Analysis of rPFS (ongoing) will be presented. SAE were reported in 33% (27/81) of pts assigned ENZA+LuPSMA vs 35% (28/79) ENZA-alone.

Conclusions: The addition of adaptive-dosing of LuPSMA (2-4 doses) to ENZA improved PSA-PFS, PSA50RR, and PSA90RR. Our data supports enhanced anti-cancer activity with the use of adaptive-dosed LuPSMA together with ENZA as first-line treatment in mCPRC.

Background: In the phase 3 MAGNITUDE study (NCT03748641), NIRA + AAP significantly improved radiographic progression-free survival in *BRCA*-mutant *(BRCA+)* pts. Here we present the FA of MAGNITUDE, a phase 3 study with the largest population of 1L *BRCA*+ mCRPC pts, reporting mature overall survival (OS) data and prespecified multivariate analysis (MVA) for OS, addressing baseline imbalances.

Methods: Eligible pts (N = 423) with HRR+ mCRPC were randomized 1:1 to NIRA + AAP (n = 212) or placebo (PBO) + AAP (n = 211) as 1L therapy. At this FA, secondary endpoints of OS and time to cytotoxic chemotherapy (TCC) were formally assessed. Updates to time to symptomatic progression (TSP) and patient-reported outcomes (PROs) in *BRCA*+ pts and to safety for all HRR+ pts are also reported.

Results: At FA, 225 *BRCA*+ pts were evaluated; 113 pts received NIRA + AAP. Median follow-up was 35.9 months. In the NIRA + AAP and PBO + AAP arms, 70% and 86% of pts received subsequent life-prolonging therapy. OS favored NIRA + AAP over PBO + AAP (Table). A prespecified MVA adjusting for baseline imbalances showed an OS benefit favoring NIRA + AAP. Continued improvement in TSP and a clinically meaningful improvement in TCC were observed with NIRA + AAP. Time to worst pain progression and time to pain interference progression also favored NIRA + AAP. No new safety signals were observed with additional treatment exposure. Pulmonary embolism occurred in 4.7% and 1.4% of pts in NIRA + AAP and PBO + AAP arms, with no cases of myelodysplastic syndrome or acute myeloid leukemia in the NIRA + AAP arm.

Table: LBA85 Endpoints at FA in pts with *BRCA*+ mCRPC, NIRA + AAP vs PBO + AAP

	HR	95% CI	Nominal P
OS	0.79	0.55-1.12	0.18
OS with MVA	0.66	0.46-0.95	0.02
TSP	0.56	0.37-0.85	0.01
TCC	0.60	0.39-0.92	0.02
Time to worst pain progression	0.81	0.52-1.25	
Time to pain interference progression	0.77	0.48-1.23	

Conclusions: OS favored NIRA + AAP for pts with *BRCA*+ mCRPC. NIRA + AAP led to improvements in TSP, TCC, and PROs. The positive benefit-risk profile supports 1L NIRA + AAP as a new standard of care for pts with *BRCA*+ mCRPC.

Background: The Prostate Biomarker (ProBio) trial is an international biomarker-driven, randomized, outcome-adaptive platform trial in men with metastatic castrate resistant prostate cancer (mCRPC) evaluating multiple agents.

Methods: We used outcome-adaptive randomization to compare biomarker-driven treatment selection (experimental arms) against physician's choice standard-of-care (SOC; control arm), and to compare agents against each other within the experimental treatment arms. Men with mCRPC were randomized based on genomic alterations in circulating tumor DNA in five biomarker signatures: (1) *AR wt and TP53 wt*; (2) *TP53 mut;* (3) *DRD*; (4) *TMPRSS2:ERG fusion*; (5) *all* biomarkers signatures combined. Androgen receptor pathway inhibitors (ARPi; abiraterone and enzalutamide) and taxanes (docetaxel and cabazitaxel) were evaluated, using progression-free survival, by no longer clinically benefiting per PCWG3 criteria (PFS), as primary endpoint. Enrollment in the experimental group was stopped when the Bayesian probability of superiority reached prespecified thresholds ("graduation").

Results: In total, 219 men were randomized: 92 to SOC, vs. 76 and 51 to taxanes and ARPi, respectively, in the biomarker-driven arms. ARPi graduated in the "signature *all*", i.e. a signature encompassing all biomarkers. The median estimated PFS was 11.3 months (90% Bayesian credible interval [CI], 9.8 to 13.1) for ARPi compared with 7.2 months (90% CI, 6.5 to 8.1) in the SOC arm, for a hazard ratio (HR) of 0.52 (90% CI 0.37 to 0.72). ARPi demonstrated superiority to taxanes within the experimental arms (HR 0.54; 90% CI 0.38 to 0.76). We observed suggestive differential treatment effects for patients with *TP53 mut* and *TMPRSS2:ERG fusion* disease. The median estimated overall survival (OS) was 37.3 months (CI, 27.7 to NA) for ARPi compared with 20.2 months (90% CI, 18.4 to 23.0) taxanes within the experimental arms.

Conclusions: ARPi increases PFS and OS both compared to SOC and taxanes in patients with mCRPC. These are directly randomized data for ARPi and taxanes, showing the first evidence of a difference in PFS and OS for these agents in the mCRPC setting.

Renal cancer

LBA87 Phase II LITESPARK-003 study of belzutifan in combination with cabozantinib for advanced clear cell renal cell carcinoma (ccRCC)

T.K. Choueiri[1], T. Bauer[2], J.R. Merchan[3], D.F. McDermott[4], R. Figlin[5], E. Arrowsmith[6], M.D. Michaelson[7], E. Heath[8], A.A. D'Souza[9], S. Zhao[10], L. Mhamdi[11], R. Perini[11], D. Vickery[11], S. Tykodi[12]

[1]Genitourinary Oncology, Dana-Farber Cancer Institute, Boston, MA, USA; [2]Medical Oncology, Sarah Cannon Research Institute and Tennessee Oncology, Nashville, TN, USA; [3]Medical Oncology, University of Miami Health System, Miami, FL, USA; [4]Medical Oncology, Beth Israel Deaconess Medical Center, Boston, MA, USA; [5]Medical Oncology, Cedars-Sinai Medical Center, Los Angeles, CA, USA; [6]Medical Oncology, Tennessee Oncology, Chattanooga, TN, USA; [7]Medical Oncology, Massachusetts General Hospital, Boston, MA, USA; [8]Medical Oncology, Karmanos Cancer Institute, Detroit, MI, USA; [9]Medical Oncology, University of Southern California, Los Angeles, CA, USA; [10]Medical Oncology, Swedish Medical Center, Seattle, WA, USA; [11]Medical Oncology, Merck & Co., Inc., Rahway, NJ, USA; [12]Medical Oncology, University of Washington and Fred Hutchinson Cancer Center, Seattle, WA, USA

Background: Initial results from the phase 2 LITESPARK-003 (NCT03634540) study showed promising antitumor activity for belzutifan plus cabozantinib as first-line (cohort 1) and subsequent-line (cohort 2) treatment for patients (pts) with advanced ccRCC. We present updated results from cohorts 1 and 2.

Methods: Eligible pts had advanced ccRCC and ECOG PS of 0 or 1. Cohort 1 included pts with no prior systemic therapy for advanced RCC. Cohort 2 included pts who had received prior immunotherapy and $\leq$2 systemic regimens for advanced RCC. All pts received oral belzutifan 120 mg and oral cabozantinib 60 mg once daily. The primary end point was ORR per RECIST v1.1 by investigator assessment. Secondary end points included DOR, PFS, OS, and safety.

Results: A total of 50 pts were enrolled in cohort 1 and 52 pts in cohort 2. Most (n = 28; 56%) pts in cohort 1 had IMDC favorable risk and most (n = 41; 79%) in cohort 2 had IMDC intermediate/poor risk. Median follow-up was 24.3 mo (range, 4.1-48.2) in cohort 1 and 39.8 mo (range, 33.1-55.0) in cohort 2. ORR is shown in the Table. Median DOR was 28.6 mo (range, 1.9+ to 35.8) in cohort 1 and 31.5 mo (range, 4.2+ to 36.8) in cohort 2. An estimated 57% of all responders in cohort 1 and 51% in cohort 2 remained in response for $\geq$24 mo. Median PFS was 30.3 mo (95% CI, 16-not reached [NR]) in cohort 1 and 13.8 mo (95% CI, 9-19) in cohort 2. Median OS was NR (95% CI, NR-NR) in cohort 1 and 26.7 mo (95% CI, 20-41) in cohort 2. Overall, 23 (46%) pts in cohort 1 and 33 (63%) in cohort 2 had a grade 3-5 treatment-related AE (TRAE). No pts died due to a TRAE in cohort 1 and 1 pt (2%) died due to a TRAE (respiratory failure) in cohort 2.

Conclusions: In this updated analysis of LITESPARK-003, belzutifan plus cabozantinib showed durable antitumor activity and a safety profile consistent with prior observations. These results further support the combination of an HIF-2α inhibitor and VEGFR-TKI as a potential treatment option for advanced ccRCC in both the first- and subsequent-line settings.

Clinical trial identification: NCT03634540, August 16, 2018.

Background: Belzutifan is a first-in-class oral HIF-2α inhibitor approved in the US for patients with VHL disease-associated RCC, pNET and CNS hemangioblastoma and has antitumor activity in ccRCC. The phase 3 LITESPARK-005 study (NCT04195750) compares belzutifan vs everolimus in pretreated advanced ccRCC.

Methods: Pts aged ≥18 yrs with KPS ≥70% and advanced ccRCC (1-3 prior systemic regimens including anti—PD-[L]1 mAb and VEGF-TKI) were randomized 1:1 to belzutifan 120 mg QD or everolimus 10 mg QD until progression or unacceptable toxicity. Dual primary endpoints were PFS per RECIST 1.1 by blinded independent central review (BICR) and OS. Secondary endpoints included ORR per RECIST 1.1 by BICR (key), safety and time to deterioration (TTD) per FKSI-DRS. PFS, ORR were formally tested at first interim analysis (IA1).

Results: 374 pts were randomized to belzutifan, 372 to everolimus. At IA1 (median follow up [fu] 18.4 mo; range 9.4—31.7), PFS and ORR were superior with belzutifan vs everolimus (Table); OS did not reach statistical significance. At IA2 (median fu 25.7 mo; range 16.8—39.1), PFS, OS and ORR results were consistent with IA1. Complete responses occurred in 13 (3.5%) vs 0 pts with belzutifan vs everolimus. More pts remained progression-free with belzutifan vs everolimus at 12 mo (PFS rate 33.7% vs 17.6%) and 18 mo (22.5% vs 9.0%). 22.6% vs 5.0% of pts had ongoing treatment; 5.9% vs 14.7% of pts discontinued study therapy due to any AE. Grade 3-5 TRAEs occurred in 38.7% vs 39.4% of pts. TTD for FKSI-DRS favored belzutifan (median not reached vs 12.0 mo; HR 0.53; 95% CI 0.41—0.69; nominal $P<.0001$).

Table: LBA88

	IA1		IA2	
	Belzutifan (n=374)	Everolimus (n=372)	Belzutifan (n=374)	Everolimus (n=372)
Median PFS, mo	5.6	5.6	5.6	5.6
HR (95% CI)	0.75 (0.63—0.90)		0.74 (0.63—0.88)	
P-value	<.001*		Not applicable	
Median OS, mo	21.0	17.2	21.4	18.1
HR (95% CI)	0.87 (0.71—1.07)		0.88 (0.73—1.07)	
P-value	0.09583		0.09941	
ORR, % (95% CI)	21.9 (17.8—26.5)	3.5 (1.9—5.9)	22.7 (18.6—27.3)	3.5 (1.9—5.9)
P-value	<.00001*		Not applicable	

* denotes statistical significance.

Conclusions: Belzutifan was associated with a statistically significant improvement in PFS and ORR vs everolimus for pts with advanced ccRCC after immune checkpoint and anti-angiogenic therapies. The safety profile of belzutifan was consistent with prior reports with no new safety signals.

Clinical trial identification: MK-6482 LITESPARK-005; (NCT04195750).

Background: New treatments are needed for advanced dedifferentiated liposarcoma (DDLPS), which is characterized by *MDM2* gene amplification. Milademetan is a selective, potent, small molecule inhibitor of the MDM2-p53 interaction that reactivates p53 to induce apoptosis of *TP53* wild-type malignant cells. MANTRA (RAIN-3201; NCT04979442) is a global, randomized, multicenter, phase 3 study of milademetan vs. trabectedin in pretreated unresectable/metastatic DDLPS.

Methods: Eligible pts: ≥18y; unresectable/metastatic DDLPS±WD; ≥1 prior systemic therapies (≥1 anthracycline regimen); radiographic evidence of PD ≤6m. Pts were randomized (1:1) to milademetan (260 mg orally QD d1−3 & d15−17 q28d) or trabectedin (1.5 mg/m^2, 24-h iv infusion q3w) until PD or intolerability. Tumor response was evaluated at w8, 16, 24&32, then q12w. Primary endpoint: PFS by blinded independent central review (BICR). Secondary endpoints: OS; ORR; DCR; DOR; PFS by investigator; safety. Study sample size was estimated to support primary endpoint in favor of milademetan (HR 0.5, 94% power, type I error 0.05).

Results: Median age: 64y (range 20−82y); white (69.7%), male (56.6%). Median follow-up: 2.1m (range 0−13m). Median PFS by BICR was numerically but not significantly higher for milademetan. While immature, median OS was comparable in the two arms, as were ORR and DCR. Most common all grade and grade 3/4 TEAEs for milademetan (Table). No Grade 5 events occurred with milademetan vs. 5 with trabectedin. Dose reductions due to TEAEs were higher but discontinuation rates lower with milademetan.

Conclusions: While median PFS was longer for milademetan, the difference was not significant. TEAEs were consistent with previous reports and manageable by dose interruptions/modifications. Further evaluation of milademetan is warranted in populations that may benefit from MDM2 inhibition.

Table: LBA89 Study findings

Efficacy population	Milademetan (n =86)	Trabectedin (n =89)
Median PFS by BICR, m	3.6	2.2
	HR=0.89 (95% CI 0.61−1.29; p=0.53)	
Median PFS by investigator, m	3.7	2.1
	HR=0.80 (95% CI 0.55−1.15; p=0.22)	
Median OSa, m	9.5	10.2
	HR=1.27 (95% CI 0.80−2.04; p=0.31)	
ORR, n (%)	4 (4.7)	3 (3.4) p=0.67
DCR, n (%)	29 (33.7)	24 (27.0) p=0.33
Safety population	**n=86**	**n=79**
Most common milademetan TEAEs, %		
Nausea	70.9	58.2
Thrombocytopenia	61.6	25.3
Anemia	44.2	36.7
Vomiting	44.2	19.0
Most common grade 3/4 milademetan TEAEs, %		
Thrombocytopenia	39.5	13.9
Neutropenia	25.6	26.6
Anemia	18.6	19.0
TEAEs − fatal/grade 5, %	0	6.3
TEAEs leading to dose reductions, %	44.2	29.1
TEAEs leading to discontinuations, %	11.6	19.0

Clinical trial identification: RAIN-3201; NCT04979442.

LBA90 A randomized phase II study of durvalumab and tremelimumab compared to doxorubicin in patients with advanced or metastatic soft tissue sarcoma (MEDISARC, AIO-STS-0415)

V. Gruenwald

Interdisciplinary Genitourinary Oncology, Clinic for Urology, Clinic for Medical Oncology, University Hospital Essen, Essen, Germany

Background: Doxorubicin (DOX) is the standard of care (SOC) in patients with advanced or metastatic soft tissue sarcomas (STS) who cannot receive combination therapy. We tested whether the combination of durvalumab (DUR) and tremelimumab (TRE) improved overall survival (OS) compared to single agent DOX.

Methods: Treatment-naïve patients with chemo-sensitive advanced or metastatic STS who were not candidates for curative surgery or combination therapy were eligible. Key inclusion criteria were: ECOG performance status 0-2, grade 2 or 3, adequate organ function. Patients were 1:1 randomized (stratified by ECOG) to receive DUR 1.5g i.v. q4wks and TRE 75 mg i.v. 3x q4wks and q12wks thereafter for a maximum of 12 months or doxorubicin 75 mg/m^2 q3wks for up to 6 doses. OS was the primary endpoint. Secondary endpoints include 2-year OS rate, PFS, ORR (mRECIST 1.1), PFS, DOR, as well as safety (CTCTAE 4.03) and health-related quality of life (EORTC QLQ-C30). All randomized and treated subjects were included in the efficacy and safety analyses.

Results: Between April 2018 and September 2020 a total of 103 patients were randomized. 55% were female. Median age was 61 (r: 23-82) years. Most frequent STS were: leiomyosarcoma (LMS; 27%), undifferentiated pleomorphic sarcoma (UPS; 19%) and liposarcoma (LPS; 18%). PFS and 6-mo. PFS for DUR-TRE vs. DOX were 2.7 (95%CI 2.4-2.9) vs. 2.8 (95%CI 2.6-4.9) mo. (P=.401) and 11.4% vs. 33.6%, respectively. OS for DUR-TRE vs. DOX was 17.4 (95%CI 9.1-23.5) vs. 12.5 (95%CI 9.6-15.6) mo., which corresponded to a HR of 0.73 (95%CI 0.54-0.99; P=.185). 2-year OS was 35.7% vs. 29.0% for DUR-TRE vs. DOX, respectively. Adverse events (AE) of any grade and AE with grade ≥3 were 90.6% vs. 89.7% and 52.8% vs. 41.0% for DUR-TRE vs. DOX, respectively.

Conclusions: DUR-TRE showed comparable clinical activity to single agent DOX in treatment-naïve patients with STS. While OS favored DUR-TRE treatment, it did not reach significance. Our study indicated the principle activity of DUR-TREM in STS and warrants further studies.

Clinical trial identification: NCT03317457; EudraCT: 2016-004750-15.

Background: Advanced STS represent an unmet medical need. We previously reported feasibility and preliminary activity data of T+O in advanced STS failing standard treatments.

Methods: In this investigator-initiated, open-label, phase 2 randomized trial, adult patients (pts) with advanced STS progressing after $\geq$1 treatment(s) were randomized in a 1:1 ratio to T 1.1 mg/m2 q21d i.v. plus O tablets 150 mg BID, or T 1.5 mg/m2 q21d i.v. Randomization stratified pts for histology (L-sarcoma *vs* non-L-sarcoma) and number of prior lines (1 vs $\geq$2). Primary endpoint: progression-free survival (PFS) rate at 6-month (PFS6m) by RECIST 1.1. Main secondary endpoints: PFS, overall survival (OS), RECIST 1.1 overall response rate (ORR), duration of response (DOR), safety. Exploratory endpoints: correlation of clinical characteristics and molecular biomarkers with outcomes.

Results: Between May-2020 and Nov-2022, 130 pts were enrolled (M/F 49/81; L-/Non-L-sarcoma 67/63; prior lines 1/$\geq$2 93/37) at 13 ISG sites. With a median (m-)follow-up of 10.2 mos, estimated PFS6m and m-PFS per intention-to-treat were 32% (95%CI 22-46%) and 4.0 mos (2.9-5.4) in T+O arm; 28.5% (19.3-42.1) and 2.9 mos (2.2-4.5) in T arm. PFS12m was 20% (12-33) with T+O and 2% (0-14) with T. Best response in 122 evaluable pts was: 6 PR, 25 SD, 31 PD in T+O arm, and 4 PR, 21 SD, 35 PD in T arm, for an ORR of 10 and 7%, respectively. m-DOR was 14.5 mos with T+O and 4.5 with T. OS events were not mature but did not differ between the two arms. Most common grade $\geq$3 adverse events were neutropenia (58%) thrombocytopenia (20%) and anemia (18.5%) with T+O, and neutropenia (31%), ALT increase (26%) and thrombocytopenia (8%) with T. 5 pts in T+O (8%) and 2 in T (3%) discontinued treatment due to toxicity. No toxic death was reported. Data on available exploratory endpoints will be presented at the meeting.

Conclusions: This is the first randomized trial prospectively testing T+O and T in advanced STS pts. PFS6m with T+O was slightly below the prespecified threshold of 40%. Notably, 20% of pts in T+O were treated for $>$1 year and deepening into biomarkers of these long responders would improve selection of pts for T+O.

Clinical trial identification: NCT03838744; EudraCT 2018-004497-10.

Background: Tarlatamab, a bispecific T-cell engager (BiTE), represents a new immunotherapeutic approach for SCLC. It binds to both delta-like ligand 3 (DLL3) on SCLC cells and CD3 on T cells, resulting in T-cell mediated tumor lysis. A phase 1 study demonstrated encouraging safety and efficacy (median duration of response (mDoR): 12.3 mo; median overall survival (mOS): 13.2 mo) in previously treated SCLC. Here, the phase 2 data from the DeLLphi-301 study are presented.

Methods: Pts with SCLC who relapsed after 1 platinum-based regimen ($\pm$ checkpoint inhibitor) and at least 1 other prior line of therapy received 10 mg or 100 mg tarlatamab Q2W. The primary endpoint was objective response rate (ORR) by blinded independent central review (RECIST 1.1). Other endpoints were DoR, progression-free survival (PFS), OS, and treatment-emergent adverse events (TEAEs).

Results: Overall, 220 pts received tarlatamab. The median follow-up was 10.6 mo for efficacy outcomes (Table). At the 10 mg dose, ORR was 40.0%, mPFS was 4.9 mo, mOS was 14.3 mo, and mDoR was not reached, with 57.5% of responders experiencing $\geq$ 6 mo of response and 55.0% still with an ongoing response. The most common TEAE was cytokine release syndrome (CRS; 51.1%, 10 mg; 60.9%, 100 mg), primarily occurring in cycle 1, and was mostly grade 1 or 2. Incidence of grade 3 CRS (0.8%, 10 mg; 5.7%, 100 mg) and grade 3 immune effector cell-associated neurotoxicity syndrome (ICANS) and associated neurologic events was low (0%, 10 mg; 4.6%, 100 mg), with no grade 4 or 5 events. Discontinuations due to treatment-related AEs were infrequent (3.0%, 10 mg; 3.4%, 100 mg). Similar safety profiles were seen with 24h or 48h inpatient monitoring.

Table: LBA92

	10 mg (n = 100)*	100 mg (n = 88)*
ORR, % (97.5% CI)	40.0 (29.1–51.7)	31.8 (21.1–44.1)
Complete response, n (%)	1 (1.0)	7 (8.0)
Partial response, n (%)	39 (39.0)	21 (23.9)
Stable disease, n (%)	30 (30.0)	27 (30.7)
Progressive disease, n (%)	20 (20.0)	13 (14.8)
Not evaluable, n (%)	2 (2.0)	4 (4.5)
Death before post-baseline scan, n (%)	6 (6.0)	13 (14.8)
No post-baseline scan, n (%)	2 (2.0)	3 (3.4)
mDoR, mo (95% CI)	NE (5.9–NE)	NE (6.6–NE)
Disease control rate % (95% CI)	70.0 (60.0, 78.8)	62.5 (51.5, 72.6)
mOS, mo (95% CI)	14.3 (10.8–NE)	NE (12.4–NE)
mPFS, mo (95% CI)	4.9 (2.9–6.7)	3.9 (2.6–4.4)

*Efficacy analysis set per intention-to-treat (ITT) analysis (Pts in safety substudy (n = 34) not included as data immature). NE = not estimable

Conclusions: Tarlatamab demonstrated impressive antitumor activity with durable responses and promising survival. Tarlatamab showed a favorable benefit-risk profile with no new safety signals, supporting the use of tarlatamab in pts with previously treated SCLC.

Clinical trial identification: NCT05060016.

Background: Combinations of immunotherapy with chemotherapy as a first-line treatment for ES-SCLC have generated mixed results. The EXTENTORCH trial assessed toripalimab in combination with chemotherapy as a first-line treatment for patients with ES-SCLC (NCT04012606).

Methods: Patients with histologically or cytologically confirmed ES-SCLC, stratified by gender and baseline ECOG PS (0 vs. 1) were randomized in a 1:1 ratio to receive 240 mg toripalimab or placebo plus etoposide and cisplatin/carboplatin Q3W for 4-6 cycles,

followed by single-agent toripalimab or placebo until progressive disease, intolerable toxicity or up to 2-year treatment. The primary endpoints were PFS as assessed by the investigator per RECIST v1.1 and OS. Tumor mutational burden (TMB) and genomic alterations were assessed by whole-exome sequencing (WES) of tumor tissues.

Results: From Sep 2019 to May 2021, 442 patients were enrolled from 48 participating sites in China. 223 and 219 patients were randomized to the toripalimab and the placebo arms, respectively. At data cut off (28 Feb 2022), median follow-up was 11.8 months, a significant improvement in PFS was observed for toripalimab over placebo (5.8 vs. 5.6 months, HR = 0.667 [95% CI: 0.539-0.824], P = 0.0002). Despite 59.4% of patients in the placebo arm received ≥3 additional lines of therapy and 25.6% received a PD-(L)1 inhibitor after the study treatments, OS was significantly improved in the toripalimab arm (14.6 vs. 13.3 months, HR = 0.798 [95% CI: 0.648-0.982], P = 0.0327) at the final OS analysis at data cut off (20 Apr 2023). WES results from 300 patients showed that improvements in PFS and OS were similar irrespective of TMB status. Genomic alterations in integrin-mediated focal adhesion complex were associated with poor prognosis for both PFS and OS in the toripalimab arm. Toripalimab plus chemotherapy had a manageable safety profile, with no new safety signals observed.

Conclusions: The addition of toripalimab to chemotherapy provided significant improvements in PFS and OS for patients with ES-SCLC with an acceptable safety profile.

Clinical trial identification: NCT04012606.

Supportive care

LBA94 Effects of short-term fasting on quality of life as an add-on option during chemotherapy

D.A. Koppold[1], C. Kessler[2], M. Wischnewsky[3], I.M. Alvarado-Rupflin[2], C. Kempter[4], M. Paul[5], B. Brueckner[4], D. Fischer[6], N. Steckhan[7], M. Jeitler[2], E. Hanslian[2], B. Kunz[2], A. Michalsen[2]

[1]Institute of Social Medicine, Epidemiology and Health Economics, and Department of Pediatrics, Division of Oncology and Hematology, Charité - Universitätsmedizin Berlin, Berlin, Germany; [2]Institute of Social Medicine, Epidemiology and Health Economics, Charité - Universitätsmedizin Berlin, Berlin, Germany; [3]Mathematics and Informatics, University of Bremen, Bremen, Germany; [4]Breast Cancer Center, Waldfriede Krankenhaus, Berlin, Germany; [5]Gynaecology, Vivantes Klinikum am Urban, Berlin, Germany; [6]Gynaecology, Klinikum Ernst von Bergmann, Potsdam, Germany; [7]Digital Health, Hasso-Plattner-Institut, Potsdam, Germany

Background: Growing pre- and clinical evidence show that short-term fasting (STF) of 48 to 72 hours around each chemotherapy (CTX) may potentially support CTX, reducing toxicity and adverse effects.

Methods: This randomised multi-center study of breast cancer (BC) patients undergoing CTX was conducted to assess feasibility and health-related quality of life (HRQoL) for 60-72 h STF compared to a plant-based low-sugar diet (PBD). HRQoL was assessed by FACT-G, FACIT-F (fatique) and further questionnaires at baseline (V0) and after each CTX session (day 7) as well as after 4 (V1) and 6 (V2) months. Laboratory parameters were collected at the same time points. CTX consisted of 4 x AC or EC, followed by either 12 x paclitaxel (Pac) (80 mg/m^2) weekly or 4 x docetaxel (Doc) three-weekly (100 mg/m^2).

Results: 106 patients were included in the study and randomized to STF (n=52) or PBD (n=56). 90 (84.9%) patients obtained AC/EC -> Pac and 16 (15.1%) AC/EC -> Doc. The 27-item generic CORE questionnaire FACT-G measuring four domains of HRQoL (physical, social/family, emotional, and functional well-being) showed no significant difference at V0 (STF 82.9; PBD 81.9; p=0.523). STF-patients' FACT-G improved at day 7 from cycle to cycle versus PBD-patients. At cycle 4, day 7, FACT-G for STF was 78.3 (std. error (SE) 2.7; 95% C.I. 72.8-83.7) and for PBD 69.3 (SE 2.6: 95% C.I. 64.0-74.6). The difference 9.0 (SE 3.8) was statistically significant (p = 0.021) and clinically relevant (9.0 > minimal important difference (MID = 5)). The differences between the corresponding FACIT-F Trial Outcome Index resp. Total FACIT-F at cycle 4 day 7 were 13.1 (SE 4.7) resp. 15.8 (SE 5.6), both in favor of STF (> MID= 6, p < 0.007). The mean Total Hospital Anxiety and Depression Score (HADS-T) shows mental distress (HADS-T ≥ 13) for both STF and PBD at V0 and cycle 4 day 7 with no statistically significant differences. At V0 mean platelet counts (MPCs) were 256.6 (SE 10.8) for STF and 266.2 (SE 9.9) for PBD (p=0.512). At cycle 4 day 7 MPCs were 209.5 (SE 13.7) for STF and 177.7 (SE 12.3) for PBD.

Conclusions: Neither STF nor PBD showed serious adverse effects in the studied population. STF during chemotherapy is well tolerated and appears to improve QoL and fatigue during chemotherapy compared to a plant-based low-sugar diet.

Clinical trial identification: NCT03162289 on 22 May 2017.

LBA95 Anamorelin and weight gain in patients with advanced non-small cell lung cancer (NSCLC) and cachexia: Efficacy and safety in the multinational phase III SCALA program

D. Currow[1], S. Chessari[2], P. Bonomi[3], R. Giorgino[4], R. Skipworth[5]

[1]Faculty of Science, Medicine & Health, University of Wollongong, Wollongong, NSW, Australia; [2]Clinical Operations, Helsinn Healthcare SA, Pazzallo-Lugano, Switzerland; [3]Internal Medicine, Rush University, Chicago, IL, USA; [4]Triallism GmbH, Allschwill, Switzerland; [5]Clinical Surgery, University of Edinburgh, Edinburgh, UK

Background: Anamorelin is a potent, selective and well-tolerated orally available ghrelin agonist. It is marketed in Japan for the treatment of cachexia in patients with lung and gastrointestinal malignancies since early 2021. Results of two phase III trials comparing anamorelin versus placebo in cachectic non-Japanese NSCLC patients are described.

Methods: Between March 2019 and August 2022, a total of 636 subjects (318 per study) with advanced NSCLC, ECOG PS 0-2, BMI<20 kg/m^2, and unintentional weight loss >2% in the previous six months, were randomized 1:1 to receive 100 mg of anamorelin or a placebo orally QD for 24 weeks in two confirmatory studies with identical design (SCALA-1 and SCALA-2). Primary endpoints were changes from baseline over 12 weeks in scale body weight and in the FAACT anorexia-cachexia 5-domain symptom score (5-IASS).

Results: In both studies, anamorelin significantly increased body weight over 12 weeks compared to placebo (p<0.0001). Least square means (95% CI) treatment difference was +1.37 kg (+0.737; +2.001) for SCALA-1 and +1.30 kg (+0.720; +1.865) for SCALA-2. Changes of 5-IASS scores for anamorelin versus placebo were not significantly different in both studies. Overall, 71.2% (anamorelin) and 73.4% (placebo) of patients experienced any Treatment Emergent Adverse Event (TEAE). There was no difference when serious TEAEs, severe TEAEs, TEAEs leading to discontinuation, and TEAEs of special interest were considered. Severe hyperglycemia was reported only in two patients both receiving anamorelin (0.6%).

Conclusions: The SCALA trials demonstrate that anamorelin improves body weight in individuals with advanced NSCLC and cachexia. The observed effect on body weight is consistent with data from all eight previously conducted double-blind, placebo-controlled studies that randomized 1,696 cancer patients. The positive benefit-risk profile strongly emphasizes the therapeutic potential of anamorelin for treating unintended weight loss in patients with advanced NSCLC and cachexia.

LBA96 Roxadustat for chemotherapy-induced anemia in patients with non-myeloid malignancies: A randomized, open-label, active-controlled, phase III study

S. Lu[1], J. Wu[2], J. Jiang[3], Q. Guo[4], Y. Yu[5], Y. Liu[6], H. Zhang[7], L. Qian[8], X. Dai[9], Y. Xie[10], T. Fu[11], T. Lee[12], Y. Lu[13], R. Ma[13], M. Eisner[12]

[1]School of Medicine, Shanghai Jiao Tong University, Shanghai Chest Hospital, Shanghai, China; [2]Cancer Hospital, Fudan University, Shanghai, China; [3]Affiliated Hospital of Jiaxing University, The First Hospital of Jiaxing, Jiaxing, China; [4]Shandong First Medical University Cancer Hospital, Jinan, China; [5]Department of Medical Oncology, Harbin Medical University Cancer Hospital, Harbin, China; [6]Neijiang Second People's Hospital, Neijiang, China; [7]The First People's Hospital of Foshan, Foshan, China; [8]Shanghai Fifth People's Hospital, Shanghai, China; [9]Xuzhou Central Hospital, Xuzhou, China; [10]Breast Surgery Department, The People's Hospital of Guangxi Zhuang Autononous Region, Nanning, China; [11]Zhuzhou Central Hospital, Zhuzhou, China; [12]FibroGen, Inc., San Francisco, CA, USA; [13]FibroGen (China) Medical Technology Development Co., Ltd., Shanghai, China

Background: Chemotherapy-induced anemia (CIA) is a common complication of cancer and an important risk factor leading to poor prognosis for patients. Recombinant human erythropoietin-α (rHuEPO-α) is standard of care for CIA; however, safety concerns remain. Roxadustat is the first hypoxia-inducible factor prolyl hydroxylase inhibitor approved for treatment of anemia in chronic kidney disease. This study evaluated the efficacy and safety of roxadustat for anemia in patients with non-myeloid malignancies receiving multi-cycle treatments of myelosuppressive chemotherapy.

Methods: In this open-label, non-inferiority, multicenter Phase III study conducted in China, patients were randomized (1:1) to receive oral roxadustat or subcutaneous rHuEPO-α three times weekly (TIW) for 12 weeks. Roxadustat starting dosage was 100 mg, 120 mg, and 150 mg TIW (patients weighing 40−<50, 50−60, and >60 kg). rHuEPO-α starting dosage was 150 IU/kg TIW. Both roxadustat and rHuEPO-α dosages could be modified to achieve hemoglobin (Hb) concentrations of 100−120 g/L. Primary efficacy endpoint was least-squares mean (LSM) change in Hb concentration from baseline to the concentration averaged over Weeks 9−13. Adverse events (AEs) were monitored.

Results: Of 159 patients randomized (n=82, roxadustat; n=77, rHuEPO-α), 140 were included in the per protocol set (n=78, roxadustat; n=62, rHuEPO-α). The LSM (95% 2-sided confidence interval [CI]) change from baseline to Weeks 9−13 in Hb concentration was 17.1 (13.58, 20.71) g/L with roxadustat and 15.4 (11.34, 19.50) g/L with rHuEPO-α. The lower bound of the 1-sided 97.5% CI for the treatment difference (−3.4 g/L) was greater than the predefined non-inferiority margin of −6.6 g/L, establishing non-inferiority. Results were supported by key secondary endpoints. AE rates were generally comparable between treatments and consistent with previous findings, supporting a positive benefit-risk profile.

Conclusions: Oral roxadustat was non-inferior to subcutaneous rHuEPO-α for anemia in patients with non-myeloid malignancies receiving multi-cycle treatments of myelosuppressive chemotherapy.

LBA97 Olanzapine for the prevention of chemotherapy induced nausea vomiting in patients receiving moderately emetogenic chemotherapeutic (MEC) regimens: Results of a prospective triple blinded phase III multicentric study (OMEC)

V.S. Ostwal[1], S. Mandavkar[1], M. Parulekar[1], A. Ramaswamy[1], P.G. Bhargava[2], S. Srinivas[3], D. Chaugule[1], D. Naughane[1], A. Kapoor[4], A. Gupta[5], B. Sansar[6], A. Sharma[7], R.K. Rai[8], P. Gupta[8], B. Mishra[9], V.K. Muddu[10], I.N. Olver[11]

Background: MEC regimens have lesser than expected control of nausea and vomiting with standard antiemetic prophylaxis. The role of olanzapine has not been adequately evaluated with these regimens.

Methods: In this randomized multicentric, triple-blind, phase 3 trial, we compared dexamethasone, aprepitant and palonosetron without (standard) or with the addition of olanzapine (experimental) in patients who were receiving oxaliplatin, carboplatin or irinotecan-based chemotherapy (MEC). The experimental group received 10 mg of olanzapine orally once at night on days 1 through 3. Complete response, defined as the proportion of subjects with no vomiting and no significant nausea, scored as < 5 on a visual analogue scale of 1-100, was the primary endpoint. The quality of life (QOL) was assessed by the Functional Living Index Emesis (FLIE). The study required to recruit 560 patients (280 patients per arm) to show preplanned improvement in CR rates.

Results: Of the 544 evaluable patients, baseline characteristics were evenly matched between the two groups. The proportion of patients with CR was significantly greater with olanzapine than without olanzapine in the overall 120-hour period (92.3% vs. 86.2%, P=0.022). The proportion of patients with no chemotherapy-induced nausea as well as combined chemotherapy induced nausea and vomiting (CINV) were significantly more with olanzapine than without in the period from 25 to 120 hours (delayed CINV) (nausea 96.7% vs. 88.5% p<0.001; CINV 95.3% vs. 86.3%; p<0.001). The overall use of rescue medications was lesser in patients receiving olanzapine (4% vs. 11.5%p=0.001). The use of olanzapine at 10 mg per day was not associated with any significant toxicities and QOL did not deteriorate by the addition of the olanzapine as assessed by FLIE.

Conclusions: The addition of olanzapine significantly improved CR rates as well as delayed CINV rates in previously untreated patients who were receiving moderately emetogenic chemotherapeutic regimens containing oxaliplatin, carboplatin or irinotecan. The use of olanzapine should be considered as standard of care in these chemotherapeutic regimens.

Background: Thymic carcinoma (TC) is a rare tumor with aggressive and poorly responsive behavior. In advanced lines, antiangiogenics showed activity in TC. Ramucirumab (R) is a VEGF2 inhibitor monoclonal antibody already approved for other solid tumors. RELEVENT trial was design to assess activity and safety of the combination of R plus carboplatin (CBDCA) and paclitaxel (PTX) as first line treatment in patients (pts) with advanced TC.

Methods: This academic open-label single arm phase II trial was conducted within the Italian network TYME. Eligible pts had naive advanced TC (pathological diagnosis was centrally reviewed). All pts received R 10 mg/kg, CBDCA AUC5 and PTX 200 mg/m2 d1q21 for 6 cycles, followed by R 10 mg/kg maintenance until disease progression or intolerable toxicity. The trial was conceived with a Green-Dahlberg 2-stage design, 30 pts were analyzed in the 1st stage (null hypothesis ORR 20%). In case of at least 5 responses, further 25 pts could have been added in the 2nd stage. The primary endpoint was ORR. DCR, PFS, OS and safety were secondary endpoints. A centralized radiologic review was performed.

Results: From 11/2018 to 06/2023, 52 pts were screened and 37 were enrolled. Median (m) age was 60.5 years, 26 (70.3%) pts were male and 32 (86.5%) had stage IVB disease. ECOG PS was 0 in 26 (70%) and 1 in 11 (30%) pts; 35 pts were assessable for the primary endpoint ORR. At the 1st stage, ORR (by investigator assessment) was 80% [95%CI 63.1-91.6] with DCR of 100% [95%CI 90-100]. At the centralized radiological review on 33/35 evaluable pts, ORR was 57.6% [95%CI 39.2-74.5], with 19 pts (57.6%) having a PR and 14 (42.4%) a SD, DCR was 100% [95%CI 89-100]. After a m follow up of 31.6 months [21.6-40.5], mPFS was 18.1 [95%CI 10.5-52.3] and mOS 43.8 [95%CI 22.5-NE] months. Of 35 pts, 28 (80%) experienced at least one treatment related adverse event (AE), 45.7% were G3 or more, (hypertension 8.8% and neutropenia 20% were the most common).

Conclusions: In previously untreated advanced TC, the addition of R to CBDCA and PTX showed highest activity compared to historical controls, with manageable safety profile. Despite the small number of pts, given the rarity of the disease, these results support the use of this combination as first line treatment in TC.

Clinical trial identification: NCT03921671.

Background: Immune checkpoint inhibitors have improved survival for patients with malignant pleural mesothelioma (MPM), but prognosis is still poor. The UV1 telomerase peptide vaccine has demonstrated robust immune response induction and promising clinical activity in several malignancies.

Methods: Patients with MPM progressing after first-line platinum-based chemotherapy were randomized 1:1 to ipilimumab and nivolumab alone (Arm B) or in combination with telomerase vaccine UV1 (Arm A). The primary endpoint was progression-free survival (PFS) evaluated by blinded, independent central review (BICR) at the time of 69 events. The study was powered to detect an HR of 0.60 in favour of arm A with a 1-sided alpha of 0.1.

Results: A total of 118 patients were included and randomized, well balanced with respect to age, gender, performance status, histology and PD-L1 status. The primary endpoint was assessed after a median follow-up of 12.5 months (95% CI 9.7-15.6). The HR for patients treated in arm A was 1.01 (80% CI 0.75-1.36, 95% CI 0.64-1.59) with a median PFS of 4.2 months (95% CI 2.9-9.8) in arm A and 4.7 months (95% CI 3.9-7.0) in arm B. Objective response rate was 31% in arm A and 16% in arm B (odds ratio 2.4, 95% CI 1.0-6.3). The investigator determined median PFS was 4.3 months (95% CI 3.0-6.8) in arm A and 2.9 months (95% CI 2.4-5.5) in arm B with a HR= 0.6 (80% CI 0.45-0.81, 95% CI 0.39-0.94). Overall survival after a median follow-up of 17.3 months (95% CI 15.8-22.9) was 15.4 months (95% CI 11.1-22.6) in arm A and 11.1 months (95% CI 8.8-18.1) in arm B, with a HR of 0.73 (80% CI: 0.53-1.0, 95% CI 0.45-1.18). The total number of adverse events and the proportion of patients experiencing a grade $\geq$3 adverse event was comparable in the two arms.

Conclusions: The primary endpoint in this study was not met. Supportive analyses indicate an increased ORR and clinically meaningful prolonged survival in the intervention arm. The results warrant confirmation in a larger clinical trial.

Clinical trial identification: EudraCT 2019-002721-30; NCT04300244.

Background: Selpercatinib is a highly selective and potent RET inhibitor approved for treatment of advanced *RET*-mutant medullary thyroid carcinoma (MTC) but has not been directly compared with approved multikinase inhibitors (MKI).

Methods: LIBRETTO-531 (NCT04211337) is a randomized phase 3 study comparing first-line selpercatinib versus physician's choice of cabozantinib or vandetanib. Eligible patients had kinase inhibitor-naïve progressive disease documented in the 14 months prior to enrollment. The pre-planned interim efficacy analysis occurred after 59 progression-free survival (PFS) events. The primary endpoint was blinded independent central review (BICR)-assessed PFS.

Results: In total, 291 patients were randomized. Baseline characteristics were well-balanced between study arms. At a median follow-up of 12 months, median PFS by BICR was not reached with selpercatinib remaining inestimable (95% CI: NE, NE) and was 16.8 months (95% CI: 12.2, 25.1) with control (HR: 0.280, 95% CI: 0.165, 0.475; P<.0001); by investigator assessment the HR was 0.187 (95% CI: 0.109, 0.321; P<.0001). BICR overall response rate (ORR) was 69.4% (95% CI: 62.4, 75.8) with selpercatinib compared to 38.8% (95% CI: 29.1, 49.2) with control (odds ratio 3.7, 95% CI, 2.2, 6.3; P<0.0001). At a median follow-up of 15 months, overall survival (OS) was better with selpercatinib (HR: 0.374, 95% CI: 0.147, 0.949). The most common treatment-emergent adverse events observed with selpercatinib were hypertension, dry mouth, and diarrhea; and with control, diarrhea, palmar-plantar erythrodysaesthesia syndrome, and hypertension. In total, 38.9% of patients treated with selpercatinib had a dose reduction (versus 77.3% in control) and 4.7% discontinued treatment due to an adverse event (versus 26.8% in control).

Conclusions: The study met the interim analysis criteria of efficacy. First-line selpercatinib delivered markedly prolonged PFS, improved ORR, and better OS compared with MKI. This study highlights the importance of selectivity in targeting *RET*-mutant MTC. Selpercatinib should be considered the preferred first-line standard of care for patients with advanced *RET*-mutant MTC.

Clinical trial identification: NCT04211337.

Translational research (agnostic)

LBA100 CUP-ONE trial: A prospective double-blind validation of molecular classifiers in the diagnosis of cancer of unknown primary and clinical outcomes

H.S. Wasan[1], J. Wang[2], E.M. Elaine McCartney[3], H. Soifer[4], K. Treuner[4], Y. Zhang[4], C. Schnabel[4], K. Carty[3], L. McMahon[3], T.R.J. Evans[5], M.C. Nicolson[6], H. Thygesen[3], J.R. Roche[3], K.A. Oien[5]

[1]Cancer Medicine, Hammersmith Hospital - Imperial College Healthcare, London, UK; [2]Cellular Pathology, UCLH - University College London Hospital, London, UK; [3]Cancer Research UK Glasgow Clinical Trials Unit, University of Glasgow, Glasgow, UK; [4]R&D, Biotheranostics, A Hologic Company, San Diego, CA, USA; [5]School of Cancer Sciences, University of Glasgow, Glasgow, UK; [6]Raigmore Hospital, NHS Highland, Inverness, UK

Background: Cancer of unknown primary remains a major challenge with poor prognoses, protracted pathways and limitations of site-determination by immunohistochemistry. Gene expression signatures (GEP) show promise as molecular cancer classifiers, but their utility in diagnosis and prognosis warrants study. The CUP-ONE Trial prospectively compared a 92-gene assay GEP versus centralized IHC (C-IHC; 10 markers).

Methods: 641 consented patients (36 UK sites; 54 mths) had local pathology & MDT outputs classified as a Reference diagnosis (RD). Tissue was allocated, double-blind, randomized to 3 arms (N): C-IHC (329); CTID (418) CancerTYPE ID, Biotheranostics & Healthscope (418; became unviable). Outputs mandated classification to 14 cancer types. The Intention to diagnose (ITD N=392) set had at least 1 available classifier output. Primary Endpoint was %match of a classifier to RD-site of origin (ratio: total number Match results and total number in ITD dataset with a confirmed or suspected RD (C/S; N=131)). Secondary endpoints included overall classifier accuracy in evaluables with a C/S site of origin, concordance of classifiers & a pre-specified diagnostic score.

Results: Investigators final classifications (N) were CUP (451), 'Suspected' (72) and revised 118 to 'known' sites. In the ITD set: median 67yrs, 50% male, 92% stage IV. 418 (65%) samples were sufficient for 1 classifier output. Sample inadequacy (C-IHC 7.3%; CTID 13.4%) lead to 306 C-IHC & 362 CTID classifications. In Pair-wise comparisons CTID correctly classified 17.2% [1.9%-29.6%; p=0.0243] more than C-IHC;

Agreement of 2 classifiers was 97%. Secondary analysis comparisons showed point estimates favouring CTID but not all statistically significant. Both classified Lung, Colorectal, Breast and Ovary well but CTID did particularly well with Cholangiocarcinoma /gall bladder (60% accuracy) but not in pancreas (9.1%) versus C-HIC (27.2%). Median OS (mths) was poor across all 3 groups CUP: 5.3 (4.6-6.4); Suspected: 9.0 (8.3-11.9); Confirmed: 7.8 (5-13).

Conclusions: CUP-ONE assessed accuracy of CTID Vs C-IHC with comparable outcomes but a higher assignment of Cholangiocarcinoma in CUP. Survival was better in the C/S subset but remains poor overall.

Clinical trial identification: ISRCTN17282276, EudraCT: 2008-000657-35.

LBA101 BRCA-DIRECT: A randomised UK study evaluating a digital pathway for germline genetic testing and non-inferiority of digitally-delivered information in women with breast cancer

B. Torr[1], S. Choi[1], S. Allen[1], M. Hamill[1], G. Kavanaugh[1], S. MacMahon[2], E. Poyastro-Pearson[2], L. Yuan[2], M. Valganon-Petrizan[2], A. George[3], V.A. Jenkins[4], L. Fallowfield[4], R. Manchanda[5], A. Gandhi[6], G. Evans[7], Z. Kemp[8], M. Hubank[9], C. Turnbull[1]

[1]Genetics and Epidemiology Dept., ICR - The Institute of Cancer Research - North Site, Sutton, UK; [2]Clinical Genomics Department, The Royal Marsden Hospital (Sutton), Sutton, UK; [3]Medical Oncology Department, The Institute of Cancer Research and Royal Marsden Hospital, Sutton, Surrey, UK; [4]Sussex Health Outcomes & Research in Cancer (SHORE-C), Brighton and Sussex Medical School - University of Sussex, Brighton, UK; [5]Cancer Prevention Unit, Wolfson Institute of Population Health, London, UK; [6]Nightingale & Genesis Breast Cancer Centre, Manchester University NHS Foundation Trust, Manchester, UK; [7]Prevent Breast Cancer Centre, Manchester University NHS Foundation Trust, Manchester, UK; [8]Cancer Genetics and Breast Units, The Royal Marsden Hospital - NHS Foundation Trust, London, UK; [9]Clinical Genomics, ICR - The Institute of Cancer Research - North Site, Sutton, UK

Background: Germline genetic testing affords opportunities for women with breast cancer (BC) relating to (i) treatment of a current BC, (ii) management of future cancer risks, and (iii) identification of at-risk family members through cascade testing. Testing remains restricted to <20% of BC diagnoses in the UK. New pathways that reduce clinical staff involvement are required to support expanded testing.

Methods: We implemented a digital pathway, incorporating saliva sampling and a Genetic Counsellor (GC) telephone helpline, for germline BRCA1, BRCA2 and PALB2 testing (BRCA-testing) in unselected women with BC recruited from two UK oncology centres. Participants were randomised 1:1 to receive information about genetic testing via (i) a GC telephone appointment or (ii) the BRCA-DIRECT web application, to evaluate non-inferiority of standardised, written information compared with current standard-of-care in relation to uptake of BRCA-testing (primary outcome), patient knowledge, and anxiety.

Results: 1,140 patients consented to the study, with 571 (50.09%) randomised to receive information from a GC and 569 (49.91%) via BRCA-DIRECT. 1,001 (87.81%) consented to BRCA-testing, with uptake in the BRCA-DIRECT arm non-inferior to the telephone arm (difference +6.07% (95%CI 2.35-9.78%); NI margin -5.50%) as well as patient knowledge (difference -1.07 (-1.39 - -0.75); NI margin -1.40) and anxiety (difference +0.51 (-0.41 — 1.44); NI margin 3.00). Overall, of those who completed genetic testing, >90% reported a satisfaction score of 4 or 5 with the method of information delivery (1 — not satisfied; 5 — very satisfied). Of 19 healthcare professionals surveyed, when asked whether elements of the pathway were equivalent (or superior) to current standard-of-care, median overall score was 4.45 (IQR 4.27-5.00) (1-strongly disagree; 5-strongly agree).

Conclusions: Outcomes demonstrate feasibility and acceptability of a counsellor-supported digital pathway as an alternative delivery model for germline genetic testing within UK breast oncology settings, potentially facilitating expanded eligibility to testing for women diagnosed with breast cancer and other groups.

Clinical trial identification: NCT04842799; ISRCTN87845055.

Background: Platinum-based chemo is the standard of care (SOC) for la/mUC. An unmet need remains as long-term outcomes are poor. Here we present EV-302, a global, phase 3, open-label, randomized study evaluating EV+P in patients (pts) with previously untreated la/mUC who were eligible for cisplatin- or carboplatin-containing chemo.

Methods: Pts with previously untreated la/mUC (regardless of PD-L1 expression) were randomized 1:1 to receive 3-week cycles of EV (1.25 mg/kg; IV) on Days 1 and 8 and P (200 mg; IV) on Day 1 or gemcitabine with cisplatin or carboplatin. Dual primary endpoints were PFS per RECIST v1.1 by BICR and OS. Select secondary endpoints included overall response rate (ORR) and safety.

Results: 886 pts (EV+P: 442; chemo: 444) were randomized; pt characteristics were balanced between arms. At data cutoff, median follow-up was 17.2 mo. PFS was significantly prolonged with EV+P vs chemo, reducing the risk of progression or death by 55% (median PFS, 12.5 mo vs 6.3 mo, respectively; HR 0.45 [95% CI: 0.38-0.54]; P<0.00001). OS was significantly prolonged with EV+P vs chemo, reducing the risk of death by 53% (median OS, 31.5 mo vs 16.1 mo, respectively; HR 0.47 [95% CI: 0.38-

0.58]; P<0.00001). Confirmed ORR was 67.7% and 44.4% in the EV+P and chemo arms, respectively (P<0.00001). Grade ≥3 TRAEs occurred in 55.9% with EV+P and 69.5% with chemo; most common were maculopapular rash (7.7%), hyperglycemia (5.0%), and neutropenia (4.8%) for EV+P and anemia (31.4%), neutropenia (30.0%), and thrombocytopenia (19.4%) for chemo. Most common (≥5%) grade ≥3 TRAEs of special interest for EV included skin reactions (15.5%), peripheral neuropathy (6.8%), and hyperglycemia (6.1%). Most common (≥5%) grade ≥3 treatment-emergent AEs of special interest for P included severe skin reactions (11.8%).

Conclusions: EV+P significantly improved outcomes in pts with previously untreated la/mUC, nearly doubling the median PFS and OS vs chemo. The safety profile was generally manageable with no new safety signals. These results support EV+P as a new SOC for 1L la/mUC.

Clinical trial identification: NCT04223856.

Background: Cisplatin (cis)-based chemotherapy (chemo) has been the first-line standard of care (SOC) for cis-eligible patients (pts) with unresectable/metastatic urothelial carcinoma (mUC) for decades, and prior attempts to improve upon this treatment have been unsuccessful. We report results for nivolumab (NIVO) plus gemcitabine-cis (GC) or GC alone in CheckMate 901.

Methods: In CheckMate 901 (NCT03036098), a global, open-label, randomized phase 3 trial, pts received NIVO 360 mg plus GC every 3 wk for up to 6 cycles followed by NIVO 480 mg every 4 wk until disease progression/unacceptable toxicity or up to a maximum of 2 years, or GC every 3 wk for up to 6 cycles. Stratification factors were programmed death ligand 1 status and liver metastasis. Primary endpoints were overall survival (OS) and progression-free survival (PFS) by blinded independent central review (BICR). Objective response rate (ORR) per BICR was an exploratory endpoint.

Results: A total of 304 pts were randomized to each arm. With a median follow-up of 33.6 mo, both OS (hazard ratio [HR], 0.78; 95% confidence interval [CI], 0.63–0.96; $P = 0.0171$) and PFS (HR, 0.72; 95% CI, 0.59–0.88; $P = 0.0012$) were significantly improved with NIVO+GC vs GC (table). ORR and complete response (CR) rates were 57.6% and 21.7% with NIVO+GC vs 43.1% and 11.8% with GC. Median duration of CR (95% CI) was 37.1 (18.1–not estimable] mo for NIVO+GC vs 13.2 (7.3–18.4) mo with GC. Grade ≥ 3 treatment-related adverse events occurred in 61.8% of pts in the NIVO+GC arm and 51.7% of pts in the GC arm.

Table: LBA7

	NIVO+GC (N = 304)	GC (N = 304)	HR (95% CI)
Median OS (95% CI), mo	21.7 (18.6–26.4)	18.9 (14.7–22.4)	0.78 (0.63–0.96);
12-mo OS probability, %	70.2	62.7	$P = 0.0171$
24-mo OS probability, %	46.9	40.7	
Median PFS (95% CI), mo	7.9 (7.6–9.5)	7.6 (6.1–7.8)	0.72 (0.59–0.88);
12-mo PFS probability, %	34.2	21.8	$P = 0.0012$
24-mo PFS probability, %	23.5	9.6	

Conclusions: NIVO+GC demonstrated statistically significant and clinically meaningful improvements in OS and PFS vs GC alone as first-line treatment for mUC with no new toxicity signals. NIVO+GC is the first frontline concurrent checkpoint inhibitor + chemo combination to improve OS in this setting. These results support NIVO plus cis-based chemo as a new SOC for pts with mUC. (Table).

Clinical trial identification: NCT03036098.

Background: Treatment (tx) options are limited for pts with HR NMIBC who have recurrence after BCG tx and are ineligible for/refuse radical cystectomy (RC). Erda, an oral selective pan-FGFR tyrosine kinase inhibitor, demonstrated an overall survival benefit over chemo in the phase 3 THOR study in pts with locally advanced/metastatic urothelial carcinoma with *FGFRalt*. We report the first randomized data in pts with recurrent, BCG-treated HR NMIBC with *FGFRalt* from Cohort 1 of THOR-2 (NCT04172675).

Methods: Adult pts with recurrent, BCG-treated, papillary-only HR NMIBC (high-grade Ta/T1) and select *FGFRalt* refusing/ineligible for RC were randomized 2:1 to 6 mg oral erda or investigator's choice of intravesical chemo (mitomycin C or gemcitabine). Primary end point: recurrence-free survival (RFS). Secondary end points: RFS rate at 6 and 12 mo and safety.

Results: 73 pts (median age: 69 y) were randomized to erda (n=49) and chemo (n=24). Study enrollment was discontinued because of slow accrual. Median follow-up was 13.4 mo for both groups. Median RFS was not reached for erda and was 11.6 mo for chemo, with an estimated hazard ratio of 0.28 (Table). 6- and 12-mo RFS rate was 96% and 77% for erda vs 73% and 41% for chemo, respectively. Grade (Gr) 3-4 tx-related adverse events (TRAEs) occurred in 15 (31%) and 1 (4%) pts with erda and chemo, respectively; 14 (29%) and 0 pts had TRAEs leading to discontinuation of erda and chemo, respectively. Central serous retinopathy occurred in 19 pts (39%) with erda (Gr 1-2, 17 pts) and resolved in 11 pts (58%).

Table: LBA102

Value (95% CI)	Erda n=49	Chemo n=24
Median RFS, mo[a]	NE (17-NE)	11.6 (6-20)
Hazard ratio[b]	0.28 (0.13-0.62) nominal p=0.0008[c]	
6-mo RFS, %	96 (84-99)	73 (50-87)
12-mo RFS, %	77 (60-87)	41 (19-62)

[a]Censoring: 1) Recurrence-free + alive or unknown status, censored at last assessment; 2) no post-baseline assessment, censored at randomization; 3) withdrew consent or lost to follow-up prior to RFS event, censored at last assessment; 4) start subsequent anticancer tx prior to RFS event, censored at last assessment before new tx start. [b]Estimated using stratified Cox proportional hazards regression model. Hazard ratio <1 indicates longer RFS in erda vs chemo. [c]Based on an unstratified log-rank test.

Conclusions: Erda prolonged RFS compared with chemo in pts with papillary-only HR NMIBC with *FGFRalt* who had recurrence after BCG tx. Erda toxicity was generally consistent with the known safety profile of oral FGFR inhibitors.

Clinical trial identification: NCT04172675.

LBA103 ICRA: Efficacy of paclitaxel with tremelimumab +/- durvalumab in metastatic urothelial carcinoma after progression on platinum chemotherapy and anti-PD-(L)1

S.M.H. Einerhand[1], J. van Dorp[2], J. de Feijter[1], A. Daletzakis[3], S. Oosting[4], C. Bruijnen[5], B.B. Suelmann[5], M.S. van der Heijden[1]

[1]Medical Oncology, NKI-AVL - Netherlands Cancer Institute/Antoni van Leeuwenhoek Hospital, Amsterdam, Netherlands; [2]Molecular Carcinogenesis Department, NKI-AVL - Netherlands Cancer Institute/Antoni van Leeuwenhoek Hospital, Amsterdam, Netherlands; [3]Biometrics, NKI-AVL - Netherlands Cancer Institute/Antoni van Leeuwenhoek Hospital, Amsterdam, Netherlands; [4]Medical Oncology Department, UMCG - University Medical Center Groningen, Groningen, Netherlands; [5]Cancer Center, UMC - University Medical Center Utrecht, Utrecht, Netherlands

Background: The prognosis of metastatic urothelial carcinoma (mUC) patients (pts) after platinum-based chemotherapy and anti-PD-(L)1 is poor. Taxanes can provide disease control and may affect the tumor micro-environment. Clinical activity of anti-CTLA4 has been reported previously and may be dose-dependent. We evaluated whether paclitaxel (P) with tremelimumab (T), with or without durvalumab (D), could induce response in therapy-refractory mUC pts.

Methods: ICRA is an open-label, randomized, multicenter phase I/II study in pts with mUC who relapsed after platinum-based chemotherapy and anti-PD-(L)1. In the safety run-in phase (n=15), we tested weekly P (70mg/m2; day 1, 8, and 15 for 6 cycles (C)) plus either T75mg, T225mg or T750mg (C2-8 every 4 weeks), or P combined with D (C2-12 every 4 weeks) plus either T75mg (C2-5 every 4 weeks) or T300mg once (C2). In the expansion phase (n=12 per arm), pts received (A) P (C1-6) plus T750mg (C2-8); (B) P (C1-6) plus T300mg once (C2) plus D1500mg (C2-12); or (C) T750mg (C1-7). Arm A was extended to n=20 based on 2 responses. The primary endpoint was the objective response rate (ORR) according to RECIST1.1, with a target ORR 30% and aim to exclude 10% (Simon's optimal two-stage design, α=0.12, power=0.85). Safety was assessed according to the CTCAEv5.

Results: The primary endpoint was met with an ORR of 26% (88%CI 14-37%; 5/19 evaluable pts) in arm A. The ORR was 8% in arms B and C. Median OS (95%CI) was 16.0 (4.4-27.5), 13.9 (9.5-18.3), and 6.6 (0.0-14.8) months in arms A, B, and C, respectively (p=0.68). Median PFS was 5.7 (4.0-7.3), 6.5 (3.7-9.4), and 2.8 (0.0-5.7) months in arms A, B, and C, respectively (p=0.27). Toxicities are summarized in the Table.

Conclusions: In heavily pretreated patients with mUC, P+T750mg showed a manageable safety profile and encouraging antitumor activity, suggesting a potential synergistic effect of taxanes and high-dose anti-CTLA4.

Background: Treatment (tx) options are limited in NMIBC that recurs after intravesical chemotherapy or bacillus Calmette-Guérin (BCG). TAR-210 is a novel intravesical drug delivery system designed to provide local, continuous release of erda (selective pan-FGFR tyrosine kinase inhibitor) within the bladder while limiting systemic toxicities. This open-label, multicenter phase 1 study (NCT05316155) evaluates the safety, PK, and efficacy of TAR-210 in pts with NMIBC whose tumors harbor select *FGFRalt*.

Methods: *FGFRalt* were identified in tumor tissue or urine cell-free DNA. Cohort 1 (C1) pts had recurrent, BCG-experienced high-risk NMIBC (high-grade Ta/T1; papillary only) and refused or were ineligible for radical cystectomy. Cohort 3 (C3) pts had recurrent, intermediate-risk NMIBC (Ta/T1) with history of only low-grade papillary disease. Before tx, C1 pts must have all visible disease resected; C3 requires the presence of visible tumors. TAR-210 systems with 2 different erda release rates were evaluated. Response is assessed every 3 mo with continued tx for up to 1 year if recurrence-free (RF) (C1) or in complete response (CR) (C3).

Results: As of Aug 29, 2023, 16 pts in C1 and 27 pts in C3 have been treated; 11 and 15 pts, respectively, had ≥1 response assessment. 82% in C1 were RF; 87% in C3 achieved CR (Table). Most common tx-related AEs were grade 1/2 lower urinary tract AEs. There were no dose-limiting toxicities, no deaths, 2 pts discontinued due to AEs of low-grade urinary symptoms, and 1 pt had serious AEs of pyelonephritis and sepsis. PK showed sustained erda concentrations in urine, with very low plasma exposures.

Table: LBA103 Toxicity

	R1 (P+T75)		R2 (P+T225)		R3B (P+T75+D1500)		A (P+T750)[1]		B (P+T300+D)[1]		C (T750)

	Grade 1-2	*Grade ≥3*	*Grade 1-2*	*Grade ≥3*	*Grade 1-2*	*Grade ≥3*	*Grade 1-2*	*Grade ≥3*	*Grade 1-2*	*Grade ≥3*	*Grade 1-2*	*Grade ≥3*
Therapy-related AEs (n, %)	3 (100)	1 (33)	3 (100)	1 (33)	3 (100)	0 (0)	20 (100)	11 (55)	11 (92)	8 (67)	11 (92)	4 (33)
Immune-related AEs (n, %)	0 (0)	0 (0)	0 (0)	0 (0)	2 (67)	0 (0)	16 (80)	6 (30)	9 (75)	3 (25)	11 (92)	4 (33)
Chemo-related AEs (n, %)	3 (100)	1 (33)	3 (100)	1 (33)	3 (100)	0 (0)	19 (95)	6 (30)	11 (92)	8 (67)	n.a.	n.a.

AEs=adverse events; D=durvalumab; P=paclitaxel; R=run-in arm; T=tremelimumab

1. Run-in arms 3A and 4 were included in arms A and B of the expansion phase, respectively.

Table: LBA104 Efficacy outcomes and Tx exposure	
Cohort 1 (n=11 with response assessment)	
RF, n (%)	9 (81.8)
Median RFS (95% CI), mo	NE (2.96-NE)
Cohort 3 (n=15 with response assessment)	
CR, n (%)	13 (86.7)
Median duration of CR (95% CI), mo*	NE (NE-NE)
Both Cohorts (n=43 all-treated)	
Median duration of tx exposure (range), mo	3.7 (0-12)
Total duration of tx, n (%)	
≥0-<3 mo	18 (41.9)
≥3-<6 mo	13 (30.2)
≥6-<9 mo	6 (14.0)
≥9-<12 mo	5 (11.6)
≥12 mo	1 (2.3)

CI, confidence interval; mo, months; NE, non-estimable; RF, recurrence-free; RFS, recurrence-free survival. *All CR in Cohort 3 were ongoing as of data cutoff.

Conclusions: TAR-210 appears safe and well tolerated with predominantly low-grade urinary system AEs and high CR rate and RF survival in pts with NMIBC with *FGFRalt*. Results justify further study of targeted tx of erda using a novel intravesical delivery system in early-stage bladder cancer.

Background: Pts with BCG-unresponsive HR NMIBC are at high risk of disease progression with limited treatment (tx) options. TAR-200, an intravesical drug delivery system, provides sustained release of gemcitabine in the bladder over many days. SunRISe-1 (NCT04640623) is an ongoing, randomized, ph 2b study assessing efficacy and safety of TAR-200 + cetrelimab (anti-PD1) (Cohort 1 [C1]), TAR-200 alone (C2), or cetrelimab alone (C3) in pts with BCG-unresponsive HR NMIBC ineligible for or refusing radical cystectomy. We report results from C2.

Methods: Eligible pts aged ≥18 y had histologically confirmed carcinoma in situ (CIS) ± papillary disease (high-grade Ta, any T1), ECOG performance status 0-2, and persistent or recurrent HR NMIBC with last dose of BCG ≤12 mo prior to CIS diagnosis. TAR-200 was dosed Q3W through Wk 24, then Q12W until Wk 96. Response assessments: cystoscopy and centrally assessed urine cytology, CT/MRI, and bladder biopsy (at Wk 24, 48, and as clinically indicated). Primary end point: overall complete response (CR) rate. Secondary end points: duration of response (DOR), overall survival, safety, and tolerability.

Results: At 24 Aug 2023 data cutoff, 54 pts (median age, 71 y; range, 40-85; 33% with concurrent papillary disease) received TAR-200 monotherapy. 30 pts were efficacy evaluable. Centrally confirmed CR by urine cytology and/or biopsy was achieved in 23/30 pts (77%; 95% CI, 58-90). Median DOR was not reached (median follow-up in responders, 48 wks; range, 12-121); 21/23 responders remain in CR with 11/11 and 6/6 having response ≥6 mo and ≥12 mo from CR, respectively. CR rate by investigator assessment was comparable with central results. 29 pts (54%) had tx-related adverse events (TRAEs); most common (≥10%) were pollakiuria, dysuria, and micturition urgency. 4 pts (7%) had Gr ≥3 TRAEs; 1 (2%) had serious TRAE; 2 (4%) had TRAEs leading to discontinuation. No deaths were reported.

Conclusions: In SunRISe-1, TAR-200 monotherapy is associated with an unprecedented CR rate, durable responses, and a favorable tolerability profile in pts with BCG-unresponsive CIS, supporting its continued investigation in HR NMIBC.

Clinical trial identification: NCT04640623.

Cancer nursing: Supportive care

CN_LBA1 Uncovering the needs of lymphoma survivors: A cross-sectional study

V. Boland[1], A. Drury[2], A-M. Brady[1]

[1]School of Nursing & Midwifery, Trinity College Dublin, Dublin, Ireland; [2]School of Nursing, Psychotherapy and Community Health, Dublin City University, Dublin, Ireland

Background: Despite the significant improvement in lymphoma survival rates in recent decades, little attention has been paid to researching the survivorship experience. This study sought to address this gap by identifying the most common unmet needs among lymphoma survivors and the explanatory factors influencing their unmet needs.

Methods: For this cross-sectional study, adult lymphoma survivors one to five years post-diagnosis were recruited from five hospital sites across Ireland. To measure the extent of unmet needs, the validated Short-Form Survivors Unmet Needs Survey was utilised, where high scores indicated a greater level of unmet need (scores ranged from 0 = No Unmet Needs to 4 = Very High Unmet Needs). Descriptive, univariate, and hierarchical multiple regression analyses were conducted.

Results: Two hundred and two lymphoma survivors completed the unmet needs survey. The most commonly reported unmet need was "coping with having a bad memory or lack of focus", with 21.4% of respondents (n=43) endorsing it. Other frequently reported unmet needs were "feeling tired" (19%, n=38), "dealing with people who expect me to be 'back to normal'" (17.9%, n=36), "changes in how my body appears" (16.9%, n=34), and "feeling stressed" (16.4%, n=33). The top seven most frequently reported unmet needs fell within the coping, sharing, and emotional needs or work and financial needs domains. Being female was consistently associated with more unmet needs across all domains. Similarly, being younger was associated with more unmet needs. Individuals without private health insurance reported greater unmet needs. The timing of diagnosis was another influential factor; those with a more recent diagnosis (one to three years ago) experienced higher levels of unmet needs.

Conclusions: Several factors were associated with higher unmet needs across domains. Lymphoma survivors may require additional psychological support or assistance with their work, financial or information needs. Identifying the prevalent unmet needs of lymphoma survivors in Ireland provides evidence for the development of future survivorship programmes and services for this population. This study spotlights the importance of addressing unmet needs to improve quality of life for this group and reduce dependency on health services.

CN_LBA2 A qualitative exploration of lymphoma survivors' unmet needs

V. Boland[1], A. Drury[2], A-M. Brady[3]

[1]School of Nursing & Midwifery, Trinity College Dublin, Dublin, Ireland; [2]School of Nursing, Psychotherapy and Community Health, DCU - Dublin City University, Dublin, Ireland; [3]School of Nursing and Midwifery, Trinity College Dublin, Dublin, Ireland

Background: Lymphoma survival has significantly improved over recent decades. Yet, survivorship research has received little attention. This study aimed to understand the unmet needs experienced by lymphoma survivors through semi-structured interviews. This qualitative study investigates the individual experiences and complexities of lymphoma survivors' unmet needs. This insight can provide a voice to lymphoma survivors, which is especially valuable for this group as an underserved population in current literature.

Methods: A semi-structured interview guide was informed by the findings of a cross-sectional survey study and a literature review conducted by the authors. The findings were derived from interviews with 14 adult survivors about their unmet needs due to lymphoma and responses from 61 participants to an open-ended survey question. A reflexive thematic analysis was conducted to identify themes and patterns of meaning across both datasets (Braun & Clarke 2019).

Results: Three major themes were identified. Survivors shared experiences of *navigating the complexities of lymphoma*, including difficult diagnosis, limited awareness of lymphoma as a cancer and challenges specific to younger adults. Survivors experienced *complex care coordination*, including disjointed cancer care, physical health concerns and the immunocompromised nature of lymphoma, particularly during the pandemic. *The cost of cancer* found challenges in balancing life responsibilities with lymphoma, difficulties during the survivorship phase, and dealing with psycho-social problems.

Conclusions: Unaddressed unmet physical needs contributed to unmet psychological needs due to the uncertainty experienced by survivors on their quest for answers to health concerns. Psychological and emotional needs were dominant and persistent problems in the survivorship phase one to five years post-diagnosis. Unmet practical and information needs were experienced from disjointed cancer care coordination; a missing link was reported by individuals with lymphoma acting as a conduit for information regarding their cancer. Navigating lymphoma from diagnosis to survivorship presents challenges for patients and healthcare professionals who would benefit from enhanced lymphoma awareness and research.

Cancer nursing: Workforce and educational issues in cancer nursing

CN_LBA3 Providing support for families when an adult with dependent children is at end-of-life with cancer: A systematic review of educational interventions for health and social care professionals

C. O'Neill[1], S. Sheehan[1], J. Hanna[2], A. Drury[3], T. McCance[2], C. Semple[2]

[1]School of Nursing, Midwifery & Health Systems, University College Dublin, Dublin, Ireland; [2]School of Nursing and Paramedic Science, Ulster University, Newtownabbey, UK; [3]School of Nursing, Psychotherapy and Community Health, DCU - Dublin City University, Dublin, Ireland

Background: One of the greatest challenges faced by adults with significant caregiving responsibilities when they are at end of life (EoL) with cancer is supporting their dependent children (<18 years). Adults with advanced cancer want guidance to communicate with their children when death is imminent. Health and Social Care Professionals (HSCPs) are ideally placed to provide this aspect of care but often lack the skills, competence, and confidence due to insufficient training. This compromises the delivery of family-centred care to address the psychosocial needs of the family.This systematic review aims to determine the content, mode of delivery, assessment and outcomes of educational interventions to equip HSCPs when delivering end of life care for adults dying with cancer who have dependent children.

Methods: A systematic review of empirical studies was conducted, following the Preferred Reporting Items for Systematic Review and Meta-Analysis for Protocol checklist. Six electronic databases (Medline, OVID, CINAHL, EMBASE, PsycINFO, Web of Science, ERIC) were searched and grey literature searches of Google Advanced Search and relevant professional bodies were conducted. Two eligible studies were identified. Data relating to content, mode of delivery, assessment and evaluation of educational interventions and outcomes were extracted and analysed.

Results: Only two studies were identified, highlighting the dearth of educational interventions available to HSCPs to provide supportive care to families when an adult with dependant children is at EoL with cancer. The identified educational interventions were of good methodological quality and were positively evaluated by participants, enhancing their confidence to engage in EoL conversations. It is imperative that interventions that use robust evaluation methods are developed and made available to a diverse array of HSCPs.

Conclusions: The review highlights the urgent need to develop accessible interventions for HSCPs to provide supportive care to families when a person at end-of-life with cancer has dependent children. This is fundamental to improving care and reducing distress for patients and families.
